"Society is nothing more than an organized and differentiated inter-unit." [3] Differentiation seemingly alienates one from the common social body to which they belong. However, the forms produced by differentiation complete and complement each other within the social body in terms of functionality. The differences in social classes, as determined by various criteria of social structure, ultimately aim towards unification and social integration. Differences can only exist if there is a common denominator. But this "common area" immutably negates dispersive tendencies. On these lines, in his anthropological study on multiculturalism, Prof. Christian Giordano describes Malaysia as a society that celebrates diversity by exploiting the myriad ethnic and religious identities concentrated in the small region of Penang, on the eastern coast of the peninsula. [4]

Usually, individuals make use of various psycho-social mechanism to diminish the distance between self-identification (what they believe themselves to be and the benchmarks against they identify themselves) and hetero-identification (as identified from the outside).

From a socio-functional perspective, identity can be viewed as a self-attributed value meant to help achieve social prestige or as a hetero-attributed one intended for social differentiation. Hence, identity becomes manifest when an actual social situation requires a prerequisite for differentiation, thus also requiring an assessment of stakeholders and which, consequently, applies to any social interaction. Once the condition of differentiation has been fulfilled, the actor must take on the socially "convenient" identity role that helps highlight qualities, skills, knowledge and social capital, symbolically favourable to them in that specific social context.

Fredrik Barth, an important representative of constructivism, is perhaps the most influential researcher to emphasize the importance of boundaries between groups, thus adding a new dimension to the study of social identity. [5] Culture is fundamentally stable against group dynamics. Therefore, group boundaries ensure quality and intensity of differentiation. As the author states, this involves at least two key dimensions, namely, transparency of borders, the extent to which group characteristics are visible from outside the group itself, and their permeability, the difficulty or ease with which boundaries can be crossed or overcome. Hence, the feeling of inclusion or exclusion is dependent on the relative proportion of these two dimensions. For Barth, there borders are what define identity, in the sense that identity is validated by the existence of borders, regardless of frequency or intensity of personal and group interactions that occur along these boundaries. The nature of these borders determines differences and similarities, i.e. social inclusion and exclusion.

Methodology

Due to the interdisciplinary nature of the present approach to social identity, the research was conducted in 2005-2007 starting from a descriptive analysis of the reality investigated, supported by surveys, attitude measuring scales and demographic document analysis. The second methodological sequence included structured interviews, direct observation, oral accounts of historical facts, analysis of documents from local archives (community centres, religious books, local monographies, press articles, as appropriate), to further support the investigation and validate the consistency of the data obtained. The methodological strategy provided a considerable amount of information as well as valid results on the subject matter.

Distinguishing between various forms of social identity also presented conclusive results, displaying both the general features, as well as those self- and hetero-identification specific in all investigated situations.

The geographical extent of the research performed was determined by the administrative and territorial boundaries of the Timiş County.

The Timis County is representative in terms of its inter-ethnic assortment within the historical region of Banat. Located in the western part of Romania, an area of 8,697 km^2, Timiş holds 3.65% of the Romanian territory.

To better define the coordinates of regional identity in Banat certain aspects must be taken into consideration. Timiş County belongs to the region of Banat, region which has been officially recognized for over three centuries. Banat does not refer to any political, military, administrative or financial affiliation, it is simply the name of a geographical area which has seen a complex and serpentine course of history. The Banat region spreads over an area of 28,562 km^2 of which 18,966 km^2 belong to Romania, one third - 9276 km^2 - to Serbia, while a small part to the Northwest belongs to Hungary (284 km^2).

Self and hetero-identification in Banat communities

Self-identification within a social group depends on the situational context to which the individual is subject [6]. Therefore, in the absence of distinctive benchmarks, in order to self-define themselves, the respondents made use mainly of positive and general attributes. The frequency of certain self-identification attributes, however, also shows specific tendencies, such as the use of the self-assigned attribute "old" in 5% of respondents from Banat.

In a self-identity non-specific context and lacking terms of comparison, the attributes used by the subjects did not cover any of the essential key traits which commonly describe affiliation to categories based on religion, nationality, occupation, age, gender, etc. Consequently, none of these categories referring to group identification received significant mention among the attributes listed by subjects to the question "'Who are you?". However, this does not make such group identification attributes less important to respondents or any less socially inclusive. It merely proves that in the absence of boundaries assessment remains general and positive. The responses given placed the subjects outside any comparative registry, beyond any social affiliation to a group they actually belong to or relevant out-group, so that identification did not aim to directly support affiliation to one group or another. Therefore, in the absence of the other, the attributes cited by the subjects did not define a particular social identity, but rather fell into a broader social context, that of socially recognized

values concerning morality (good), work (hard-working, diligent, thrifty), education (educated, trained, literate) and honesty (honest , fair)

Similarly, analysis of ethnic self-identification categories places the social life of the community among the top choices of the interviewees and demonstrates specific social representations identification features.

Hence, answers to the question "Who are we, the Romanians?" addressed to Romanian nationals interviewees from Banat, can be grouped into the following categories: openness towards the community, level of poverty, level of education (through positive feedback by use of attributes such as: smart, educated literate), other attributes and moral-religious identity. As in the case of self-identification, attributes referring to common social values (morals, work, education) have the highest frequency. However, aside from stereotypical depictions such as: "Romanians are: hospitable, kind, hard-working and smart", more specific self-identification attributes can be observed in relation to the dynamics of the villagers' social lives. Poverty, a present issue the rural population in particular must face, is another common occurrence among responses, ranking third in order of importance among self-identification attributes in Romanians.

National identity, defined through social distance from other national groups and hetero-identification, demonstrates a high social acceptance rate in most Romanians towards all other national groups: between 44.5% and 49.5% of Romanian declare themselves willing to marry members of other ethnic groups, with the exception of the Roma ethnic group (which recorded lower values - 30.2%).

From the Romanians' point of view, the greatest social distance manifests itself with regard to the Roma ethnic group (7.20% of Romanians consider Roma ethnics should be expatriated). Hetero-identification of Romanians in relation to all other national groups is positive.

The study also reveals other social stereotypical representations, such as: Germans are fair and cold, Jews are good traders and belong to a particular religious group, while the Roma are thieves, lazy and dirty. Results show that social distance correlates directly with hetero-identification. The significant differences between the frequency with which Romanians identify the Roma ethnic group by negative traits (50 %) and negative hetero-identifications for other groups considered (frequencies between 8% and 16 %), show a clear tendency towards negative social representations with regard to the group located at the greatest social distance: Roma ethnics.

Analysis of endogamy and linguistic behaviour confirms the results of the "Who are you?" test, as well as the social distance scale scores for national identity. Areas with a majority of Romanian population report high Romanian-Romanian in-marriage rates: 79%. Other national groups, Bulgarians, Ukrainians and Roma also record high in-marriage rates. The Timis County comprises three villages with a significant concentration of Bulgarian population; the low distribution of families in but a few enclave villages thus explains endogamy within these local communities: Bulgarian-Bulgarian in-marriage rate of 74%. Moreover, analysis results on hetero-identification in Bulgarians depict an overall positive image, which lacks, however, any specific features of this national group. The Romanians thus described Bulgarians using significantly positive attributes: "Bulgarians are good (15 %) and hard-working (13%)." This positive but neutral image, appreciative but lacking distinctiveness, denotes weak relationships and reduced frequency of social interactions between Romanians and Bulgarians. In the case of Ukrainians, the significantly high percentage of endogamous marriages, 69%, is explained by the Ukrainian community customs, strictly preserved after their migration to this region of the country, customs which weigh heavily on the choice of a marriage partner. Hence, the spouse is mainly selected from the same language community (Ukrainian), from the same religious community (Old Rite Orthodoxy), from a community with similar social practices (significantly higher population growth rate than the standard Banat model and higher seasonal or temporary migration rates among male community members choosing to work abroad), from a community with common history and origins (organized migration of descents of today's founding heroes of Ukrainian villages in Timiş).

Among Roma, the reasons for endogamy lie in prejudice, negative stereotypes and intolerance, readily observable from the results of the "Who are you?" test and the maximum social distance perceived by the Romanian subjects. Intolerance of other national groups, manifested through social, cultural and even spatial isolation of Roma ethnics, still active in the collective memory, explains both negative social representations and great social distance perceived by the subjects, as well as the endogamous behaviour of more than half of the population of the Roma ethnic group.

Consequently, relatively isolated ethnic communities have the advantage of preserving their habits, customs and socio-cultural traditions, but, on the downside, are subject to elevated endogamous behaviour and limited socio -economic and cultural exchange with other communities within the social proximity space.

Dynamics of identity elements

The communities investigated revealed complex identity building and assertion strategies, observable in specific cultural elements. The case studies sought to describe and analyse the elements underlying the

development of social identity: community symbols, distinctive local figures and places, community specific religious festivities and customs, community spirit, and inter-ethnic relationships.

In rural communities throughout Banat, mutual assistance is a common phenomenon, based on the old system of statute labour. Mutual help most often occurs between neighbours living on the same street or between all villagers during a period of crisis. However, from the villagers' point of view, the current poor economic situation has also had a negative impact on the frequency of mutual aid. Exceptions are relatively closed communities, such as the Ukrainian community of the village Ştiuca, where "a house is built in a month and people help each other even when working the fields" (village elder, Ştiuca).

Therefore, in recent decades, the identity of the village, of the community united for better or worse, has seen much change on account of economic, socio-cultural and demographic factors. Changes in rural community religious and ethnic patterns generated by migration are supplemented by structural changes, as the result of property exchange, infrastructure and means of mass communication. Predominantly, these changes have affected the value of mutual aid within rural communities.

In terms of inter-ethnic interaction in the rural areas of Banat, the relationships between different ethnic communities are mostly positive and inclusive. "Ethnicity is irrelevant to us, people understand each other very well. Look, I'm Romanian but I get along with the Russians [...], our Gypsies are hard-working. Then there's the Ruthenians, Lippovans" (village elder of Romanian nationality, Ştiuca).

The primacy of social integration presides over any separatist or social isolation tendencies. In spite of all conservatism in terms of social practices, safeguarded after their migration from the region of Maramureş, Ukrainians have adopted the cultural models of the Germans (a majority in the village of Ştiuca before the arrival of the first Ukrainian settlers), the Catholic ritual practices in celebrating the Orthodox church, the Banat Swabian village architecture (large houses, whitewashed every spring, etc.) and follow suit when integrating Ukrainian newcomers.

Similarly, Roma ethnics are integrated into the village community despite the overall negative image that dominates the collective mind with respect to this ethnic group. One may argue that intolerance, separation or social isolation from any "foreign" group dissolve with the increase of significantly strong long-term group social interactions, as the community exerts social control to integrate the "stranger".

Once integrated, the outsider becomes "one of us" in terms of social practices and internalisation of valuesand system regulations pertaining to the village community. This mechanism of opposite representations with respect to the same social group shows the dependence of social identity to affiliation to certain categories as well as to more or less direct social experience with the relevant other. Individuals find themselves on a scale of opposition-resemblance-identity, based on previous social experience and social categories identified by inbred social perceptions and representations.

Conclusions

In general, individuals tend to provide a socially desirable image of their own group, to build a positive social representation of their own in-group. The concept of positive identity is supported by numerous studies and psychosocial theories according to which identity aids self-esteem in the development of the psychological and social self [7]. Identity attributes, whether real or perceived as being real, are used to create a positive self-image within a specific social context [8].

Identity manifests itself in relation to the out-group or in relation to the other, affirmation, validation, confirmation being determined by the extent to which social interaction exists. Regardless of the level or form of interaction, the individual will always bring into attention on the field of interaction those personal traits that are positive or perceived as positive. Identity is re-negotiated within every social context and is essentially determined by the specific nature of a group or community.

In the absence of interaction, identity can manifest itself only against precast social images, such as stereotypes and prejudice. To this end, changes in identity and self-image become relevant to social representation of Roma ethnics in the rural communities investigated throughout the present research. Altogether, when discussing Roma ethnic outsiders, hetero-identifications are mostly negative, while references to Roma residents of the community provide a substantially more positive image.

If religion, nationality, gender or affiliation to a social group, provide a stable identity, unanimously accepted and all time validation, the dynamics of social reality prove just the opposite. Continuity is subject to change, tradition, customs and habits rank second in all social interactions originating between actual individuals or groups.

Abstract

This work is focused on the concept of resilience in professional situation.The members of an organisation , at all hierarchical levels,could be submissive to the contexts of crises.The objective of the work is double.It is concerned to the construction of a questionnaire which to define an indicator of resilience for a person into a organisational context.The indicator will espress into a score.It is also concerned by the manner this indicator is sensitive to certain variables:labelling, social visibility.The participants in this experiment are the vietnamese workers also students of a second french cycle in Hanoi.Our problematic is linked to science of information and communication which explains why our approach on the resilience emphasises particularly the mobilisation of informational and communicational capacites.There are also emphasised the aptitudes to acces and process the informations, the abilities to create a narrative on past crises , or the possibility of an individual or of an organisation to be included into a social network, a community membership or much simple into a family or friendly entourage,capable to sustain the person in difficulty.

Keywords:organisational resilience, cleverness of the mads, information-communication, capital social, labelling, social visibility, Vietnam, questionnaire.

Introduction

Ce travail s'intéresse au concept de résilience en situation professionnelle. Les membres d'une organisation, à tous les niveaux hiérarchiques, peuvent être soumis à des contextes de crises. Notre problématique est ancrée dans le concept de résilience organisationnelle tel que défini par Mac Mannus & al. [1], c'est-à-dire considérant la résilience comme la prise de conscience d'une organisation de sa situation globale. Ceci permet une double approche : non seulement mettre en place des processus de résilience dans un contexte post-crise mais aussi élaborer une planification en pré-crise pour être à même d'anticiper au cas où la crise apparaitrait. Pour ce faire, l'organisation doit mettre en œuvre un management des "vulnérabilités clés", et des capacités adaptatives au sein d'un environnement complexe, dynamique et interconnecté. Ce management passe par des individus et la question est alors posée de savoir comment travailler sur le niveau de résilience d'une personne pour faire en sorte qu'elle surmonte ces situations pour aider son organisation. Mais aussi comment la résilience de l'organisation peut faciliter la résilience des individus qui la composent. Norris & al. [2] identifient quatre types de capacités auxquelles peut recourir l'individu résilient : le développement économique, le capital social, l'information-communication et la compétence communautaire. Du fait de notre appartenance disciplinaire (les sciences de l'information et de la communication), nous nous intéressons plus particulièrement à la mobilisation des capacités d'information-communication et de capital social. Des travaux français [3] [4] évoquent aussi la valeur ajoutée des liens et le rôle positif des tuteurs dans la capacité de recouvrement d'un individu, comme facilitateurs de la résilience. Dans une telle approche informationnelle et communicationnelle, sont valorisées les aptitudes de disposer et de traiter des informations de première main, d'être capable de mettre en récit la crise vécue ou tout au moins de pouvoir bénéficier de l'expérience de supérieurs hiérarchiques par la mise en récit des plans de sortie de crise mis en place avec succès par le passé. Le capital social fait référence quant à lui à la possibilité d'un individu ou d'une organisation de compter sur un réseau social, une communauté d'appartenance ou plus simplement un entourage familial ou amical capable de soutenir la personne en difficulté ; ce qui faciliterait le processus de résilience.

Effet de l'étiquetage sur le score de résilience individuel d'un individu en contexte professionnel

Dans ce travail, nous proposons la construction d'un instrument de mesure de la résilience a priori adapté au contexte organisationnel vietnamien. Comme le stipulent Ionescu et al. [5] du fait de la multiplicité des acceptions du terme de résilience, il en ressort un manque d'homogénéisation des échelles de mesure, les chercheurs ayant tendance à construire leur propre outil au regard du terrain investigué. Notre contribution est double :

- Le premier objectif est tout d'abord de construire un questionnaire permettant de définir un indicateur de résilience d'une personne dans un contexte organisationnel. Cet indicateur se traduit par un score. Il est très difficile de rendre compte d'un phénomène fin et qualitatif comme la résilience à travers un score performatif. Pour arriver à produire ce score, nous sommes partis d'un état de l'art des travaux existant [5] [6] [7] et d'une approche qui mobilise la sagesse des foules [8]. L'hypothèse de notre approche est la suivante : il est difficile de construire un score meilleur que les autres. Il est plus facile de proposer plusieurs scores, correspondant chacun à leur logique propre et de les agréger ensuite. Le score défini intégrera des paramètres intrinsèques à la personne et d'autres paramètres situationnels décrivant l'environnement info-communicationnel de travail.
- Le second objectif est d'étudier si la théorie de l'identification de l'action avec étiquetage [9] [10] est un paradigme porteur pour accompagner des professionnels vers plus de résilience. Selon Grandjean & al. [10] l'étiquetage consiste *« à délivrer à l'individu qui vient de réaliser un comportement, une information lui permettant de s'attribuer un trait de personnalité positif en lien avec ce comportement »*. Les auteurs identifient deux formes d'étiquetage : l'étiquetage fonctionnel, portant sur le comportement, et l'étiquetage social portant sur la personne elle-même et dont le niveau d'identification s'avère supérieur au premier. Nous avons souhaité aussi mesurer la possible efficacité de la variable « visibilité sociale » telle qu'elle est définie dans le paradigme de la communication engageante dérivée de la théorie de l'engagement [11] [12]. Ainsi on peut supposer que si une personne bénéficie d'un étiquetage social devant un public, alors son identification à l'action sera supérieure à celui d'une personne dont le même étiquetage aura été fait en tête-à-tête.

Pour tester l'impact de ces deux variables sur le score de résilience de notre échantillon, nous mettrons en oeuvre une approche expérimentale. Dans un premier temps un questionnaire permettra de connaitre le score de résilience de personnes. Les individus seront alors, en fonction de leur groupe d'appartenance soumis à un étiquetage et/ou un contexte de visibilité sociale. Le score de résilience sera une nouvelle fois calculé pour la population étudiée. Les écarts seront mesurés, discutés, analysés.

Méthodologie de construction du questionnaire :

Classiquement la construction d'un questionnaire passe par la mobilisation d'experts. Nous avons choisi au contraire d'élaborer un questionnaire en mobilisant le principe de sagesse des foules ou d'expertise distribuée. La « sagesse des foules » [8] montre que, sous certaines conditions, (diversité, indépendance des jugements, décentralisation), l'agrégation d'un nombre de points de vue individuels candides donne des résultats très supérieurs à celui donné par l'expert. En constituant un groupe diversifié, on augmente les chances de représenter la réalité dans toute sa complexité. Les partisans de la sagesse des foules reconnaissent le principe de rationalité individuelle limitée. Chacun a une vision imparfaite du monde. L'agrégation permet de représenter une vision d'ensemble. Pour ce qui nous concerne, nous avons donc mobilisé 35 salariés d'entreprises vietnamiennes à Hanoi dans les domaines bancaires et financiers, par ailleurs étudiants en cours du soir de second cycle universitaire, dans le cadre d'un séminaire sur la conduite du changement (master 2 de l'université de Toulon délocalisé à l'Academy of finance, université publique à Hanoi). Ionescu et al. [5] soulignent les risques de vouloir calquer des échelles de mesure de la résilience transculturelle. De ce fait, notre recours à la sagesse des foules permet de construire un possible instrument de mesure en adéquation avec la culture visée. La construction du score de résilience retenu s'est fait en trois étapes :

Etape 1 : Les étudiants se sont regroupés en groupe de 3 et on travaillé durant 48H de manière exploratoire à une recherche documentaire sur la résilience. Il s'agissait de formater le moins possible les esprits sur une vision partagée mais au contraire de susciter la recherche d'informations diverses. Suite à ce travail documentaire, les étudiants sont en charge d'élaborer un questionnaire de 15 questions maximum débouchant sur un score de résilience sur une échelle de 0 à 20. La construction de ce questionnaire prend 24H.

Etape 2 : A l'issue de l'étape 1, nous disposons de 11 questionnaires de 15 questions chacun. Dans un second temps, les groupes d'étudiants ont été reconstitués sur des bases nouvelles. Chaque nouveau groupe comporte 8 étudiants maximum et chaque groupe est constitué à partir d'éléments d'au moins 4 groupes de l'étape 1. Chaque groupe prend alors connaissance des questionnaires et scores élaborés dans l'étape précédente

par les 11 groupes. Chaque groupe a 24H pour élaborer un nouveau questionnaire de résilience conduisant à un score. A l'issue de cette étape, nous obtenons 3 questionnaires permettant de construire le score de résilience.

Etape 3 : En dernier lieu, deux chercheurs, (nous-mêmes, Boutin et Duvernay), se penchent sur les questions retenues par les 3 groupes. Ils identifient différentes familles de questions et reconstituent un questionnaire conduisant lui aussi à un score, s'appuyant prioritairement sur la mobilisation des capacités d'information-communication et de capital social [1] [2].

Les 3 questionnaires de l'étape 2 et le questionnaire de l'étape 3 ont été soumis aux étudiants qui y ont répondu. A l'issue de cette soumission, nous avons, pour chacun des 35 étudiants, 4 scores de résilience. Une étude de corrélation est réalisée pour juger de la corrélation entre ces 4 scores. Les résultats du calcul sont dans le tableau ci-dessous.

Tableau. 1 : Etude des corrélations des 4 scores de résilience

	QUEST GR1	**QUEST GR2**	**QUEST GR3**	**QUEST RECONSTITUÉ QUEST 4**
Q1		**0.39**	**0.13**	**0.80**
Q2			**0.11**	**0.67**
Q3				**0.199**

Les coefficients de corrélation sont positifs ce qui indique que les scores des 4 questionnaires vont dans le même sens. Si on retient un seuil de significativité de 0,8, on observe que la seule corrélation significative concerne le questionnaire du groupe 1 et le questionnaire reconstitué à l'étape 3. Dans la suite de ce travail nous avons retenu le questionnaire 1 et 4.

La finalité de ce travail est d'identifier des variables d'action susceptibles de favoriser la production d'un meilleur score de résilience chez la population observée. Le travail de terrain a été réalisé ainsi. Dans un premier temps, les 4 questionnaires ont été administrés à notre échantillon. A l'issue de cette administration, le lendemain exactement, une information a été communiquée aux personnes interrogées individuellement ou en groupe. A la suite de cette information, les 4 questionnaires ont été présentés à nouveau. Notre objectif est de mesurer l'impact de l'information communiquée entre les deux administrations de questionnaire. Cette information communiquée a joué sur deux niveaux. Deux variables peuvent donc être identifiées :

V1 : ETIQUETAGE La première variable consiste à jouer sur l'étiquetage social qui est fait à une personne d'une certaine capacité de résilience. Après l'administration du questionnaire, nous avons attribué à chaque membre de notre étude un score de résilience mais ce score n'est pas le score calculé sur la base des 4 questionnaires. Il s'agit d'un score défini aléatoirement mais les personnes de notre échantillon ne le savent pas. Certains individus se voient attribuer un score élevé (personnes résilientes) et d'autres un score faible (personnes non résilientes). A l'issue de cet étiquetage, les individus sont soumis une nouvelle fois aux 4 questionnaires et leurs nouveaux scores sont comparés aux anciens. Nous souhaitons voir si l'attribution d'un certain niveau de résilience a un impact sur le niveau de résilience mesuré par le score après l'expérience.

V2 VISIBILITE SOCIALE La seconde variable est la visibilité sociale. Pour certains individu l'annonce du score de résilience a été réalisée publiquement, c'est-à-dire dans une classe devant les autres. Pour d'autres, cette annonce a été faite lors d'un tête à tête avec l'expérimentateur.

Nous avons réparti les personnes interrogées en 4 groupes plus un groupe contrôle :

Tableau 2 : Répartition des 4 groupes dont Groupe 5 = groupe contrôle

	VISIBILITE SOCIALE DE L'ANNONCE	**NON VISIBILITE SOCIALE ANNONCE EN TÊTE À TÊTE**
ETIQUETAGE SOCIAL VOUS ÊTES RÉSILIENTS	**GROUPE 1**	**GROUPE 2**
ETIQUETAGE SOCIALE VOUS N'ÊTES PAS RÉSILIENTS	**GROUPE 3**	**GROUPE 4**

Chaque groupe comporte 7 personnes dont nous allons analyser les résultats dans les deux parties suivantes en termes d'impact, tout d'abord de l'étiquetage, puis de la visibilité sociale, sur la mesure de la résilience.

Impact de l'étiquetage sur la mesure de la résilience

Le tableau ci-dessous compare deux groupes d'étudiants : ceux à qui on annonce qu'ils sont résilients et ceux à qui on annonce qu'ils ne le sont pas, et bien évidemment, un troisième groupe contrôle à qui l'on ne dit rien (ils sont d'ailleurs physiquement écartés de cette séance d'étiquetage).

Tableau 3 : Impact de l'étiquetage sur la mesure de la résilience

	MESURE DE LA RESILIENCE QUESTIONNAIRE AVANT	**MESURE DE LA RESILIENCE QUESTIONNAIRE APRES**	**EFFECTIFS**
PERSONNES DECLAREES RESILIENTES *	**3.11**	**3.2**	**14**
PERSONNES DECLAREES NON RESILIENTES	**3.23**	**3.23**	**14**
GROUPE CONTROLE	**3.25**	**3.06**	**7**

**Cette déclaration se fait de façon aléatoire indépendamment du score de résilience calculé lors du questionnaire*

Nous avons pratiqué un étiquetage social, interne, dont l'acte subséquent serait de voir le score de résilience augmenter, lors de la passation du deuxième questionnaire *« Félicitations ! Votre score fait partie des plus élevés, vous êtes une personne particulièrement résiliente »*. Le fait d'être déclaré résilient renforce le score de résilience mesuré par le second questionnaire. Cet effet est renforcé par le fait que le score du groupe contrôle diminue entre le questionnaire avant et le questionnaire après. Joule et Beauvois [11] relatent une expérience similaire : des chercheurs ont annoncé à un groupe d'adultes qu'ils avaient réussi un test de personnalité (les résultats étaient donnés arbitrairement et ne reflétaient pas la réalité des réponses). En même temps que l'annonce de leur score, était pratiqué un étiquetage social en lien avec la thématique du test, du type *"vous êtes quelqu'un de particulièrement bienveillant"*. Les individus de ce groupe ont été ensuite plus nombreux, comparativement au groupe contrôle, à ramasser un paquet de carte qu'une personne avait laissé choir devant eux. Ces auteurs spécifient en outre que l'étiquetage ne peut être que positif, *« on n'étiquette qu'avec des traits favorables à l'estime de soi »*, ce qui peut permettre d'expliquer que le fait d'être déclaré non résilient, dans notre expérimentation, n'a pas d'effet négatif sur le score de résilience après.

Impact de la visibilité sociale sur la mesure de la résilience

Le tableau ci-dessous compare deux groupes d'étudiants : ceux à qui le score de résilience a été annoncé publiquement de ceux à qui le score a été annoncé lors d'un entretien en tête à tête.

Tableau 4 : Impact de la visibilité sociale sur la mesure de la résilience

	MESURE DE LA RESILIENCE **QUESTIONNAIRE AVANT**	**MESURE DE LA RESILIENCE** **QUESTIONNAIRE APRES**	**EFFECTIFS**
ANNONCE FAITE DANS UN CONTEXTE DE VISIBILITE SOCIALE *	**3.26**	**3.31**	**14**
ANNONCE FAITE LORS D'UN ENTRETIEN EN TETE A TETE	**3.08**	**3.12**	**14**

** Cette déclaration s'est faite dans une salle de clase réunissant 14 personnes, dont 7 ont été, nominativement, étiquetés comme particulièrement résilients, sans pour autant aficher leur score.*

On aurait pu s'attendre à ce que l'étiquetage public ait un impact de boost sur le score de résilience après. Tel n'est pas le cas. Ce résultat nous a interrogé car il va à l'encontre de la théorie de la communication engageante qui postule que le caractère public d'un acte est plus engageant qu'un acte réalisé dans l'anonymat [12], ce qui est corroboré par d'autres expérimentations conduites par différents chercheurs et relatés par Joule et Beauvois [11] notamment. Ces expériences réussies ont été conduites dans le cadre d'un contexte occidental. De ce fait, nous avons recherché des éléments explicatifs spécifiques à la culture vietnamienne qui seraient susceptibles de comprendre pour quelles raisons la visibilité sociale serait peu, voire non agissante. Une thèse de doctorat [13] sur le concept de « la face vietnamienne » fournit des éléments susceptibles de nourrir notre réflexion sur ces curieux résultats. Le fait que cette thèse soit rédigée par un doctorant vietnamien, alors étudiant en France, mais sur un terrain dans son pays d'origine (une école à Cantho) nous prémunit quelque peu du risque de biais ethnocentrés, le concept de face étant aussi prégnant dans la culture occidentale, en témoignent les travaux de Goffman [14]. Tran Van [13] souligne comme particularisme de l'importance de la face au sein de sa culture, celui de ne pas se mettre en avant, en tant qu'individu, par rapport aux membres de son groupe. Notre étiquetage social a consisté à étiqueter positivement 7 personnes sur un groupe de 14 personnes, réunies physiquement dans la salle de classe, en affichant au tableau les noms des sept personnes particulièrement résilientes (sans mentionner le score obtenu). Par défaut, les 7 autres personnes peuvent en déduire qu'elles ne sont pas, a minima, aussi résilientes, voire non résilientes. *« En relation avec les autres, les Vietnamiens n'aiment pas ceux qui cherchent à dépasser les autres membres du groupe en se faisant valoir ou remarquer par leurs actes trop marqués »* [13]. Ce particularisme permettrait d'expliquer que lors de la passation du second questionnaire, les étudiants annoncés comme résilients, n'aient pas cherché à performer davantage, comme auraient pu le faire leurs homologues occidentaux, afin de préserver l'union du groupe dans le but de protéger la face. En appui de cette approche, lors de sa participation à un colloque de psychologie à Hanoi en 2007, Cyrulnik [15] a été interviewé sur place sur le thème de la résilience et du Vietnam. Il déclare alors *« Les Vietnamiens ont des difficultés avec le "je" et le "moi", avec la notion très occidentale de l'individu »*. Selon Cyrulnik, le Vietnam peut être considéré comme un pays fortement résilient, dû à sa capacité de s'être relevé de plusieurs décennies de guerre, sans trop souffrir de lourds traumatismes. Dans ce contexte, la résilience communautaire aurait sans doute plus de sens que la résilience individuelle, les problèmes d'un individu étant alors pris en charge collectivement dans la tradition vietnamienne. (Le contenu de cette interview est consultable en ligne à l'adresse : http://www.forumvietnam.fr/forum-vietnam/le-vietnam-son-passe-son-histoire/2560-la-resilience-dans-loptique-dun-neuropsychiatre-francais.html)

Durant l'expérimentation nous avons découvert une troisième variable. En effet le questionnaire primitif permet d'attribuer un score de résilience à la personne. Ainsi pourrait-on dire, sur la base de ce questionnaire, qu'une personne se trouve, soit plus résiliente que la moyenne, soit moins résiliente que la moyenne. Or dans l'affichage qui a été fait, ce n'est pas ce score qui a été retenu mais un score de résilience aléatoire. Ainsi a-t-on pu dire à une personne qu'elle était résiliente alors qu'elle ne l'était pas ou le contraire. Quatre situations peuvent

se présenter : elles sont définies dans le tableau ci-dessous avec, dans le cœur du tableau, le score de résilience de chaque catégorie au niveau du premier questionnaire, puis au niveau du questionnaire administré après :

Tableau 5 : Emergence d'une 3eme variable non prévue

	ON DIT A LA PERSONNE QU'ELLE EST RESILIENTE	**ON DIT A LA PERSONNE QU'ELLE N'EST PAS RESILIENTE**
LE SCORE DE RESILIENCE DE LA PERSONNE EST FORT LORS DU QUESTIONNAIRE 1	**3.48→3.38**	**3.57→3.30**
LE SCORE DE RESILIENCE DE LA PERSONNE EST FAIBLE LORS DU QUESTIONNAIRE 1	**2.75→3.03**	**2.89→3.16**

Résilience questionnaire avant→ résilience questionnaire après. On peut analyser ce tableau de différentes façons.

Il ressort de ce tableau que les personnes qui ont obtenu un haut score de résilience ont tendance à avoir un score plus faible lors de la passation du second questionnaire quoiqu'on leur dise.

Il ressort de ce tableau que les personnes qui ont obtenu un score de résilience faible ont tendance à avoir un score de résilience qui s'améliore lors de la passation du second questionnaire quoiqu'on leur dise.

Ces résultats pour le moins contrastés ne sont pas évidents à interpréter. Pour quelles raisons des personnes réellement non résilientes progresseraient lors du second questionnaire ? Les travaux de Milgram [16] mettent en exergue la soumission à une figure d'autorité : les individus agissent dans le sens qu'ils supposent être attendu par cette figure d'expert. Ici, l'expert est représenté par les chercheurs qui se trouvent être dans le rôle également de l'enseignant dans le cadre du cours de Conduite de changement d'un Master 2 délocalisé au Vietnam. A cela s'ajoute les particularités de la société vietnamienne, sous le joug d'un parti unique autocratique et communiste. La soumission à l'autorité est présente à toutes les échelles : le pouvoir patriarcal familial, le chef au travail que l'on se garde de critiquer, la propagande politique présente dans la presse, dans les quartiers via des haut-parleurs diffusant la bonne conduite à adopter au quotidien, dans les murs de l'université et ses différents comités et autres cours de propagande.

Toutefois, cette soumission à l'autorité devrait aussi s'exercer avec les personnes réellement résilientes. Or leur score ne progresse pas, et tend à diminuer. Dans l'expérience de Milgram [16], 35% des sujets ne se sont pas soumis à la demande de la figure d'autorité. Cette désobéissance est expliquée, par le chercheur, par un recours à des valeurs élevées qui tendent à réduire l'influence des droits que s'arroge la figure d'autorité. Ainsi, nous avons donc cherché du côté des caractéristiques individuelles de l'individu résilient si ce dernier serait mieux armé pour résister à l'autorité. Cette intuition serait confirmée par la mise en perspective de Ionescu et al. [5], des différentes échelles de mesure de la résilience, différents chercheurs tels que Jew & al. [17] ou Hurtes & Allen [18] s'accordent à relever l'indépendance des individus résilients, leur capacité à prendre des décisions risquées pour elles-mêmes plutôt que d'accepter les règles d'autrui.

Conclusion

En conclusion, nous tenons à souligner que toutes ces observations ont été réalisées sur un nombre d'observations trop faibles pour donner lieu à généralisation. Toutefois, ces premiers résultats exploratoires fournissent des pistes qui pourront dans le futur faire l'objet d'approfondissements. Dans cette perspective, nous envisageons une approche comparative nécessaire sur des étudiants français en alternance d'une licence professionnelle en spécialité banque et assurance, pour confirmer l'efficacité de l'étiquetage social sur le score individuel de résilience, nous assurer de la justesse des interprétations culturelles quant à l'explication du non fonctionnement de la visibilité sociale de l'étiquetage en contexte vietnamien. Nous sommes conscients que nos explicitations concernant la troisième variable doivent être envisagées avec prudence, comme une première tentative d'éclairage dont la légitimité scientifique reste encore à creuser. Des entretiens compréhensifs [19] conduits auprès des étudiants vietnamiens pourraient nous aider à comprendre ces attitudes paradoxales des « vrais résilients » et « vrais non résilients » qui ont émergé à l'analyse du questionnaire, en marge de nos hypothèses de départ. Enfin, nous souhaiterions confronter ce travail à l'expertise d'autres équipes de chercheurs sur la résilience individuelle en contexte organisationnel, pour nous assurer que nos questionnaires mesurent bien de la résilience. En effet, Ionescu & al. [5] signalent qu'une partie de la communauté scientifique [20] [21] postule que la résilience ne pourrait pas être directement mesurée, mais inférée à partir d'autres concepts qui lui

sont liés (risque, adversité, compétence, adaptation réussie). Cyrulnik & al. [22] énoncent un certains nombre de limites, dont linguistiques, autour de « l'effet-baudruche » du concept de résilience. Des limites socio-culturelles s'appliquent aussi à notre approche, quant à la mise en oeuvre d'une culture sur son processus de résilience.

Abstract

The rapid globalization of business urges international firms to be competitive by acquiring employees with global management skills. These employees are usually called expatriates and are sent by their organizations to a related unit in a new country, with the aim of accomplishing an organizational related goal for a temporary period of time. Usually, family members accompany the expatriates in this international relocation experience full of challenges, such as cross-cultural adjustment and the bidirectional work-family conflict. Using the family stress and family resilience theory, we explored the expatriates' perception of the bidirectional work-family conflict in the presence stressors (job hours and parental demands) and existing resources (work and home support). We also explored the influence of the stressors, resources and expatriates' perception of the bidirectional work-family conflict on their level of cross-cultural adjustment. By analyzing the answers from 139 expatriates (65 males, 74 females) who filled in the online questionnaire, we found out that job hours were positively related to the perception of work-family conflict and the work support received from the colleagues. The work support received from the supervisor was negatively related to the perception of work-family conflict, while home support was negatively related to the perception of family-work conflict. As expected, the stressors and the perception of the bidirectional work family conflict influenced the expatriates' cross-cultural adjustment in a negative way, while the existing resources influenced it in a positive way. These results emphasize the resources' importance in the expatriates' relocation and urge for a multi-informant perspective study.

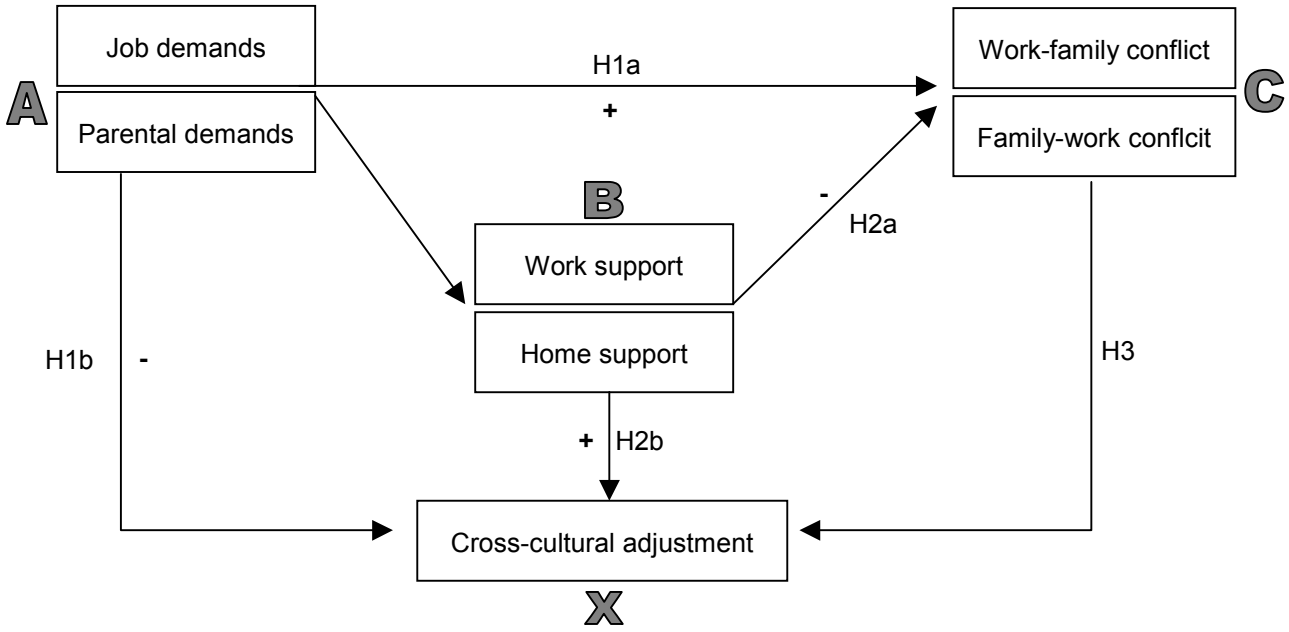
Keywords: expatriates, work-family conflict, cross-cultural adjustment

Introduction

The accelerating pace of globalization has been pressuring international firms to be competitive, by hiring employees with global management skills [1]. These competences are usually acquired through an expatriate assignment which consists in "a predefined timeframe job transfer that takes employee to a workplace outside the country in which he or she is a citizen."[2] According to recent surveys conducted by GMAC-Global Relocation Services (2011), family members are, most of the times, part of the expatriate assignment, since 80% of the expatriates are accompanied by their spouse and 47% by the children [3].

The move of these families to a new country is a challenging and stressful experience. Several studies indicate that the difficulty in successfully adjusting to a foreign culture, along family and work concerns are the most prominent challenges, which contribute to an unsuccessful expatriate assignment [4,5,6].

Having this in mind, we decided to take a closer look at the family and work microsystems and their influence on the expatriates' cross-cultural adjustment. Specifically, we applied the family resilience theory [7], which stated that family adjustment may be achieved through an interaction between demands (e.g. stressors), capabilities (e.g. resources) and meanings (e.g. family identity). These factors are also present in the classic ABCX theory [8]; where stressors (A) and social supports (B) interact with the meanings givens to the stressors (C), to affect the crisis (X). In the expatriate assignment, cross-cultural adjustment can be seen as a crisis, since the expatriate has to overcome this prominent challenge. The way the expatriate overcomes it, can be highly influenced by the stressors (A), the expatriates' perception of them (C) and the existing resources (B) just as the theoretical model (Fig. 1) illustrates.



H1a: Job demands will be positively related to work-family conflict, just as parental demands will be positively related to family-work conflict.
H1b: Job demands and parental demands will be negatively related to cross-cultural adjustment.
H2a: Work support will be negatively related to work-family conflict, just as home support will be negatively related to family-work conflict.
H2b: Work and home support will be positively related to cross-cultural adjustment.
H3: The bidirectional work-family conflict will have a direct effect on cross-cultural adjustment.
H4a: Work support will mediate the relationship between job demands and work-family conflict.
H4b: Home support will mediate the relationship between parental demands and family-work conflict.

Fig 1. Theoretical model and hypothesis

1.1 Stressors (A)

Family-related and work-related issues are pointed out to be a major source of stress for expatriates on international assignments. The most prominent examples of such stressful events are the parental and job demands. At a broad level, indicators of parental demands are the presence or absence of children and their ages [9], while job demands can be measured through the number of job hours per week.

1.2 Resources (B)

In order to buffer the stressors effect, expatriates may rely on the available resources, such as social support. According to Leavy (1983) [10], social support can be defined as "the availability of helping relationships and the quality of those relationships" (p. 5), which can be of two different types: practical and emotional. The practical support includes instrumental (e.g. loan of certain materials) and informational resources (e.g. suggestions) while the emotional support encompasses more affective resources, such as attention and comprehension [11]. Research on social support has acknowledged that individuals obtain support from various sources such as coworkers, supervisors, friends and families [12]. Therefore, expatriates' resources can be divided into home support and work support from coworkers and supervisor. Several studies indicate that supervisor support is an important resource for dealing with stress at work [13,14] while spousal support has been identified as a critical source of home support [15].

1.3 Meanings (C)

Just as mentioned in section 1.1, the most prominent stressors are family and work related issues. According to ecological systems theory, work and family microsystems can interact and influence one another, resulting in the work-family mesosystem [16]. This mesosystem is broadly cited in the literature as the bidirectional work-family conflict, which can be defined as "a form of inter-role conflict in which the role pressures from the work and family domains are mutually incompatible in some respect. That is, participation in the work (family) role is made more difficult by virtue of participation in the family (work) role" (p.77) [17].

1.4 Crisis (X)

The move to a new country has many challenges associated, which can be considered a crisis for expatriates to overcome. Among all the challenges, cross-cultural adjustment is the most prominent one. The broadly cited definition of cross-cultural adjustment states that it is a multifaceted construct which evaluates the degree of psychological comfort and familiarity regarding different aspects of the host country [18]. More precisely, it focuses on the food and climate of the host country (general adjustment), the performance standards and values (work adjustment) and different communication and relational styles used in the host country (interaction adjustment). Searle and Ward (1990) [19] distinguished two types of adjustment: psychological and socio-cultural. The psychological adjustment denotes internal aspects such as mental health and psychological well-being, while the socio-cultural adjustment focuses on external factors which connect the individuals to the new environment (e.g. the ability to cope with family and work problems).

Methods

1.1 Sample

The 139 participants (65 males, 74 females) in this study worked in the education and international/exterritorial field at large sized organizations (more than 250 people) and small departments (between 1 and 10 people), located in Lisbon, Portugal. On average they worked 46 hours per week and most of them (44.6%) earned an annual household income exceeding 70 001 euro. The majority of the respondents visited Portugal before the international transfer (69.1%) and were able to speak Portuguese (81.3%). Considering the country of origin, Germany (22.3%), USA (17.3%) and United Kingdom (15.1%) were the most predominant ones.

On average, participants were 43 years old (SD=7.94, and most of them were married (75.5%). The respondents were accompanied on this international relocation experience by their spouse and/or children. In terms of the number of children each expatriate family had, it could be observed that it varied between 1 and 4, with most having two children (43.9%).

1.2 Measures

The online questionnaire contained items that measured demographic characteristics as well as a number of scales measuring the bidirectional work-family conflict, resources (work and home support), stressors (job hours and parental demands) and cross-cultural adjustment. Table 1 presents the descriptive statistics, reliability coefficients and inter-item correlations.

Table 1. Means, standard deviations and inter-item correlations

	Mean	SD	1	2	3	4	5	6	7	8	9	10
1. Practical home support	2.342	.614										
2. Emotional home support	2.600	.565	.698**									
3. Work support from colleagues	3.775	.628	.136	.057

*$p < 0.05$ ** $p < 0.01$ *** $p < 0.001$

1.3 Procedure

The expatriates who participated in this study were recruited from different organizations, such as international schools and companies, located in the Portuguese districts with a high representation of expatriates. We sent an e-mail to the director of each organization explaining the study and requesting its disclosure among all members of the organization. In order to facilitate the disclosure process, a letter was provided with the description of the study, the questionnaire's link and the inclusion criteria, which consisted in having an active professional life and living in Portugal with the spouse and/or children. This letter was also posted in some expatriate social networks and closed internet address books, in order to increase the number of participants and ensure a participation of the majority of expatriates living in Portugal.

Results

We first examined the variables in this study, in terms of correlations, means and standards deviations (see Table 1). Overall, participants perceived a greater interference of work in the family environment than vice-versa, received more support from the colleagues and at home were provided with more emotional than practical support. In terms of the proposed hypothesis, we were able to determine that H1a was partially confirmed since job hours were positively related to work-family conflict (r=.299, $p<.05$), while parental demands were not positively related to family-work conflict (r=-.110, $p>.05$). H1b was also partially confirmed, due to the fact that only parental demands were negatively related to one dimension of cross-cultural adjustment - interaction with locals (r=-.192, $p<.05$).

In terms of H2a which was related to the relationship between the resources and the bidirectional work-family conflict, we found out that just the work support from the supervisor was negatively related to work-family conflict (r=-.178, $p<.05$), while both dimensions of home support (practical and emotional) were negatively related to family-work conflict ($r_{\text{practical support}}=-.172$, $p<.05$; $r_{\text{emotional support}}=-.172$, $p<.05$), just as we predicted. The same can be affirmed regarding the predicted negative relationship between home support and cross-cultural adjustment. This allows us to affirm once again a partial confirmation of a hypothesis (H2b); since contrary to home support, the relationship between work support and cross-cultural adjustment is not fully confirmed, due to the non-significant relationship between work support (from supervisor and colleagues) and one dimension of cross-cultural adjustment (interaction with locals). This dimension was also the only one that was not significant in the predicted negative relationship between the bidirectional work-family conflict and cross-cultural adjustment (H3).

In order to test the mediation model (H4a and H4b), we followed the three-step procedure proposed by Baron and Keny (1986) [20]. The first step states that the mediator variable should be regressed on the predictor variables, aiming to prove that their effect is statistically significant. Step 2 states that regression weights for the predictors should also be statistically significant, when the criterion variable is regressed on the predicting variables. In the third step, statistically significant effects are expected when the criterion variable is regressed on the mediator and the predictor variables.

Table 2 and 3 are related to the first mediation model, which predicts that work support will mediate the relationship between job demands and work-family conflict (H4a). Table 2 depicts the first step of the mediation model, indicating that there is support only for the relationship between job hours and work support from colleagues ($\beta= .180$, $p<.05$). In the second and third steps illustrated in Table 3, we can see that the relationship between job hours and work-family conflict is significant ($\beta= .299$, $p<.001$) only in step 2, when the mediator variable is not regressed. Therefore, we cannot confirm H4a, since contrary to what we expected work support did not mediate the relationship between job demands and work-family conflict. The same can be affirmed regarding H4b, since we did not find any support for the predicted relationship, as it can be observed in Table 4 (step 1 of the mediation model) and 5 (step 2 and 3 of the mediation model).

Discussion

The move of a family to a new culture implies a change of dynamics and a predisposition to overcome and adapt to the new environment. Therefore, it can be assumed that the expatriate along with his/her family may go through a crisis period while adjusting and overcoming the existing obstacles, such as the interference of work in the family environment and vice-versa [5,7]. Using the family stress and family resilience theory, we explored the expatriates' perception of the bidirectional work-family conflict in the presence stressors (job hours and parental demands) and existing resources (work and home support). We also explored the influence of the stressors, resources and expatriates' perception of the bidirectional work-family conflict on their level of cross-cultural adjustment.

Congruent with previous studies, the encountered results indicate that expatriates perceive higher levels of work-family conflict than family-work conflict [7,16], which can be influenced by the high number of job hours. The work support received from the supervisor may play an important role in reducing the work-family conflict, even though it does not mediate the relationship between job hours and work-family conflict. The same can be affirmed about the home support regarding its relationship with parental demands and family-work conflict. Both sources of support (work and home) influenced the cross-cultural adjustment in a positive way, while stressors influenced it in a negative way, just as expected. Therefore, we can conclude that the resources play an important role in the expatriates' relocation experience, helping them to overcome the existing obstacles and adjust better to the new environment.

For future studies, it will be useful to use a multi-informant perspective, involving the members of the family and determine their perspective on the variables involved in the ABCX model. At the same time, the spouse career should be taken into consideration and the model tested in dual career

expatriate families. In addition, other types of expatriation (e.g. self-initiated expatriation) in order to surpass the limitations of this study and determine to what extent are the results similar/different from the ones encountered in this study.

The failure of status achievement

Fulger Ioan V., Hirghiduşi I.

University of Petroşani, Romania

Abstract

In this paper we wish to show the importance of a societal environment able to constantly ensure the existence of the factors and conditions which allow the occurrence and development of resilience at the members of the society, regardless of the social class they belong to. We consider especially the factors and conditions that make the educational environment (mainly the formal one, which continues the primary socialization valorizing the habitus of the social class from which every member of the society comes from), the democratization of the educational system through the decrease of the scholar inequities etc, combined with the social development seen especially from an economic perspective.

Keywords: social success, education, family, status recapitalization

Introduction

Social success, understood by placing someone in a higher societal position is, or it should be, a logical consequence of the professional level of education and training available to every member of the social body. In turn, the level of training is the result of a long effort of the individual and those who supported him in his achievement, and we consider the family as the first social group with a role in providing financial, material, emotional and social support. Formal and non-formal education (in addition to the informal education which is related to the intimate environment) must be supported by the family. Without this support, the social success chances of the child drastically decrease especially where the education is recognized with preeminence in status achievement. In such a case, the child / children get to face a series of problems related to social exclusion.

Analyzing the education as a tool of social inclusion, or more specifically of social inclusion strategies through education, comes amid multiple discussions on a similar theme, for as M. Cherkaoui iterates, the research of the relationship between education and society was the domain which held the attention of most sociologists after the second World War, on one hand in terms of educational inequalities arising from social-institutional or individual mechanisms, and or on the other hand in terms of the effect the training has on the socio-economic status of individuals[1].

The importance of the family in child's life is fundamental, the specialty literature allocating generous space to the treating of the family-child relationship, the summary conclusion being that the family must operate intra and extra-familiarly[2] for its members to actually have equal opportunities (not just legally) compared with the other members of the society. In addition, only the functional family lends to the child the confidence that he is supported and guided in every moments of its existence, especially during the time he is depending on the parents. In this way the child acquires the capacity to build good resilience, because on the one hand he is aware of family's support and on the other hand he gains self-confidence to overcome some trials.

Methodology

In the present study we used a combination of several databases resulting from two field researches, everything being analyzed and interpreted in the light of specialty literature devoted to the role that the education has in the social success of the individual as well as the importance of the family in sustaining the individual effort towards status achievement. The first survey was conducted in the student practice in the summer of 2013 and took place on the entire area of the Jiu Valley on a sample of 600 individuals based on the method of the inter-correlated quotas (age, gender and percentage of population in each administrative territorial unit of the six that make up the Jiu Valley) and is representative for the area's entire population, allowing the extrapolation of the results. The tool used was the questionnaire (prepared on the basis of a preliminary operationalization of the concepts we worked with) which was applied on the field by the students at the domicile of the respondents in the form of direct face to face investigation. The aim of this research was to capture the involvement of the families that have children in the process of scholar education (regardless of

level) in support of this effort that prefigures the shaping of the social position. The second survey took place at the end of 2013. The method used was also the sociological investigation based on a questionnaire (filled simultaneously but individually as a pop quiz), the subjects were students of sociology and social assistance from the Faculty of Sciences of the University of Petrosani. The questioned number of subjects is not large (49) but enough to get an idea about how the students would react to a failure of status achievement and what is the extent of the family's support in such a situation.

Results

Following an investigation conducted by us throughout the entire Jiu Valley, we have obtained a number of interesting responses regarding the family involvement in providing the necessary things for the children to acquire a good education by creating an optimal environment which favors the internalization of values that are transmitted by a secondary socialization. The obtained answers are more eloquent in emphasizing the role of the family as they are coming from an area that has been subjected to a severe economic reform since 1997 that has affected the very way in which a family fulfills its functions which consecrates it as organized or not. Analyzing the goods and services provided to children by the families in the Jiu Valley, we have chosen to focus mainly on the school tutoring from two points of view. Firstly because tutoring is a more expensive service than paying the monthly internet fee, than the acquiring of books that will become the student's library or than the taking possession of a computer. Secondly because the phenomenon known as tutoring is part of the so-called "parallel education" which is an extension of the education carried out in formal educational institutions. This phenomenon is known in both the developed and developing societies, only that unlike the first category in which it is subjected to some well defined rules in the second category it can be easily placed into the frameworks of corruption because the scholar promotion may also depend on the payment of the tutoring [3].

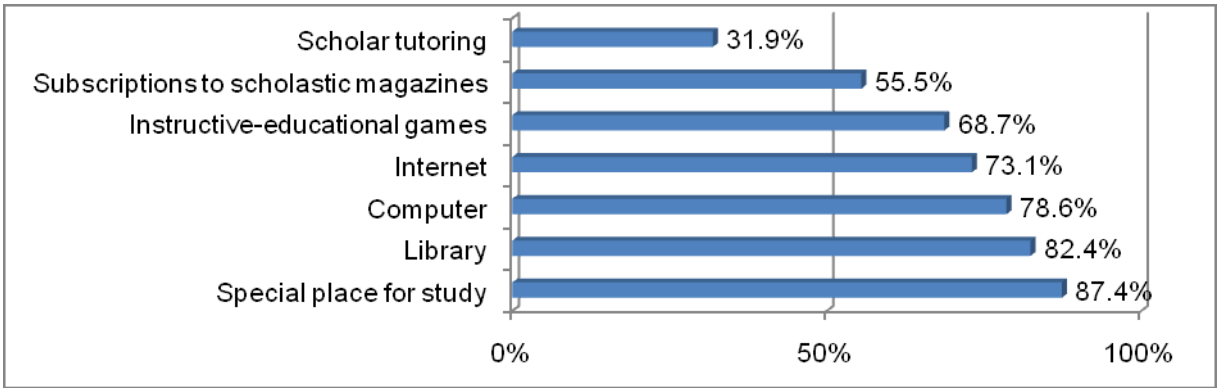

Fig. 1 The goods and services provided by the Jiu Valley families for their children

And not only that: although the stated purpose of tutoring is to achieve better school results they produce a perverse effect, emphasizing the social inequalities, because only certain categories of population can afford the financial resources to pay for their children's tutoring [4].That this is so it is proved by the correlation between the monthly revenues available to the Jiu Valley families (those families that passed the filters from the used tool and have minor children that are attending the classes of different teaching institutions) with the school tutoring that they can afford to acquire for their children at different disciplines. It can be seen from figure 2 that for all families with children in school and whose monthly income is up to 750 lei (we took into account the guaranteed minimal income beneficiaries, hence amounts to 350 lei or between 351-500 lei, depending on family size) tutoring is an educational service which they cannot afford for their children. Once the limit of 750 lei is exceeded, appear the signs of this phenomenon which tends to increase as the monthly income is becoming greater. Only after a monthly income of 2,500 lei the families begin to afford on a wider scale (57.1% of such income category) such an educational benefit. Also note that in the category of families whose monthly income is over 3,000 lei, all the kids are following additional training outside the formal and non-formal education, which we recognize as tutoring. We chose to represent with the aid of two frequency curves the income of the Jiu Valley families, making the dichotomy between those with children in school and the families throughout the Jiu Valley just to show that we have perceived this difference, closely following the families who have children. In full agreement with those shown above we appreciate that it can be felt a louder educational segregation depending on family resources, which has as finality, over the years, increased social inequalities in the

generational body. And this in context of greater chances of social mobility generated by the growing of the educational level.

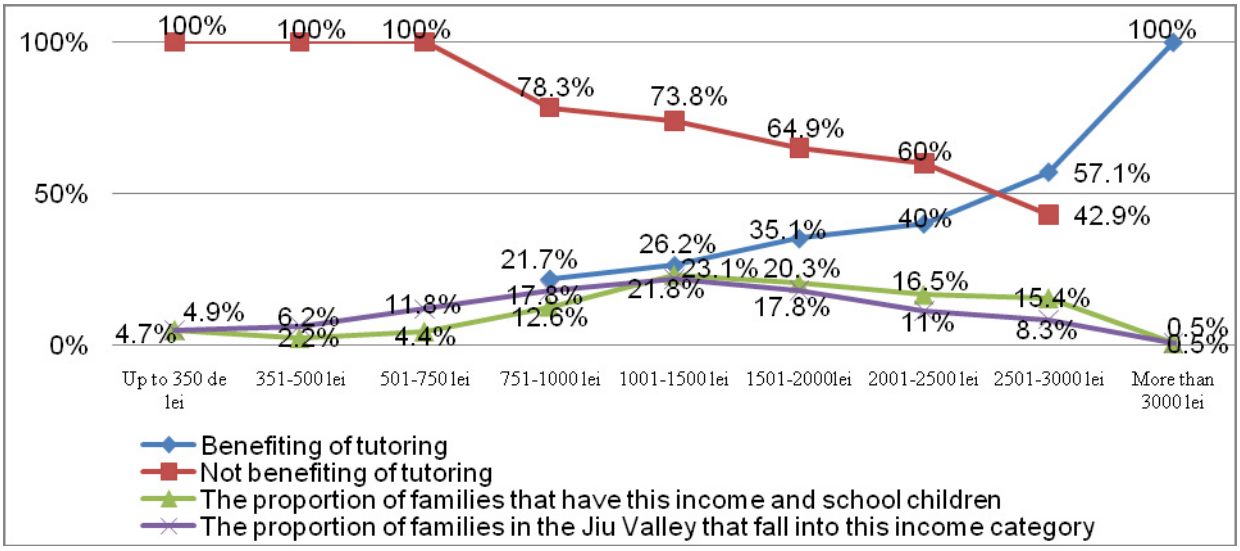

Fig. 2. The correlation between monthly family income and the children's tutoring, fitting by percentages of the Jiu Valley families by income.

In fact, what we have observed is a long noted phenomenon in the Western society. P.M. Blau and O.D. Duncan in their book *The American Occupational Structure* have analyzed the ways of social mobility in the United States. Their hypothesis was one that at least in theory seemed to be confirmed, namely: the lower the placement in the social hierarchy is, the higher the chances of social mobility will become. They brought the argument that the number of available social positions is much higher for those at the bottom of the social pyramid than the number of positions available for those who are already placed in the upper floors of the same social pyramid. The results of field researches have disproved this hypothesis by showing that the best chances of social mobility belong to the families that are already placed on top of the social hierarchy [5]. Besides, it is a situation replicated in the European space and the famous french sociologist P.Bourdieu in collaboration with J.C. Passeron developed the work *Les Héritiers, les étudiants et la culture*, which concludes that the school system is finally a tool for the reproduction of the positions inside the upper social strata [6]. Moreover, for P.Bourdieu the formal education is a form of symbolic violence that it imposes arbitrary aiming at the upper classes supremacy and the social stratification that favors them. The idea of social reproduction, developed by P.Bourdieu, is centered on the cultural reproduction, ie valuing the cultural capital of the dominant classes. We recognize here the implicit concept of habitus, understood as a way of personal thinking but with deep roots in the social class from which each person comes from. Or the school as an institution promotes and valorizes the habitus of the upper classes, which makes the individuals coming from lower classes to become disadvantaged in their struggle to fill a higher social position [7]. On the couple school-social mobility, in terms of impact, M.Cherkaoui puts several questions: to what extent the current society is hereditary? The rising of the individuals from the lower classes through school, is it real, approaching the meritocratic model, or conversely, we assist to the perpetuation of a myth, the current society being actually open to the past, undemocratic? M.Cherkaoui noticed a growing democratization of the educational system towards the decrease of the educational opportunities with the mention that it is still depending (very strongly) on the social origin [1]. The influence of social origin is also observed and recognized by A. Girard, which, in his book *La reusitte sociale en France* concluded with an interesting statistic about the social origin on approximately 2000 different personalities from all domains of activity, in 1961. Thus, the workers, the farmers, the traders and the craftsmen were providing 19% of all personalities, the officials and average professionals provided in turn 19%, and finally ,the business managers, the liberal professions and senior officers were providing the greatest mass of personalities, no less than 62% [8]. In his turn R.Boudon addresses the issue of the education stressing that the school was long seen by sociologists as the main tool in developing a policy for social equality, in that it contributes (or it should contribute) to the increase of social mobility. Boudon even appeals to one of the works of L.C. Thurow (Education and Economic Equality) to show the influence of increasing tuition rates on income distribution. Thurow's conclusion, to which Boudon adheres, is that the development of the educational system has not led to a decrease of the economic inequality, on the contrary, it increases the inequalities due to the social positioning by birth. Moreover, the development of the educational system does not cause an increase in

social mobility, but it only assumes the decrease of inequalities of the educational opportunities [9]. Just on such grounds Boudon sees the educational development from the position of one that conceives it as having unexpected and perverse effects: unexpected because the results of educational development provoked disappointment, and perverse because they induce in the social body the feeling of distrust regarding the finalities of the educational act, understood as a system [10].

However, at least among the students surveyed by us, the desire of status achievement is great, 55.1% of them choosing the profile they are preparing for a career. So this is not a conjectural choice but one with strong implications for the future from a personal but also professional perspective. On the other hand the achievement of a social position is perceived by the students as being conditioned by obtaining of an university degree, 61,2% of the respondents having such an opinion. At the same time the students seem to answer the question raised by M.Cherkaoui regarding the extent to which the modern society is a hereditary one from the perspective of the couple level of education-social mobility:

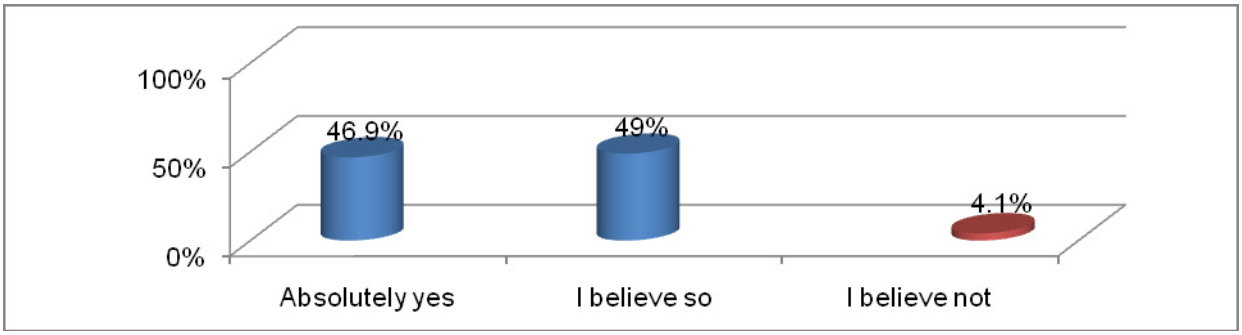

Fig.3 The opinion that the university graduates which come from families that are socially well placed have more chances to be employed

Cumulating the series of positive answers we have obtained the measure of the reality perceived by the students regarding the employment after the training stage from the faculty: 95,5% agree that the social origin is influencing the chances of employment, or otherwise of social mobility. In this case it occurs the actual materialization of what is called the achievement of status, avoiding unemployment, employment in jobs below the level of training or the professional reorientation. The completion of higher education studies should coincide, at least in the meritocratic model, if we were to refer back to M. Cherkaoui, with the social ascension of the individuals, especially of those from the lower classes. We have asked the students to estimate the chances that they have to be employed in the profession after the graduation, and the answers are interesting. Although they had at their disposal the option to estimate their chances to be employed in their profession as *totally*, not even one of the students used it. Very few of them (8,2%) estimate their chances to be employed as *great*. It is true that most of them (49%) consider their chances as *appropriate* but equally true is that by merging 42.9% estimate them as *small* to *nonexistent*.

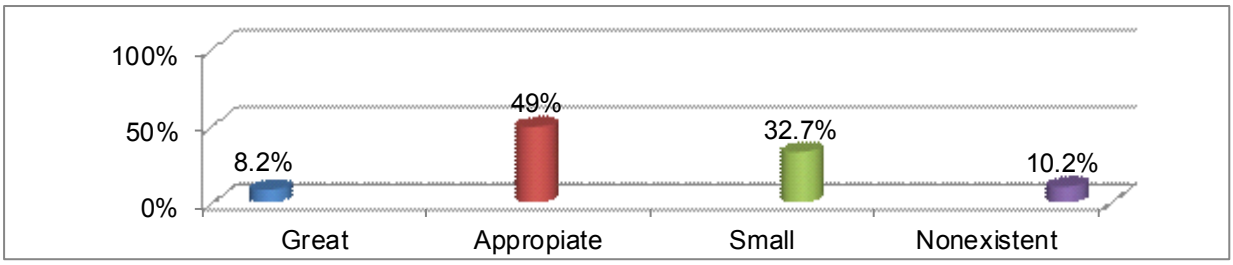

Fig.4 The estimation of chances of employment in profession after graduation

Therefore it seems to be confirmed the long noticed fact by M. Cherkaoui, L.C. Thurow or R. Boudon that the development of the educational system means above all its democratization by decreasing the educational inequalities and of a lesser degree the decrease of the economical inequalities through the alleged increase of the social mobility. In such a case those which are coming from families positioned towards the base of the social pyramid have within reach (outside unemployment) at least two ways of social recovery. The first

is that of employment in a different field of activity placed under the academic training they have. The acceptability of such a situation, with the nuances it brings, is presented in the following:

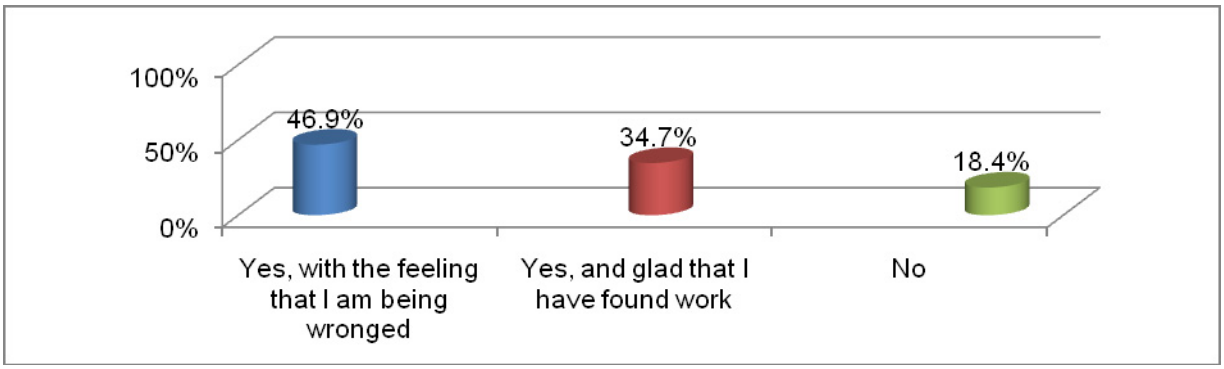

Fig. 5 The acceptability of employment in a workplace beneath the training level

Less than a fifth (18,4%) would refuse employment below their qualification. This high degree of acceptability is worrisome showing the flaws of the economy and of the entire social system. The young people that are placed in this situation are not only the product of a formal educational system but also (and especially) the result of the financial, material and psycho-affective effort of the families they belong to. Only in this register we can understand the decision of many of them (61,2%) that in case of failing in the status achievement to use what we have called *the status recapitalization* by acquiring new skills after graduating another academic specialties. It is, we think, a good example of resilient families which managed to develop their children's skill so that they become ever more able to face the challenges of life [11], the children of resilient families becoming themselves resilient[2]. Even if the families are resilient and are further transmitting the ability to adapt to their children, an important role in maintaining the resilience belongs to the community of origin (community resilience) and to the societal system as a whole (societal resilience). In the absence of well-organized social structure, optimally developed on all of its levels, all these elements can turn into sources of social exclusion:

-self-exclusion. This is an individual choice related to the cultural model someone finds himself in or because of disinterest. These individuals reject or renounce to a certain form of social participation;
-the system. The whole social system is not prepared to react through social policies against various social problems;
-the community to which the individual belongs to / area of residence, because some communities and regions are richer, others are poorer [12]. Moreover, the resilience of the community is given by the social, cultural, human, financial and political capital available [2].

At the level of the entire Jiu Valley we had already distinguished the awareness of the inhabitants that they belong to a community that is no longer resilient or which is about to lose its resilience: 60.5% of the parents said that the chances of social success of their children in relation to the children in the major cities of the country are smaller, the economic degradation of the area being primarily responsible for all the negative phenomena that have occurred or are occurring here simultaneously: unemployment, depopulation of the area because of the decrease of the birth rate and the emigration of the youth, the lack of investments etc.

Conclusions

The individuals may have the capacity to adapt to new situations they find themselves in throughout life, such as, for example, the ability of many students to overcome failure of status achievement because of the impossibility to be employed in the profession they initially prepared for, by following the classes of other faculties. This type of individual and familial resilience must be sustained for the entire societal environment, by ensuring those factors and conditions that allow the individuals to overcome difficult situations. Or we have remarked the weakening of a community in its entirety and the accepting of the idea that the chances of social success of its younger members are greatly diminished than those of the youth from another communities, especially of those from larger cities. We can say, therefore, that a strong community lends to its members the trust in their social success, the sense of belonging to a group whose set of values is not disputed nor is about to be diluted. The democratization of the educational system, in the sense of decreasing the educational inequalities through the permeabilization of the educational system has no positive effect on reducing the economical inequalities (and hence on social mobility) as long as it is not combined with social development in terms of

economic growth. Only on these terms the social mobility through status achievement can be felt into the lower strata of the society and the social inclusion by education becomes effective.

Adaptation de l'*échelle de facteurs de protection* au contexte socioculturel des femmes camerounaises

Kimessoukie O.É., Jourdan-Ionescu C.

Université du Québec à Trois-Rivières (Canada)
kimessou@uqtr.ca, Colette.Jourdan@uqtr.ca

Abstract

The resilience is a complex phenomenon, an exceptional experience, a permanent construct ,the result of the positive interaction between the risk factors, the protective factors, the available resources, and the adaptative or motivational forces of a person.It takes part of salutogenic paradigm.A better knowledge of the resilience allows better health promotion interventions ; primary, secondary and tertiary prevention.The objoct of thi study was to adapt The Protection Factors Scale, elaborate in context quebecois, to the 20 to 55 years old Camerun women's sociocultural context.The analysis of the scale's items shows that it is advantageously destinated to the young universitary adults.We made the semantic adjustments and the addition of specific items of the cultural context of Camerun women's, which are still low educated on certain regions.It is about items concerning traditional medicine and the religious practice.The adapted version of the scale consists in 37 items.The study of the construct's validity, allows to finalise this scale adaptations process

Key words: scale adaptation, Camerun women's sociocultural context, protection factors, résilience.

Introduction

La résilience est le résultat d'un processus au cours duquel des personnes confrontées à une forte adversité, à un stress chronique, à des traumatismes parviennent à ne pas sombrer dans des troubles psychologiques, à reconstruire leur vie autour de ces expériences pénibles, et à présenter un meilleur fonctionnement psychique [1-3]. Il n'existe pas encore à ce jour de consensus sur la définition de ce concept qui subit l'influence des principaux courants de pensée en psychologie. Le nombre d'études réalisées sur la résilience (en date du 25 janvier 2014, dans les bases de données PsycInfo et Web of science, on dénombrait plus de quinze mille études en rapport avec le concept de résilience), l'absence de consensus autour de sa définition, les différentes entités qui en font l'expérience (individu, famille, société, etc.), et la singularité du vécu chez chacune d'elle en font une complexité bien difficile à étudier dans le réductionnisme scientifique (qu'on soit dans le paradigme positiviste ou interprétatif) et dans l'enfermement disciplinaire ou contextuel [1, 4-7].

La résilience n'est pas un acquis définitif, puisqu'on peut être résilient à un moment et ne pas l'être à un autre, dans un contexte et ne pas l'être dans un autre, etc.[1, 3, 5, 8, 9].C'est un construit permanent qui est fonction de l'interaction entre les facteurs de risque en présence, les facteurs de protection, les ressources disponibles, et la force adaptative ou motivationnelle de la personne. La complexité du phénomène de résilience suggère que ses outils d'évaluation soient adaptés à une population et à un contexte socioculturel donné. Cet article a pour objectif d'adapter l'*échelle de facteur de protection* [10] au contexte socioculturel des femmes camerounaises âgées de 20 à 55 ans. Un facteur de protection est une qualité personnelle ou environnementale, une qualité émergente des interactions écosystémiques pouvant permettre l'adaptation face à des situations de risque ou de forte adversité ou en prédire une bonne issue [11-13]. Il est donc spécifique au champ de la promotion et de la prévention primaire et convient d'être distingué du concept de ressources qui est plus large. La reprise d'un développement après un traumatisme ou une désorganisation est de l'ordre de la reconstruction, de la réadaptation, de la restauration. Il s'inscrit dans la prévention secondaire et tertiaire, et fait appel à des ressources individuelles, familiales et environnementales. C'est le cas d'une personne atteinte d'une psychose chronique, d'une dépression, d'un viol, d'une addiction, d'un traumatisme craniocérébral modéré ou grave, etc., qui peut aussi après un point tournant, reprendre un développement avec bénéfice [11, 14, 15]

Une consultation des bases de données PsycInfo et Web of Sciences (25 janvier 2014) montre seulement trois études sur ce phénomène au Cameroun. Ces trois études [16-18] se sont déroulées pour la plupart en zone rurale anglophone et ont utilisé un devis de recherche qualitatif (ethnographie et théorisation ancrée). L'une s'est intéressée aux stratégies de résilience utilisées dans la gestion de la pauvreté chez les populations Bakweri de la région anglophone du Nord-Ouest [17]. Une autre, dans une approche qualitative exploratoire, à

l'aide des focus group discussion, s'est intéressée à l'adversité vécue par des femmes handicapées de cette région [18]. L'on constate, à partir des données de la recherche documentaire effectuée, qu'il n'existe pas d'outil d'évaluation des facteurs de protection élaboré ou adapté au contexte socioculturel camerounais et utilisable en prévention primaire.

Le Cameroun, pays d'Afrique centrale, compte 51% de femmes, plus de 200 ethnies vivant dans des paysages écologiques très différents (forêts, savanes, montagnes, littoral, etc.) et dans lesquels on observe un syncrétisme culturel. Les conditions des femmes sont particulières. Elles sont de grandes multipares, avec un indice synthétique de fécondité de 5,2 enfants. Elles subissent la pauvreté et la précarité de l'emploi qui sévissent de manière endémique. Un quart des ménages sont dirigés par des femmes, dont 40% sont des veuves parmi lesquels seulement 36% sont alphabétisées. De 2001 à 2007, l'on a observé que la pauvreté diminuait chez les femmes alors qu'elle augmentait chez les hommes. Par ailleurs un tiers de promoteurs d'entreprise sont des femmes[19]. Bien qu'elles vivent en contexte d'adversité, elles semblent s'appuyer sur des facteurs de protection pour favoriser leur adaptation et, pour d'autres, leur résilience. La disponibilité d'un outil d'évaluation des facteurs de protection, adapté au contexte socioculturel des femmes camerounaises, a pour finalité de contribuer à améliorer l'étude de la résilience chez celles-ci. Deux objectifs spécifiques ont guidé cette première étape d'adaptation de l'*Échelle de facteur de protection* : établir l'équivalence sémantique et la validité de contenu. La validité de construit sera étudié dans le cadre d'un travail doctoral portant sur l'adversité et les ressources favorisant la résilience des femmes camerounaises.

Méthode

Cette première phase du processus d'adaptation de l'*Échelle de facteurs de protection* s'est faite en deux étapes. L'échelle a d'abord été soumise à cinq femmes camerounaises ayant au moins un baccalauréat (licence) et des connaissances en sciences sociales et humaines (une anthropologue spécialisée en question de genre, une anthropologue de la santé, une infirmière clinicienne, une étudiante de maîtrise en sciences infirmières, une gestionnaire). Il leur a été demandé de relever les items qui posent des problèmes de compréhension, ceux qui ne semblent pas adaptés au contexte socioculturel de la femme camerounaise âgée de 20 à 55 ans, et de faire des propositions d'items spécifiques aux facteurs de protection utilisés par les femmes camerounaises. Les résultats obtenus ont été discutés lors d'une réunion du Groupe Aidenfant affilié au Laboratoire de santé mentale de l'Université du Québec à Trois-Rivières, en présence de la plupart des auteurs de l'échelle. Dans un deuxième temps, la version ajustée de l'échelle a été soumise en prétest à 14 élèves aides-soignantes et 10 étudiantes infirmières diplômées d'état. L'instrument a été administré en groupe dans une salle de classe.

L'*Échelle de facteur de protection* [10] est un questionnaire dichotomique de 35 items conçu pour évaluer les dimensions individuelles (12 items), familiales (12 items) et environnementales (11 items) des facteurs de protection. Son coefficient alpha de Cronbach est de 0,82. Ses items s'inscrivent dans le processus cycle de vie, partant de l'enfance à la phase adulte.

Résultats

Les résultats de cette première phase d'adaptation de l'*échelle de facteurs de protection* sont présentés dans le tableau ci-dessous.

Tableau1
Analyse des items de l'Échelle de facteurs de protection dans le contexte socioculturel de la femme camerounaise

Dimension de l'échelle **Éléments d'analyse**	**Facteurs de protection individuels**	**Facteurs de protection familiaux**	**Facteurs de protection environnementaux**	**Justification**
Items non modifiés	N°10 & 11	N°14, 15, 18, 20 & 22	N° 29 & 30	Les informatrices et les participantes au prétest n'ont pas signalé de problème de compréhension
Items posant des problèmes d'équivalence sémantique	N°3 (tempérament), N°5 (ouverture d'esprit), N°7 (habiletés sociales), N°8 (estime de soi N°9 (humour), N°12 (stratégies d'adaptation)	N°19 (soutien émotionnel)	N°23 (réseau social), N°28 (modèles de pairs), N°31 (mentor)	Les concepts utilisés se réfèrent à un langage spécialisé inaccessible à des personnes de niveau d'instruction faible
		N°17	N°24	Dichotomie des propositions
	N°1, 2 & 6	N°13, 16 & 21	N°25, 26, 27, 33, 34 & 35	Nécessité d'une clarification, spécification ou simplification des items pour en faciliter la compréhension
Item supprimé pour inadaptation au contexte socioculturel			N°32 en rapport avec les animaux de compagnie	Au Cameroun, les animaux domestiques ne jouent pas très souvent le rôle d'animaux de compagnie
Items ajoutés en rapport avec la culture			N°36 (recours à la médecine traditionnelle)	Selon l'OMS (2002), 80% de la population en Afrique recourt à la médecine traditionnelle.
			N°37 (pratique religieuse)	Elle est très forte et répandue au Cameroun
Spécificité de la population cible			Possession d'objet culturel ou spirituel pour la protection	En remplacement de l'item N°32
			N°26 (étude universitaire)	Taux d'alphabétisation encore faible chez la femme camerounaise
		N° 13, 15, 17, 19, 20 & 21 en rapport avec les parents.	N°27 en rapport avec le conjoint	Aucun item en rapport avec les enfants qui peuvent être source de protection et représentent une grande richesse au plan culturel.

Discussion

Les résultats obtenus à l'issue de cette première phase d'adaptation font ressortir les différences au niveau des caractéristiques socioculturelles entre la population québécoise auprès de laquelle l'outil a été développé et la population féminine camerounaise pour laquelle l'outil est adapté. Il s'agit notamment du niveau d'instruction ; de la période développementale de la population cible qui semble celle de jeunes adultes faisant des études universitaires ; des pratiques culturelles dont il était prévisible qu'elles soient différentes, de par la singularité de chaque peuple. Le taux d'alphabétisation des femmes camerounaises reste encore très faible dans certaines régions, notamment septentrionales, où il est inférieur à 40%[19]. Cette différence de niveau général d'instruction, la spécialisation du langage et les aspects linguistiques contextuels entraînent des problèmes d'équivalence sémantique qui nécessitent une reformulation de certains items.

L'*échelle de facteurs de protection* semble être adressée à de jeunes adultes. Elle insiste plus sur les parents (items 13, 15, 17, 19, 20 et 21), moins sur le conjoint (item 27) ou les enfants (aucun item) qui peuvent aussi être source de protection. En 2009, l'indice synthétique de fécondité était de 1,73 au Québec [20], alors qu'en 2012, il était de 5,2 chez les femmes camerounaises. La plupart des femmes au Cameroun deviennent mères entre 20 et 25 ans [21], alors que l'âge moyen de la maternité au Québec en 2009 était de 29,8 ans [20].

S'agissant du contenu, l'item 32 ne semble pas adapté au contexte socioculturel camerounais. Dans la plupart des cas, le rôle dévolu aux animaux domestiques n'est pas souvent en rapport avec la compagnie, mais plus avec la sécurité ou la chasse aux rongeurs. D'un point de vue culturel, les informatrices anthropologues ressortent le recours des populations à la médecine traditionnelle pour la protection, les soins ou la résolution des problèmes considérés comme coutumiers ou mystiques, ainsi que la forte tendance à la pratique religieuse. En Afrique, 80% des populations recourent à la médecine traditionnelle pour répondre à des besoins de santé [22].

Conclusion

La première phase d'adaptation de l'échelle de facteurs de protection a permis d'obtenir un accord sur l'équivalence sémantique et de procéder à un ajustement au niveau du contenu des items en vue d'une adéquation avec le contexte socioculturel de la femme camerounaise. L'outil final comprend 37 items répartis comme suit : 12 facteurs de protection individuels, 12 facteurs de protection familiaux et 13 facteurs de protection environnementaux dont cinq sont spécifiquement en rapport avec la culture. Il convient toutefois de rappeler que si les items de la version adaptée de l'*Échelle de facteurs de protection* sont mieux compris par les femmes camerounaises, il est important de déterminer ses propriétés psychométriques. Par ailleurs, une étude du processus de résilience dans une perspective cycle de vie montrera si ces facteurs sont effectivement retrouvés dans l'expérience de résilience des femmes camerounaises.

Building capacity in public health nursing students to respond to adversity experienced in the reality of practice

Lindley P., Hart A.

School of Health Sciences, University of Brighton, UK
p.lindley@brighton.ac.uk, a.hart@brighton.ac.uk

Abstract

Adversity experienced in professional practice has been identified in the fields of health care, social work and teaching with implications for the ability of practitioners to maintain their own wellbeing and to be effective in their roles. For public health nurses working in the field of child and family health in England such adversity has been exacerbated by significant reduction in their numbers, coupled with the widespread financial constraints and organisational change. The notion of 'practitioner resilience' is established in the literature. The challenge for educators is to support development of such resilience in student practitioners.

This paper reports on a doctoral study exploring how student public health nurses' experience in higher education and practice settings contributed to development of their capacity to respond to the adversity experienced in the practice role. Case study methodology, rooted in a critical realist approach, utilised a series of focus groups and semi-structured interviews to collect data from twelve students over the year of their course. A conceptual web of learning for practitioner resilience, drawing on resilience and transformational learning theory and reflecting the levels of critical realism, emerged from literature review and preliminary data collection. Key findings identify links between transformative learning and promotion of resilience.

Key words: 'Practitioner resilience', 'transformative learning', 'critical realism', education,

Introduction

There has been growing interest in practitioner resilience, particularly in relation to health, social care and education professionals, and the adversity that they may experience in their roles. McCann et al [1] define professional resilience as "the ability to maintain personal and professional wellbeing in the face of on-going stress and adversity" (p 61). Adversity in the context of work is taken to include difficult, or negative experiences with the potential to have an adverse impact on the functioning of the practitioner [6, 4]. Previous research has indicated that many entering the caring professions have experienced adverse personal circumstances [2]. In addition they may experience vulnerability through the contexts in which they work, expectations of their employers and society, and vicariously through exposure to the experiences of the populations, communities and individuals with whom they engage [3]. These factors combined with negative workplace experiences including growing workloads, diminishing resources, organisational change and poor organisational culture contribute to the experience of adversity in professional life [4, 5].

The public health nurse (Health Visitor) workforce in England has recently experienced a significant level of disinvestment. This has contributed to discrepancies between broad public health standards, against which these nurses' specialist professional education is validated, and the reality that they are exposed to in practice. Financial constraints and significant organisational change in the NHS have coincided with the reduction in staff numbers. Newly qualified Health Visitors (HVs) therefore experience practice that can impact negatively on their functioning and wellbeing.

There is recent research reporting on the occurrence of stress and burnout in nurses, social workers and teachers [6, 7]. Links are made with causes and protective factors and identifying remedial action [8, 9]. A role for professional education in promoting practitioner resilience has been identified [4, 6, 9-13]. Although the importance of building resilience through professional education has been recognised, little has been written about how this can be achieved. In the last few years a growing interest in specific interventions in professional education and their impact on building capacity to respond to adverse experiences, has started to emerge [4, 10, 14-16]. However, there is a lack of research examining the whole experience of student learning and the means by which this may enhance practitioner resilience. In addressing this issue the doctoral study explores 12 student

public health nurses' expectations of their new role and the reality of their experience, together with learning experiences that have contributed to development of existing or new abilities to respond to this reality.

Methodology

Critical realism, the stance from which the study is approached, situates the researcher in a position in which reality may be taken to be 'out there'; there is a real world but it is not unchangeable or unchanging. The way in which sense is made of this world is not fixed but affected by the social and historical contexts of the individuals experiencing the world. Distinctions are made between "things we experience and things that cause what we experience" [17 p.3], through: what exists (real), what is experienced (empirical) and the elements that are introduced into the system and their consequences (actual), these three levels of reality being brought into alignment through social action [18]. Intrinsic case study methodology [19] rooted in a critical realist perspective allowed for analysis of the complex, non-linear relationships between what students bring to learning, what they experience and what causes those experiences.

Ethical approval was gained from the University of Brighton and participants were recruited from a cohort of 35 students prior to the start of the course. Case study allowed for multiple methods of data collection. Qualitative data was collected through focus groups and semi-structured interviews. Some basic biographical data was also collected from the participants. 12 students volunteered to take part in the focus groups and 6 subsequently took part in individual semi-structured interviews. The sequencing of three focus groups over the year and interviews in the last two months allowed for emergence of issues and experiences that could be followed up at an individual level, enabling complexity to be explored.

Data collection

Data were collected from 12 participants through two series of 3 activity-based focus groups, run in parallel over the year's duration of the course. Semi-structured interviews were carried out with 6 of the participants. Course documents provided the context of the planned curriculum.

Activities in the focus groups included mind-mapping expectations, ranking resources promoting capacity to respond to adversity, and using a tower building game to explore how learning was built through the course.

The longitudinal nature of the data collection allowed for triangulation through examining the complexity of the issue from a number of perspectives [20] and an iterative approach to both data collection and analysis. A conceptual web of learning for practitioner resilience, drawing on practitioner resilience [4, 10, 13, 21-23] and transformational learning theory[24-26] and reflecting the real, actual and empirical domains of critical realism[18], emerged from initial literature review and preliminary data collection, providing a framework for data analysis.

Findings

Content analysis of the data against the conceptual framework resulted in clustering of data linked with each category. The domains and cluster themes are summarised in Table 1. That health visiting was a complex activity involving 'difficult' work emerged clearly from the data. Tensions in the participants' individual expectation and reality were overlaid with significant adversity being observed and experienced in practice, and to a lesser extent adversity experienced in the university. This adversity was evident in relation to the participants and their HV colleagues in practice settings and in their individual experience of being students, confirming the need for promotion of practitioner resilience at both individual and organisational levels.

Table 1: Cluster themes by domain emerging from content analysis.

Domain	**Cluster themes**
Real: Exposure to the HV role in the real context of practice	Identification of expectation and reality
	Challenges emerging from the structures and mechanisms
	Social contributions to building individual and collective resilience
Actual: The organisation of learning	Starting points
	Scaffolding learning for resilience
	Endings
Empirical: The experience of becoming a health visitor	Creating an identity
	Learning from negative experience
	Health Visitor as a "chameleon"

In congruence with critical realism relationships were not linear and links were evident between domains in the conceptual framework. Key to this linkage was praxis *ie* the participants testing out their learning in practice. In transformative learning, spaces are created to allow the students to 'take action' in their learning [26], that is to explore the use of their knowledge through praxis. Identification of these spaces takes us some way to understanding how the process of praxis may be promoted.

Theoretical content, delivered through student-centred Problem Based Learning (PBL) integrated with exposure to socio-economic deprivation in the client populations challenged the participants' assumptions and beliefs provoking an 'inequalities imagination' [23]. Participants were surprised by what they saw in practice, finding it emotionally difficult to cope with. This exposure, which could have been disempowering and undermine their resilience, actually acted as an incentive to do something about it, a 'resilient move' [27] in response to what was being seen. This action contributed to participants' objectives to 'make a difference' something voiced repeatedly throughout the study. Recognition of having done so was a positive influence on their resilience and ability to persist in their role.

'Openness' was identified as a central factor promoting resilience in the participants. This was evidenced in a number of contexts: individual openness to participate in reflective practice, the openness of leaders to see and hear what was happening in their teams and to respond to what was being expressed, and openness within teams. 'Openness' contributed to building a 'safe place' for reflection within the individuals that they could then take into any context. The development of openness was supported through honesty and trust established in relationships between the students in the context of their formal learning and in their social interaction. The participants identified the importance of the trusting, honest social support networks established in the university with their peers. At times breaks and mealtimes were identified as more important than the taught content. Small group work in PBL trigger groups, Action Learning Sets (ALS) and sustained contact with the same tutors provided environments that nurtured this trust and honesty in the formal curriculum. Numerous spaces for reflection and modes of its application were identified across contexts, with good evidence of participants' commitment to its use and value as a resource for resilience. Negative experiences were an important source of learning if handled well by those involved with reflecting on the experience, however they had the potential to severely undermine resilience if handled badly.

Role modelling and observation were widely recognised as ways in which participants learnt resilient behaviours, as well as learning how not to behave. This related to building resilience into their identity in their new role, a 'way of being' in that role, and the way in which they would lead and work in their teams.

Team dynamics and leadership influenced the existence of both individual and team resilience. Adversity as a collective experience was clearly evident [28], and links between individual and team resilience were identified by participants who recognised that a single team member lacking resilience had the potential to undermine the resilience of the HV team collectively and individually.

Conclusions

The study contributes new knowledge regarding the development of practitioner resilience through the transformational learning experience of the course. The critical realist approach facilitated the emergence of relationships between individual and team experience of resilience that is based in social theory. The conceptual framework of a web of learning for practitioner resilience contributes to understanding the complexity of causal relationships in transformative learning for building resilience.

Participants appeared to have developed a number of resources promoting resilience through the transformative learning experience of their course. Learning is not a linear process, and praxis is critical in the scaffolding of learning for resilience.

The study suggests limited application of practitioner resilience at an individual level, and supports the application of a wider social theory of resilience.

laurentiu.mincu@fpse.unibuc.ro, eugen.avram@fpse.unibuc.ro

Abstract

Purpose. The aim of this study is to analyse the life satisfaction predictors in participants having a currently perceived health problem. The life satisfaction is being conceptualised by the means of the LiSat-11 model, which has been extended to some new dimensions. Conceptually, the study includes several new elements and is consistent with current ongoing worldwide research. Social support is being analysed using a resource-oriented approach, the physician-patient relationship satisfaction is discussed ethically, and the couple satisfaction is investigated through a proprietary instrument that contains both cognitive and attitudinal elements. Additionally, body wellness and optimism are also included, as determinant factors of life satisfaction.

Method. The questionnaire technique was used. Multiple scales were included.

Results. Multiple regression has shown that social support, satisfaction in the physician-patient relationship, couple satisfaction, body satisfaction and optimism are all predictors of life satisfaction in people having a currently perceived health problem. Life satisfaction is lower in participants having more than one health issue than in those with only one such issue. Social support is lower in persons that have not been hospitalised than in those who have been. The social support is also lower in those who have undergone a lengthy period of drug administration than in those who have not. The physician-patient satisfaction is lower in subjects who have been administered medication for lengthy periods of time.

Conclusions. The study highlights the following predictors of life satisfaction: social support, medic satisfaction, body satisfaction and couple satisfaction. Satisfaction towards the physician-patient relationship awards the subject self-confidence, as well as confidence in the medic, which leads to an increase in positive perception and trust in his own abilities, physical as well as psychological, to face illness. The longer the treatment is, the more negative the patient's social support perception becomes; similarly, in the case of long treatments the levels of satisfaction with the physician-patient relationship tend to drop.

Keywords: Social support, satisfaction with the physician-patient relationship, couple satisfaction, body satisfaction, optimism, life satisfaction.

Introduction

The somatic discomfort and the perception of the general health state variations is associated with a decrease in life satisfaction Rogers [1]. Life satisfaction can be defined as a cognitive component of the subjective well-being. [2] Life satisfaction reflects the degree to which the basic needs are satisfied and the degree to which a variety of other purposes are perceived as achievable. It deals with the perception of difference between reality and the personal needs in the activity, participation and functioning areas.

Life satisfaction is also an indicator of health and general well-being that leads to a general feeling of physical and mental health, usually associated with a greater longevity. It is the degree to which an individual evaluates his life's global quality as satisfactory. The main areas of attention in life satisfaction evaluation are: life as a whole, vocation, economy, leisure, contacts, sexual life, activity of daily living, family life, partner relationship, physical health, psychological health. These aspects are integrated in the LiSat-11 questionnaire, an evaluation model developed by Fugl-Meyer . [3]

One of the most important determinants in life satisfaction is income. A higher than average income is associated with high levels of life satisfaction and psychological well-being. Income does not exert a significant

influence on life satisfaction after a certain threshold has been reached, due to the fact that the basic needs have been satisfied and income does not have real usefulness for anything else.[4]

Physical well-being is associated with high levels of life satisfaction. [5] Also, life satisfaction can be influenced by social functioning, marital status, psychological functioning, age [6] and cross-cultural variations (Needs and Values) [7]

The present study wishes to thoroughly investigate the presence of life satisfaction determinants in persons with perceived health problems. Previous works have suggested other predictors of life satisfaction, such as life fulfilment [8], future perspective perception,[9] Marital status [10], physician-patient communication [11], body image [12]. Other areas of particular interest are the degrees to which life satisfaction is predicted by: social support (the dynamics of the support/resources relationship), the physician-patient relationship satisfaction (the dynamics of expectancy / needs / reality), couple satisfaction (the quality of the relationship is the main focus, regardless of the marital status of the couple), body satisfaction (which is the satisfaction the subject feels towards his own body parts) and optimism (which is relevant in the classic dispositional approach).

1.1 Social support

Interpersonal support relationships hold great value in maintaining health, well-being and lowering stress. [13] The perceived help, worry, comfort and respect coming from the peers blend into the concept of „support".

Social support is the help a person is being offered by his peers in a defined situation or in general. Social life aspects (family relationships, group memberships) and resources that fulfill personal needs are included in the social support. Social support has various ramifications: actional/instrumental, economic/financial, informational, emotional. Other experts catalogued social support as informal, when it is being provided by family and friends [14] or formal, when it is provided by the state or by private institutions.[15] Patients evaluate social support according to the relationship between the external offer and the internal need for support.

Social support is evaluated according to the type and frequency of social relationships or according to the character of the resources involved (material or non-material). Some studies underline the role change and equity plays in providing social support (especially when provided between generations) and their impact on life satisfaction. The exchange, or equity, approach provides essential insight about intergenerational support and its relationship with the life satisfaction of the elderly.[16]

Psycho-social support plays a major role in alleviating the damaging effects of stressful events and, thus, in reducing the progress of health issues.

The important role of social support on the psychological well-being and life satisfaction of the individual has been highlighted since as early as the 1970s by Siu & Philips (2000).[14] Research has shown that the qualities, as well as the quantity, of the support are deeply connected to life satisfaction.[17] Other studies show that social support reduces,[18] has a profound impact on reducing the negative impacts of stress on mental and physical health. [19]

1.2 Satisfaction with the physician-patient relationship

The patient's satisfaction is a measurement of the relationship between expectancy he has from the health services and what he actually receives or experiments. The expectancy is different according to the sociodemographic characteristics of each patient and to the complexity of his illness.[20] But the perception of the quality of care has no connection whatsoever to the seriousness or complexity of the patient's pathology.[21]

Patient satisfaction is in accordance with several key factors, such as: the performance of the medical service, [22] the communication skills of the medic treating him, with the humanism of the medic [23], the medication (fast occurring, short-term effects and long-term medication results),[24] the impact the treatment has on daily activities, the patient's health monitoring quality by medical personnel.[25]

Considering facts from an ethical perspective, the patient's satisfaction can be translated as the result of his perception of the medic's shown ethical behavior. Using this ethical perspective, we can understand the main approaches the patient has when evaluating the medic: *the virtues' approach* (he values his ethic principles that enable him to develop or save human lives), *the common good approach* (he works in everyone's favour, treating every patient in the exact same way), *the honesty and justice approach* (he acts correctly, in a non-discriminatory fashion, communicating the truth), *the rational judgement approach* (he protects people's rights and morality), *the duty ethics approach* (he treats people as ends rather than means), *the utilitarian approach* (he produces results and does not intervene if he does not have the guarantee of success in accordance to the principle of „primum non nocere").[26]

This is the perspective of this research approaches. Additionally, the effect the medic-patient satisfaction has on the beneficiary's life satisfaction will be studied, taking another hypothesis into account: people do not forget experiences they had with medics, these affect them either positively or negatively.

1.3 The body image

The concept of "self" is the nature of the beliefs an individual has about himself. The body image represents the perception of one's own body as opposed to an ideal body image.[27] The body image is conceptualised as a multidimensional construct that reflects the way individuals think, feel and behave regarding their own physical attributes.[28] Body self-esteem is an individual's satisfaction towards his own body image. There is a strong connection between body self-esteem and self-esteem.[27] Poor body image perception leads to lowering self-esteem and to unhealthy behaviors (such as eating disorders) [28].Body image is an important part of global self-esteem.[29] Body self-esteem is associated with satisfaction in the couple and with life satisfaction.[30]

A negative body image leads to psychological and physical negative consequences. Women with a negative body image are predisposed to anxiety and depression, they are less prone to engage in relationships and make self-oriented statements. Furthermore, they experience a lower couple satisfaction and low levels of life satisfaction.[30] Individuals with high self-esteem are more confident in their relationship, and more prone to undertake emotional risks as solutions to various situations. Individuals with high self-esteem are more confident in their interpersonal abilities.[30]

1.4 Couple satisfaction

Romantic relationships are a central aspect of an individual's life. The couple satisfaction is an interpersonal evaluation of the relationship's quality in contrast to his own goals and other aspects of attraction and engagement towards the partner, including the relationship's expenses and rewards.[31] Couple satisfaction is also a by-product of the cognitive process of comparing one's partner to personal expectations, previous relationship experiences and personal observations of others. This type of satisfaction manifests itself through concrete, positive behaviors such as openness, reassurance, diving tasks among the couple or reciprocal help in the development of social life. Couple satisfaction is also analysed through the quality of communication and openness towards the partner.[31] Couples with high levels of satisfaction communicate more efficiently and adopt problem and conflict solving strategies. Couples with low levels of satisfaction minimize or avoid conflicts.

1.5 Optimism

Optimism is defined as the extent to which an individual has a stable tendency of manifesting positive expectancies towards the results of various life events [32]. Dispositional optimism is a person's tendency of being motivated by a belief in the easiness of obtaining the desired results [33]. Optimism is a positive emotional state that acts against psychological disorders (like hope or courage).[34]. Optimism has beneficial effects on the physical and psychological health of people.[33]. It contributes to the general psychological wellness through the improvement of the individual's ability to cope with stress.[33]. It is a major contributing factor in the quality of life in hospitalised subjects.[33].Optimism has been associated with significantly high rate of healthy behaviors.[35]. They tend to face the psychological, medical or physical adversities better than those with lower levels of optimism (fact that has been proven while experimenting with epilepsy patients) [36] and they act when confronted with health issues in order to reduce risk.[37] Optimists have positive health habits,[35] benefit from a better immune system.[35]. Optimism leads to different life expectancies than pessimism.[37]

Methods

For this exploratory study, the strategy of transversal research was chosen, alongside the correlational method and keeping the major focus on highlighting the predictor quality of the following variables: social support, satisfaction with the physician-patient relationship, couple satisfaction, body satisfaction, optimism and life satisfaction. This major objective was analysed for the criteria variable in subjects who consider their general health condition as afflicted in some way.

Other than the objective of testing the role predictor variables play on the life variable we have also considered testing how certain variables, such as health issues (one or more health issues), medical history (with or without medical history), illness history (with or without hospitalisation) and medical treatment (with or without administered medicine) influence the level of life satisfaction, the perceiving of social support and the satisfaction in the physician-patient relationship, variables which, in this case, have the status of independent variables.

1.1 Participants

The questionnaires were applied on general population, participants having been previously interviewed on the subject of their medical health and the possibility of having health issues that require a special treatment or regime. Out of 102 applied questionnaires, only the ones that mentioned a present health issues and scored lower-than-average on the GH (General Health) scale were selected. 30 males and 32 females with ages ranging from 21 to 63 years old (M-44.5, SD=16.5) were selected in the final stage. Out of these, 33 stated the existence of at least another health issue other than the previously mentioned one.

1.2 Material and procedures

The Life satisfaction criteria variable has been measured on the LiSat-11 scale, with the addition of 7 items: the comfort of the residence, the standard of living, the daily lifestyle, life, the accomplishments, future perspectives and financial situation. The psychological health item was eliminated and the resulting instrument has a Cronbach's Alpha =0.92.

The current perceived health problems were evaluated with the GH scale from the SF-36 Quality of life questionnaire. Additionally, four other items have been introduced: main health issue, the existence of a secondary health issue, hospitalisations and surgical treatment.

The predictor variable „Social support" was measured with the Patient Perceived Social Support (author E. Avram), an instrument consisting of 15 items that requires the patient to indicate(on a scale from 1 -very little- to 5 -very much-) the helpfulness of the following aspects: guidance, emotional and moral support, care received, communication (information/advice), financial support, material aid (objects, food etc.), visits/the presence of other people, trust, confidential information, various problem solving, given time, promptitude, availability, care for household errands, help in all ways possible, physical support (Cronbach's Alpha =0,94).

Satisfaction with the physician-patient relationship (author E.Avram) has 24 items which represent evaluative behavioral anchors that describe the medic using morally-based traits or behaviors (e.g. approachable, offers explanations, tells the truth, respectful, calm, competent, disciplined etc.) (Cronbach's Alpha = 0.97). The patient evaluates the doctor on a Likert scale from 1 to 5.

For the measurement of the relationship with the partner quality the Couple Satisfaction Scale was used. This is a 13 item instrument, 3 of those being negative. It contains such items as: „The quality of the relationship I have with my partner is very good", „If I were to pick again now, I would pick the same partner", „Our relationship influences my health in a positive fashion", „I have a series of frustrations in this relationship" etc. (Cronbach's Alpha=0.94).

The Body Satisfaction Scale is a modified version of The Body-Esteem Scale (35 items, by Franzoi & Shields, 1984; Franzoi, 1994) [38] which consist of 37 items that address the body parts of the subject, along with their traits (e.g. height, weight, head size, eyes, nose etc.). The patient expresses his level of satisfaction with these items on a scale from 1 to 5. (Cronbach's Alpha =0.92).

Optimism has been measured with the Life Orientation test (Scheier et al., 1994).[39] It has 10 items that measure the dispositional optimism (Cronbach's Alpha =0.70).

Results and discussions

Firstly, we have used the Bravais-Pearson bivariated statistical correlation procedure to highlight the correlations between variables. The linear regression analysis was applied to highlight the relations of prediction. The averages, standard deviations and correlation coefficients' values of the studies' variables are presented in Table 1.

Table 1. Descriptive statistics and correlation coefficients

Variables	Mean	Std.Dev.	1	2	3	4	5	6
1. Social support	52.38	15.76	-	0.39**	0.28*	0.40**		
2. Satisfaction phys.-pat. rel.	93.06	19.88	0.39**	-	0.41**	0.41**		
3. Couple satisfaction	47.50	12.77	0.28*	0.51**	-	0.38**		
4. Body satisfaction	130.52	31.37	0.42**	0.41**	0.38**	-		
5. Optimism	30.82	5.82	0.51**	0.33**	0.48**	0.34**	-	
6. Life satisfaction	14.66	4.59	0.40**	0.41**	0.56**	0.42**	0.51**	-

Legend:

** Correlation is significant at the 0.05 level (2-tailed)*

*** Correlation is significant at the 0.01 level (2-tailed).*

We can notice the fact that all correlations display positive values and that the „Life satisfaction" criteria variable records average values of correlations with the other predictor variables, especially with couple satisfaction and optimism. Social support correlates strongly with optimism. The satisfaction with the physician-patient relationship has a lower correlation with optimism. Couple satisfaction correlates more with optimism. Body satisfaction correlates with life satisfaction.

The study has shown multiple results through simple linear regression analysis (Table 2.). Simple linear regression analysis has shown that social support ($\beta = .40$, $p < .001$), medic satisfaction ($\beta = .41$, $p < .001$), couple satisfaction ($\beta = .56$, $p < .000$), body satisfaction ($\beta = .42$, $p < .001$) all represent independent predictors of life satisfaction.

Table 2. Simple linear regression analysis for independent predictors of life satisfaction

The predictor variable	B	SE(B)	β	t	Sig. (p)	R square
Social support	.11	.03	.40	3.40	.001	.16
Medic satisfaction	.09	.02	.41	3.53	.001	.17
Couple satisfaction	.20	.04	.56	4.73	.000	.31
Body image	.06	.01	.42	3.62	.001	.18

Criteria variable: life satisfaction

The variance of the criteria variable is explained by the following predictors: social support (16%), couple satisfaction (31%) and body satisfaction (18%). A positive body image leads to a higher degree of life satisfaction. Likewise, a high level of couple satisfaction, excellent social support and increased medic satisfaction all lead to a rise in the same criteria variable.

The simple linear regression analysis revealed that that the body image ($\beta = .38$, $p < .005$) and optimism ($\beta = .48$, $p < .000$) predictors are both independent predictors of couple satisfaction. A positive body image and a high level of optimism are associated with high levels of couple satisfaction. Body image explains 15% of the criteria variable's variance, while optimism explains 23% (Table 3).

Table 3. Linear regression analysis for independent predictors (body image and optimism) of couple satisfaction

The predictor variable	B	SE(B)	β	t	sig. (p)	R square
Body image	.15	.05	.38	2.93	.005	.15
Optimism	1.01	.26	.48	3.83	.000	.23

Criteria variable: couple satisfaction

The simple linear regression analysis has shown that social support ($\beta = .47$, $p < .000$) is a predictor of optimism. A high level of social support leads to an increase in optimism. Social support explains 22% of the variance of optimism.

Table 4. Simple linear regression analysis for optimism predictors (social support)

The predictor variable	B	SE(B)	β	t	sig. (p)	R square
Social support	.17	.04	.47	4.16	.000	.22

Criteria variable: optimism

The comparative study was carried out using the t-Student test on independent samples. Patients with more than one health issue (M=13.51, SD= 4.16) have a lower level of life satisfaction than those who have declared only one health issue (M=15.96, SD=4.76) (t=-2.15; p<0.05). The determination coefficient is $r^2 = 0.08$.

Patients which have been hospitalised (33 cases) (M=59.21, SD=15.04) have a higher social support than those without a consistent medical history (M=45.17, SD=12.74) (t=3.89; p<0.01. The determination coefficient is $r^2 = 0.20$.

Patients following a drug prescription for a long period of time (n=44, M=49.18 şi SD=15.57) have a lower perception of social support than those who have not undergone such treatment (M=58.56, SD=13.53) (t=-2.13; p<0.05). The determination coefficient is $r^2 = 0.08$.

The same patients have a lower level of medic-patient relationship satisfaction (M=103.56, SD=11.82) than those who have not undergone a lengthy treatment (M=90.52, SD=20.54) (t=-2.39; p<0.05). The determination coefficient is $r^2 = 0.10$.

Body image is also a predictor of the partner's involvement and openness inside the relationship. This leads to a better communication and an improved conflict management which, in turn, leads to a higher degree of couple satisfaction that supplies the high levels of life satisfaction.

Optimism is another important factor in couple satisfaction, as optimist partners display higher levels of couple satisfaction. It is influenced by social support in the sense that a high social support leads to higher levels of optimism.

The church's contribution to the resilience of the child institutionalised in romania in view of his integration into society

Ion P.

prof_religie_ion@yahoo.com

Abstract

In Romania there is a connection between the public social assistance and the ecclesial social assistance, and the very research in this paper proves this aspect in today's Romania. Taking into account life quality in Romania, we can easily paint the big picture of the problems of institutionalised children, not only as regards their life in the protection institution, but also their existence after leaving it. The low living standard, the problems related to family life etc., all these cause the instability of Romanians' life. In this situation, the Church plays its part in Romania's social work and assistance system, and our research, starting also from the Romanians' national culture, shows the connection between the Church and the public system of social work and assistance in Romania, as component of the institutionalised child's resilience in view of his integration into society.

Key words: child protection, institutionalised children, resilience, Church, priest

Introduction

The sociological research conducted in these past two decades has proved that Romania is a country still committed to traditional values[7]. In other countries of the world, we may also find high enough scores as regards each individual's religiosity [7], but in Romania religiosity is directly proportional with the use, for instance, of Christian symbols in public spaces, which in other secularised states is not possible and is even forbidden by law. In public spaces such as institutions of education, health, social work and assistance and even in administrative and top executive bodies, on the local, county and even central level we find Christian symbols placed in honoured positions. Religiousness among Romanians is not only a declarative aspect, but something that proves a certain empirical character, irrespective if it is connected only to the fact that we speak about superstition or about a concrete commitment to a religious life conform with the Church theological gnoseology. As the religious conduct of Romanians is rather strong, both on the individual level and in society at large, we may claim that we can speak about a Romanian identity specificity [6].

The Church is inclined, grace to its very formation, toward aid and assistance [2], which have taken new forms nowadays, different from traditional philanthropy, but the very Church in Romania practices a professionalised social work, either through its own social work activities, or by its involvement, with resources and pastoral-missionary activity, in the public practice of social work and assistance. "The analysis of religious structures and mentalities in Romania and of their transformation during these past two decades should start from an adequate comprehension of the operation mechanisms of the religious sphere in the Communist period. The idea of a religious reviving specific to post-communist countries is often presented as a logical reaction to the deep secularisation of the previous period, marked by a true atheistic ideologisation. Religion has followed, within communist societies, a more complex trajectory which, despite religious persecutions, drastic regulation of church activities and political secularism, has survived in the private sphere of the family environment "[1]

Within the dynamics of contemporary society we can remark the involvement of the Church on the social level, especially as regards social work. Researches throughout Europe present the West-European regions, where the secularisation process was more intense, and religion has a rather important contribution to the societal commitment as an institution of social work and assistance, sometimes professionalised. This is due to the fact that the population of this European area has been intensely fed with the spirit of secularisation. In exchange, on the East-European aria, the things are different. We find peoples strongly anchored in religion, and the institutional Church involvement is rather important, because the state-Church relation is different, and secularisation is an almost unexisting process.

After 1990, the Church in Romania has also gained a high confidence from the part of Romanians [8]. Among the institutions preferred by Romanians we find the Church and the Army, these two being in turn in the first and second positions in the population's trust top. Due to political instability during this period, the Romanians' confidence has been focused on the Church, as we also find a high percentage of Romanians who declare to be religious. In fact, the Romanian society has still remained strongly anchored in traditionalism and thus it is not strange that the Church is still one of the institutions offering Romanians a high degree of credibility.

The protection of the institutionalised child in Romania: summary aspects

In the communist era, until 1990, the child protection policy in Romania had a categorically centralised character, favouring the institutionalisation of children and less the responsibilisation of family and community, system specific to the communist ideology, when it was thought that the system masters the social situation of the country without major social problems. That is why we have very easily reached a rather serious situation in the matter of the institutionalised children, because, along with the fall of communism, the international press has written and presented materials showing the inhuman situation of the children from Romania's orphanages, as the system used to provide the strict bear necessities for existence: clothes, food, superficial education etc.

The milestone year for child protection was 1997, when the Romanian Government adopted the Emergency Ordinance no. 26/1997 regarding the protection of the child in difficulty, laying the foundations of a new protection system. In the subordination of county councils and local and Bucharest district councils, the law ruled the creation of bodies responsible for the establishment, application and monitoring of the protection of the child in difficulty: *Commissions for the child protection*, conceived as specialised organisms of the local public administration; *Specialised public services for the child protection,* public institutions conceived as "executive" bodies of the commissions, with the mission to provide protection to the child in need, granting assistance in the realisation and exercise of their rights and awarding support to the family for the prevention of the situations endangering the child's security and development [5].

The general division is the public institution with legal personality, created in the subordination of the county council and the local council of the Bucharest city district, through the merger of the public service of social assistance and of the specialised public service for the child protection on the level of the county, town and Bucharest city district, by the afferent take-over of their attributions and functions. The general division implements, on the county and local level, the measures of social assistance in the field of the protection of family, single persons, old people, handicapped persons and any other persons in need.

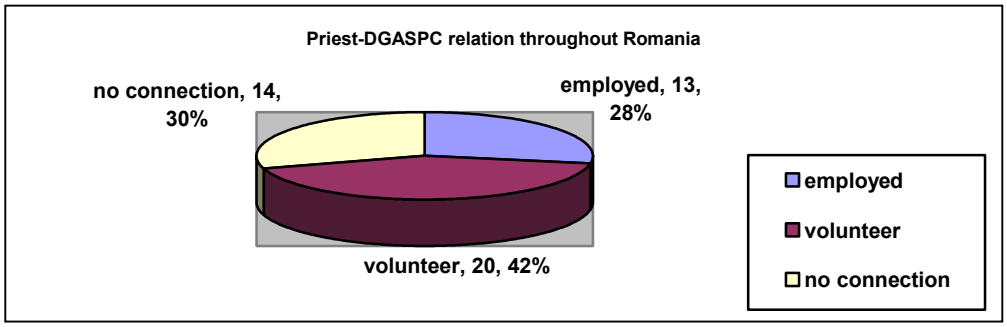
Formal and informal involvement of priests within the General Divisions of Social Assistance and Children's Protection (DGASPC) of Romania. Research aspects on national level

Most reforms in social assistance in Romania since 1990 have taken place in child protection and regarding child protection. Thus, our summary scientific endeavour of the paper will be focused on what is already an empirical certainty related to the presence of the Church by its involvement, grace to its specific activity in the field of child protection in Romania.

We shall briefly present a qualitative survey following a data collection by means of psycho-social inquiry in all 47 DGASPC offices (41 counties + 6 Bucharest districts) throughout Romania. We should mention that this research of ours was answered by all 47 Romania's. DGASPC offices. We must also highlight the high percentage of the *incidence of affirmative answers, significantly higher than in the psycho-sociological inquiries of the years 2000-2013 conducted in Romania, which sometimes used to exhibit a response rate o only 20%-30%.* In the case of our research, the percentage is very high: almost all DGASPC Offices in the country transmitted official and personalised answers, except three DGASPC Offices that were contacted by phone and offered a response through this communication medium. The research assembled on this occasion aimed at validating the following hypothesis:

Within the DGASPC organisations of Romania the incidence of the priests' involvement is majority;

As for the relation of the priest with the DGASPC institution, we shall present the data received from the field research, first under the form of a graph meant to suggest the situation in percentages too: concretely, how many priests are employed by DGASPC, how many are voluntary, and how many divisions in the country there is no connection with the priest. This can be seen in the **Graph 1** below.



Graph 1. *Priest –DGASPC relation throughout Romania*

As regards the priest-DGASPC relation in Romania, we have the following data presented in **Graph 8**: priests employed (counties who are currently employing priests in their apparatus): we find them in 13 counties of the total 41 counties + 6 Bucharest districts, representing 28%; priests who are volunteers: there are 20 counties in Romania, representing 42%, working with volunteer priests, and finally the counties where there are no priests present, in any form, are in number of 14, representing a 30% percentage.

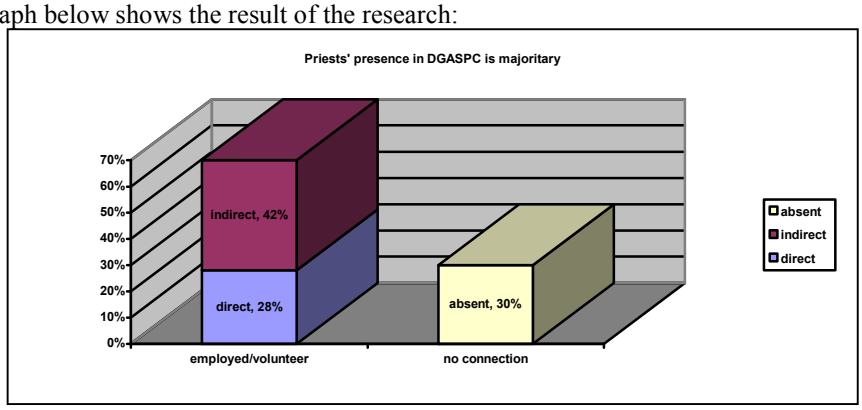
The number displayed next to the priests employed by DGASPC in the country is one representing in fact the number of counties that have such positions within their apparatus. It does not represent the total number of priests employed by DGASPC offices throughout Romania.

Moreover, I have already referred to this aspect in the present paper, and we shall present it briefly. When we say *voluntary priest*, we do not refer to mere volunteering we are used to promote, but to the volunteering that is connected to the higher leading bodies of the Church. For instance, there are very many cases when a young theology graduate can be ordained as missionary priest within leading bodies of the Church, such as deanery, diocese etc. If partnerships are concluded between DGASPC şi and the aforementioned ecclesial organisms, the liaison person between the two institutions becomes the missionary priest who is present in the programme of the institutions of child protection without being the actual employee of the DGASPC, but only a volunteer.

In order to quantitatively test ***Hypothesis 1*** of the research we shall define the three variants of response as follows:

1. Employed priest —***direct*** presence of the priest in DGASPC
2. Voluntary priest —***indirect*** presence of the priest in DGASPC
3. No connection — ***absence*** of the priest from the DGASPC institution

The graph below shows the result of the research:



Graph 2. *Validation of hypothesis*

Using this official data, throughout Romania the priest-DGASPC relation is one of complementarity because the ***Research hypothesis*** was validated. Although the number of counties that have a position of priest within their apparatus is slightly lower than the counties with no connection with the priest, we encounter volunteering (indirect presence of the priest in DGASPC), which provides a rather high result. The fact that throughout Romania there are so many counties that are currently employing priests in their DGASPC apparatus means that these positions of priests within DGASPC in the country have not been and are not sporadic. The 28% percentage aggregated with the 42% of volunteering leads to the 70% - presence of the priest within the public institutions of child protection, which means more than 2/3 of the total value of the data collected through the research conducted.

Conclusions: Contribution of the Church by the involvement of the priest in the resilience of the institutionalised child in view of his insertion into society

For several centuries, the process of separating laic power from ecclesial power has been increasingly obvious. The State-Church relation in the Western countries has become rather cold, the word of order between the two being neutrality. In Romania, things are different. In fields such as social work and assistance, in our country the State-Church relation is one of complementarity. Even in the projects started in Romania grace to European institutions and with European financing, in laic social assistance the Church is not regarded as a mere non-governmental organisation , but as an extremely important institution in the Romanian society, especially in the rural area. Starting from the involvement as a priest in laic social assistance, more precisely in the field of child protection, we conducted a national survey meant to assess the relation between the Church and DGASPC, co-operation that confirms the role currently played by the Church in the child protection institution in Romania.

Our scientific endeavour is relevant. The author's experience as a priest in a laic institution of social work and assistance is not unique, so we do not refer to a mere singular case in the region or in the country. The commitment to help in children's needs and crisis situations represents a very important thing in order to stabilise the institutionalised child. His integration into society after the exit from the system is necessary, and the Church participates also in this effort by the priest's formal or informal involvement.

Abstract

From 2008 to 2013, we conducted an extensive action research coeducational in three cities from Belgium in significant economic, social and psychological distress. Increasing poverty of their population causes extremely negative impact on school and social adjustment of young people and the educational practices of parents, teachers and the community in general. To cope with this crisis with eminently traumatic effects, it germinated the idea of (re) invent the Cities of Education. To achieve this, it was necessary that everyone takes action: not only educational institutions but also the political, social and scientific bodies, business ... to develop a partnership for a common educational project.

Throughout and at the conclusion of the action research, we conducted both quantitative and qualitative assessments. The results show that collective consciousness can build and generate benefits at all persons, especially in children (regarding especially the language).

Why can we say that the City of Education became a Resilient City? Because it has allowed many subjects to engage in a new way of emancipating development due to various factors, that has encouraged its emergence: the installation of a reliance between different actors (affective factor) better control of knowledge and meaning of events (cognitive factor), the introduction of new power relationships (social factor) and thinking about new values to guide action (conative factor).

Keywords: Poverty, Action Research, Cities of Education, Co-education, Resilience

Introduction

De 2008 à 2013, nous avons mené une vaste recherche-action dans trois villes de Belgique en grande détresse économique et sociale. (La recherche-action « Parents partenaires de l'éducation – Expérience-pilote à l'école maternelle » que nous avons dirigée a été subsidiée par la Fédération Wallonie-Bruxelles – Ministère de l'Enseignement obligatoire. Les chercheurs ont été : P. Couvreur, V. Della Piana, A. Hachat, F. Hardy, D. Horlin, M. Houx, B. Humbeeck, J. Lecompt et A. Tutak. Le concepteur graphique de « Polo le Lapin » a été M. Berger.) La pauvreté croissante de leur population provoque des retombées extrêmement négatives sur les comportements d'adaptation scolaire et sociale des jeunes et sur les pratiques éducatives des parents, des enseignants et de la communauté en général. Dans ces villes, nous avons constaté que les parents ne savaient plus comment éduquer, les enseignants ne savaient plus comment enseigner, les responsables politiques ne savaient plus comment gérer les problèmes sociaux et les enfants ne savaient plus comment apprendre. Pour faire face à cette crise aux effets éminemment traumatiques, a germé l'idée de (ré)inventer les Cités de l'Education. Eduquer dans la Cité, par la Cité, relier les désirs et les forces de chacun, créer de la reliance, émanciper ses habitants tels furent les objectifs de cette recherche-action. Pour y parvenir, il fallait que chacun se mobilise : non seulement les instances éducatives mais aussi les instances politiques, sociales et scientifiques, les entreprises… pour développer un partenariat visant un projet éducatif commun. Le but a visé une coéducation école-famille-communauté en vue d'une synergie fructueuse et ce au départ d'outils créés pour la circonstance.

Tout au long et à l'issue de la recherche-action, nous avons effectué des évaluations tant quantitatives que qualitatives. Les résultats montrent qu'une conscience collective peut se construire et susciter des effets bénéfiques chez tous et notamment chez les enfants (en ce qui concerne le langage particulièrement). Des zones d'éducabilité, trop souvent ignorées, existent bel et bien et nous incitent à poursuivre l'action entreprise. Etant donné les résultats engrangés, de multiples villes dans différents pays se sont engagées dans un tel projet, tant et si bien que nous avons été amenés à créer un Réseau International des Cités de l'Education (RICE), régi par une charte et une convention d'engagement.

Pourquoi peut-on dire que la Cité de l'Education est devenue une Cité résiliente ? Parce qu'elle a permis à de nombreux sujets de s'engager dans une voie nouvelle de développement émancipateur en raison de divers facteurs dont elle a favorisé l'émergence : l'installation d'une reliance entre les divers acteurs (facteur affectif), la meilleure maîtrise des connaissances et du sens des événements (facteur cognitif), l'introduction de nouveaux

rapports de pouvoir (facteur social) et la réflexion à propos de valeurs nouvelles pour guider l'action (facteur conatif).

L'objectif poursuivi dans les propos qui suivent sera de préciser les retombées négatives du chômage de longue durée qui nous ont amenés à mettre en œuvre la recherche-action « Parents partenaires de l'éducation », laquelle a débouché sur la création de « Cités de l'Education » dont on peut dire qu'elles sont devenues de véritables Cités résilientes.

La pauvreté et ses retombées

Les trois villes dans lesquelles nous avons mené notre recherche-action – Charleroi, Péruwelz et Etterbeek (Commune de Bruxelles) – se caractérisent par un contexte économique très difficile. Le chômage de longue durée y règne en maître. On sait que cette situation n'a pas qu'un impact financier. Elle entraîne aussi des conséquences sociales, médicales, psychologiques et éducatives désastreuses. S. Ionescu et E. Bouteyre [1] consacrent un chapitre de l'ouvrage « Traité de résilience assistée » (sous la direction de S. Ionescu, 2011) à la résilience assistée en situation de chômage. Ils y décrivent les connaissances les plus récentes à propos des effets du chômage sur la santé mentale et mentionnent les modèles qui expliquent ces effets. Nous reprenons ci-après quelques résultats de la méta-analyse de Paul et Moser (2009), cités par les auteurs précités.

Les effets négatifs du chômage sur la santé mentale sont confirmés. Ils se traduisent par un large spectre de manifestations : détresse, dépression, anxiété, symptômes psychosomatiques, diminution du bien-être subjectif et de l'estime de soi. Ils sont plus importants chez les chômeurs de longue durée : ils se stabilisent à un niveau élevé au cours de la deuxième année et une nouvelle hausse intervient pendant la troisième et la quatrième années.

S. Ionescu et E. Bouteyre [1] citent le modèle de la privation proposé par Jahoda (1981, 1982) qui souligne que la détresse des personnes sans emploi est liée à la privation de différentes fonctions bénéfiques du travail : celui-ci, en effet, structure le temps, favorise les contacts sociaux, permet d'atteindre un but collectif (se sentir utile), fournit un statut et satisfait le besoin d'activité. Ils mentionnent aussi Hayes et Nutman (1981) pour qui le bien-être matériel, obtenu grâce au travail, permet de maîtriser l'environnement et contribue à satisfaire le besoin de créer. Ils citent encore Fryer (1986, 1997) et Fryer et Payne (1986) qui soutiennent que la pauvreté empêche l'anticipation de l'avenir, favorise le pessimisme et rend plus difficile la mise en place de stratégies proactives pour faire face à la situation vécue. C'est dans un tel contexte de détresse que vivent de nombreux enfants de Charleroi, de Péruwelz et d'Etterbeek.

Par ailleurs, nos recherches, notamment une étude longitudinale menée sur une durée de 30 ans, ont montré :

- le poids considérable de la famille dans le développement et l'adaptation scolaire des enfants [2] ;
- la précocité des déterminants de la trajectoire scolaire [3] ;
- la faible diversité des pratiques éducatives des parents en milieu démuni [4] ;
- la reproduction, d'une génération à l'autre, des comportements et attitudes éducatives qui discriminent les groupes sociaux [5].

Ainsi, un lourd déterminisme, lié à l'environnement, pèse sur la trajectoire scolaire et sociale des individus. Avec l'accroissement de la pauvreté, les problématiques éducatives ne font qu'augmenter.

Les jeunes issus des milieux où règne la pauvreté connaissent des conditions de vie désastreuses et expriment le plus souvent leur mal-être soit par la passivité, soit par la révolte. Peu s'en sortent. Comment encore apprendre à l'école quand on est submergé par des sentiments d'impuissance et d'injustice ? Les parents, sans repères et vulnérables, sont démunis face à l'éducation de leur(s) enfant(s) et reçoivent peu de soutien. Les enseignants eux aussi sont en désarroi devant l'immensité des difficultés.

Si l'ensemble des apprentissages sont concernés par cette problématique, l'apprentissage du langage apparaît comme particulièrement touché par celle-ci. Ainsi, nos recherches [6] et celle de Bentolila [7], traitant des acquisitions linguistiques des jeunes enfants fréquentant l'école maternelle, montrent les énormes disparités qui existent entre les enfants selon le milieu social dont ils sont issus et la précocité de l'installation de celles-ci.

Or, des travaux tels que ceux de Vygotsky ou de Bruner mettent en évidence le rôle du langage dans la construction de la pensée. On sait aussi que la maîtrise du langage est un puissant facteur de réussite scolaire. Mais, par-delà, l'apprentissage d'un code langagier permet à l'individu, dès son plus jeune âge, de s'inscrire dans un jeu de pouvoir, donne du sens à ce qu'il vit et détermine la nature des liens qu'il établit avec les autres. C'est dire toute l'importance du langage dans la formation de l'être humain : il possède une fonction tout à la fois sociale, affective et cognitive. De plus, des enfants issus de la pauvreté et/ou de l'immigration vivent une situation très difficile parce que les codes linguistiques utilisés dans leurs divers milieux de vie – dans la famille, à l'école, dans la communauté – sont différents.

C'est donc une multitude de difficultés qui atteint les enfants vivant en situation de pauvreté. On peut parler, pour beaucoup d'entre eux, de traumatisme, le trauma prenant la forme d'une épreuve durable susceptible de produire chez eux un fracas, une véritable effraction psychologique.

Par ailleurs, les relations école-familles pauvres sont, en général, soit absentes, soit très conflictuelles. Pour les parents qui, fréquemment, ont mal vécu leur scolarité, les rencontres avec les enseignants rappellent des souvenirs douloureux et peuvent constituer une menace pour leur équilibre psychique : ils les évitent donc ou les abordent avec violence. Pourtant, de nombreuses études et recherches-actions rapportent, depuis longtemps, les effets bénéfiques sur la réussite scolaire de l'implication des parents dans le système éducatif scolaire [8]. Là aussi, les enfants issus de familles pauvres sont perdants et il devient compréhensible que certains s'orientent vers des comportements anomiques, la défiance à l'égard de la société puis son rejet s'installant lorsqu'ils prennent conscience que celle-ci ne leur donne pas les moyens pour atteindre les objectifs qu'elle propose et ne respecte pas les valeurs qu'elle préconise.

Or, à toute société incombent deux missions : celles de protéger et d'émanciper. Nous venons de voir qu'avec les familles pauvres, on est loin du compte. Il devient donc indispensable et urgent d'agir. Mais comment faire ? Le contexte ambiant incite le plus souvent au fatalisme et au sentiment d'impuissance. Tout se passe comme si les milieux – école, famille, communauté – fermés les uns aux autres étaient incapables de mettre en place les opportunités permettant aux individus de faire preuve de résilience. Si, isolément, les milieux ne peuvent aboutir à un résultat probant, alors un partenariat école-famille-communauté au sein d'une Cité de l'Education peut, quant à lui, produire le changement.

C'est pourquoi nous avons mené, de 2008 à 2013, une recherche-action, dans les trois villes précitées, en prenant pour cible, dès l'école maternelle, le langage oral, dans ses dimensions lexicale, syntaxique et phonologique. Si, comme nous l'avons signalé, le langage est une composante importante du développement humain, il a surtout été le moyen de favoriser la coéducation entre les différents milieux de vie de l'enfant.

La coéducation se distingue de la simple relation professionnels-parents par le fait que les acteurs unissent leurs forces afin d'atteindre un objectif commun, à savoir le développement optimal de l'enfant, à l'aide d'outils communs, basés sur un référentiel commun, à savoir une définition partagée de ce que recouvre le développement psychosocial et langagier de l'enfant.

Nous décrivons ci-après la recherche-action « Parents partenaires de l'éducation » qui, au fil du temps, a donné naissance au concept de « Cité de l'Education ».

La recherche-action « Parents partenaires de l'éducation »

1.1 Ses Caractéristiques

Il importe de souligner d'entrée de jeu que la recherche-action menée s'inscrit dans un contexte écosystémique en ce sens qu'elle implique une indispensable articulation entre les sphères politiques (les autorités municipales, le pouvoir organisateur), scientifique (l'Université) et pédagogique (les parents, les enseignants, les chefs d'établissement). Durant les trois années de la mise en œuvre de la recherche-action, de nombreuses rencontres de types différents ont eu lieu : réunions de concertation et d'accompagnement, colloques, forums, séminaires… avec les divers acteurs scolaires et politiques, avec les parents, avec des experts… Le plus souvent, les acteurs politiques et pédagogiques ne disposent pas des outils nécessaires pour entreprendre une démarche partenariale. Il est donc indispensable d'innover. C'est là que peut intervenir la sphère scientifique pour élaborer, expérimenter et évaluer des outils efficaces pour aider les sphères politique et pédagogique à agir sur leur terrain.

Ainsi, trois outils essentiels ont été produits : une série d'activités langagières, un recueil d'activités de coéducation et un programme d'éducation familiale.

La mise en place d'un contexte éducatif visant à stimuler le langage oral chez l'enfant de 3 à 6 ans a impliqué la production d'un ensemble d'activités à travers lesquelles le parent et l'enseignante agissent ensemble comme partenaires d'un acte éducatif commun. Issues des pratiques des enseignantes, des activités ont été regroupées dans 10 fascicules pour chacun des âges (3, 4 et 5 ans), proposant à l'enfant de se livrer à la fois à l'école et en famille à de petits jeux visant à renforcer ses compétences lexicales, syntaxiques et phonologiques. Les fascicules ont été construits autour d'un personnage récurrent : Polo le lapin. Celui-ci a aussi été matérialisé par une peluche qui « voyage » avec l'enfant de l'école vers la famille. Souriant et rassurant, ce petit personnage a la capacité d'exercer un impact affectif considérable et de susciter la motivation à apprendre.

Au cours de cette recherche-action, nous avons également répertorié les pratiques innovantes de coéducation créées par les enseignantes. Ce recueil, intitulé « Coopérative d'activités de coéducation », s'est enrichi au fur et à mesure du développement de l'expérience.

Par ailleurs, un programme d'éducation familiale a été élaboré dans le but d'enrichir les pratiques éducatives des parents de façon à ce qu'elles répondent le plus largement possible aux besoins affectifs, cognitifs et sociaux des enfants. Neuf fascicules ont vu le jour à la fois comme support aux groupes de parole pour

stimuler la conscientisation, la réflexivité, l'auto-analyse et l'expression du vécu et comme outil complémentaire pour les parents, à domicile. L'animation des groupes de parents n'est pas assurée par les enseignants mais par un intervenant extérieur en lien avec l'école.

A côté des fascicules, une plateforme internet présente la recherche-action et met à disposition, pour le téléchargement, les activités de langage et de coéducation. La traduction (en 7 langues) des consignes a été réalisée pour les parents non francophones.

L'ouverture aux médias est également une démarche favorisant l'intérêt pour la recherche-action. Ainsi, dix émissions « Une éducation presque parfaite » ont été réalisées et diffusées sur deux chaînes locales. Ces émissions sont aussi utilisées comme support à la discussion dans les groupes de parents.

A l'issue de la recherche-action, un guide intitulé « Stimuler le langage en maternelle par un partenariat école-famille » a été réalisé. (Les fascicules de langage et le guide sont téléchargeables sur le site : http://www.eduquonsensemble.jimdo.com)

Lors de la phase extensive de la recherche-action, ce sont quelque 106 classes des villes de Charleroi, Péruwelz et Etterbeek qui ont participé à la recherche-action.

1.2 Son Evaluation

1.2.1 Evaluation quantitative des gains de langage

Lors des trois années durant lesquelles s'est déroulée la phase extensive de la recherche-action, nous avons comparé les gains de langage d'un groupe expérimental qui a participé au projet à ceux d'un groupe contrôle qui n'y a pas participé. Chaque année, trois tests de langage (2 tests de vocabulaire et un test de syntaxe) ont été appliqués en pré-test (en octobre) et en post-test (en mai). Un indice global de maîtrise du langage a aussi été calculé (regroupement des 3 tests). Par ailleurs, des variables signalétiques et contextuelles relatives à l'enfant, à sa famille, à l'enseignante et à l'école ont été prises en compte.

Les résultats au test-t montrent que le gain global (les 3 tests réunis) est, pour les trois années consécutives, très significativement supérieur chez les enfants du groupe expérimental. Nous observons aussi que les gains aux trois tests et pour les trois années successives sont supérieurs chez les sujets du groupe expérimental, souvent très significativement.

Si nous examinons les relations (au test-t) qui existent dans le groupe expérimental entre le gain global langagier et les variables signalétiques et contextuelles et qui se recoupent d'année en année, nous observons que le gain global langagier des enfants est significativement supérieur quand :

- l'implication pédagogique et la satisfaction de l'enseignante dans le projet sont élevées;
- l'approche méthodologique tend à être moins conforme à ce qui a été proposé dans le programme (activités fragmentées avec approfondissement de chaque partie ou innovations personnelles dans la présentation des activités) ; ce constat rejoint celui de l'implication pédagogique ;
- la mascotte Polo est employée en classe et « voyage » de l'école vers la famille et inversement ;
- la participation de la famille au projet est important ;
- les élèves sont issus d'écoles caractérisées par une hétérogénéité des milieux sociaux, contrairement à ceux qui fréquentent des écoles recrutant dans un milieu défavorisé homogène (il n'y a pas d'école composée d'élèves issus d'un milieu exclusivement favorisé).

Par contre, aucune association significative n'est observée avec les variables : genre de l'enfant, structure familiale, réseau d'enseignement, quartier de l'école, niveau socio-économique de la famille, année scolaire fréquentée par l'enfant et langue parlée au foyer. Pourtant, on observe des gains plus élevés (sans être significatifs) chez les enfants de niveau social inférieur, chez ceux de 1ère année maternelle et chez ceux dont la langue maternelle n'est pas le français.

Ainsi, nous pouvons affirmer que, d'un point de vue quantitatif, le programme de stimulation au langage associé à des pratiques de coéducation, améliore les performances et compétences langagières de l'enfant en vocabulaire et en syntaxe. L'objectif visant à optimaliser la maîtrise du langage oral des enfants en maternelle est atteint.

Soulignons également que l'efficacité du projet est liée à la mise en place de pratiques pédagogiques innovantes des enseignantes et de participation des parents.

1.2.2 Analyse des entretiens avec les enseignantes

Un recueil d'informations systématisé a été réalisé auprès de 24 enseignantes issues des groupes expérimentaux. L'*implantation du projet* est perçue favorablement car beaucoup d'enseignantes étaient en recherche de solutions face au problème de langage et donc d'outils pour travailler plus efficacement. Elles apprécient en outre que leur chef d'établissement joue un rôle mobilisateur à l'égard du projet.

Si, dans un premier temps, les enseignantes tendent à se conformer aux indications et suggestions présentées dans les fascicules, très rapidement, elles adaptent les activités proposées de façon variée et diversifiée. Beaucoup réalisent un matériel complémentaire à visée pédagogique. La peluche Polo est fréquemment utilisée en classe, « voyage » régulièrement de l'école vers la famille et, au retour, est le prétexte pour stimuler l'expression orale de l'enfant chez qui elle a séjourné. Par ailleurs, la disponibilité des chercheurs a permis aux enseignantes d'être sécurisées et valorisées dans leurs pratiques. La participation des parents n'a, par contre, pas été à la hauteur de leurs espérances. Elles réclament le soutien des chercheurs pour trouver des solutions plus efficaces à cet endroit.

Le *bilan du projet* est perçu de façon positive. Les enseignantes reconnaissent que les activités de langage qu'elles mènent sont désormais devenues à la fois beaucoup plus réfléchies, systématiques et plaisantes. Elles ont constaté un accroissement des compétences langagières chez leurs élèves tant sur le plan lexical que syntaxique. Des changements positifs sont survenus chez tous les enfants et particulièrement chez les « petits parleurs ». Les effets bénéfiques de l'affectivité générée par le personnage Polo ont aussi conduit les enseignantes à porter un autre regard sur leurs élèves et à porter plus d'attention à leurs besoins et à leurs progrès. Ainsi, les attitudes plus positives des enfants et des enseignantes se renforcent mutuellement, créant un véritable cercle vertueux.

Toutefois, les attentes initiales quant à l'implication active des parents dans la coéducation restent quelque peu insatisfaites. Ce constat n'est cependant pas démobilisateur pour beaucoup d'enseignantes car il les incite plutôt à s'interroger et à se remettre en question. Au final, faire participer tous les parents est pratiquement le seul point difficile du projet qui a eu un impact positif sur les pratiques et le rôle des institutrices maternelles. Celles-ci estiment qu'il serait bon de poursuivre les activités au premier cycle de l'enseignement primaire en vue d'établir une continuité d'apprentissage.

1.2.3 Évaluation du programme d'éducation familiale

Les informations concernant le programme d'éducation familiale ont été recueillies par des entretiens collectifs, des entretiens individuels et des questionnaires auprès de 31 parents issus de 5 écoles différentes.

Le programme a été vécu de façon très positive par les parents. Développant une méthode implicative qui fait appel aux expériences vécues, il favorise, selon les parents :

- la reliance au sein du microsystème (échanges et dialogue accrus avec l'enfant et avec d'autres membres de la famille), du mésosystème (nouveaux rapports entre l'école et la famille, entre les participants au sein du groupe de parole ; perception d'un soutien social) et du macrosystème (prise de conscience de l'impact des contextes économique, social et politique sur l'éducation ainsi que des causes externes aux difficultés rencontrées dans l'éducation) ;
- la réflexivité tant dans les attitudes (curiosité, auto-analyse de leurs expériences d'éducation) que dans les compétences (questionnement sur leurs pratiques, décodage, mobilisation des apports théoriques, reconstruction mentale) ;
- l'estime de soi, se manifestant par un accroissement de l'amour de soi (auto-reconnaissance de son identité, satisfaction par rapport à soi-même), de la vision de soi (évaluation de soi, auto-reconnaissance de ses compétences) et de la confiance en soi (conviction d'être capable d'agir, perception d'un regard positif d'autrui sur soi, sentiment de reconnaissance de sa compétence par autrui) ;
- l'enrichissement des pratiques éducatives, grâce surtout aux échanges avec les autres participants.

De manière générale, les parents interrogés se disent satisfaits de la méthodologie proposée. Ils ont pu dépasser leurs craintes, voire leurs réticences de départ (prendre la parole dans le groupe) et leurs frustrations (recevoir des recettes est plus facile). Ils ont aujourd'hui beaucoup d'interrogations nouvelles et désirent poursuivre leur formation. Pourtant, la participation des parents n'est pas facilement régulière. Elle demande une sollicitation constante de la part de l'animateur (choix de l'heure, rappels…). La pérennisation d'un tel programme d'éducation familiale suppose de dégager une personne-ressource et une institution-relais qui soient porteuses du projet et qui puissent assurer les missions de *sensibilisation* auprès des écoles concernées, des parents et des autres partenaires potentiels, de *réactualisation constante* en fonction des publics, des demandes, de la dynamique du groupe, etc. et d'*évaluation* continue, mais aussi au terme de chaque rencontre.

Vers la Cité de l'Education

La Cité de l'Education est un pas de plus vers l'alliance éducative car on dépasse ici la seule coéducation école-famille pour y intégrer la communauté dans son ensemble. Les sphères politique, scientifique et sociopédagogique (parents, enseignants mais aussi intervenants sociaux et éducatifs) s'articulent autour d'un objectif éducatif et d'un canevas méthodologique communs, ce qui permet de coordonner et de dynamiser l'ensemble des initiatives prises dans le domaine de la coéducation et du soutien à la parentalité au sein d'une

même entité, la Cité de l'Education. Les différents partenaires disposent ainsi d'un cadre structurel au sein duquel les projets peuvent être mis en place dans les différents espaces investis par les parents : crèche, école, accueil extrascolaire, maison de la parentalité, centre public d'aide sociale, commune, entreprise…

Un tel dispositif nécessite la mise en place d'une double stratégie : l'une de formation de chacun des partenaires sociaux, l'autre d'une mise en réseau des différents projets concernés par la problématique de l'éducation. Il vise à faire réfléchir les acteurs sur leur action, en articulant les différents projets autour d'un référentiel commun qui donne une cohérence à l'ensemble de l'action. Ce concept d'approche intégrée implique à la fois le respect de la spécificité de chacune des approches et le développement d'un corpus de pratiques cohérentes.

Tout pouvoir organisateur peut décider d'implanter une Cité de l'Éducation : ce peut être une ville, une commune, un quartier, une école, voire une classe. Sa finalité est de concrétiser des pratiques de coéducation en créant du lien social, en reconnaissant les responsabilités éducatives de chaque partenaire et en recherchant l'émancipation de chacun de ses membres.

Comme nous l'avons déjà signalé, le projet de coéducation « Parents partenaires de l'éducation » et le concept de Cité de l'Education reçoivent beaucoup de demandes d'information et/ou d'accompagnement émanant de la Belgique mais aussi de l'Italie, de l'Espagne, du Portugal, du Québec, de la Grèce, de la France… Un Réseau International des Cités de l'Education (RICE) a été créé, dont les membres signent une charte, actuellement disponible sur le site de l'AIFREF (Association Internationale de Formation et de Recherche en Éducation Familiale www.aifref.org)

Conclusion : La Cité de l'Education, une Cité résiliente

Les résultats de la recherche-action menée apparaissent à l'évaluation indiscutablement positifs. En fait, les familles pauvres disposent de ressources souvent insoupçonnées et insuffisamment mobilisées. En aucune façon, la société ne les accueille, ne les valorise et ne les stimule. Elle ne suscite pas leur projection dans le futur, ne communique pas avec elles, ne les outille pas, ne leur donne pas de repères éducatifs, ne les conscientise pas aux enjeux d'une éducation émancipatrice. Avec la recherche-action « Parents partenaires de l'éducation », c'est chacun de ces éléments non pris en compte que nous avons voulu réhabiliter tout à la fois chez les enfants, les parents, les professionnels et d'autres acteurs de la Cité, comme, par exemple, les entreprises qui, elles aussi, peuvent devenir éducatrices.

Ainsi, il existe d'extraordinaires richesses dans tous les milieux et il faut non seulement les débusquer (en milieu démunis, elles ne se voient pas) mais aussi faire du processus de coéducation un facteur permanent de reliance école-famille-société, un outil de maîtrise de l'environnement qui (re)donne du sens à la vie et un moyen de recouvrer du pouvoir pour accéder à plus d'autonomie. N'est-ce pas là les ingrédients nécessaires à une trajectoire de résilience ?

Pour favoriser un tel parcours, nous avons rompu avec une vision éducative « scolarocentrée » pour nous orienter vers une logique d'alliance, de collaboration, de mise en réseau des différents lieux et des multiples acteurs socio-éducatifs. Dans cette perspective, nous avons aussi renversé le principe sur lequel repose généralement la relation éducateur-éduqué : le processus que nous proposons suppose que ce ne soient plus seulement les éducateurs qui éduquent mais aussi les éduqués qui fassent œuvre d'éducation puisque c'est la ville, avec tous ses acteurs, qui se fait, dans ce cas, apprenante.

Pour qu'une telle action soit efficace, il importe que le désir d'agir ensemble repose sur une série d'objectifs généraux communs et d'objectifs opérationnels qui leur sont liés. C'est ce que nous avons réalisé à travers les activités de coéducation et de stimulation du langage « Eduquons ensemble avec Polo le lapin ». Par ailleurs, le programme d'éducation familiale ainsi que celui qui, toute la durée de la recherche-action, a guidé la formation des enseignants et des autres acteurs socio-éducatifs ont contribué tout à la fois à susciter la réflexivité de chacun par rapport à ce qu'il fait et à inciter à une production, en tant qu'auteur, en fonction de l'expertise de la personne. Soulignons que l'ensemble des activités menées (programme de stimulation au langage, programme d'éducation familiale, émission TV « Une éducation presque parfaite », coopérative d'activités de coéducation, formation continue des enseignants) repose sur un modèle du développement psychosocial : le modèle des douze besoins psychosociaux de Pourtois et Desmet (1997) [10]. Celui-ci permet d'articuler les réflexions autour d'une définition commune de l'éducation et des objectifs d'émancipation que l'action menée s'est fixés.

Ces objectifs, intégrés dans un véritable projet politique, ont progressivement mis en place une Cité résiliente au sein de laquelle chaque individu garde son historicité, sa propre spécificité mais devient en même temps acteur, voire auteur de son développement.

Resistance and resilience in active minority behaviours

Stan D.

Department of Sociology and Social Work, "Alexandru Ioan Cuza" University of Iaşi
dtrustan@yahoo.com

Abstract

Regarded from a psycho-sociological perspective, human acts are either rich in reasoning, or rich in energy. The rational dominant is encountered especially in group manifestations and it offers group members arguments to be together. On the other hand, the energetic or reactive expression is mainly encountered at the level of individuals, who must provide quick responses to the various stimuli they are facing. In relation to groups and persons that adapt positively to various critical circumstances by using the force of both rational elements and of their impulse, it is being said that they perform acts of resilience. The essential objective of any minority is to reproduce itself as a group and, implicitly, to resist the "tyranny of the majority". For this purpose and depending on the context, minorities mobilise traditional and modern, deliberate and residual, selfish and altruist, constructive and destructive aspects, brands and patterns etc. Becoming aware of threatening situations is stressful and challenging for all minority groups. Consequently, each minority responds, when it is capable of resilience, through active, mutually advantageous negotiations of extra-group relations and by creating an intra-group system of social work. The present study outlines a number of aspects related to the majority – minority relations, as well as some standards that the active minority could use to amplify its resilience ability. We have proceeded in such manner so as to conclude that the active resilient minority promotes an accentuated community spirit, has abilities that ought to be valued by society, and the minority status is no longer disagreeable.

Key words: minority, majority, resilience capacity, active minority, community, social justice, socio-cultural resistance

Heterogeneity and the unity of social spaces

Contemporary societies are social bodies of too little homogeneity. Modernity, and especially postmodernity, have turned social spaces into mosaics; therefore, what we now call society is, in fact, a huge demographic environment, highly segregated, to which most individuals and groups subscribe only for the sake of various advantages: collective identity, sustainable security, social protection, formal education, social justice etc.

The more densely populated societies are, the more numerous elements that separate their members come into play, the higher the probability of critical internal situations occurring, and thus the more constrained they are to amplify their resilience capacity. Therefore, in all societies, by way of more or less rational and organised procedures, the sources of alienation of individual and social normality are identified, risk factors are ranked according to the danger that they pose and the imminence of their outburst, as many resources as possible are localised with the aim of being mobilised in anti-crisis reactions, rules are formulated to supervise inter-human relations, conditions are cultivated so as to functionally correlate various structures and to create stable social units etc. Ultimately, all such endeavours construct an image that facilitates the social contract, and individuals and groups of all categories understand that their adhesion to the contractual state is not random, but compulsory. The effects thereof are vital [1] and some of such effects deserve to be recalled: guaranteeing the fluency of the relations between majority and minority groups; establishing the individual's main standing towards the group and the relationship between personal will and collective will; making compatible the heterogeneous components of society by the unitary use of a normative system; stimulating the actors of social life to become aware of the advantages resulting from the status of a contract party, as well as of the disadvantages that they encounter when they express escapist, segregationist and exaggerated views; the endemic transmission of natural resilience strategies within the social body and, implicitly, amplifying the resilience capacity at individual and group level.

The lack of homogeneity in societies becomes easily noticeable when we compare them: if we ignore the elements that pertain to the natural logic of the structuring and functioning of the social – according to which there are parties (family, economy, religion, leadership etc.) and functions (reproduction, care, education, order

etc.) that are similarly or unifying for the entire world – the means and images expressed by social agents (persons, communities, societies) depend on social positions, predispositions, dispositions, attitudes, capacities and choices [2] that they hold or perform in a certain context.

"Distinctiveness" characterises one society by reference to another, starting from the simplest cultural features – such as good manners, favourite colours for clothing, culinary tastes, bribing practices, styles of communication – up to the most complex ones: the will to highly performance, attitudes towards war, resilience capacity, tenacity in work, popular manners, the members' axiological options.

The abundance and the obviousness of the differences between the socio-cultural models applied by various societies constrain us to avoid or renounce holistic and generalising visions on societies. At the same time, they encourage us to opt mainly for actual analyses of the social bodies, so as to discover their inner connection and the forces that constitute their capacity for resilience. In this last situation, we consider the "status quo" of a nominal society, whose particular features are identifiable not only in connection to what happens outside it, but to what happens inside it. The lack of homogeneity is easy to notice this time too; however, in the case of a single society, the heterogeneous composition is transformed by the social contract into "coherent heterogeneity" [3]. In this respect, P. Bourdieu argues that the space of any normal society is an "ensemble of distinct and coexisting positions, external to each other, mutually defined in connection with the others by *mutual exteriority* and by proximity, closeness or distance relations, as well as by order relations such as above, below and in between" [4].

In a particular society, its members differ with age, physical appearance, residential environment, marital status, wealth, social class, educational capital, religion, political views, resilience capacity, ethnic origin etc. Consequently, the sum of the indicators that disperse individuals along various registers of classification is very comprehensive. This is why it is relatively difficult to rank persons with a mosaic of features as belonging to the same community or society unit. Yet, their qualities usually place them, one in relation to another, on positions of functional interdependence. The range of relations among individuals as parties to the social contract remains very broad, comprising variants connected to super-ordination, subordination, collaboration, indifference, harmony, conflict, ignorance, tension, assistance, incompatibility etc., yet their relation of complementarity remains the most important because: **a.** it provides a solution to the discomfort created by the lack of homogeneity among social environments, involving apparently disconnected components; **b.** it forces social agents to reconsider their position towards what is minor or minority in the society and it highlights the special roles that they can play in special contexts; **c.** it increases resilience capacity at individual and group level by joining together the forces of most departments of socio-cultures.

Demographic majority and minority

From a sociological perspective, each indicator that demarcates the characteristic features of society becomes a criterion for the statistical distribution or for the division of population in two categories which are disproportionate in number: *the majority and the minority.* The first of the two categories designates the group that comprises more than half of the members of a society; group belonging is the consequence of the automatic registration of individuals among those who have or lack a certain quality, or by the similarity of the content of the wills, positions, opinions, attitudes etc. of most of those comprising the respective society. The second one, the minority, defines any group unit that has different socio-cultural and / or physical characteristic features from those of the larger population, with which it formally coexists in the same juridical-administrative space, and risks being discriminated by the majority precisely on account of its long-preserved differences.

The simplistic and dichotomous allocation of population among these categories of groups leaves space for interpretations and even criticism [5]:

- **a.** according to a certain criterion (for instance, skin colour), an individual can belong to the majority, but at the same time he or she can belong to the minority through his or her religion or language etc.;
- **b.** the presence of an individual within the majority segment does not imply his or her automatic association with success, a state of comfort, social advantages etc., just like his or her belonging to the minority group does not necessarily represent a predisposition to failure, inferiority, trauma, stigma, the need for social work;
- **c.** at various stages in historical experience, minorities were understood as spaces of social abnormality, while the majority was imagined as a source of axiological correctness, a legitimate axis of values and a space of normality;
- **d.** a minority's behaviour is tolerated and defined as normal, up to the moment when it distances itself too much from the expectations of the majority, and if the majority does not get used to the specificity of the minority group, the occurrence of discrimination is possible;
- **e.** discrimination emerging in such context appears to be a procedure to constrain and sanction, and the minority defends itself from the abuses of the majority by "refugee behaviours", by boycotting the social projects in which it is not co-interested, by identifying a subsidiary protection system etc.;

f. when the majority puts pressure on a minority group and fails to obtain the desired outcomes, society turns into a conflicting space that engages energies, prejudices, vanities etc. which can dissolve the psycho-social climate;

g. if the majority's essential goal is not the "collective good", but success, at any costs, in the confrontation with the minority group, then the state of the social contract is deeply affected, and the minority adopts the natural defence attitude towards the "tyranny of the majority" [6];

h. the crisis of the relations between the majority and the minority should lead, in a rational way, to increasing the society's resilience capacity, but its only actual outcome is the reactive increase of the residual resistance of the groups inside it, which are preoccupied more with conserving and reproducing their identity than with developing their own forces.

When evaluating the social roles occupied by the majority and the minority, people tend to assign the most favourable positions to the majority group and to associate minority groups with the marginal areas of social comfort. Seen from the perspective of demographic weight or of access to the elements of power (administration, politics, economics, legislation, decision making etc.), the majority seems to outperform minorities: the majority has most members in power, distributes statuses, grants certificates, supresses and elaborates norms, manages material resources and so on. By analogy, it can be argued that the *majority always has a high resilience capacity, while the minority's resilience reaches only a minimal potential of resistance* or of survival.

As resilience is understood as the "capacity to succeed in a socially acceptable way, despite stress or adversities that normally involve the severe risk of a negative outcome" [7], we can conclude that *minority resistance is a form of pseudo-resilience*. Minorities demonstrate a respectable capacity for resilience when: they do not isolate themselves but are in dialogue; they do not subordinate themselves unconditionally, but obtain equality; they do not give up traditions, nor limit themselves to their protective force only; they do not deny it when they undergo critical periods, but turn them into opportunities to optimise the state of the group; they are not satisfied with simple "imports" from the other coexisting groups but offer them solutions arising from their own experience; they do not resort to immoral and subversive ways to impose themselves in the social space, but they identify constructive alternatives for action, to consolidate the social contract and to increase their own prestige. Through such a philosophy of engagement in the functioning of the social space, a minority becomes active and increases its capacity for resilience.

Active minorities and resilience

In the present democratic societies, socio-cultural models promoted by the majority are no longer unconditionally accepted by minorities. On the contrary, the latter perceive many of the majority's initiatives and decisions as threatening or utterly tyrannical. Moreover, ethnic, religious, political, linguistic, sexual, occupational minority structures etc. react, trying to balance social forces and to gain access to favourable positions that are easily available for the majority. Such demographic segments constitute the minorities of a society, and on account of their proven reactivity, they are also called *active minorities*. Essentially, such a minority represents the "assembly of individuals who, without benefiting from numerical force, power or acknowledged prestige, reject the norm accepted by the majority of group members and determine social change" [8] in the direction that they are targeting.

The activism of minorities can be channelled in a dissolving, anomic, constantly disputing direction, during the minorities' relation with the majority. On account of their conspicuously disproving and deliberately exaggerated orientation, an active minority of this type can also be entitled *counter-normative*. Its capacity for resilience is low and continuously diminishing, consuming many resources only to be nihilistic towards the initiatives and behaviours of the majority. On the other hand, when a minority deconstructs the socio-cultural model recommended by the majority, but proposes in exchange a better performing option, the process being useful to all categories of individuals, including those who form the majority, such minority can be entitled *pro-normative*.

It is desirable for any society to comprise only *active pro-normative minorities*. Such minorities would monitor the activity of the majority, for constructive purposes, and they would interfere so as to optimise the functioning of the entire social environment. In parallel with the action-based success of this type of active minority, the capacity for resilience would be developed not only within the minority group but also in the society to which it belongs. Unfortunately, in very many societies, both in the East and in the West, the mentality of the majority remains of an exclusivist type, admitting discriminations for various reasons and forcing minorities to contend themselves with the pseudo-performance of surviving or of being tolerated.

Overcoming these failings implies the activation of the capacity for resilience through the involvement, by the minority group, of multiple factors from an incredibly large spectrum: from energies that come genetically and advantages arising from geographic position or from historical antecedents etc., up to forces that derive from organisational affiliations, spiritual adhesions, moral practices, conscious and elevated accumulations of cultural

capital. At the same time, the societies set out principal measures concerning the social health of the relationship between majority and minority, which we can associate to the concept of "assisted resilience" [9] and which can be considered genuine methodological orientations in the use of the capacity for resilience:

a. solving conflicts between the minority and the majority by resorting to the "win-win" strategy and by emphasising the parties' cooperation and complementarity in decision-making;
b. promoting a positive image of a minority by encouraging it to be present at moments of evaluation initiated by the public opinion, especially so as to showcase its outstanding accomplishments and thus claim and obtain the social respect that it deserves;
c. engaging relations between the majority and the minority starting from the *in group* position of both parties and from the idea of their equality of rights / duties;
d. educating the minority in the spirit of the rejection of positive discrimination, so as to avoid cases when the majority could consider that it is being discriminated via the special protection granted to minorities; **e.** stimulating communication between the majority and the minority, their association in situations that suppose solidarity and community spirit – without thus forcing the assimilation or subordination of one of the parties by the other;
e. expressing, unequivocally, the views on the various crises that impact society, so as to remove all suspicions connected to the potential duplicitous or centrifugal behaviours of either the majority or of the minority;
f. constructing a national legal system that protects all types of minorities, but which also inhibits anyone tempted to commit discriminations;
g. disseminating the international legislation fighting discrimination, including the provisions that do not encourage minorities to turn the right to minority's existence into a privilege or a special source of rights;
h. analysing critically and periodically the national and international legislation, so as to adapt legal norms to current realities and to have the guarantee that legislation is always non-discriminatory / anti-discriminatory;
i. promoting, on a large scale, national and international cases of good practices in negotiating the dialogue between the majority and minorities, with the aim of educating these groups in the spirit of social justice and of the availability to share social protection, rights, obligations and benefits [10].

Conclusion

The implementation of the lines of action listed above requires, inter alia, that certain conditions connected to the financing, duration and special means of communication are met, that cultural and political personalities embrace this cause, that the egalitarian / democratic community spirit is sensitised. Irrespective of their number, these conditions must be fulfilled, as long as stakes depending upon them are :

a. the development, inside society, of the feeling of "us" by having both the majority and minorities concurrently subscribing to it;
b. the preservation of the status of minority by individuals and groups, yet without associating it to stigmata, ingratitude and social non-integration issues;
c. harmonising majority-minority relations by transforming minorities into active pro-normative groups;
d. the development, by each minority community, of the internal resilience capacity and, implicitly, the increase of society's standards concerning social work.

Social processes of resilience among young men leaving the care of girls and boys town, South Africa

D. Van Breda A.

University of Johannesburg (SOUTH AFRICA)
adrian@vanbreda.org

Abstract

The vulnerability of those aging out of residential and foster care has become widely recognised in recent years. Much attention has been given to the structural measures required to buffer care-leavers from this vulnerability. However, the resilience of care-leavers is less well documented. This paper draws on data from those who have left the residential care of Girls and Boys Town in South Africa. Using grounded theory research, four social processes in which young men engage emerge. These include Striving for authentic belonging, Networking people for goal attainment, Contextual responsiveness and Building hopeful and tenacious self-confidence. This paper provides a brief overview of all four processes, followed by closer attention to the ways in which the study participants interact with their social environment to increase their resilience. The importance of addressing resilience at the interface between people and their environments, thus an ecological perspective, is emphasised.

Keywords: Care-Leavers; Resilience; Belonging; Child and Youth Care; After-care; Independent Living.

Introduction

The vulnerability of young people aging out of residential and foster care has become widely recognised in recent years [1]. Young people typically enter care because of various deficits in their personal functioning and/or social environments. Even when quality care is provided, these young people frequently leave care vulnerable. They return to social environments that have usually not improved during their time in care. The picture that these young people present is often seen as bleak, resulting in researchers calling them "one of the most vulnerable and disadvantaged groups in society" [2]. Outcome studies on young people leaving care have demonstrated rather disappointing outcomes [3], including homelessness, poor health, poverty, substance abuse, early parenthood, and involvement in crime [4] [5]. All told, the research on care-leavers makes for "depressing reading" [6].

Despite this unhappy situation, some young people, perhaps even many young people, do exit care successfully and transition successfully into adult living, establishing themselves in life, finding stable work, securing safe accommodation, establishing meaningful relationships and avoiding drugs and crime [7]. There has consequently been a steadily growing interest in the resilience of young people leaving care, to determine what kinds of factors contribute to successful transitions into adult life [8]. Resilience as a theoretical framework has become increasing important and valued in care-leaving research, because it recognises and celebrates the strengths of young persons as they navigate through the challenges of life. It aligns well the values of child and youth care work and social work's strengths perspective [9].

This paper draws on grounded theory research conducted among young men who had left the residential care of Girls and Boys Town (GBT) in South Africa several years previously. The study sought to understand the social processes that young men engage in as they navigate through the transition from care towards independent living. Four primary processes emerged through this research. This paper gives particular attention to the ways in which the young men interacted with their social environments to increase their resilience. The importance of addressing resilience at the interface between people and their environments, thus an ecological perspective, is emphasised.

Literature review

This study is located within resilience theory, with a particularly ecosystems perspective. Resilience has become quite widely recognised as an important and valuable theoretical lens for research in the field of care-

leaving, and an ecosystems or ecological approach to resilience has been enjoying increasing favour in recent years. Resilience as an umbrella construct refers to the capacity and processes that enable individuals or systems to recover after stress. Vaillant's [10] well-known definition is that resilience is "both the capacity to be bent without breaking and the capacity, once bent, to spring back". The bending is the stress or adversity, while the flexibility is the recovery. Resilience incorporates both facets (adversity and strength) distinguishing it from, for example, the strengths perspective in social work, which emphasises only the strengths [9]. I have operationally defined resilience as "the ratio between the presence of protective factors and the presence of hazardous circumstances" [11].

An increasing body of care-leaving research has begun to show the kinds of resilience factors that contribute to greater success in adjusting to life after residential care. These emerge from studies that have uncovered that while the outcomes for care-leavers are not excellent, they are not universally bad. Some young people – many young people – do well in their journey out of care. Research has endeavoured to identify what enables these youth to do well, despite the challenges of care-leaving. Stein [12] has recently pulled these factors together, emphasising things like: attachments, positive school experiences and problem solving while in care; social networks and gradual transitions while exiting care; and employment, education, self-determination and resolving past conflicts with their birth families after care.

However, much of the resilience research (including studies on the contributors to positive outcomes, which are not necessarily conducted from a resilience perspective) has foregrounded structural resilience factors, that is, factors located in the social environment that are provided as part of a social welfare system. These include independent living programmes prior to leaving to care, mentoring in the transition out of care, the provision of aftercare, facilitating or funding educational advancement, assistance with employment and the provision of a range of social welfare benefits through policy initiatives [13].

While all of these structural factors are good and appropriate, few of them are available in resource constrained environments like South Africa, and indeed most of the developing world. The centrality of these factors in the literature can, perhaps, be attributed to the fact that much of this research is conducted in the UK, USA and parts of Europe and Australia – much better resourced, first world countries. While putting in place structures that facilitate healthy transitioning out of care is essential, young people in currently resource constrained environments are finding their own resilience factors that enable them to transition successfully into adult life. The current study is particularly interested to identify these factors.

While this research actively focuses on the social processes that young people themselves engage in and deliberately looks beyond structural factors, it is nevertheless conducted with due regard for the person-environment interface. The ecological perspective, which attends to the person-in-environment nexus, is entrenched in social work [14]. This perspective has more recently been written about as the social ecology of resilience [15]. Ungar views resilience as an interactional process between individuals and their social environments. It is not just that there are protective resources available in the environment. And it is not just that individuals have internal resources that foster well-being. It is the intersection between these two that constitutes an ecological perspective on resilience. It involves complex interactions between people and their environments, drawing on both individual and environmental assets. When these two sets of assets line up, a resilience response is seen.

The current study, however, does not emphasise the resilience producing properties of the environment as much as Ungar does, preferring to focus on the point of interaction between individuals and environments. Consistent with the strengths perspective [9], all environments, even resource constrained environments, are seen as full of resources. Young people leaving care draw on these resources. Frequently it appears that the environment generated the resourcing response, but this study's assumption is that care-leavers are adept at triggering these resourcing responses, by the ways in which they work at this person-environment interface.

Methodology

This qualitative study made use of a grounded theory (GT) design, specifically, constructivist GT [16]. GT was selected because of its focus on social processes and actions, rather than themes or factors. The constructivist version of GT was valued because it attends to the ways in which research participants and researchers construct rather than discover theory – research becomes a process of sense-making, rather than discovery.

The population was defined as all young persons who had been in GBT's care for at least 18 months and had disengaged from care four to six years previously. Nine members of the population of 74 individuals were sampled using availability sampling. Due to the lack of a GBT aftercare programme, most members of the population could not be traced. The nine participants were the only ones that could be. Although the population included a few women, they could not be located, thus the sample comprises only men. These men represented various demographic groups, occupational status and family situation.

Data were collected using an unstructured interview schedule, by a team of three researchers who conducted the entire project (from conceptualisation to report writing) as a team – this use of a team contributed to the rigour of the study [17]. Participants were asked to narrate their life story since leaving care, giving particular attention to successes and challenges. Data were collected and analysed iteratively in two rounds. Interviews were transcribed verbatim and analysed by the team, using GT methods. The study was informed in advance by resilience and ecosystems theories, but a thorough literature review was conducted only after data had been analysed. The full report is available at www.adrian.vanbreda.org.

Findings

Figure 1 below illustrates the central findings from this study. Four themes emerged, which describe the social processes of resilience evidenced by these young men as they journeyed towards independent living. *Striving for authentic belonging* emerged as a fundamental process, as care-leavers invested, albeit ambivalently, in establishing secure, meaningful and familiar relationships in which they felt validated and accepted. Care-leavers *networked people for goal attainment*, identifying the right people in the right places, often people they had little or no relationship with, who could help them get ahead in life. The young men showed a knack for *contextual responsiveness*, reading their social environments, identifying opportunities and threats, and responding in constructive ways. And despite the ongoing challenges they encountered in life, they continued to *build hopeful and tenacious self-confidence*, believing that they will overcome and trusting that things would work out okay. These four social processes were expressed within contextual boundaries – contexts with numerous limitations and lack – at the person-in-environment interface.

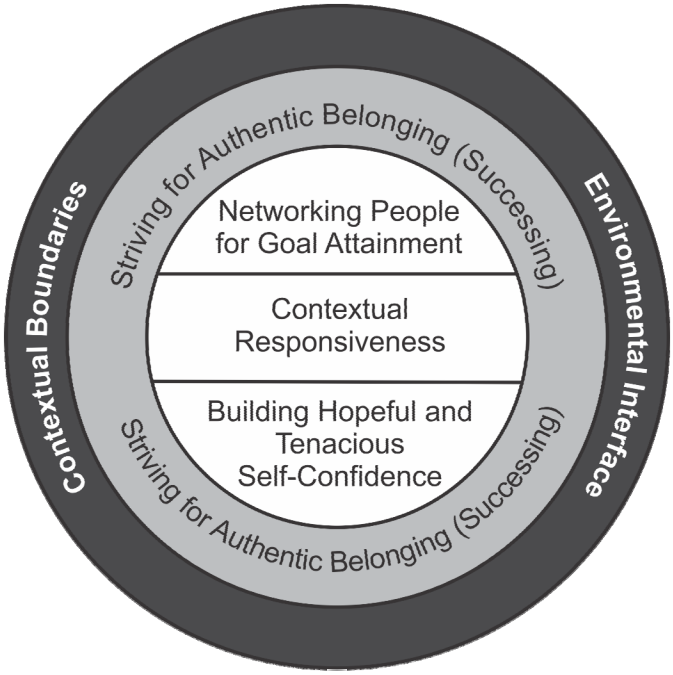

Figure 1. The Social Processes of Resilience among Young Men Leaving Residential Care.

All four social processes emphasise the young men's interaction with the world around them. They do have cognitive, affective, volitional and behavioural elements that are personal – located inside of them as individuals. But they are played out in the social arena. This is in contrast to many resilience processes, such as sense of coherence [18] or hardiness [19], which are primarily located inside individuals. It is also in contrast with the demographic aspects of resilience, such as the finding that the older people age out of care the better they do [20], over which young people may have little control. And it is also in contrast with the more structural or environmental focus of much resilience research on care-leaving, which emphasises for example the importance of providing secure accommodation or support for further studies [12]. Instead, the data from this study emphasise the ways in which young people initiate engagement with their social environments that is conducive to their own development.

Striving for authentic belonging is one good example. This process emphasises the young person's effort – their striving – to establish relationships that satisfy a deep and often unmet need for genuine

relationship and the sense of belonging. Belonging has been increasingly recognised as central in the lives of all young people [21] and vital in facilitating successful transitioning out of care [22].

Germaine, for example, expressed a high need for close, familial relationships and was successful in establishing these kinds of relationships with ex teachers, friends and even a drug lord. He articulated that this was rooted in the absence of a sense of authentic belonging in childhood: "*I was alone all my life [from age six when he left his mother's care], I had to stand on my own two feet, stand by myself. I had nobody to depend or to fall back on*". He associates this early experience of being dislocated from his maternal relationship with his subsequent descent into: "*Smoking weed, doing drugs – scoring a whole of wrong stuff*". Perhaps in response to these early belonging deficits, Germaine strives to construct new opportunities to experience authentic belonging through being likeable, friendly and, in some ways, childlike: "*I attach to people quite quickly.*" These social processes have been highly successful for Germaine, and he has experienced meaningful authentic belonging in several family-like relationships.

Other care-leavers have developed authentic belonging in the context of intimate relationships. Thabo, for example, related how disclosing his GBT history deepened his relationship with his girlfriend. "*She was one of the first people I confided in and said, 'I am a Boys Town boy', told her about a lot of stuff, so when I talked to her she would understand me.*" Her acceptance of who he was and her willingness to guide him out of the challenges of his past were instrumental in the path he chose for his future: "*I had to make some hard decisions for my life, and she was instrumental in helping me say look, remember what you learned, remember where you come from.*"

The need for authentic belonging, while universal, is rooted for many young people in care in the deficits experienced in early attachments [3]. Fractured attachments leave young people particularly hungry for authentic belonging and, paradoxically, ambivalent towards such belonging. Andre, for example, related a key life event, when he was 8 years old, as the traumatic loss of his brother in a car accident: "*I lost him there in a car accident, and I tried to replace him because I was heart sore."* He cites this loss as the motivation behind some of his behavioural problems: "*From that age I started stealing heavily.*" His ambivalent stance towards his need for authentic belonging interferes with his ability to establish steady intimate relationships: "*Every time when I meet someone new I always find a way without me noticing to mess it up. I always, always. But I keep on telling myself that's my bad luck.*"

Networking people for goal attainment is a second important social process that is particularly located at the person-environment interface. It refers to the ways care-leavers engage with others in ways that elicit helpful responses from others than help the care-leaver achieve his goals. While these others are sometimes people the care-leaver knows well (such as a family member), they are frequently acquaintances or strangers.

Dean, for example, who had started his own apparently successful business, struck the interviewer as *"mature and confident without being boastful or bragging. It felt like he had been used to being successful in his life already – self-assured"* (from the interviewer's field notes). After the interview was completed and the recorder switched off, Dean *"said something like, "Now that I have done something for you, would you mind doing something for me? I would like you to share my business card with the [GBT] campuses that may then use my business'."* Here Dean uses the interviewer to network for work opportunities, drawing on his friendly, easy going and self-assured manner to mobilise the interviewer, despite them having had no prior relationship.

Even quiet, shy individuals, like Christopher, are able to network for goal attainment: *"I decided to start looking for another job. I was walking around just to get away for the day and I walked into [a restaurant] to have a nice lunch. I saw that the place was quite busy and the waiters were running up and down. I asked to see the manager and the manager came to me and I asked him, 'Are you perhaps looking for waiters?' and he said, 'Yes, I am. Are you interested?' I said, 'Ja [yes], I wouldn't mind coming to work here as a waiter'. And he said, 'Well okay, you're starting tomorrow'."*

Social capital theory is helpful in explaining the importance of relationships in helping care-leavers get ahead in life and navigate successfully through life's challenges [23]. However, it emphasises the depth of these relationships, rather than the breadth, as being most important [24], while networking people for goal attainment more often plays out with strangers or passing acquaintances than with enduring relationships. Granovettor's [25] theory of 'weak ties' provides a helpful theoretical explanation. He argues that strong ties, which social capital theory emphasises, link one to others who share one's relationships, leading to a rather closed network which is less likely to introduce new information or opportunities. On the other hand, weak ties (e.g. passing acquaintances) connect one to other networks with whom one has no relationship, and are thus much more likely to offer new information and opportunities.

When one is therefore in need of assistance, housing, a job or some other opportunity, weak ties have great value. But one does have to be willing and able to engage with strangers, recognise opportunities and elicit helpful responses. Networking for goal attainment was evidenced in all the narratives of the young men in this study.

Discussion and Conclusion

These findings were generated in a resource-constrained environment. South Africa, unlike countries such as the United Kingdom, has no legislation or policy on care-leaving, and most children who age out of care exit the child welfare system with no support or protection. This requires them to adjust almost instantly to adulthood, particularly because of the lacks in their family networks. Within such a context, young people are forced to rely on themselves to construct a social environment that is supportive and enabling. This environment is not provided as part of a standard of care to those leaving residential care – it is not a norm. Therefore, to survive in an environment that has numerous deficits and that does not provide focused support to those exiting care, care-leavers must create such an environment themselves.

I have focused in this paper on just two of the four care-leaving processes that emerged in this study, because they best illustrate how young people construct these environments, by investing in the development of the interface between themselves and their environment. Striving for authentic belonging attends to the relational and psychological needs of young people – their affective social support needs. Their well-being and psychosocial survival depends on having relationships that satisfy the deep and often ambivalent need for attachment. Care-leavers show skill in establishing these kinds of relationships, though they are often also self-defeating in maintaining these relationships, recapitulating their early experiences of attachment failure. Networking people for goal attainment also attends to the relationships of care-leavers, but stresses the ways in which care-leavers mobilise other people, mostly weak ties, to assist them in achieving their goals for employment, housing, education and food – their instrumental social support needs.

Arguably, when a young person exits residential care back into a reasonably well-functioning and caring family, their need for authentic belonging may be naturally met by their social environment and they may be less likely to 'strive' for authentic belonging. Similarly, when a young person exits residential care and is provided with instrumental support through well-functioning and policy-driven aftercare programmes, they may be less likely to 'network people' for goal attainment. In such environments, the needs for authentic belonging and goal attainment are satisfied and the young person does not have to strive or network.

Resilience theory is premised on the assumption that adversity triggers coping resources and processes in people, which are intended to aid them in overcoming adversity. Theoretically, in the absence of adversity, there would be no resilience. Rutter refers to this as "steeling" [26] – small experiences of adversity, successfully managed, prepare a person to deal with later greater experiences of adversity. By implication, adversity is a prerequisite for steeling.

In resource constrained environments, such as South Africa, the solution to the challenges of care-leaving may lie less in trying to change the social environment and more in developing the resilience of the care-leaver. This is not to say that the social environment should not be addressed. Legislation and policy to support care-leavers are required and independent living and after-care programmes are essential. However, with limited resources, the feasibility and impact of such initiatives may be less than what is required. In the meantime, young people need to be equipped to deal with the current social environment.

This requires social service professionals, such as social workers and child and youth care workers, to invest in developing the interpersonal skills of young people in care. Particular attention can be given to developing their social skills – those skills that facilitate authentic and enduring relationships with friends, family and lovers, and those skills that are effective in mobilising people towards supportive and helpful responses. Among the authentic belonging skills are found honesty, I-messages and constructive conflict management. Among the networking skills are smiling, ingratiation and self-confidence. Much greater attention should be given to developing these kinds of social skills among young people in care, because by doing so we increase their resilience, by equipping them to navigate the challenges of real-world social environments.

Social economy for Roma population – intervention strategies for supporting the social integration of Roma ethnics in Romania

Cace S.[1], Sfetcu L.[2]

Abstract

In the last few years, social economy has been given lots amounts of attention in Romania, mainly as a result of the interest shown by the European Social Fund in this matter, interest materialized in important financing programs being directed to Romania in order to develop this sector of the economy. Moreover, in Romania have been made substantial efforts in the last two decades in order to socially and economically integrate the Roma population which, in general, is poor and low educated, with important cultural differences relatively to the majority of the population. All these efforts have not fully reached the desired outcomes but they didn't totally failed either, some important changes being made over the years. This study illustrates the strategies used in a couple of Roma communities that managed to develop social economy organizations and improve their living conditions, theorizing them and building recommendations for those interested in replicating these good practices in other Roma communities.

Keywords: Roma, resilience, social economy, good practices.

Introduction

The topic of social economy is trending in Romania for a good few years now, more and more people and organizations talking about and trying to operationalize this concept both theoretically and practically. Although the tradition of social economy exists in Romania for a long time, the infusion of funds from the European Social Fund (ESF) into its development has given this concept an important boost in popularity in the last years [1]. There is no legislation regulating the field of social economy in Romania yet but the social economy entities, a legislative project for social economy being discussed for more than a year now and there are no certainties on its contents or on its adoption timeframe. The latest regulations regarding social economy can be found in form of a draft law on social economy in which there are many confusions regarding the relationship between the public and private sectors [2]. Part because of its novelty, part because it is not clearly explained, nor properly regulated, the term "Social Economy" is given lots of different interpretations, some of them limiting and others extending its attributes, hence the need for further research of the concept and for proper correlation with other, adjacent ones. Identifying and evaluating good practices in social economy could ensure the promotion and the consolidation, both conceptually and theoretically, of the specific aspects of this form of economy [3].

Roma ethnics have been living in Europe for a considerable amount of decades but they are still having important integration issues that more and more states are facing and searching solutions for [4]. Although the process of obtaining ethnic integration has become a legitimate objective of the state and is considered to be a public good, the public opposition against integrating Roma ethnics has not decreased in intensity [5], nor are there perspectives of it diminishing in the near future. In 2006, Ionescu and Cace [6] estimated that the Roma ethnics were making up to 10% of the total stable Romanian population, meaning between 1.5 and 2.5 millions of Roma ethnics were living in Romania. There are more than 200 NGOs promoting the social inclusion of Roma ethnics in Romania that are active in diverse fields such as promoting political participation of Roma ethnics, improving their access to education and health services, improving their living conditions and their participation in economic activities [7].

From a social point of view, Roma ethnics had a symbolic position within the main society, their traditional professions being regarded as archaic but with enhanced symbolic value [8]. In Romania, Roma population is closely related to social economy by the projects developed by a diversity of NGOs militating for

Roma ethnics' social and economic inclusion. In this paper we will discuss some of the most important initiatives focused at improving Roma population's social inclusion mainly through growing their employment odds in their communities.

Social economy in Roma communities

Social economy took birth as there was a growing need of fulfilling the needs that the state or the market could not fully attend. These needs were too fragmented, each community facing different issues or even similar ones but with enough variety, hence a centralized system could not successfully manage all of them [4], [7]. Successful social economy initiatives are known to have been started from within the communities, with the communities' needs in focus [6]. In analyzing social economy projects developed in Roma communities, two main ways of actions have surfaced. The first one starts from the principle of participatory community development and it mainly consists in facilitating the organization of initiative groups within the communities that are encouraged to take action and begin solving the local problems. Another approach to social economy projects implemented in Roma communities consists in offering professional training courses for Roma ethnics, courses meant to include them in the labor market and, as a result, to socially include them [9].

The employment situation has not changed significantly in the last decade for Roma ethnics, studies highlighting the Roma minority as having a high degree of illiteracy. According to a study conducted by the Quality of Life Research Institute, 25% of the population over 16 is illiterate [10], a low level of qualification: 39.2% of the employed and the unemployed (unemployed and housewives) who sought a job in the last year declare themselves that they have no qualification, while 77.3% have a level of education which does not allow any formal qualifications [9], an employment rate below the national average: 57.7% compared with 63% in the age group 18-64 years, 39.6% in the age group 18-59 years having weak or occasional jobs and 21% working only in their households; for those over 15 years, an occupancy rate of approximately 40% compared to 58.8% nationally in 2010; population of 16 years and over, 51.5% say that they haven't worked ever and only 10% have worked continuously over the last years [12].

Just over half of the Roma ethnics have no trade or practice activities that do not require prior qualification through formal training system. According to the *Regional Action Plan for Employment and Social Inclusion 2009-2011 SE*, approximately 33.5% of the Roma population have no qualifications, 14.3% are farmers and 4.6% are day laborers. Modern qualifiers can be found in 37.3% of the cases and 10.3% in the traditional case.(PRAO SE 2009-2011, available online at: http://www.fsesudest.ro/271_PRAO_2009-2011_STP_SE_varianta_finala_cu_coperta.pdf (accessed 10 Feb. 2014)) According to the National Agency of Labor Force Occupation (ANOFM) activity reports (2006-2010): the number of Roma included in professional programs of the ANOFM declined steadily in recent years: 2283 (2006), 1613 (2007), 1109 (2008) and 775 (in 2009). Roma people have been constantly employed in temporary employment programs, but their number has steadily decreased over time.

In the recent years there have been a number of social economy initiatives in Roma communities, and some of them attempted to reevaluate traditional Roma crafts and adapting them to modern trades. Studies that have examined the entrepreneurial potential of Roma highlighted the main obstacles they face and stressed the importance of national dissemination of examples of good practice identified [8].

1.1 Romano Cher – integrating Roma traditions into the main body of culture

A study in this regard was „Romano Cher - Casa Romilor" initiated by KCMC - K Consulting Management and Coordination (2010-2013) in partnership with the Community Development Agency „Împreună", co-financed by the ESF. (The project's description is available online at: http://mesteshukar.ro/i_acasa.asp?SMID=36&ARTID=91;http://www.agentiaimpreuna.ro/files/Casa_Romilor.pdf accessed 10 Feb. 2014). The project aimed to integrate traditional Roma artists on the labor market and in the active life of the community, to reevaluate traditional Roma crafts and to adapt them to the nowadays' market demand. Assuming that one of the aspects that constitutes a positive communication capital relative to the Roma minorities is the practice of traditional crafts (blacksmith, chopping wood, manufacturing household items, manufacturing bricks etc.) the project initiated a campaign for combating the stereotypes related to Roma ethnics with a pragmatic approach to Roma traditional crafts in order to adapt them to the requirements of the current market context. As a result of this project, there have been created 30 artisan cooperatives as representative social economy entities through which Roma craftsmen received consultancy services and benefited of training programs in areas that allowed them to adapt merchandising strategies for their products for a free market based on the added value of their crafts and the process through which they have been made. In the practical phase of the project, the craftsmen have been trained in modern techniques of marketing, financial management, social economy, in workshops that were held in turn in five regions. The communicational component of the project

involved, in addition to disseminating and communicating the results of the project, the foundation of the Roma Culture Museum in Bucharest, the first institution of its kind in Romania.

1.2 Touched Collection – from art therapy to social economy

Building on some activities conducted as a way of doing art therapy at the maternal center „Casa Agar", the Touched Romania Association managed to develop a social economy enterprise for financially sustaining and motivating the mothers living there. The social economy enterprise's main objective is to create jobs for the most skillful mothers of both Roma and Romanian ethnicity in manufacturing and selling jewelry. The jewelry is commercialized mostly at different fairs for companies and NGOs, but they are also intended for the general public. Besides its commercial activities, this social economy enterprise is aiming at creating a support group for the women working there, at helping them write their CVs and applying for other jobs, in participating in professional trainings and workshops. The commercial profits of the organization are shared between the mothers working there and the maternal center „Casa Agar". The social entrepreneurship Touched Collection is aiming at achieving financial independence for the mothers at the maternal center and is actively involving in solving the community's problems. The occupational therapy reached its objectives by raising the self-esteem, the self-trust and dignity of the mothers in difficulty and their children. Besides the mothers hosted at the maternal center, there are two Roma ethnic women working in the maternal center's staff [13]. It is highly important to empower women by facilitating their social inclusion by way of jobs or supporting them into development of entrepreneurial skills so that they could become more independent [14].

1.3 Fem.Rom – Roma ethnic women on the labor market

Fem.Rom was a project implemented in 2009-2014 by the Department of Equal Opportunities between Women and Men in the Ministry of Labor, Family and Social Protection, aimed at improving the access of Roma women in the labor market through the development of integrated services for them (information, guidance and counseling, and also specialized and personalized employment by creating cooperatives for women). (The project's description is available online at: http://www.femrrom.ro/ro/proiect/prezentare-proiect (accessed 10 Feb. 2014))The project aims to mobilize disadvantaged groups in order to participate as active players in the labor market, supporting economic growth, revitalizing Roma communities and promoting social inclusion of vulnerable groups through their integration in the labor market. The main results of the project consisted in opening three "one-stop-employment" workshops, five pilot production cooperatives for Roma ethnics, the development of a national network for cooperatives that employ Roma ethnics and the development of an international support network for entrepreneurs. Within the "one-stop-employment" workshops, there have been offered services for over 1000 persons and more than 200 persons have been assisted at their workplace. More than 550 Roma women benefited of professional training courses and the five pilot production cooperatives provided workplaces for more than 50 women. Roma ethnic women are found in a position of double vulnerability as they are discriminated both based on gender and ethnicity [15], hence the need for improved support directed toward them.

Discussion and conclusions

The analysis of the studies and projects aimed at the social inclusion of Roma ethnics demonstrates that the socio-economic rights of this minority are recommended to be implemented in practice, hence to equalize their chances of access to decent jobs. The improving of living condition and the quality of life for Roma ethnics represents the main purpose of the majority of organizations preoccupied by the problems of Roma population, this purpose being unattainable if access to education, jobs, social services etc. is not facilitated for them. There are tight links between all the causes and conditions leading to Roma population's weak social integration and consistent and sustained efforts need to be conducted in order to bridge the gap between Roma population and the main body of the society.

Throughout the practices adopted by the civil society in its efforts to socially integrate Roma ethnics, a special attention is paid to activities promoting the traditional culture and traits specific to Roma population. Through this kinds of attempts, it is promoted a kind of integration by diversity, an approach that has more success than trying to force them to incorporate the main population's culture. The fact that NGOs are interested and active in undertaking sustained efforts to support the social integration of Roma ethnics demonstrates that they understood the importance of being able to live together in harmony and diversity [7]. The amount of attention paid to developing Roma population's social inclusion often has two main effects in Romania. The general perception of the main population is regarding the projects and programs intended for Roma ethnic's social integration is that of positive discrimination, while for the direct and indirect beneficiaries of these actions, they are means of enhancing resilience and aligning them with the society.

The role of family democratization in the adaptation process to circulatory migration

Ciortuz A.

"Eftimie Murgu" University of Resita (Romania)
adaciortuz@ymail.com

Abstract

Circulatory migration has become so prevalent in so many countries that its effects on families have been widely investigated in the literature. However, the research results remain contradictory. Some studies highlight positive effects while other documented numerous negative consequences. In this paper we use as explanatory variable of these contradictions the level of democracy within the family. How the family democratization influence the adaptation process to circulatory migration it is analysed from the perspective of changes in family roles and power relationships between family members. The questionnaire based survey conducted among 386 couples (N=772) in which at least one partner practice circular migration confirms that the strongest predictor of the consequences of circular migration is the family democratization. For democratic families the influence of circulatory migration is positive: marital satisfaction post-migration is high, the propensity to divorce is reduced and deviant behaviors among children are rare. Democratic families successfully manage the tensions induced by the changes in family roles and power relationships because the communication between the family members is open, the practice of sharing the family roles is well established and the authority within the family is not normative but constantly negotiated.

Keywords: Family democratization, family roles, family power relationships, circulatory migration.

Introducere

In many developing countries circulatory migration is the most dynamic form of social mobility. The phenomenon has become so prevalent in these countries that its effects are felt acutely both by those who leave and those who remain at home. In these circumstances, understanding how families can successfully adapt to the challanges of circulatory migration is critical.

Family separation due to circulatory migration can lead to one of the following scenarios: (a) a parent remains at home with the children and the other parent migrates to a country of destination; (b) both parents migrate to another country, leaving children with the grandparents - either at home or outside the nuclear family's home; (c) both parents migrate to another country, leaving children in the care of relatives or friends.

Although many studies have investigated the subject, the effects of circulatory migration on families are discussed contradictory in the literature. Some authors emphasize positive effects while others document negative consequences.

The positive effects are driven by the increased living standards as a result of remittances sent by the migrant partner [1], [2]. Remittances are seen to strengthen the relationship between the conjugal partners and the children welfare. Also, circulatory migration presumes a level of women empowerment often leading to their emancipation. Migrant women from traditional societies of origin have access to financial resources and a more egalitarian cultural environment, which strengthens their power in relation to men. Equally, the women who are performing at home the instrumental roles held previously by men achieve a level of empowerment that transcends boundaries of gender affiliation.

Numerous other studies, however, highlight negative social costs, such as the tendency to divorce and deviant behavior among children [3], [4], [5], [6]. Studies conducted in Asia [4], [5] and Latin America [6] show that distances and lack of regular and effective communication weaken conjugal relations between partners and family relationships in general. In the Philippines [7] divorce and separation rate among migrant women was 4.4 times higher than the national average and migrant women had a 15 times higher probability of being separated or divorced than men. With regard to women's empowerment, Debnath and Selim [4] argue that it is temporary not permanent, women resuming their traditional roles with the return of their spouse. Moreover, the same authors show that men left behind are not always willing to take on the responsibilities of wives, fact which undermines women's emancipation trends.

Despite these contradictions there is a broad consensus in the literature that the circulatory migration leads to changing family roles and power relations between family members [8], [9], [10]. Both changes are usually described as disturbing and generating tensions [11].

As in other circumstances which change familly dynamics (e.g. divorce, death of the parents) circulatory migration generates new roles [8], [9]. Partner who remains at home will take expressive or instrumental roles hitherto met by the migrant partner. This adaptive behavior is stressful because of the pressure of overlapping roles (in terms of perceived incompatibility between the roles and additional workload), some of the new responsibilities go beyond the expertise of the partner or transcends the gender boundaries. Adaptive behaviors are particularly typical with the migration of mothers, but each family member who migrates fulfills roles that family members who remain at home will have to assume.

The gender reconfiguration of the family practices generated by migration changes also the power dynamics within conjugal partnerships [10]. Circular migration produces major changes on power relations between partners by women's empowerment mechanism. Women reposition themselves on the labor market, take control and assume the role of familly provider. In addition, the contact with more liberal societies allows them to confront the hegemony of men in the domestic sphere. From the perspective of power relations, the tensions induced by the changes in family roles are particularly disruptive when migrants return and try to reassume the roles they have met before leaving.

Since changes in family roles and power relations are key elements of the families' adaptation to circulatory migration, the fact that in some families the situation is better than in others may be due to how these families manage the tensions induced by these changes. The egalitarian literature [10] investigating adaptive processes within families suggest that democratic families recover from disasters better than undemocratic families. Since the involvement of families in circular migration can be as dramatic and disruptive, in this paper we conceptualize and use as explanatory variable for the success or failure of adaptive processes of these families, the construct of family democratization. The statements of truth tested by a questionnaire-based survey are: (H1) The lower the familly democratization is, the higher are the tensions induced by the changes in family roles; (H2) The lower the familly democratization is, the higher are the tensions induced by the changes in family power relations. Research results confirm that the level of family democracy is the strongest predictor of how families adapt to circulatory migration.

The construct of ”family democratization”

To assess the level of family democratization, first of all we have to discuss the measurement domain of this construct. Critical review of the literature on egalitarianism [11], power relations [12], decision-making processes [13], and communication [14], within families led us to a multi-dimensional conceptualization of the construct. From this perspective democratic couples have an egalitarian power structure, each partner contributing to the decision-making process. Partners have equal power, they can express their views and family roles are disaggregated and fluid. The 5 dimensions conceptualized and used to measure the "family democratization" are: the desegregation of family roles, the fluidity of family roles, decision making process, authority and communication between family members.

By desegregation of family roles we understand the gender integration of family roles. In democratic families, roles are not segregated according to gender affiliation but are flexible and interchangeable. Equality and democracy allow family members to fill the various roles of any other member. Family roles are not rigid but fluid. In a crisis situation varied tasks can be exchanged and made by someone else according to the situation. If one conjugal partner can not fulfill its roles, in a democratic family te other partner or another family member may exercise relatively easy those roles.

Also, in democratic families the decision-making process involves negotiation between partners. Each partner contributes to the decision making process. If power is exercised by a single dominant partner, or the other partner refuses to negotiate, complies without supporting its views or seemingly accept the other partner decision the democratization of the family is low. Dimension "decision process" includes four sub-dimensions (negotiation, rejection, compliance, influence).

Methodology

Hypothesis testing was done through a questionnaire-based survey. Although the psychometric variations of the scales across socio-demographic variables it has been considered and analyzed, the representativeness of the sample in relation to the total population was not a mandatory requirement. The aim of the research was to test the statements of truth developed through the systematic review of the literature and not to generalize results to the entire population. For this reason sampling was non-probabilistic, opportunistic, being included married couples from Caras-Severin County (Romania) in which at least one conjugal partner practice circular migration to other European countries. From a total of 3046 questionnaires that have been distributed,

1086 completed questionnaires were collected and 1036 questionnaires were considered valid. Some questionnaires (N=213) were directly administered by an operator. The remaining valid questionnaires (N = 823) were self-administered. The response rate of the self-administered questionnaires was 28.65%. 772 questionnaires were completed by both partners (386 couples) and 264 questionnaires were completed by a single partner (182 women and 82 men). To test the hypotheses have been used only the data collected from those 386 couples. All couples participating in the research were heterosexual.

In determining the sample size were taken into account on one hand the number of items of the focal construct "family democratization," and on the other hand the matrix developed on the basis of socio-demographic variables and those that describe the migration behavior. Each construct, measured by a Likert scale with 7 levels (-3 = strongly disagree, 3 = agree strongly - and null option: do not know/can not answer), was analyzed under three aspects: (1) the reliability of the measurement scale, (2) convergent validity and (3) discriminant validity. As a statistical tool for checking the reliability coefficient was used Alpha-Cronbach. The scales with level of Alpha-Cronbach of at least 0.7 have been considered valid (according to Nunnaly [15]).

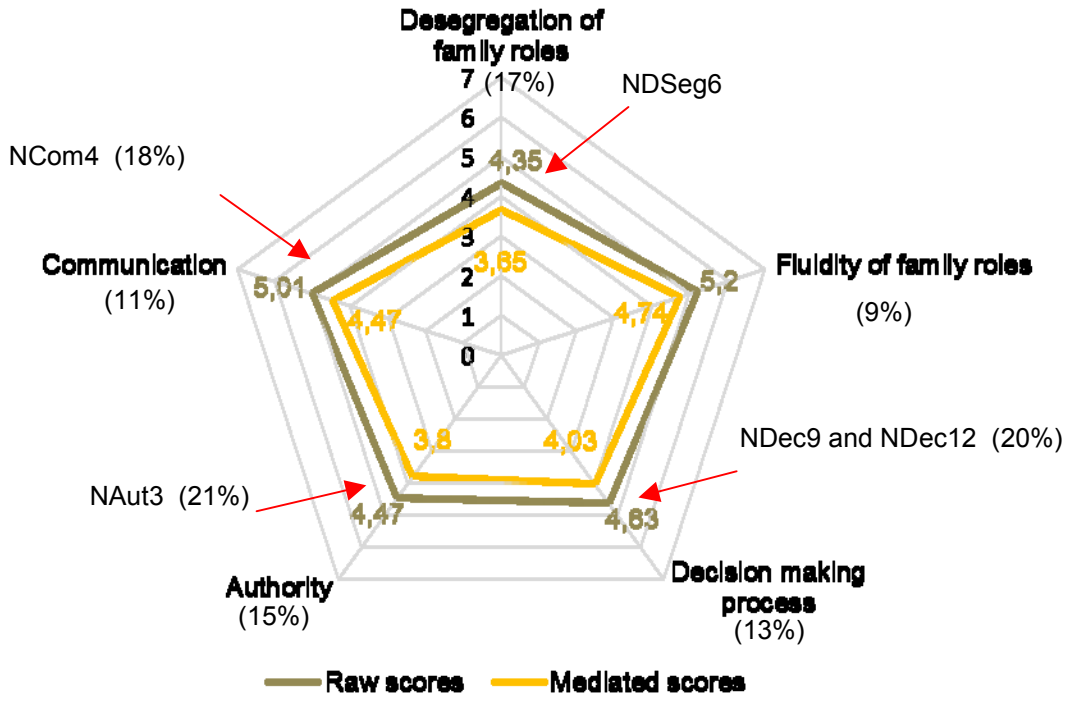
An important statistical treatment was applied to collected data measuring the family democratization construct. Although data were collected at the individual level (each conjugal partner was the reporting unit), the reference unit was the conjugal couple (the family). As they were taken into account only data collected from both partners, a mediating algorithm was used to determine a unique score for the unit of reference (the family). The developing of the algorithm was based on two principles: (1) whether partners' views converge, the family democratization is around level expressed by the partners, (2) where opinions diverge; this divergence reflects a low level of family democratization. Algebraic algorithm should, in these conditions, include the mean of the scores (to satisfy the principle (1)) and the absolute value of the difference between the same answers (to satisfy the principle (2)). It was also intended that the algorithm is valid and consistent for all possible pairs of responses. Algorithm that meets all these criteria is translated into the following mathematical formula: famN = ((N1 + N2) - |N1 -N2 |) / 2 (where famN represents the mediated score at the family level and N1 and N2 are the answers to the two partners).

Rezults

All scales have proved to be valid according to established criteria (Alpha-Cronbach coefficient of at least 0.7). The scales for measuring the tensions induced by changes in family roles and power relations have been measured by 4 items each and Cronbach Alpha was 0.831 respectively 0.721. Scale measuring the level of democratization included 34 items and Alpha-Cronbach value after the removal of the 8 items was 0.769. Both hypotheses were tested by multiple linear regressions. The hypotesis were considered confirmed if the the significance level of the relationship between the antecedent and the dependent variable was less than 0.05 ($p < 0.5$).

On a scale from 1 to7 (where the scores from 1 to 3 describe a low level of family democratization and scores from 5-7 high levels), the level of family democratization reported by respondents prior to the application of the mediating algorithm was greater than 4 ($\mu ND=4.73$) for all dimensions of the construct (Figure 1). The highest level of democratization was recorded for two dimensions: Fluidity of family roles ($\mu ND=5.2$) and Communication ($\mu ND=5.0$). After applying the algorithm family democratization scores have decreased on average by 13% ($\mu NDm=4.13$) (Fig. 1). The biggest differences are for the dimensions Desegregation of family roles (17 %) and Authority (15%). The items on which the perceptions of men and women are strongly divergent are: NDSeg6 (husband should bring home more money than his wife - 20%), NDec9 (I know how to approach the partner to get what I want - 20%) , NDec12 (although he/she is not always right often I accept the partner's point view - 20 %), NAut3 (I'm the real boss in the family - 21%) and NCom4 (When I have a disagreement with my partner I get carry a way and and say things that I did not want to say - 18%).

Figure 1. The changes in family democratization scores after applying the mediating algorithm



H1 hypothesis testing result shows that the research hypothesis is confirmed (Table 1). The relationship between the antecedent and the dependent variable is statistically significant (p=,000). The level of family democratization affects how couples manage the tesnsions induced by the canges in family roles role (b = -, 574).

Table 1.
Linear regression coefficients of the relation between independent variable The democratization level of the partnership and dependent variables Tensions induced by changes in family roles[a] and Tensions induced by the changes in power relations[b]

Model		Unstandardized Coefficients		Standardized Coefficients	t	p
		B	Std.Error	Beta		
1	(Constant)	-,145	,035		-4,109	,000
	NDEMOC *The democratization level of the partnership*	-,604	,037	-,574	-16,482	,000
a. Dependent Variable: ESROL Tensions induced by changes in family roles[a] (R Square=,328)						
2	(Constant)	-,106	,040		-2,642	,008
	NDEMOC Nivelul de democratizare al familiei	-,341	,042	-,329	-8,151	,000
b. Dependent Variable: ESPUT Tensions induced by the changes in power relations[b] (R Square= ,106)						

Negative values of standardized beta coefficients show that the variables are inversely correlated: the lower the familly democratization is, the higher are the tensions induced by the changes in family roles. The level of family democratization yet explains only 32% of variations in roles tensions (R^2 = 328).

H2 hypothesis testing result shows that this research hypothesis is also confirmed. Statistical analysis of the hypothesis H 2 (Table 1) demonstrate that the significance level of the relationship between the antecedent and the dependent variable was less than 0.05 (p=,000). The level of family democratization affect how couples manage the tensions induced by the changes in power relations (b = -,329). Negative values of standardized beta coefficients show that the variables are inversely correlated: the lower the familly democratization is, the higher

are the tensions induced by the changes in family power relations. The level of family democratization explaines only 10% of the power tensions variation ($R^2 = 106$).

Conclusions

The practicing of circulatory migration by one or both conjugal partners determines the changing of family roles assumed by both partners and the power relations between them. Both adaptive processes are potentially disruptive and generate family tensions. Research results show, however, that adaptive processes must be understood in relation to the level of family democratization which significantly influences how couples manage these tensions. The lower the familly democratization is, the higher are theboth types of tensions.

Conjugal partnerships with a high level of democratization will be able to successfully manage the tensions induced by changes in family roles, on the one hand because partners have the exercise of sharing the roles, are not criticizing each other, do not feel frustration by assuming simultaneously expressive and instrumental roles, and secondly because the good communication between partners defuse these tensions. In democratic families the practice of good communication and the fact that authority is not normative but constantly negotiated makes the bond between the partners to remain strong and parental ties with the children to be close and open.

Research shows that in democratic families the change of power relations following the emancipation of women is constructively accepted. Since the decision making process is based on negotiation, in these families power tensions are significantly attenuated.

The research confirms the observations of many authors [16], [17], who argue that when both conjugal partners are interviewed several gaps are revealed. Studies based on a single set of answers can not describe the whole picture of family democratization. The results thus obtained reflect only how a certain family member perceives it. Perceptual differences between conjugal partners are highlighted not only by the discrepancy between the mathematical values of the reported scores but also by the differences in the meaning of these scores.

If we consider only the discrepancy between the values of the scores, the level of democracy of the couples included in the sample, although low, is positive for all dimensions of the construct ($\mu ND = 4.73$). The differences between the scores reported by women and men describe a perceptual bias of 4.06 % on average. Unlike men, women tend to describe the level of democratization of the partnership as being high. They perceive conjugal authority rather negotiated and not normative and family roles as disaggregated. This result puts into question the widely accepted claims of the literature on power relations that men tend to overestimate and women to underestimate their power in the family. On the one hand, the result may be due to the presence in the measuring instrument of attitudinal variables describing the partner's aspirations and not necessarily the actual facts. In other words, women's aspirations for freedom and aspirations of men to preserve the patriarchal status quo may be causing this perceptual bias. An argument for this explanation is that the mathematical differences are significantly higher the scores measuring two dimensions Desegregation of family roles (6.4 %) and Authority (7.5%). These two variables were measured mainly by attitudinal items. Actually, the biggest differences were recorded for the attitudinal items NDSeg3 - not normal for men to carry out work which belong exclusively to women (or vice versa) except occasionally and NDSeg5 - men should share housework as washing dishes and cleaning, respectively NAut1 - man should be head of the family. The other three dimensions of the family democratization construct is measured almost exclusively by descriptive items (items describing how facts as perceived by respondents).

On the other hand, the lower scores reported by men may be due to current cultural expectations that the wives should not have more power than men. In other words, men feel the pressure of traditional cultural matrix reporting a patriarchal family structure even when conjugal partnership is actually more egalitarian. Why women would report a higher level of family democratization than the real one is difficult to explain other than by the lack of convergence of perceptual realities of the partners. Such an explanation is supported by results obtained after applying the mediating algorithm.

The meaning of the scores describes a particular perceptual reality. The lack of convergence of these perceptual realities between male and female partners is sanctioned by the mediation algorithm. The results show that after applying the algorithm the level of family democratization of the sample decreases on average by 7%. In other words, not only did partners report different mathematical scores when describing the family democratization but in 7% of the cases one partner percieves the conjugal structure as egalitarian and the other as undemocratic. This confirms the results of the studies investigating the family decision making processes which show that perceptual differences between partners may have a magnitude of up to 55-76% [16].

Research shows that conjugal satisfaction also depends on the level of family democratization. Couples who enjoy a high level of democratization are more satisfied than those with poor egalitarian practices. It follows that the emancipation and empowerment of women as a result of circular migration has positive effects on family life.

Within the conjugal couples with high marital satisfaction prior migration, the tensions induced by the changes of family roles and power relations are low. Therefore, we conclude that the level of family democratization moderates the role and power tensions through both a direct and an indirect influence. The indirect influence is mediated by the level of conjugal satisfaction prior migration.

Abstract

Background: This study aim was to explore resilience and metacognitions in the understanding of changes in patients with generalized anxiety disorder (GAD).

Method: 57 patients were included in a randomized controlled treatment trial for GAD. The patients were randomized to three conditions, waiting list, cognitive behavioral therapy (CBT) and metacognitive therapy (MCT).

Results: This study explored how resilience (*Resilience Scale for Adults* [1]) and metacognitions (*MCQ-30*; [2]) predict changes in GAD symptoms measured by e.g. *PSWQ*. To the best of our knowledge this is the first time these predictors are explored in such a context.

Conclusions: Understanding how resilience factors and metacognitions predict the changes of GAD symptoms related to treatment may potentially give a new perspective to treatment related changes in GAD patients.

Key words: Resilience Scale for Adults, GAD, CBT, MCT

Introduction

Resilience has become a conceptual umbrella for protective factors associated with good outcomes despite experiences with adversity [3, 4]. It therefore includes protective resources across very many different domains. The general accepted consensus is that protective resources are 1) individual positive dispositions, 2) family coherence, and 3) supportive social environment outside the family [5, 6, 7]. The classical studies of resilience are prospective studies that identify protective factors that contribute to adaptation. Some studies have explored resilience in relation to interventions [e.g. 8, 9, 10, 11]. The general approaches is to base interventions on a selection of protective factors, or target a selection of clinical useful tools and explored these result in increased levels of resilience or better adaptation. However, the relatively few studies have studied levels of resilience derived protective factors as predictors of outcome from effective psychotherapy for a specific disorder. That is the aim of the present paper.

Method

The patients were included in a randomized controlled treatment trial for generalized anxiety disorder (GAD). The patients were randomized to three conditions, waiting list, Cognitive Behavioral Therapy (CBT), and Metacognitive Therapy (MCT [12, 13, 14, 15, 16, 17]. CBT has shown effect for 50% of patients with GAD [18], and focuses principally on thoughts and the content of thoughts. MCT has been show effective for 75-80% of patients [19] and focuses principally on the thought process and not on the content. Both treatment conditions are effective treatments of GAD. The aim of the present paper was to explore if direct measures of resilience derived protective factors would predict reduction in the level of worry symptoms in GAD patients that underwent efficient psychological treatment.

Sample

In all, 57 patients were included, the mean age was 37.4 years (*SD* = 12.5), and 72.8% in the sample were women.

Measures

Penn State Worry Questionnaire (PSWQ; [20]) is a 16-item self-report scale that assesses the tendency to worry. It is considered to be a content-nonspecific measure, and measures tendency to worry but it is independent of the topic of worry. The internal consistency (r = .86 to .93) has been found to be good among patients with anxiety disorders, college students, and community samples [21, 22 ,23], as well as for older samples. The test-retest reliability is relatively high (r = .74 to .93). Convergent validity has been supported with positive associations between the PSWQ and other worry or anxiety measures [21, 24]. Associations between the PSWQ and measures of depression and anxiety ranged from high to moderate [23].

Metacognitive questionnaire-30 (MCQ-30; [2]) is a 30 item that measures levels of maladaptive metacognitions. It is a short version of the original 65 item Metacognitions Questionnaire [25]. It is a self-report scale with a 4 point Likert based scale format, with no reversed items. The higher the scores the more maladaptive metacognitions the individual reports. It is designed to measure meta-cognitive beliefs, cognitive confidence judgements and selective attention to mental events and cognitive self-consciousness. Cartwright-Hatton and Wells (1997) found significant positive correlations between the MCQ and measures of different anxiety states like trait anxiety, obsessive thoughts, obsessive checking, social worrying and health worry. These results have later been replicated [26, 27]. Positive significant correlations were also found for a range of obsessive compulsive symptoms [2]. Positive associations were found with anxiety and depressive symptoms as well as stress [28], and MCQ-30 also explained a significant and substantial part of the variation in anxiety and depressive symptoms. Further, the MCQ-30 has shown significant positive correlations with alcohol use and problematic drinking [28]. It is a good measure of metacognitions which is associated with a range of other psychological symptoms and maladaptive behaviour.

Resilience Scale for Adults (RSA; [1, 29]) is a 33 item self-report scale for measuring protective resilience factors among adults [30, 31]. Higher scores indicate higher levels of protective factors associated with resilience. The reliability and validity of the RSA has been found satisfactory in several studies [e.g., 29, 30, 31, 32, 33, 34, 35]. It uses a seven point semantic differential scale in which each item has a positive and a negative attribute at each end of the scale continuum [36]. Half of the items are reversely scored in order to reduce acquiescence-biases. Initially, a five-factor structure was reported, but later confirmatory factor analyses indicated a better fit when splitting one of the five factors. The final version has a six factor solution [30, 34] with factors named: 1) *Perception of self* (Cronbach's α = .74), 2) *Planned future* (α = .73), 3) *Social competence* (α = .83), 4) *Structured style* (α = .80), 5) *Family cohesion* (α = .80), and 6) *Social resources* (α = .74) [30, 34]. It measures protective resources that statistically and conceptually are separate from measures of measures of vulnerability and symptoms of psychological disorders [33], and the RSA predicts levels of hopelessness even when controlling for gender, age, stressful life events, levels of depressive symptoms and the entire NEO-PI-R personality inventory [35]. It covers the three overarching categories of protective factors associated with resilience, namely 1) personal positive dispositions, 2) family coherence and 3) social resources outside the family. An independent evaluation of existing resilience measures gave a favorable evaluation of the RSA [37].

Results

The results indicated that the scores on PSWQ were significantly reduced from pre to post treatment, which was also the case for the scores on MCQ-30. The scores on the RSA increase significantly from pre to post treatment. Separate hierarchical regression analyses indicated the changes from pre to post treatment in metacognitions and resilience predicted levels on the PSWQ post, even when controlling for the pretreatment PSWQ scores. In addition the prescores of resilience predicted PSWQ post scores, when controlling for the PSWQ prescores. Finally a moderation hypothesis was explored and the results indicated that resilience partially mediates the relation between metacognitions and levels of GAD symptoms. This indicates that changes in metacognitions promote higher levels of resilience which again contributes to reduction of symptoms.

Conclusions

Understanding how resilience factors and metacognitions predict and contribute to the changes of GAD symptoms related to treatment may potentially give a new perspective to treatment related changes in GAD patients. Potentially it also gives an indication of the relation between symptoms, vulnerability and levels of protective factors that may be relevant for other disorders, or mental health in more general.

Abstract

This presentation focuses on the development of an instrument for measuring the resilience of people with cognitive impairments or intellectual disabilities. In these people, the resilience is to present the best possible development deal with specific adversities that are encountered, to target the well-being and social integration (Jourdan-Ionescu and Julien Gauthier, 2011). The assessment instrument was developed from the Resilience Scale Wagnild and Young (1993, translated into French by Ionescu et al., 2010). The items in the scale were first adapted: reformulation of items based on cognitive characteristics of the target population and adoption of the interrogative form items. Subsequently, changes were made on the listing and procurement standards they are inspired by the work of Blocher (2004) on measuring the resilience of people with disabilities. The adapted instrument was tested with the target population (three cohorts) and a training program to the award of the scale is developed. It aims to facilitate communication and interaction between people with cognitive impairments or intellectual disabilities and evaluators. The presentation includes the main steps to achieve the instrument: adaptation of the items to the original scale, validation, testing as well as the development of training program evaluators. It is discussed in connection with the use of this scale in the context of rehabilitation intervention, which aims to support the social integration and participation of people.

Keywords: Evaluation, Resilience, Persons with intellectual disabilities, Adaptation, *Scale of Resilience* – Wagnild and Young, Social Integration

La résilience est la capacité de composer avec sa condition ou un contexte particulier et d'envisager l'avenir de façon confiante et positive [1]. La résilience naturelle intervient sans aucune aide de la part de professionnels et se construit à travers l'interaction de la personne avec l'entourage.

À l'opposé des modèles traditionnels d'intervention basés sur la pathologie, mettant l'accent sur les déficits et les problèmes d'adaptation, la résilience s'appuie sur les forces de la personne [2] et vise la mise en place de stratégies pour construire à partir de ses ressources et de celles de son entourage [3]. Chez les personnes ayant des déficits cognitifs ou des incapacités intellectuelles, la résilience consiste à présenter le meilleur développement possible face aux adversités particulières qui sont rencontrées, afin de viser le bien-être et une pleine intégration sociale [4]. Elle se développe dans l'interaction de la personne avec des mentors, des tuteurs de résilience ou des réseaux de soutien social [5].

Cette étude vise le développement d'un instrument d'évaluation de la résilience des personnes ayant des limitations cognitives ou des incapacités intellectuelles. Pour mesurer la résilience de ces personnes, l'*Échelle de résilience* de Wagnild et Young ([6], traduite en français par Ionescu [7]), construite à partir d'entrevues avec des personnes considérées comme résilientes, a été sélectionnée. Cet instrument d'évaluation, dont les qualités psychométriques sont solides, a été expérimenté dans différents contextes, auprès de populations diverses et de culture variées [8]. La version de l'*Échelle de résilience* [6] choisie est celle qui comprend 25 énoncés, évalués à partir d'une échelle de type Likert (cotation de 1 à 7). La traduction de cet instrument a été ajustée au contexte culturel québécois par trois experts des domaines de la psychologie et de l'éducation. Une attention particulière a été portée à la pertinence de la formulation des questions afin de s'assurer d'obtenir les informations souhaitées.

Par la suite, les énoncés de cette version ont été reformulés en « langage simplifié » [9] afin de les rendre accessibles aux personnes ayant des limitations cognitives [10]. La syntaxe des énoncés a été modifiée en privilégiant la forme interrogative afin de réduire la tendance à l'acceptation présente chez ces personnes [11].

Exemple:

- *When I'm in a difficult situation, I can usually find my way out of it* (original)
- *Lorsque je suis dans une situation difficile, je trouve habituellement une solution* (traduction)
- *Est-ce que tu réussis à te sortir d'une situation difficile ?* (adaptation)

Les normes de passation de l'instrument ont été modifiées, en s'appuyant sur les résultats de recherches récentes sur la passation d'instruments de mesure aux personnes ayant des limitations cognitives (Julien-Gauthier, Jourdan-Ionescu, & Héroux, 2009). La passation de l'instrument a été effectuée à l'oral, pour faciliter la compréhension (p. ex., joindre le geste à la parole pour aider la personne à bien saisir la question ou d'autre part, permettre à l'examinateur de repérer les attitudes d'incompréhension chez la personne). Pour chacune des questions, il est possible pour l'examinateur de répéter si la personne semble éprouver des difficultés de compréhension. Il lui est aussi possible de reformuler la question, à partir d'un deuxième énoncé prévu à cet effet, pour assurer l'uniformité du protocole (chaque question comprend deux énoncés) :

Exemple :

- *Est-ce que tu réussis à te sortir d'une situation difficile ?*
- *Quand tu vis une situation difficile, est-ce que tu réussis à trouver une solution ?*

La cotation des énoncés a aussi été adaptée, passant d'une échelle de type Likert en sept points à trois options de réponse : oui (2 points), parfois (incluant « ça dépend », « un peu », « pas toujours », etc. pour 1 point) et non (0 point). Le protocole de passation a aussi été modifié, afin d'être mieux adapté aux caractéristiques des personnes ayant des limitations cognitives dans le traitement de l'information.

Lors de la passation, l'examinateur pose chacune des questions dans l'ordre à la personne et après l'obtention d'une réponse, il suscite un ajout de contenu en utilisant des incitatifs verbaux (p. ex., répétition du dernier mot ou de la finale de la phrase) ou non verbaux (p. ex., regard significatif, moment de silence) [12]. Cette forme de passation, où la personne produit une réponse qui est complétée par la suite s'inspire des travaux de Blocher [13]. La passation est enregistrée sur bande audio et le verbatim est transcrit intégralement. Les réponses à chacun des énoncés sont par la suite analysées, selon la méthode de l'analyse fonctionnelle [14].

Une pré-expérimentation de l'instrument a été réalisée auprès de sept personnes qui avaient des limitations cognitives légères ou modérées. Les résultats ont permis de réaliser une première évaluation de la résilience auprès de ces personnes et de préciser certains aspects de son développement et sa consolidation. Ainsi, lors de la passation, les personnes ont mentionné l'aide apportée par l'entourage, par des mentors, tuteurs de résilience ou réseaux de soutien social, ce qui permet d'émettre l'hypothèse que dans cette population, le processus de résilience est similaire à celui de la population générale, où il se développe par les interactions avec les autres, des mentors, tuteurs de résilience ou réseaux de soutien social [5]. Les personnes ont aussi détaillé certaines formes de soutien, entre autres l'accès à des activités qui favorisent le développement de liens sociaux et la connaissance de ressources dans l'environnement. Elles ont également abordé les structures municipales ou communautaires qui facilitent l'accessibilité aux ressources, telles le service de Transport adapté (déplacements) ou les centres d'alphabétisation (information).

Les résultats de cette pré-expérimentation ont aussi permis d'améliorer la formulation de cinq énoncés qui avaient été compris par une partie seulement des personnes. Des ajustements ont été effectués, afin d'assurer une meilleure accessibilité de l'instrument aux personnes ayant des limitations cognitives.

Les résultats ont aussi permis d'identifier quelques constats : le premier est que dans sa forme actuelle, l'instrument est accessible aux personnes ayant des limitations cognitives légères. Des modifications à la structure de l'instrument (ajout de repères) ou aux normes de passation (utilisation de mises en contexte ou ajout de moyens facilitant la compréhension, tels des scénarios représentatifs) sont nécessaires afin qu'il puisse être accessible à des personnes ayant des limitations plus importantes. Toutefois, comme les personnes ayant des limitations cognitives ou des incapacités intellectuelles présentent dans une proportion d'au-delà de 85 % des limitations cognitives légères [15], il permet de mesurer la résilience de la majeure partie de cette population.

Le deuxième constat fait référence à la nature des questions comprises dans l'instrument, qui font en majeure partie référence aux émotions (acceptation de la vie, confiance en soi, détermination). Or les personnes ayant des limitations cognitives ne sont pas familières avec leur univers émotionnel. Plusieurs auteurs [16, 17, 18] soulignent « la négligence de l'intérêt envers la vie affective et les difficultés émotionnelles ressenties par les personnes ayant des limitations cognitives, quel que soit leur âge » [4, p. 290]. Il faut mentionner ici que les intervenants qui offrent de l'aide aux personnes ayant des limitations cognitives ont manifesté de l'étonnement, en prenant connaissance de l'instrument. Plusieurs ont mentionné que dans l'aide offerte à ces personnes, la capacité d'exécuter les différentes tâches liées à l'autonomie sociale ou résidentielle constituait l'essentiel des apprentissages ou du soutien offert. Comme le mentionnent Langevin et ses collaborateurs, l'aide est orientée

vers une autonomie d'exécution [19] et les aspects visant l'autonomie de décision ou le bien-être sont trop souvent négligés.

Les résultats de l'étude ont permis d'élaborer et d'expérimenter une première version d'un instrument de mesure de la résilience des personnes ayant des limitations cognitives ou des incapacités intellectuelles. Dans la période de raréfaction des services que connaissent actuellement les organismes qui offrent de l'aide à ces personnes, l'évaluation de la résilience des personnes peut contribuer à l'évaluation de la qualité des programmes et services qui leur sont offerts et permettre de cibler les plus efficients. Dans les autres milieux dans lesquels les personnes évoluent, qu'il s'agisse du milieu scolaire, d'un milieu de travail ou d'une ressource résidentielle, l'évaluation de la résilience peut être utile. Elle permet une mesure du bien-être de la personne et contribue à identifier des éléments qui l'aident à surmonter les difficultés qui se présentent en raison de sa condition ou du contexte. À l'instar de la population générale, le développement de la résilience des personnes ayant des limitations cognitives est un aspect important de leur évolution et doit être pris en considération, au même titre que le développement des capacités physiques ou intellectuelles.

Abstract

Introduction: Economical migration together with ethnical belonging (e.g. Roma) impact severely over the child's education, health and various psychosocial traits. Examining children's drawing gives us important insights into how drawing fits into the overall physical, emotional and cognitive development of the young child. Drawings represent the child's experience of the world, because children are using their mind and emotions as they engage in the physical act of drawing.

Purpose: To understand and signal the importance of resilience in children undergoing social and cultural discrimination.

Material and methods: The study comprised 50 children aged 6-10 years that were divided into two equal groups. The first group (L) included children from the "We grow up together" Program of the Save the Children in Romania Organization and consisted of Roma children living within a large community in the absence of one or both parents. On the other hand, the second group (S) consisted of children living in a small community in the absence of only one parent. Behavioral, emotional and cognitive development was investigated by applying projective techniques (drawing techniques) like: Tree test, Draw-a-Person (DAP) test, Kinetic family drawing (KFD) test and SDQ questionnaires (The Strengths and Difficulties Questionnaires).

Results: Total SDQ retuned abnormal results in 68% of L and 36% of S ($p=0.025$), with a larger percentage of abnormalities in the subdivisions: hyperactivity ($p=0.001$) and prosocial ($p=0.006$). The KFD test revealed immaturity traits ($p=0.041$) and instrumental disorders ($p=0.029$) within L group. Whereas, the Tree test showed traits of: trauma ($p<0.0001$), fear ($p<0.0001$), impulsivity ($p<0.001$), lack of energy ($p<0.0001$), cautiousness ($p=0.03$), quarrel of opposing trends ($p=0.015$) and choleric temper ($p<0.0001$) within L group and traits of: narcissism ($p=0.027$), opportunism ($p=0.03$) and need for affection ($p=0.0069$) within S group.

Conclusions: Childhood is a time of exploration and trying new behaviors rather than trying to remove life's challenges, we need to support children to develop self-confidence, skills and abilities that make them resilient. Developing these skills will benefit children as they move into adolescence and adulthood.

Key words: Roma population, children, economical migration, community, resilience

Introduction

Children are meaning-makers *par excellence*. They use many signs to create meaning and represent reality within the means of drawing [1]. While there are many possible approaches to the study of cognitive, behavioral, social, contextual and organic factors, assessing a child's drawings can provide a window into their representational world of how they represent knowledge and encode events [2]. Resilience refers to patterns of positive adaptation in the context of significant risk or adversity. (Masten and Powell) When a person is called resilient, we are able to make distinctions and achieve a balanced viewpoint about a person matching

characteristic features of resilience. It is also important to keep in mind that identifying resilience is not assumed to describe people in totality, to define their lives at all times, or to be doing well every minute of the day, under all imaginable circumstances.[3]

Although the impetus for resilience research originally aimed "at risk populations", resilience-oriented programs may target those populations which are most in need of intervention, like children, that have the same needs for care, skills, self-esteem, autonomy, and other components of resilience [4].

One of the so called "at risk people" is the Roma population, that throughout time was portrayed as an idle, dirty, and criminal people [5]. It was often claimed that these nomads posed a threat to women and children of local societies or that they harbored disease and were responsible for its dispersion. It is suggested that psychology, behavior and moral character of Gypsies/Roma is determined by their biological inheritance [6]. Another stereotype is that of a romantic Gypsy figure, evolving with the rise of the Romantic Movement during the 19th century, where the Gypsy was portrayed as an exotic and picturesque figure that remained in harmony with nature, and stayed independent from the advancing industrial society [7]. Roma people have different language and distinctive cultural features and so they have acquired the status of a minority group. Nonetheless, they face problems like low socio-economical status, less education, a vanishing culture and the experience of not being fully accepted into society [8].

Moreover, facing diverse issues, resilience differs in the presence of protective factors. One of these factors might be considered a small community acting as a support group, compared to a large community in which support is difficult to achieve. Therefore, this study aims to understand and signal the importance of resilience in children undergoing social and cultural discrimination.

Material and methods

Within a population, the town is considered to be a community. In this respect, communities can be large, medium or small. Such is the case of two towns in Romania, Călan of Hunedoara County and Timişoara of Timiş County. Călan is a former industrial small town (about 11.000 inhabitants) [9], in which due to almost complete cessation of the industrial platform, unemployment rates exploded leaving its population in serious economic and social problems leading to a great rate of economical migration. On the other hand, Timişoara is a bigger town (about 300.000 inhabitants) [9] situated in the western part of Romania, close to the border, with smaller economical issues, however known to be a multiethnic town (e.g. Serbian, Bulgarian, Hungarian, German, Jewish, Roma, etc.).

In various types of communities, people tend to create a physically and emotionally safe environment for children. Such is one of the goals of the Save the Children in Romania Organization that has 16 branches all around the country. One of these branches is in Timişoara and it provides complex social and educational services for children and teenagers originating from disadvantaged communities (e.g. Roma). Among these programs are: "Second chance" (school integration/reintegration), "School after school" (offering educational support) and "We grow up together" (aims to reduce the negative impact related to parents' migration on home-alone children) [10]. On the other hand, in Călan, local schools organize various activities within the Children's club, involving the child's creativity and development.

Within this cross-sectional study are comprised 50 children, boys and girls, aged 6-10 years (Fig. 1, 2), and it was conducted in between November 2013 - February 2014 in Călan and Timişoara. The studied population was divided into two equal groups (N=25) based on the type of community they originate from. Group L (Large community) comprised children from the Program "We grow up together" Timişoara, of the Save the Children in Romania Organization and consisted of Roma children living within a large community that are cared for by a single parent or another family member (blood related or not – e.g. grandparent/s, aunt, uncle, stepmother/-father), with little or no communication with their biological parents. Whereas, group S (Small community) consisted of children living in a small community (Călan), cared for by a parent or a blood related family member (e.g. grandparent/s), but with a strong and healthy communication with their biological parents.

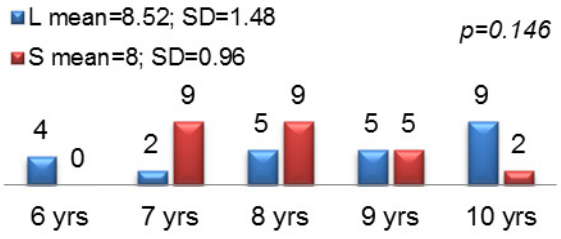

Figure 1. Age distribution within the studied population

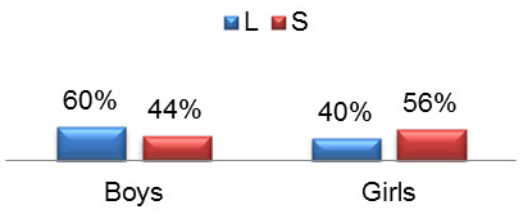

Figure 2. Sex distribution within the studied population

Behavioral, emotional and cognitive development was assessed by applying projective techniques (drawing techniques) as: Tree test, Draw-a-Person (DAP) test, Kinetic family drawing (KFD) test and SDQ questionnaires (The Strengths and Difficulties Questionnaires). The abovementioned techniques were applied under the supervision of a Child and Adolescent Psychiatrist and a Psychologist, who also gathered and interpreted the materials.

Based on these materials, data was collected and organized in a Microsoft Excel 2007 data base and analysis was performed using SPSS (Statistical Package for the Social Sciences) version 17.0 and EpiInfo 7. The groups were compared using unpaired t-tests or the $\chi 2$ test. $P<0.05$ was considered significant.

Concerning statistical analysis within this study, the DAP test interpretation used a series of terms defined in connection to scoring, as follows: Superior >111 pts, Normal = 86-110 pts, Dull = 76-85 pts, Mild cognitive disorder traits = 56-75 pts and Moderate cognitive disorder traits = 46-55 pts. Each child gathered a number of points on the basis of his/her drawing. These points were related to the standard coefficient by age, and the final score consisted of a percentage resulting from the proportion of standard pts for the age and the given pts.

Parents and caregivers signed an informed consent prior to applying the projective techniques. The study was approved by the Ethics and Research Committees of each institution included.

Results and discussions

A total of fifty children coming from different types of communities were assessed through projective techniques. Concerning their home environment, 16% of L and 60% of S were cared for by grandparents (χ^2=8.49; p=0.0036), 20% from L were cared for by another family member (blood related or not – e.g. aunt, uncle, stepmother/-father) (χ^2=3.56; p=0.059), while the others were cared for by one of the parents.

1.1 Strengths and Difficulties Questionnaires analysis

The informant-rated SDQ comprises 25 items, grouped in 5 scales (Emotional problems, Conduct problems, Hyperactivity, Peer problems and Prosocial behavior) [11]. These were used and interpreted both in the raw form of scores and classified as normal, borderline and abnormal. Worth mentioning is the fact that abnormal score of the total difficulties scores can be used to identify likely "cases" with mental health disorders [11].

Therefore, a total SDQ score was significantly higher in L sample compared to S sample (L mean=17.4, SD=5.22; S mean=13, SD=7.06; p=0.016), retuning abnormal results in 68% of L and 36% of S (p=0.025), with a larger percentage of abnormalities in the scales for: Hyperactivity (40% of L and 4% of S, p=0.001) and Prosocial behavior (40% of L, 4% of S, p=0.006) as shown in Table 1.

Table 1. SDQ scores

	SDQ Emotional Problems					SDQ Hyperactivity			
	L	S	χ^2	P		L	S	χ^2	P
Normal	84%	52%			Normal	44%	92%

1.2 Drawings

1.2.1 Draw-a-Person test

The DAP test revealed no significant difference between the two samples (L mean=20, SD=6.26; S mean=20.24, SD=4.26; p=0.88), with cognitive results as: Superior (L 0%; S 16%), Normal (L and S 56%), Dull (L 24%, S 12%), Mild cognitive disorder traits (L and S 12%) and moderate cognitive disorder traits (L 8%, S 4%).

1.2.2 Tree test

The Tree test interpretation was divided into general traits and traits of: adaptability, personality, environmental relations. The general traits were also divided into skills for resilience and concerns for resilience (Table 2).

Table 2. Tree test – general traits

Large community group		Small community group	
Skills for resilience	Concerns for resilience	Skills for resilience	Concerns for resilience
Vitality ***(χ^2=15.68; p<0.0001)***	Irritability ***(χ^2=16.64; p<0.0001)***	Gentleness ***(χ^2=23.16; p<0.0001)***	Shyness ***(χ^2=15.68; p<0.0001)***
Vivacity ***(χ^2=8.036; p=0.0046)***	Quarrel of opposing trends ***(χ^2=5.98; p<0.015)***	Scrupulosity ***(χ^2=24.08; p<0.0001)***	Lack of vivacity ***(χ^2=8.036; p<0.0046)***
Extroversion	Impulsivity	Socially active ***(χ^2=5.98; p=0.015)***	Fear
Will to adapt	Choleric temper ***(χ^2=24.08; p<0.0001)***	Enthusiasm	Infantilism
Need for physical contact	Anxiety	Fantasy	Irritability
	Aggressiveness	Active imagination	Low self esteem
	Signs of depression	Message for the father	Anxiety
	Inhibition	Need for affection ***(χ^2=7.29; p=0.0069)***	Aggressiveness
	Lack of energy		Signs of depression
	Anguish towards reality		Choleric temper
	Lack of affectivity		

Thus, adaptability traits as low intelligence were more frequent in the large community sample, whereas the need for affection, prudence and passivity were only signaled within the children from the small community. Personality traits more frequent in the L group comprised: adaptability, altruism, immaturity, impulsiveness, signs of psychological trauma (χ^2=16.09; p<0.0001), insecurity, fear (χ^2=15.53; p<0.0001) and introversion (χ^2=4.735; p=0.0296) compared to the S group where more frequent were traits of: criticism, narcissism, practical person, stiffness, shyness and vivacity.

Within traits of environmental relations more frequent in the large community group were: enthusiasm, impulsivity (χ^2=12.224, p<0.001), inhibition, lack of energy (χ^2=18.667, p<0.0001), insecurity, cautiousness (χ^2=4.735, p=0.03), gentleness, sociability, fear (χ^2=4.735, p=0.0296), introversion and the will to succeed. The children from the small community group showed: aggressiveness, extroversion, fantasy, fear of reality, independence, narcissism (χ^2=4.878, p=0.027), opportunism (χ^2=4.735, p=0.0296).

3.2.1 Kinetic family drawing test

The KFD test revealed a series of traits that were divided into skills for resilience and concerns for resilience (Table 3).

Large community group		Small community group	
Skills for resilience	Concerns for resilience	Skills for resilience	Concerns for resilience
Extroversion	Instrumental disorders ***(χ^2=4.734, p=0.029)***	Acceptance	Ambivalent attachment towards mother
Message for the father	Immaturity ***(χ^2=4.196, p=0.041)***	Self-centered	Low autonomy
Open and available to listen to adults	Low autonomy	Message for the father	Emotional disorders
Docile	Aggressiveness	Narcissism	Difficulty in expressing their own feelings
Desire to be noticed	Anxiety traits	Need for affection	Low energy
Expansion	Depression traits	Repressed aggression	Aggressiveness
	Not oriented towards society	Controlled behavior	Anxiety traits
	Sense of not belonging	Good self-esteem	Depression traits
	Low self-esteem		Shyness
	Inner conflict		

Discussions

In this study we found that a high percentage of Roma children are prone to develop behavioral disorders, with an emphasis on hyperactivity and prosocial behavior as opposed to other, nonRoma children but with a similar risk factor. Our hypothesis that ethnical minority children have a higher risk of developing mental health disorders, can be sustained by results obtained in a Norwegian longitudinal study comparing changes in mental health [12]. On the other hand, well known is the fact that hyperactivity is likely to hinder successful positive interaction with peers [13] and that children with hyperactivity are maladaptive. Thus, these children may be at a serious disadvantage with regard to their social [14] development.

Considering the family, children from both samples came from a somewhat "disorganized family". Thus, the children from the small community came from a family in which they were cared for by a parent and/or one/both grandparents, whereas children coming from a large community (the Roma children), were in the care of a nonparent member of the family (blood related or not – e.g. aunt, uncle, stepmother/-father). As Amato [15] found too, these facts influenced severely their emotional and social well-being. Moreover, Amato [15] also said that many single parents and caregivers are less emotionally supportive of the children, have fewer rules, dispense harsher discipline, are more inconsistent in dispensing discipline, provide less supervision, and engage in more conflict with their children. So, children growing up with single parents have an elevated risk of experiencing cognitive, social, and emotional problems. Keeping this in mind, within the analysis of the DAP test of this study there was a slight difference among the two groups. Notably is the fact that all the children that presented traits surpassing their biological age were from S group. Issue also highlighted by the fact that most Roma children live in deprived communities with poverty rates four times higher than the national average, together with the little value in children attending school rather than helping support the family financially [16].

However, the lack of statistical significance in this sense may be explained by the limitations of this study, namely the small samples analyzed and the short period of time in which the study was conducted, thus not having a prospective feature.

In our study al children underwent a more or less obvious psychological trauma, that of not being in a "well organized" family. In addition to this, children from L group presented two more risk factors, namely: the appurtenance to a world mal-seen ethnical minority (Roma) and the absence of an economical well-being. In this respect, the perception of these children upon nature (Tree test) and family (KFD test) revealed strong signs of psychological trauma together with fear, introversion, impulsivity, lack of energy, cautiousness, quarrel of opposing trends and choleric temper. Supporting these findings several authors found that psychological trauma in children increases the risk of mental health problems, including depression and anxiety, substance abuse, delinquency and crime and future perpetration of child maltreatment [17]. Moreover Herrenkhol [18] said that protective factors associated with resilience in maltreated children include characteristics of the individual child (e.g., intelligence, positive temperament, personal agency) and of the child's social environment. Similar features

were revealed within these children's drawings as well (e.g. adaptability, altruism, enthusiasm, gentleness, sociability, etc).

Overall the human being is to live within a community and this is, mainly, due to the presence of several resilience proximity protective factors. In this respect within the traditional community parents and grandparents are usually present. Thus throughout the child's psychological development the primary attachment figure may as well be one of the grandparents.

Through globalization several changes appeared in the general term "family". More and more families are single parent families, or children are left in the care of a nonrelated family member. Moreover, these changes are also well seen within minority ethnic groups, as Roma, where not long ago tradition requested that they should stay within family. Nowadays, even though this is still a request of tradition, most Roma people cannot carry-out their lives in tents and manifest their nomadic features, leaving most of their offsprings to evolve in an alien culture and environment. Furthermore, living within a large community, the child and his/her problems may become invisible. This is why resilience should be ensured by specific organizations and programs.

Conclusions

Childhood is a time of exploration and trying new behaviors rather than trying to remove life's challenges. In addition, we need to support children to develop self-confidence, skills and abilities that make them resilient. In this respect our study offers an insight regarding the need for programs and organizations that help avert ethnical discrimination and promote the developing of skills for resilience by teaching both parents and children how to cope with the given situation

Abstract

Recent European Social Fund (ESF) co-financed projects demonstrate that social economy offers innovatory alternatives to employment of the ones in need especially vulnerable people. Still, sustainable development of entrepreneurship initiatives or self-employment needs local support in terms of technical assistance provision, financial support, mutual acceptance, and nondiscrimination.

The research hypothesis of the paper is what makes poor community able to face various challenges. The paper overviews case studies of best practices in the field of social economy. The community resilience is analyzed as local focal point in supporting development strategy toward social inclusion through economic opportunities.

Keywords: community resilience, Roma minority, social

Social economy and vulnerability

The research of social economy emphasized its openness to match economic activities with social profit [1], [2], [3], [4], [5]. A growing number of people are working in social economy at European level [6]. Their values and principles are in line with Social Economy Charter adopted in France in 1980 (revised in 1995) and with the Charter of Principles of Social Economy (2002). It includes: solidarity, responsibility, freedom, equal opportunities for all members, mutual respect, democratic control by members, and reinvestment of obtained profit in the benefit of its members, democratic and voluntary participation, private character, independence and autonomy [1]. Probably the best known social economy principle is one voice one vote. Without reducing social economy to labour market insertion of vulnerable people, social economy continues to be promoted as one of the tools in fighting unemployment. A comparative research including nine European countries concluded that domestic public policies reflect social economy in connection with solving social problems [1].

Social exclusion from education, health, housing and labour market are main sources of social exclusion and vulnerability [7]. In terms of targeted public policies, the research shows that more than 60 groups were identified as vulnerable within Romanian public policies [8]. We are not going to list them in the paper but briefly refer to poor Roma people as one of the most significant vulnerable groups. Analyze of public policies in the field of education, housing, employment and health targeting Roma reflect an increased interest during Romanian's accession to European Union [9].

In terms of vulnerability and high exposure to discrimination, more than two-thirds of Roma from Central and Eastern Europe are living in Bulgaria, Czech Republic, Romania and Serbia. Almost 9% of Roma in Europe are living in Romania. Employability perspectives of Romanian Roma reflect a younger workforce poorly able to enter labour market mainly in low paid jobs, unskilled or low up to medium qualification [10]. Predictor factors of poverty risk in Romania include: number of children, residential regions, education level, occupations status and ethnicity (higher poverty rates in the case of Roma) [11]. European comparisons shows that Romanian Roma confronts discrimination in labour market either at work either looking for a job [12]. In terms of demographic structure, Roma minority in Romania is much younger than the rest of population. The active Roma population represents 60.3% with a distribution of men 60.55% and women 60.11% [13]. Still, Roma workforce is not fully valorized and investment in this direction is supported by its positive dynamics

[14]. Due to migration flows of Roma minority, domestic as well as European preoccupation on this subject could potentially positively impact in terms of reducing the pressure on the pension system caused also by increase life expectancy.

Case studies of Best practices

In direct connection with local environment the development of community resilience take into account the fact that "social resilience of vulnerable groups is, thus, a problem of the community as a whole, because, as part of it suffers, the entire community suffers" [15].

We refer to community resilience in terms of recent swift from „predict and prevent paradigm in the context of specific hazards, to building capacity communities" [16].

This section presents a selection of best practices in developing win win strategies in local communities. The dissemination of such day to day practical experiences would inspire other entrepreneurs. From the methodological point of view, the research is a secondary analysis on identified best practices in the field of social economy in Romania [17], [18], [19], [20], [21].

The selection of best practices was done in accordance with characteristics of community resilience: knowledgeable and healthy, organized, connected, has infrastructure and services, had economic opportunities, and can manage its natural assets [16].

1.1.1 Biocoop cooperative

Paradoxically, in a preponderant agriculture country as Romania, the market of ecological food is an emergent one supported by public concerned about responsible consume and environment protection.

Biocoop cooperative was established in 2006 as a supportive platform for peasants in Sibiu county willing to directly sell their products to buyers without going through secondary intermediates (hypermarkets, traditional markets and so on). As pre-history, the entrepreneurial initiative was based on trade exchange firstly between agriculture producers and secondly with Sibiu citizens concerned about their responsibility in assuring a decent life and healthy food for their families. Awareness about healthy food and promotion of locally produced aliments are one of the top priorities in setting up long term transparent and trustfully collaboration between producers of ecological food and ordinary consumers. In order to reduce the involved costs, once a week, food producers are selling their products in a small shop rented in the historical part of the city. Their direct contact with clients allows the provision of any need information. The producers are focus on keeping a high quality small business based on traditional methods than growing. As win win strategy, hundreds of family benefit from this agriculture cooperatives while the producers can provide a decent life to their families.

"The cooperative is the most democratic organisation form to work" declared the founder of Biocoop. The innovatory character is due to promotion mechanisms of small producers. Once they build a group of constant buyers, they give their space in the shop to a new arrival by moving their business directly to their farms. This social economy initiative is technically and financially supported by international and national partners [17].

1.1.2 Pater Paulus ferm, Bacova village

With the support of Caritas Timisoara, the farm functioning in Bacova village was launched in 2000. Workers at the farm are homeless from Timisoara willing to change their life. The farm includes agriculture activities, a craft workshop, and gardening activities. The craft workshop provide furniture for Caritas nigh shelters for homeless living in Timisoara. "I can think again to my future here, I have a job, a monthly income and a safe home, maybe I can still change something in my life" declared one of the homeless employed there. The farm is financially supported by Caritas and other international partners [17]. In 2011 the farms has won a grant the Ministry of Labour through an ESF project to diversify its activity.

1.1.3 Hercules Association

Hercules is an association involved in education of children from poor families with parents as long term beneficiaries of minimum income guarantee or working abroad. The lack of employment opportunities, low incomes, high unemployment, and undeveloped infrastructure has an impact on neglecting children. In the case of left home children while with parents are working abroad the risk of dropout school is high. The Association provide social economy services through a social enterprise focus on organising events (marriages, parties). The obtained small profit is reinvested in two meals per day for each of 55 children, and after school activities [17], [18]. The Association was supported by national and international partners including public administration. Hercules Association was selected among the winners of NESsT social enterprise competition. The provided technical assistance supported the development of future activities.

1.1.4 Mutual organisation for employed people in education Fălticeni

This mutual organisation was established in 1926 with the purpose of financial mutual support of teachers confronting difficult situations. During the time, the mutual opened to all the ones interested. It provides financial services adapted to various current needs. Efficient and continuous activity of this social economy entity is recognised at national level. During the last years it was constantly included in top 5 mutual organisations for employed people associated within National Association of Mutual Organisations for Employees [17].

1.1.5 Sweat health

Social insertion enterprise Valea Barcaului was established in 2011 thanks to a grant from the Ministry of Labour provided through an ESF project. This entrepreneurship initiative is based on the partnership between Agapis Foundation and Valcau de Jos city hall. Beekeepers and fruit growers have the possibility to valorise their natural products through the social insertion enterprise. Small dimension traditional family businesses are supported in producing at high quality standards. The profit is reinvested in promoting access to education of children confronting school dropout risks due to financial problems, in promoting rural tourism, and a decent income for local producers [19].

1.1.6 Braiding workshop Tamajda

The workshop was set up as a successful partnership between Ruhama NGO and Avram Iancu city hall from, a poor village relatively isolated by big cities with a large Roma community. The social enterprise was opened with the financial support of a grant won in 2011 from the Ministry of Labour through a ESF project. The possibility to conduct an economic activity using local resources is an alternative answer to low employment opportunities [18]. Tamajda social enterprise was nominated among 2013 winners of NEST social enterprise competition.

Conclusions

From the methodological point of view, the paper was based on comparative analysis between Romanian social economy entities assessed as best practices in promoting social inclusion through employment of vulnerable groups. Their selection was based on potential to encourage economic opportunities as one of the characteristics of community resilience.

Empowerment of local stakeholders especially public administration, use of local resources, and long term investment in supporting local entrepreneurs are key elements which could support the development of a win win strategy in the case of rural community concerned about social inclusion of poor people.

The role of the elite Roma population in their community development.

Zamfir E.

Research Institute for Quality of Life, Romanian Academy (ROMANIA)
ezamfir1@gmail.com

Abstract

This paper is based on an exploratory research focuses on Roma elite population (intellectuals, community leaders, and businessmen) which I coordinated in late 2012 within the Research Institute for the Quality of Life of the Romanian Academy. It attempts to depict a positive image of an increasing segment of the Roma population, with promising implications for social change within their community. This research aimed to shift perceptions by choosing not to focus on the poor and marginalised segments of the Roma population whose development is seriously hampered by strong societal barriers, instead, it focused on the social segment that overcame difficulties and was able to take advantage of new opportunities. This socially successful segment of the Roma population represents the potential future of a presently marginalised group; it paints a new picture of the Roma population and it endorses new life styles through the social success narratives of a narrow, but expanding, group. In our survey, we selected ten geographical areas representative for the variety and complexity of success scenarios of the Roma population in Romania. However, the sample does not have the representativeness across the country, because the successful segment of the Roma population is sometimes difficult to identify; it is not very visible within Roma communities.

The objective of the paper is to bring a positive image of an increasing segment of the Roma population, with promising implications for social change within their community.

Key words: Roma elite, educational policies, positive discrimination, success factors, work culture, labour market integration

Political context of transition and the explosion of opportunities for minorities

The 1989 of December Revolution produced a radical change in the situation of the Roma. They were formally acknowledged as a distinct ethnic group. Initiatives of support to help them break away from the state of marginalisation emerged. Roma organisations were established, which were promoting their interests. An important support was granted for the assertion of the Roma culture. During this period, the Romany language became written language; own cultural manifestations appeared and the Romany history was taught in schools. Politically, particularly special attention was paid to the struggle against the various forms of discrimination of the Roma. The political status of the Roma improved substantially. But the economic crisis, starting with ’80, revived, however, the adoption of strategies of survival at the margin of the society, often contained to homogenous, poor and often closed communities. Political winners, the Roma were the great economic losers of the transition [1].

This contradictory process strengthened the social image of the Roma as a community situated at the margin of the society showing no sign of integration within a modern society. The economic isolation strengthened. The collective image of a poor and marginal population consolidated, with negative effects for the life of the Roma. This situation is reflected in time in many sociological studies [1], [2], [3], [4], [5].

The number of sociological studies that focused on the situation of the Roma increased dramatically after 1989. The image resulting from these studies depicted the Roma as placed outside the dominant community, with a precarious economic situation, using survival means that opened large socio-economic-cultural gaps between the Roma and the majority of the population.

The Roma who left their 'Gypsiness' behind, who tried to integrate with the general flow of modernisation, tended to disperse within the Romanian community at large with a rather hesitating attitude towards self-identification. This explains why many samples of those sociological surveys represent strongly the traditional poor segment and very unsystematically the segment of the Roma people engaged in a process of change and social integration. Beyond their important role of diagnosis of the real problems confronting the Roma, the sociological surveys had a secondary, perverse effect: the consolidation of a rather negative image of

the Roma. Thus, individually, the typical Roma tends to be the Roma with no education, with no paid job, living on modest, marginal resources, at the limit of legality, is a member of poor communities, socially and ethnically homogenous [6]. A population that cannot fit within a general flow of modernisation becomes the hopeless prisoner of a negative history. Therefore, the poor segment is highly socially visible and easily identifiable by the researcher.

In the same time, there were several factors that stimulated and supported the fast development of this upper social segment:

- The explosion of opportunities for school participation and professional training
- National and international policies of support for ethnic minorities, and Roma in particular
- Supportive family environment ensuring a competitive advantage for individual success
- Increased capacity of the Roma population to cope within the new social and economic context and to provide a stimulating environment for the new generation.

The opportunities to develop small businesses were also significant for the improvement of the self-esteem and of the social status of the Roma. In addition to these, the Roma took advantage of the freedom of movement within the European Union; this, however, had some undesired effects on their image abroad. The opportunities for economic initiatives were rapidly overshadowed by the economic recession and massive job cuts that affected especially the Roma; as I mentioned in the recent past time [7], [8], [9]. Many people, including Roma, lost their jobs and very few managed to get a new job within the formal economy. Thus, many of the future aging Roma will be deprived of a pension.

Despite these obstacles, an important opportunity for the future of the young generation remains the access to education. It became much easier and much more encouraging for the Roma to stay in school after the introduction of several measures that stimulated enrolment in school and higher education. During the early 1990s, as our studies showed, the Roma population was highly socially and economically homogenous in poverty and marginalisation, with a low level of formal education and professional integration in the formal economy [1], [2], [7], [10].

The school attainment was very low in 1992. Thus, the ability to use new educational opportunities provided by the Revolution was very low, as well as the occupational integration within the modern economic system. For instance, in 1992, of the total sample of 5,968 active Roma people, 16.1% had modern professions, 3.9% traditional professions and 79.4% had no profession at all [1].

The novelty of this survey is its distinct sociological perspective that focused on the elite segment of the Roma population, characterised by social, economic, and professional success, rather than on the poor, vulnerable groups, at risk for severe poverty. We are thus trying to overcome the bleak image of an increasingly poor population. Hence, the originality of the study resides in its emphasis on the positive aspects of the Roma, which has the potential to motivate changes within the community. The systematic omission of the upper, elite segment of the Roma from the sociological survey, in favour of the poor segment, decreased the odds of success of many ordinary Roma people. Their initiatives to stand up and do something to change their lives are often blocked by a feeling of despair and "learned helplessness"/disabilities. Their efforts to overcome their "Gypsiness" seem hopeless [1]. The Roma elite group is not always visible within the community, despite the fact that its influence in real life communities cannot be ignored. Because it is not an explicit and visible part of the sociological surveys, it cannot be perceived publicly and properly by the majority population. Nevertheless, the successful Roma, as an integral part of their communities, help depict a comprehensive picture of the modernising Roma ethnicity. To further complicate the issue, successful Roma are often perceived as being assimilated by the majority group. During the transition period, a group of the Roma population ascended the social ladder very rapidly. This group is small, but is nevertheless significant for the Roma community and it consists of intellectuals, business people, and social, political, and religious leaders.

After the Revolution, The University of Bucharest had the positive discrimination initiative to introduce a number of special places for Roma students. In the beginning these places were for Social Work students only, but other departments adopted this measure as well [4], [9], [11].

We may thus conclude that the 1989 Revolution provided ample but uneven opportunities: on the one hand, it created important advantages for a small part of the Roma population, but, on the other hand, it intensified the process of social exclusion for an important segment of it. Although the Revolution opened possibilities for cultural, political, economic and intellectual integration for the Roma (improved access to education through positive discrimination, etc.), not all the Roma were entirely ready to embrace them. Some of the Roma remained passive and demoralised and continued to have very poor educational attainment. However, the most active of Roma were able to capitalise on their traditional aptitude for entrepreneurship. It is worth noting that in our sample of successful Roma businessmen, only 25% of participants had graduated from higher education and 37.5% had an elementary or middle school education.

The Roma elite and the Romany culture

Historically, both the Roma community and the Roma culture were received by the majority population with a rather negative connotation. Romany culture didn't receive a formal status or political support. The fact that it was oral and didn't have any correspondent in a written culture allowed it to crystallize only to the extent that it could be expressed and transmitted orally. Under these circumstances, it unavoidably suffered of chronic underdevelopment.

The ethnic self-identification of the Roma has some particularities. For most of the Roma, their ethnic affiliation was socially visible. Most often this was due to the marginal-poor social situation and to their traditional life style. On the other hand, the negative branding of the Roma by the majority population often pushed many Roma to avoid self-identifying with their ethnic group. The 1992 census register a much lower number of Roma nationals than they actually are. The 1992 census reported about 440,000 Roma people. Our studies estimated a larger number, around one million. The Roma NGOs and the Roma leaders produced much higher figures (about 2.5 million) due to obvious reasons of asserting their identity and because they need financial support [1], [2].

The Roma dispersed within the bulk of the community experiment harder the double identity: ethnic and citizenship. Many were expected to consider themselves Romanian citizens first, and only secondarily, Roma people. This is more so as the ethnic identity is not included in the official documents, just the citizenship. Part of the Roma intellectuals, active in the process of assertion/support of the Roma, were obviously motivated to state their ethnic affiliation.

The increasing number of self-identified Roma, by about 200,000 from 1992 to 2012, is difficult to explain. One may consider that the Roma were motivated to state openly their affiliation to the group due to the growth of the birth rate (not so high, however), or in response to the improved social image of the Roma following the process of social inclusion. However, they may also be another factor, the larger homogenous groups of Roma people where the ethnic self-identification is more likely.

It is a widely shared point of view that the establishment of houses of culture, clubs or cultural centres is desirable and that they would make an important contribution to the development of the Romany culture and of the self-awareness of the Roma people. The intellectuals are slightly reserved, but two thirds of them support this idea.

The arguments are very interesting. They too aroused passion bringing forth a lot of ideas and comments. Of the total 432 subject, only 325 came up with reflections and proposals.

Following is a selection of proposals and of cultural policy fears that might manifest during the functioning of the cultural institutions. The fear relates to the risks of ethnic cultural conflicts that may appear due to the improper management of the dialogue or due to the intersection/communication of cultures. The political options for the development of cultural life strategies of the Roma must come from the group of successful Roma, thus helping the decision-making factors by:

- Establishing a space of communication and information/organisation of events by special private, NGO or public cultural institutions.
- Preserving and promoting the Roma culture and traditions.

Roma elite and Roma cultural institutions

The Roma consider that they urgently need an institutional space which to accomplish a package of vital functions**.**

Actually, these institutions must be conceived as a space for mutual acknowledgement, for improving the social image of the Roma, as supported by the evaluations.

This group of questions about the Roma culture stirred up passions expressed in the wealth of ideas. The general feeling is that more has to be done for the development of the culture and for its dissemination within the Roma community and within the communities of the majority population.

The study of the successful Roma group started from the premises, supported by the psycho-sociological theories, emphasizing the intrinsic, motivating role of the individual success. As the Romanian psycho-sociologists Mihai Ralea and Traian Herseni were stating in their book "Sociology of success: nothing maintains the success better than success itself" [12].It is known that the intrinsic motivation of the actions supports performance in the best possible way, accompanied by socially acknowledged achievements/successes confirmed and accepted as significant for the community.

Conclusion

The major objective of the research was to make an analysis, as clear and as close as possible to the big complexity of the socio-economic and cultural diversity/ of the Roma community. Our purpose was to raise the awareness and to help the community and institutional factors to imagine strategies for the development of conservative, traditional patterns of the Roma culture within the context of the global transformations affecting presently the modern civilisation. The presence of services of information and knowledge of the cultural diversity and of the result of the culture intersections helps forming a tolerant, flexible attitude of accepting the diversity of the cultural patterns of life, requirement of the process of globalization. Furthermore, it contributes to removing the prejudices underlying the intolerance to other cultures (ethnocentrism) and the cultural discriminations of all kind that may bring serious prejudices to the community security, harmony and balance.

Self-concepts and resilience by Roma youngsters living in poor communities

Roth M.[1], Pop F.[2], Raiu S.[3]

1Babeş-Bolyai University, Faculty of Sociology and Social Work, Cluj-Napoca, Romania

Abstract

This paper is based on interviewing 20 Roma adolescents, from residential homes and from poor Roma communities. We are looking at how their self-concepts and future orientation are marked by their disadvantageous environments, as well as the resources they have to maintain themselves hopeful. In this context we try to draw the line between ecologic normality, seen as turn-away of youngsters from mainstream education and career aspirations, and resilient behaviour, seen as maintenance of positive illusions and continuous struggle towards educational and vocational attainment and social integration. Applying the concept of positive illusion [1], we examine their capacity to maintain positive mental health and self enhancement capacity expressed in positive illusions about themselves, about maintaining control and future orientation [2].

Keywords: resilience, Roma youth, transition to adulthood, aspirations

Introduction

Definitions of resilience vary according to their theoretical roots, but it is most often viewed as a strength based concept, a process that refers to exposure to adversity and adaptation resulting in positive outcomes [3]; [4].

The transition to adulthood is a period when adolescents face a number of risks, but in this paper we argue that Romanian Roma adolescents face even more adversity, which can translate into difficulties in making a successful transition to adulthood. This is based on several studies that point at the multiple disadvantages experienced by the Roma minority ethnics, ranging from poverty, inadequate housing, low enrolment in education and employment and lack of political participation [5]; [6]; [7].

Theoretical reflections on risk, protective factors and resilience

The ecological-interactional-developmental (EID) approach is a useful perspective for integrating the resilience approach into research. The EID draws particularly on the bio-ecological model of human development [8], which is a theoretical system evaluating human development as the phenomenon of continuity and change in the biopsychological characteristics of individuals and groups [9].

Adverse experiences of poverty and social threat can have long-lasting and pervasive impact on many but not all children's development and sense of well-being. Resilience in cases of adversity is mostly understood as a dynamic developmental process that results in positive adaptation despite such experiences or trauma [10]; [11].

According to the positive illusions theory [12], inflated self-views function as a psychological resource and resilient coping strategies to buffer the negative emotional impact of events that are threatening children's development. This view opposes reality-based theories holding that whatever the direction of the distorted self-views (inflated and deflated), they have detrimental consequences, and only realistic self-views are emotionally healthy [10].

Methods

This study was conducted in Cluj-Napoca, the second largest city in Romania, with a population of 324.576, out of which 1% Roma minority ethnics [13]. The sampling procedure was non-probabilistic, following the diversity principle. We interviewed 20 Roma adolescents coming from different socioeconomic backgrounds in terms of education, housing, family history and employment status: Roma high school students who either live in Cluj-Napoca or commute to Cluj-Napoca for school from localities nearby (17-18 years old, 5 females and 3

males); Roma adolescents who live in the biggest segregated area in Cluj-Napoca (16-21 years old, 4 females and 6 males, living and collecting garbage at the landfill); and Roma adolescents living in residential homes in Cluj-Napoca (20 years old male student, 18 years old female high school student).

Three researchers were involved in conducting the interviews, and all made use of an interview guide. Adolescents and parents/guardians were asked for their consent to participate in the study and to record the interviews and were informed about the ethical aspects of the research. After the interviews were transcribed, we employed deductive analysis in relation to the main themes of our research.

Results

1.1 Perception of Adulthood

As the majority of other adolescents, our participants state that becoming an adult means to be able to start a family, to find employment and provide for their family. In addition, our interviewees also mention that one should also become independent, wiser, more responsible and overall an honest person. Adolescents living in residential care and those living at the landfill particularly stressed the importance of having their own house, even if this means working very hard in any type of employment.

When asked where they see themselves in the transition process to adulthood, adolescents refer once again to what should one achieve in order to become an adult and stress that there are still things they need to accomplish.

"I don`t consider myself an adult yet (...) And you know why? Because I don`t have children yet, I don`t have a wife, and I don`t think about these things yet (...). Maybe when I`m older, 20 or more, but not until then. No, because I don`t need things to worry about, like providing food for my children and my wife (...)." (Male, 18 years old, high school student, living and working at the landfill)

1.2 Future Orientation, Education and Context-Based Aspirations

Adolescents` narrations about aspirations include aspects referring to obstacles and resources in their environment which have shaped their understanding of what might be achievable for them. In terms of aspirations, our interviewees` answers vary significantly. High school students mostly described graduating from high school and getting a graduation diploma as their short term plan, followed by continuing their studies and finding employment in their field of interest. For the adolescents living in residential care, prolonging education is of particular interest since this entitles them to stay in care shelters until they finish their studies. Being aware of this aspect, adolescents describe their struggle to become independent by getting a diploma and subsequently finding employment. Interviewees living at the landfill, out of which the majority have abandoned school, describe their future plans as related to their dream to leave the landfill and start a new life which includes having a formal job, avoiding the health dangers of the landfill and providing the wherewithal for their families.

"There are a lot of plans… To start with, I would like to graduate and get my graduation diploma, and then I would like to continue my studies, maybe in the field of nursing or physiotherapy (...). Basically to find employment, be accomplished, find your place, and not to depend on anyone and the rest will follow: friends, marriage, and children." (Female, 18 years old, high school student)

As emerges from the ecologic theory, the optimism or pessimism, the activism or passivity of the Roma adolescents from poor communities depend on the characteristics of their communities, families and the support they get from social services or support persons.

1.3 Self-Reliance

According to the theory of positive illusions, Roma adolescents identify a number of personal characteristics which they consider as resources for them reaching their goals. Perseverance, hard-work and patience to build things one by one are some of the personal qualities adolescents identify in themselves. Once again, answers are different among our interviewees, ranging from their capacity to get a high school graduation diploma to their work experience in the informal sector, which prepared them for different jobs and should help them in finding employment.

"Now it is up to me to succeed with my dreams, my family has done a lot so far…and about becoming a policeman, I have some qualities, I am disciplined and ambitious… but I know I need to trust myself a little bit more (...)." (Male, 18 years old, high school student).

1.4 Family Influence and Education

We investigated this aspect only with adolescents who are in their family`s care. The influence of family members in shaping adolescents` self-concepts and future plans emerged in all interviews, but this aspect

was heavily linked to issues of poverty and disadvantage. Adolescents living at the landfill particularly refer to their family as influencing their decision to abandon school, but mostly explain this as the need to help their family survive or parents` low education level. Some of them stress that even now, when they are out of school, their family members encourage them to go back, but given the context, they are aware that this is only a dream. For the adolescents who are still in school, family`s support is perceived as one of their main resources for the future. However, in these cases, adolescents do not describe their families as being as impoverished as adolescents at the landfill do.

"I abandoned school when I became pregnant and I was too ashamed (...) to continue going to school (...). My grandparents were very upset [because I abandoned school], they didn`t approve…We fought and then time passed, I didn`t listen to them and this wasn`t good for me (...). I loved school very much, I really loved going to school." (Female, 17 years old, living and working at the landfill)

"My parents would really do whatever it takes to see us fulfil our goals, and help us become someone (...) to see me accomplished, so that I am satisfied and they are satisfied too. They work in commerce; they work very hard for us (...).I would like to go to university, this would be my main goal, but it depends on my parents, if they can help me with the money. " (Roma male, 18 years old, high school student)

Taking into consideration the influential role of parents for the interviewed adolescents, in the case of adolescents living in residential care, we consider the focus should be on the role of non-parental adults in their environment.

1.5 Friends, Neighbourhood and Organisations

A common aspect throughout the interviews is adolescents` perception of religious organisations as resources for them. Others mention their friends either as sources of support in difficult situations but also as risk factors for them in the decisions they have already made (such as the decision to abandon school). Nonetheless, community organisations or other NGOs are also perceived as protective factors, in some cases even preventing them from turning away from their desired educational and career path. Besides the school setting, none of the adolescents mention any other institutional support.

"I have a neighbour, he graduated the police academy (...), and he is very satisfied with his work. Indeed, he spent a lot of time studying, but he is not sorry. He earns good money, people show him respect, and so he reached his goal." (Male, 18 years old, high school student)

"I use to go to church, the Baptist Church (...) yes, there are many young people like myself in this church (...). We hang out together sometimes after rehearsals [Sunday choir rehearsals]. (...) We plan to start a study theme about life...particularly about married life. A lot of us are now in this stage, at the point of getting married (...)." (Male, 20 years old, post graduate student, living in residential care)

Conclusions

According to adolescents` narratives, the main influences in shaping their aspirations are parents, friends, school personnel and members of non-governmental organisations. Role models from their environment turn to be of particular significance for adolescents while describing their transition to employment, especially if they can relate to success stories of their similar like. Despite the positive influence that some non-parental adults have on adolescents' envisaging their future path, some other are seen by adolescents as perpetuating discrimination.

The situation of adolescents living at the landfill needs particular attention since it illustrates a high risk phenomenon which is not singular in Romania. It describes among others the case of (and in the same time the results of) residential segregation, early school abandonment, perpetuation of informal labour and extreme poverty. How should one discuss resilience in respect with these young people? They identify numerous obstacles, and they admit that they hardly see themselves going back to school, but they hope that once they will get the chance to leave the landfill, more opportunities will be available for them, such as formal employment or a house of their own. Applying the theory of positive illusions, helping landfill young people has to envisage their emotional needs, and encourage their aspirations, whatever these might be.

Based on our findings, we share our interviewees` concerns about the difficulties they face or they are about to face in their transition to adulthood. We argue that the specificities of each category we approached in our research should be a priority for practitioners and policy makers when designing interventions and policies for these target groups. Programs aimed at building resilience for these adolescents should by no means overlook adolescents` understanding on what can help their transition to adulthood become more successful.

Best practices in the resilience process of the human trafficking victims

Askew M.

United Kingdom
Michael.Askew@pliglobal.com

Abstract

Exploitation is seen as an increasing issue across Europe as well as in the world. Unfortunately, the victims are some of the most vulnerable of our society and particularly susceptible for re-victimization. The traumas suffered by these victims are usually very severe due to the fact that human trafficking is a complex crime and the victims have been intensely exploited throughout several months and sometimes even years. Achieving the state in which these victims manage to cope with the stress and adversities they were forced to face is a very complex and long-lasting process. The solution is for all the agencies to work together to tackle the situation in a holistic manner. One UK Non Government Organisation has taken this a stage further and as well as providing support to victims has started to establish investigation hubs across the UK to act as a bridge between the victims and the police. The presentation will outline this new dynamic approach and how it could be applied as a new measure to improve the current approaches and achieve an efficient "healing" of the victims.

Keywords: Resilience, Victims, Traumas, Vulnerability, Human Trafficking.

Background

1.1 The Problem

1.1.1 Trafficking is a hidden crime.

Many victims are never identified. This issue is a combination of the covert nature of criminal activity and a lack of awareness on the part of too many staff, whose job is to interface with vulnerable people, caused by a lack of training. In 2013 the UK National Referral Mechanism (NRM) received 1746 referrals of potential victims of trafficking. This represents a 47% increase on 2012 referral totals. The 1746 referrals were comprised of 1122 females (64%) and 624 males (36%) with 1295 (74%) referred for adult exploitation categories, 450 (26%) being referred for minor (child) exploitation types and 1 (<1%) of unidentified age at time of exploitation. [1]

1.1.2 Traffickers often operate across several borders, national and organisational

The victims found in the UK in 2013 were reported to be from 112 countries of origin. This represents a 18% increase on 2012 country of origin totals. This makes them difficult to detect and means investigations can be highly complex and multi-jurisdictional. Without a coordinated approach to fighting trafficking in which everyone is clear of their own part to play and of whom else they should be communicating with, the traffickers will maintain their upper hand. This is why it remains crucial that frontline staff, like police personnel and social workers, share their suspicions and information with the UK Human Trafficking Centre, local police and with other related parties. If a victim arrives in the port of Dover and is trafficked via London where he is passed from one trafficker (the transporter) to another trafficker (the recipient) and ends up in Bradford, the investigating officer needs to share his intelligence with the UK Human Trafficking Centre, the police constabulary in West Yorkshire, Kent and SCO9 in the Metropolitan Police. There also may be additional agencies who need to know this information e.g. Gangmasters Licensing Authority (if the victim has been working in the food or food related industry), Her Majesty's Revenue Collection (in the event of child benefit fraud), Benefit Fraud department of Department of Work and Pensions (in the event of other types of benefit fraud).

1.1.3 Some victims are too fearful or too traumatised

Victims don't come forward and identify themselves as trafficked or give evidence because of their experience. In some cases encountered by Hope for Justice, victims actually encountered police officers directly but were too afraid to disclose their situation and passed up the opportunity to exit it because of the violence and threats made against them.

1.1.4 Victims are prosecuted

Victims that have come forward, or been intercepted by the police, have been prosecuted themselves for offences committed whilst trafficked as a result of desperation or duress. In contravention of the Convention on Human Trafficking and of Crown Prosecution Service Guidance it was found, between 1 April 2009 – 28 February 2010, that a staggering 40% of victims who received a positive Reasonable Grounds Decision (indicating that they were likely trafficked) were in prison at the time of referral.[2] A further 29.7% were being held in immigration detention centres at the time of their referral to the Government's National Referral Mechanism which exists to identify trafficking victims. Here in the UK, we may well be convicting or deporting more victims of human trafficking than perpetrators.

1.1.5 The traditional approach has not worked

The traditional approach has not worked. A new approach has been needed to bridge the gap between victims and the police, who through no fault of their own have focused on other pressing priorities.

Hope for Justice New Approach

1.1 A British NGO

1.1.1 Hope for Justice

Hope for Justice is an anti-human trafficking organisation working to uncover and abolish the hidden crime of modern-day slavery. Their unique vision is to assist the police practically through intelligence gathering and rescue within the UK. Human trafficking is not someone else's problem, it's happening in our communities, in our neighbourhoods, in our country. In 2004, in his fight against this "modern day slavery", Ben Cooley, a concerned individual, booked the Birmingham National Exhibition Centre to raise awareness. At least 6,000 people atended and Hope for Justice was born. Hope for Justice was created to be the practical solution to human trafficking with four areas of operation:

1.1.2 Area 1 - Investigating and bringing about the rescue of victims from the abuse of human trafficking

The Hope for Justice Investigations Team responds to intelligence received from frontline agencies and community groups they've trained to recognise the indicators of trafficking. This work enables them to debrief victims, identify them as trafficked, inform them of the National Referral Mechanism (system for identifying victims and providing appropriate support), rescue victims from situations of exploitation and transfer them to aftercare providers. Intelligence is submitted to the police and can form part of the picture where a larger organised crime culture exists. With so many victims arriving from countries with disreputable policing, and so many others wilfully instilled with a terror of UK police, the need for a third party is distinct and urgent. Hope for Justice builds bridges of trust between police and victim, and act as a conduit for intelligence that would otherwise simply never see the light of day.

The public are encouraged to report human trafficking directly to Hope for Justice. "If you suspect a case of human trafficking and/or think you may have identified a victim, then contact Hope for Justice on: **0845 519 7402 or operations@hopeforjustice.org.uk.**" This could result in more reports in cases where the public do not want to contact the police directly.

Hope for Justice have developed a number of Regional Investigation Hubs around the country. The first Hub was in West Yorkshire and the second Hub is in West Midlands. The Investigation Hubs are staffed with experienced investigators who are familiar with police procedures. They are often retired senior police officers with a great deal of experience. Each Investigation Hub is named after a victim that has been rescued i.e. Emma's Hub, Zoe's Hub. They have developed intelligence sharing agreements with the local police force and are often involved with operational raids to rescue victims. They take on cases that clients don't want to report to the police. This helps to provide a bridge between victims and the police and overcomes a barrier.

In only 15.6% of cases from 2011-2012, did the victim feel confident and safe enough to cooperate with police investigations on the day they exited exploitation (Hope for Justice, 2012). However, after a few weeks in aftercare, the number of victims requesting Hope for Justice to advocate for a police investigation and prosecution of their oppressors rises to 78%. This shows that NGOs can bridge the gap between victims and the police and increase reporting.

Hope for Justice celebrate every victim that is rescued in a unique way that creates a powerful internal culture that keeps all staff motivated on the vision to eradicate human trafficking in our lifetime.

1.1.3 Area 2 - Assisting in the protection and rehabilitation of victims

Aftercare in the UK is overseen by the Salvation Army, who hold the Government tender at a cost of £3m, and they subcontract to a number of organisations who provide safe houses and accompanying services. Hope for Justice Aftercare Coordinator makes it their business to know about the standards of care offered at each facility. Follow-up phone calls and visits are also made to those Hope for Justice rescues and the team track each individual's progress. After 1-2 weeks in safe accommodation 78% of the victims Hope for Justice have assisted request that Hope for Justice advocate on their behalf for police investigation and prosecution. They work closely with the national Human Trafficking Centre. "The UK Human Trafficking Centre (UKHTC) is a multi-agency organisation led by the National Crime Agency. Its role is to provide a central point of expertise and coordination in relation to the UK's response to the trafficking of human beings. The Centre seeks to facilitate a coordinated, cooperative and collaborative way of working within the UK and internationally. Its work to combat human trafficking and provide victim-centric support covers three key inter-linked areas:

- Prevention
- Protection
- Prosecution

This work involves a wide group of stakeholders and partners, who together deliver a diverse set of programmes designed to prevent and reduce the harms caused by human trafficking. The UKHTC's partners include police forces, the UK Border Agency, HM Revenue & Customs, the Crown Prosecution Service, the Gangmasters Licensing Authority, non-Governmental organisations (NGOs) and many charitable and voluntary expert groups."

The National Referral Mechanism (NRM) is a framework for identifying victims of human trafficking and ensuring they receive the appropriate protection and support. The NRM is also the mechanism through which the UKHTC collects data about victims. This information contributes to building a clearer picture about the scope of human trafficking in the UK.

The NRM was introduced in 2009 to meet the UK's obligations under the Council of European Convention on Action against Trafficking in Human Beings. At the core of every country's NRM is the process of locating and identifying 'potential victims of trafficking'.

To be referred to the NRM, potential victims of trafficking must first be referred to one of the UK's two competent authorities. In the UK the two Competent Authorities are:

- The UK Human Trafficking Centre, which deals with referrals from the police, local authorities, and NGOs.
- The UK Border Agency, which deals with referrals identified as part of the immigration process, for example where trafficking may be an issue as part of an asylum claim.

Once a referral has been made, trained experts in the Competent Authority will assess the case and make a decision on whether an individual is a victim of trafficking.

This initial referral will generally be handled by an authorised agency such as a police force, the UK Border Agency, social services or certain NGOs. The referring authority is known as the 'first responder'. First responder agencies include: National Crime Agency / UK Human Trafficking Centre, Local Authorities, UK Border Agency, POPPY Project, TARA Project (Scotland), Migrant Helpline, Kalayaan, Medaille Trust, Salvation Army, Gangmasters Licensing Authority, UK police forces, National Society Protection of Cruelty to Children/CTAIL, Local Authority Children's Services, Barnardo's, Northern Ireland DHSS, Northern Ireland Public Safety, Unseen.

1.1.4 Area 3 - Ensuring perpetrators are held responsible for their crimes via prosecution

According to the Crown Prosecution Service, between April and December 2011 the British Government prosecuted 87 offenses of trafficking for sexual exploitation. There were 29 offenses of labour trafficking or other forms of exploitation, prosecuted under the Asylum and Immigration Act; and 11 offenses for slavery and servitude prosecuted under the Coroners and Justice Act. The Government did not provide

comprehensive sentencing data for convicted trafficking offenders in 2011; however, the Government reported the average penalty for convicted trafficking offenders in 2011 was 27.2 months' imprisonment, and the average sentence for non-sex trafficking sentences was 55.2 months." TIP Report 2012, p.358 [3]

Hope for Justice works with the UK Human Trafficking Centre (UKHTC), a branch of the National Crime Agency, and local Constabularies to ensure perpetrators are brought to justice. Hope for Justice's Legal Team focus on evidence and intelligence gathering to generate more robust prosecution cases and have developed strong, professional relationships with law enforcement agencies.

Hope for Justice regularly submit intelligence in respect of on-going investigations. It was recently part of a multi-agency operation, in Leeds, as part of a police investigation into human trafficking, which saw 17 men, women and children rescued from exploitation.

The three-day operation saw 60 West Yorkshire Police officers, supported by Hope for Justice, Leeds City Council staff, health agencies and the Salvation Army, visit 25 addresses across Leeds to offer help to families identified as being potential victims of trafficking.

Hope for Justice provide specialist training for the police as victims are not always obvious when they come into contact with a police officer who is very busy. Hope for justice include in their training full offence outlines with guidance notes and a breakdown of the elements of each offence for use by police officers and frontline agencies trying to identify victims and pursue perpetrators.

Listed below are the existing human trafficking-related offences in UK legislation:

- Holding Someone in Slavery, Servitude and Forced or Compulsory Labour (Section 71 Coroners Act 2009)
- Paying for the Sexual Services of a Prostitute Subject to Force (Section 14 Policing and Crime Act 2009)
- Trafficking into the UK for Sexual Exploitation (Section 57 Sexual Offences Act 2003)
- Trafficking within the UK for Sexual Exploitation (Section 58 Sexual Offences Act 2003)
- Trafficking out of the UK for Sexual Exploitation (Section 59 Sexual Offences Act 2003)
- Trafficking People for Exploitation (Section 4 of the Asylum and Immigration Treatment of Claimants Act 2004)

1.1.5 Area 4 - Campaigning at a local, national and international level to ensure the laws on human trafficking work effectively to combat the problem

As Hope for Justice develop relationships in Whitehall, their advocacy and legislative agenda is growing with over 100 ACTFORJUSTICE community groups joining their call for action and awareness. They are an established part of the anti-trafficking NGO community and a member of the Human Trafficking Foundation, the umbrella forum chaired by Anthony Steen. They closely work with other organisations and often advise on legislation which improves the rights of victims.

The Human Trafficking Foundation (HTF) is a UK-based charity which grew out of the work of the All Party Parliamentary Group on Human Trafficking. The Human Trafficking Foundation was created in order to support and add value to the work of the many charities and agencies operating to combat human trafficking in the UK. Their vision is of a UK:

- which presents a hostile environment for human traffickers;
- where there is widespread public awareness of the evils and existence of trafficking;
- where there is tangible and accessible support for trafficking victims;
- where traffickers are swiftly and effectively brought to justice.

Hope for Justice sits on the Human Trafficking Foundation Forum which meets quarterly to discuss the legislative and policy issues surrounding human trafficking in the UK.

1.1.6 Numbers of victims rescued and results for 2013

In 2013 Hope for Justice:

- Assisted 104 victims of human trafficking;
- Including the rescue of 57 victims of human trafficking.
- Assisted 8 children who were victims of human trafficking.
- Housed 18 victims of human trafficking who would otherwise have been homeless.

- Rescued victims ranging in age from one year old to 58 years old.
- Trained 729 participants at 30 training events about tackling human trafficking.
- Had a 100% success rate in appealing negative benefits decisions for victims of human trafficking.
- Provided legal advice to 32 victims of human trafficking and to four other agencies/lawyers.
- Continued to work on our longest case to date which began on 11th January 2011 and is still ongoing.

The whole Hope for Justice approach is unique and traditionally NGOs have focused on victim support. Hope for Justice, as well as focusing on victim support, are focused on investigation and intelligence functions that have traditionally been the role of law enforcement agencies. It is hoped that this new approach will help to bridge the gap between victims and the police and help more victims to be discovered, rescued and for more perpetrators to be brought to justice.

Human trafficking victims and the process of resilience

Borlea C.

Pro Prietenia Foundation (Romania)
borleac@gmail.com

Abstract

It is obvious that victims of human trafficking have had experiences of such intensity and impact on their psyche that most people can't even grasp the full extent of the traumas those experiences can cause. The abuses most of the victims were subjected to will never be a part of a normal human being's life. Starting with deprivation of liberty, physical and mental abuse, up to witnessing other people being beaten as an example, to even executions in some cases, can compare these person's experiences to those of the war victims or combatants.

Since war victims and participants in armed conflicts were the subject of countless psychological studies, especially in the 60's with the test subjects being World War II, North Korean War and Vietnam War combatants and veterans, the discovery and deep understanding of the coping mechanisms has become a very popular and important chapter of psychology as a science. The input coming from the people involved in these conflicts helped psychologists and psychiatrists understand how the human mind copes with major traumas and overcomes the intense feelings associated with it, in short: how people have the capacity to "forget" what they felt and what methods are used in the process.

This article is going to draw a comparison between the traumas suffered by the war veterans and victims, and the traumas suffered by the victims of human trafficking, and then compare how the same coping mechanisms apply or do not apply towards solving the trauma in each case.

Keywords: resilience, victims, war, coping mechanisms, trauma

The concept of resilience:

Technology describes resilience – according to Campbell, Flake C. (2008) as *"the ability of a material to absorb energy when it is deformed, and release that energy upon* unloading [1]*."*

If we were to convert the technological definition of resilience into a psychological one, it would sound something like this: Resilience is the ability of the human psyche to absorb harmful energy that deforms it and release that energy in the form of self-restructuration.

We took the freedom to speculate upon the definition of psychological resilience for two reasons: firstly because the term, in two completely different fields, measures such similar properties, and because there is no widely accepted epistemological definition for it, only *an agreement regarding two essential points:*

- *Resilience characterizes a person that has, or is going through a traumatizing event or chronic adversity period and shows strong adaptability […]*
- *Resilience is the result of an interactive process between the person, its family and the environment.[2]*

We could summarize by saying that resilience is simply the resistance of a person to traumatizing events, chronic adversity, or the measurement of the coping mechanisms a person can mobilize, in order to overcome difficult situations or an overwhelmingly stressful existence. This though, would be wrong. Things are not as easy or simple. Resilience is different from resistance, and the very concept of it goes beyond the measurement of the capacity to cope with stress, adversity or trauma, beyond the simple solving of internal conflicts resulted from aversive events and experiences while keeping mental sanity.

1.1 Psychological "strength"

Psychological strength is often used at an empiric level to define a person's capacity to stay mentally stable and cope with situations and circumstances in which others would lose their hope or fall into despair. It only regards surviving situations which seem disastrous and which have a very high potential of destroying a

"weak" person's mental sanity or appetite for life, the very difference between the "strong" and the "weak" – at an empirical level – being the capacity to stay alive and keep mental sanity after such an experience. We avoided using the term "*mental toughness*" since it doesn't underline the empiric aspect of psychological strength, of a "strong person", being something seemingly similar but actually very different.

Psychological strength is confined largely to the identification and activation of coping mechanisms through native or artificial methods.

Native methods are, in fact, innate techniques and mechanisms which the individual possesses – motivational and energo-dynamic systems, (temperament) – operated and handled through emotional intelligence – *intrapersonal intelligence* [6] – which acts the same as general intelligence, managing processes, systems and psychological mechanisms more or less effectively. The more developed intrapersonal intelligence is, the higher the chances that developed and existing coping mechanisms to be intuited and applied effectively, making the person stronger and more equipped to face terrible odds.

In contrast to native methods, artificial methods are acquisitions of psychological techniques and coping mechanisms learned from experience or through the support and help of others such as family, relatives, friends or through means of therapy or professional counselling, which might even help – according to the person's age – to enhance and develop intrapersonal intelligence and the introspection tools of the person artificially, through learning, just like, for instance, chess or math can significantly develop logical-mathematical intelligence. While artificial methods rely more on cognition and rationalization of emotional processes with support from the environment, native methods rely more on innate systems of control that are more or less consciously applied as filters on the emotional processes, and are highly related to the energo-dynamic system.

Obviously, these two methods are not parallel; they intertwine, being strongly correlated and interdependent. No sane individual is deprived of the ability to sense coping mechanisms or the necessary intelligence for their management and application, which combined with experience, support and learning from external sources guarantee the existence of necessary mental tools and techniques needed to cope with traumatizing events.

All in all, we could say that some individuals have a "talent" to withstand catastrophes in their lives, and their talent only helps them as much as any talent would help in any other field.

1.2 Mental toughness

Mental toughness is a term created by James Loehr, a sport psychologist in 1986, and it is commonly being used by coaches, sport commentators and business leaders to define a person's ability to persevere through difficult circumstances or the challenges implied by a competition.

One of the definitions of the term is "*Having the natural or developed psychological edge that enables you to: generally, cope better than your opponents with the many demands (competition, training, lifestyle) that sport places on a performer; specifically, be more consistent and better than your opponents in remaining determined, focused, confident, and in control under pressure*." [4]

According to this definition we might make the confusion that mental toughness is the same thing with psychological strength. Even though they are similar concepts and very interdependent, there are quite some differences between these concepts. While psychological strength is an empiric concept used to define someone that has the will to survive when odds are against them, mental toughness is an epistemological concept that defines the ability to fight and continuously search for ways to improve your resistance when faced with many demands, staying focused on a task and keeping control under pressure.

Even so, the concept being mostly used and tested in sports, where the demands are related to physical activity, willpower is channeled specifically on physical activity and competition, be it overcoming pains or fatigue or the frustration involved in poor personal or collective performance. Of course, a professional athlete has a background of very-well polished discipline which required ambition and willpower. These were built up throughout years of training and you could expect from such an individual to be determined and focused when aiming for something. Yes, it would be logical and could be true; in theory. Reality though, shows us the fact that such individuals are as exposed to the risk of committing suicide following a romantic deception – for instance – as anyone else and regardless of their polished ambition and discipline or training – which includes self-discipline and a high level of mind toughness – they cannot cope with certain types of situations which imply other coping mechanisms.

Therefore, mental toughness cannot guarantee the mindset and/or equipment necessary for coping with affective disasters, illness or aversive overall existence for instance; apparently ambition, determination and willpower has to be channeled in certain directions, in certain areas of existence and practiced in the right area in order for it to have a proper impact on the individual's adaptability capabilities.

1.3 Differential concept of resilience

While Psychological strength and mental toughness are concepts related to resilience, the process of resilience is broader, its composition is complex and reaching resilience is a long process which involves successive transformation stages:

1. Becoming aware of acute stress and toxic situations
2. Creating a self-care, personal, renewal program
3. Surrounding oneself with four kinds of friends
- *the prophet (a person who stretches us and challenges us to go to the scary place that we may have been avoiding, but where we may ultimately find freedom.)*
- *the cheerleader (a person who offers us unabashed, enthusiastic, unconditional acceptance)*
- *The harasser: (someone to make us laugh at ourselves, to rip up our unrealistic expectations, and to "regain and maintain perspective" by way of gentle teasing.)*
- *Guides: (people who help us uncover the voices that are guiding us, and "especially the ones that make us hesitant, anxious, fearful, and willful.)*

4. Recognizing and concentrating on signature strengths
5. The examination of oneself and acceptance of shortcomings
6. The practice of mindfulness and meditation [5]

In order to differentiate the process of becoming resilient from the other concepts, it is important to understand that resilience is not just resisting, not just surviving, but a process of change, of rearrangement of one's mindset, the main difference between it and other resistance systems being it's very dynamic and adaptable character, the fact that, instead of just resisting a traumatizing event or a chronic aversive condition, a rechanneling process begins which transforms the triggering event into a motivational motor that pushes the individual forward in a new direction.

According to Ionescu (2013) the avoidance of colaps system is divided into two axes: one stretches from resistance and its opposite – "irresistance", and the other one from resilience and its opposite – "iresilience". While resistance ensures the maintenance of evolution in terms of *"not giving in under the effect of an antagonic pressure",* irresistance leads to divestment which means that "*the subject tends to divest a part of his or hers development potential and to give up one or more of his or hers evolution sources"*. While iresilience will lead to alienating neo-development, resilience will lead to liberating neo-development. [2]

As seen above, resistance will lead to stagnation in a certain measure while resilience will necessary lead to "*neo-development*" which does not only means development but a certain type of development which completely transforms the individual at a mental level, the individual ceases to be what he or she has been before the triggering event and starts anew, "from scratch", changing its path through life from that point on.

Resilience implies evolution, rechanneling and rewiring of one's self using all forms of coping systems and defensive mechanisms, to relieve stress and anxiety or depression, going in and out of states of resistance/irresistance, and even iresilience in the process of actually achieving the goal of becoming a resilient individual.

Resilience in victims of human trafficking

Resilience and the process of becoming resilient is of great importance for any individual of any age, sex, and from any social context, but especially for individuals which are exposed to certain experiences of a traumatic nature on a daily bases, be it because of their work or carrier which might be particularly dangerous or it could expose them to scenes that have the capacity to traumatize; be it because of the life conditions and/or social circumstance is of such nature as to cause traumas or harsh living conditions; or just because the current general status is aversive.

Human trafficking being a form of modern slavery exceeds from the point of view of the magnitude of the psychological impact upon the victim, the impact which slavery used to have on its victims back when slavery was a common practice. In modern society, where slavery is unimaginable, the impact of the slave status upon the human psyche is amplified compared to the times when slavery was a legal practice and the slave status was directly observed, known, and thus, considered a possibility.

The triggering event of the trauma is the trafficking of the individual itself. When the individual realizes that he/she is being trafficked, it is usually too late to try to escape or get away, mainly because of the techniques that traffickers use to make their slaves "loyal" immediately after the trafficking started. Used methods are well known, starting from threats and beatings, up to torture and forcing victims to see other victims suffering, aimed to seed panic and terror, thus cutting down any intention or ambition of escape or mutiny.

Aside from the initial trauma suffered by the victim, instead of having a break, an aversive period starts to which they have to adapt, still bearing unhealed scars of the initial trauma, some of them still being in shock

for quite some time afterwards and/or in denial. But probably, the most painful and destructive state of mind these victims are experiencing are the feelings of uncertainty and helplessness.

Uncertainty regarding their own future, but most of all, regarding loved ones, especially when there are children involved, or close relatives, who might be endangered and the situation is being exploited by the trafficker as a means of control over the victim.

Helplessness, since the victim is incapable of any action that could change the situation he or she is in at the moment and the prospect of being able to change the situation in the future is dimmed by fear and terror.

The same two characteristic emotions that the victims of human trafficking are experiencing, and similar shocks followed by aversive periods, are also being experienced by victims of war, and, in some cases, war combatants.

Starting from traumatizing sights of: bodies, (especially children), witnessing death or brutality and rape, up to suffering themselves various abuses, human trafficking victims who were heavily exploited and war victims share the same types of traumas; and one of the few aspects setting the two categories of victims apart, is the fact that war victims are in the sphere of collective trauma.

Collective trauma can be defined as simply a traumatic psychological effect shared by a group of people of any size, up to, and including, an entire society or population. This type of trauma is different in terms if impact of course, and is characterized by duality. On one side, collective trauma affecting large numbers or entire populations has a deep, drastic effect on the individual. The sheer magnitude of change – in a natural catastrophe or total war for instance – and the many facets of the change triggered in an unexpected and/or unpredictable way, causes the individual to find himself in a totally changed environment to which he has to adapt in so many ways – family and relatives, friends, may or may not be there anymore, possessions might be taken or destroyed – and the individual finds himself forced to adapt to a completely new order which was never imagined or pictured before. From this point of view, collective trauma is catastrophic at an individual level, but its dual nature shows itself in the form of solidarity and collective empathy, somehow alleviating the state of mind of the individual through a process of collective resilience; usually the more resilient individuals tending to pull up, support and help the less resilient or emotionally liable ones in which would not happen in other circumstances in the same way.

Aside from this effect, of a society or population trying to cope collectively with the trauma, the lack of positive alternative helps individuals overcome the traumas easier.

While the victims of wars and catastrophes suffer collectively, victims of human trafficking, in most cases, suffer by themselves – at least after the traumatic event or aversion period comes to an end and a healing or rehabilitation process begins. Their upper hand in comparison to collective trauma is that victims have the possibility of getting back to loved ones and to normality. The difference in this particular case between resistance and resilience, would be the perception of the victim regarding both the triggering event and/or aversion period, and the normality, and whether or not that normality includes going back to whatever the victim was before the trauma occurred; or, to take a different path and develop in a different direction instead of trying to restore their lives to a previous state – before the trauma that is. If the victim finds coping mechanisms and resets his/her life to a previous state it means that no development on new paths has taken place and the victim just "lost time" – both the time spent in the traumatic event/aversive period, and the time spent during the healing period – and the victim has just resisted the trauma and overcame it without reaching resilience, or without realizing that – in most cases – the very state he/she was in before the trauma, contributed to the events that triggered the trauma. If the victim becomes resilient, it means that when the rehabilitation process begins, he/she realize that the "old ways" were flawed, trying to achieve a development on a different path that would have much lower chances of taking them back into a circumstance or situation in which they were at the moment the traumatizing event was triggered.

Both victims of human trafficking and victims of collective traumas can achieve resilience if all means – native, internal, external and supportive – are used. Combined with therapy and professional help, almost any individual is able to achieve resilience and thus take full control over their own lives.

Ana Muntean (2011) has an ingenious comparison towards understanding precisely what resilience is: *"While immunity refers to stressor biological factors (microbes, bacteria, viruses); resilience emerges as a psychic immunity towards psycho-emotional stressors which represent or imply violence against the individual or the social group"*[6]

Considering the above, it is easy to understand how resilience works in comparison to survival, coping or resistance. While the other processes act as mental medication towards solving the internal conflicts and healing the scars left by the traumas, resilience acts like a vaccine, which, with successful administration inoculates the individual, rendering him resilient to future traumas through a process of self-enlightenment, neo-development and productive rehabilitation.

Resiliation cannot assure that the person will become necessarily better in the eyes of others, but it can guarantee change, and it can guarantee that the person will be better in his/her own eyes. Resilience is

permanent, just like immunity is permanent, once inoculated, there is no going back, and immunity rarely has a negative connotation.

The resilience of mother-child couple in domestic violence

Dumitrescu A. M.

Social Work Department University of Piteşti (Romania)
amdumitrescu81@yahoo.com

Abstract

Irrespective of the fact that the concept of *domestic violence*, as form of attack on the mother-child relationship, is not new, it is rarely approached in social work practice. The abuse tactics compromising this relationship are part of a continuous direct and indirect attack leading to the undermining of mother-child relationship and to erecting a barrier within the couple. The present paper proposes to analyze the impact on mother and children, thus focusing on risk and resilience. In this case, resilience reflects, first of all, the mother's ability to preserve her paternal skills under extremely difficult circumstances and creating protective factors to provide and develop in the child the ability to adapt, change and cope with continuous stress. Consequently, the need to consolidate the relationship between mothers and children begins at a point in time when children and young people consider, in general, this relationship as a positive and very important one. It is proof of the resilience in the mother-child relationship the fact that these positive perceptions are preserved even when the relationship can be submitted, directly or indirectly, to undermining during several years of family abuse. Therefore, in the intervention process we are supposed to take into consideration the role the social workers and psychologists must hold in identifying and valuing these strengths and in working together both with the mother and with the child.

Keywords: domestic violence, mother-child couple, risks, resilience, intervention

Introduction

The last decades have emphasized and prioritised the debates on the aspects connected to the act of violence against women in private life, but especially the violence against children and their subsequent long- and short-term consequences. These issues have been interpreted as a result of the deterioration in the moral structure of nowadays family but also in the community as such. Social work services, in most of cases, have approached these cases separately, but we are aware that family violence is much more complex, since it stands for an attack not only on the adults' relationship, but also on the mother-child relationship. The direct attacks, which are the most extreme, involve one's depriving of the maternal relationship through: the child's homicide [1], attacks during pregnancy leading to spontaneous abortion, child abduction, or turn women into servants of their families, and the only people who are allowed to be a "mother" to the child are the husband's female relatives [2].

Other direct attacks on mothers are represented by the abuser's insults and criticism which are addressed to mothers in the presence of children: sexual insults, accusations of sexual infidelity, accusations concerning irresponsible behaviour towards children, the mother is criticised for not being able to "control" and nurture her children, etc. [3]. This constant surveillance and undermining of maternity are reported to be deeply problematic [4]. In the case of mothers who are obliged to prostitute themselves, they are separated from their children and forced to spend their lives away from them, and the children who lack their mother's love and protection may undergo emotional and behaviour problems. Other aggravating factors are the desire to keep the secret and the lack of communication between women and children about their life experiences concerning violence and the abusers' using children as "weapons" against mothers when fathers/abusers lose the other ways of harassing and controlling them. However, the most critical situation can be found in the abuser's attempt to kill the mother, which highly inflicts damage upon the children's psyche.

Unfortunately, violence acts are often repetitive and continuous and may leave women and children feeling dazed and bereft [5].

In these situations, the indirect effects on the mother-child relationship are created through ensuring that women are unavailable for their children by disabling them physically [6], or mentally [7].

Risk and resilience in cases of abuse

The strategies used by the abuser to undermine mother-child relationships and maternal authority are limitless and such interference tends to continue or increase post-separation [8].The emotional recovery of children who have been exposed to domestic violence depends on the quality of their relationship with their mother more than on any other single factor; therefore, the undermining of that relationship by a person who behaves violently can have powerful implications.

For women who have left abusive partners, developing a sense of control is fundamental to surviving and positioning in the future [9].

In this situation, the mother confronts two kinds of difficult decisions. First of all: how will she protect herself and her children from the physical dangers posed by her partner? Secondly, how will she provide for her children? This second set of social and economic risks are central for the mother in order to ensure the children's safety.

In addition, the mother must prove the ability to be resilient, namely, to preserve her paternal abilities under extremely harsh circumstances (harassment and violence on the part of her former partner, the absence of a shelter, health problems, financial problems, changing their lifestyle, the loss of or separation from close persons, relatives, neighbours, a change in social networking, etc.) and to have the ability to support her child so that he/she could adapt to the stress caused by the new situations via developing new protective factors.

Anyhow, both the protective factors and the risk factors can vary a lot in a child's life. Some children have been "labelled" as skilled, resilient, and even invulnerable [10], having competent parenting and healthy attachment relationships, easy temperament, intellectual resources and, social competence; others, however, lack the ability to face the situations generated by violence without specialized help. Among the factors met with in the case of children, we mention: behaviour problems, premature birth, hereditary mental illness, illegal substance consumption, physical abuse, exposure to violence, lack of shelter and poverty. These factors vary and most of the times they are associated with a high risk of undergoing precarious physical, emotional and behavioural development. Most researchers agree that risks of a chronic, rather than an acute nature are most likely to have damaging long-term effects [11]. On the other hand, the protective factors (the child's positive temperament, intellectual capacity, social competence, caring adults, secure attachments to caregivers, and strong relationships with others, as living in a supportive, safe community), are those variables which can improve the impact of effects resulted from children's exposure to violence.

From the point of view of resilience, efforts that target the major developmental tasks of early childhood, as well as those that directly reduce the impact of the stressors faced by children exposed to domestic violence should be effective in helping young children negotiate developmental challenges. Masten and Coatsworth (1998) propose that such strategies should fall into three major categories: (a) risk-focused (focusing on reducing or preventing risk and its impact), (b) resource-focused (adding resources to counterbalance risk) and (c) process-focused (strategies that focus on the processes underlying competence, such as parent-child relationships, social skills, and self-regulation) [12].

As a consequence, each and every child, be they exposed or not to violent situations, should be offered the chance to healthy development which will lie at the basis of their life. We will also mention those factors which are relevant for understanding the impact of exposure to domestic violence: 1. developing a safe attachment relationship especially with the mother (the attachment status reflects the balance between a child's willingness to explore and the need to stay close to a mother/caregiver after ca short separation from her [13], 2. the beginning development of a self-regulatory system that enables a child to exercise control over emotions and behaviours (the development of self-regulation is a prerequisite to the development of social skills that allow individuals to successfully negotiate complex social situations and to develop reciprocity and empathy, i.e., connections with others) [14], 3. social and peer relationship skills that prepare a child for entering school [5] (social competence is a key task of the preschool to school-aged period, and high social competence has been associated with better behavioural control and increased sociability and agreeability [5].

As such, children's resilience (created since childhood) leads to the consolidation of the relationship between them and their mothers, thus turning it into a positive, sure, special and very important relationship. Moreover, in order to preserve this relationship (even under circumstances of continuous attacks which can last sometimes several years) the mother also need have personal resources, inventiveness, determination to solve problems, personal development even after leaving the abusive partner, but also a good health to cope with challenges.

Current research have shown that early intervention can offer important ways through which the mother-child couple, exposed to domestic violence, might be able to access the necessary services in order to minimize the risks it is exposed to. Both the mother and the child can request protection but also legal and social services, economic resources which are necessary for their survival and for creating a certain financial stability and emotional comfort.

For that purpose, the intervention strategies of the social work system must consider the fact that separating services for women from those for children is not efficient. One must aim at the recovery and

consolidation (subsequent to family violence) of the relationship by mutual activities and by highlighting the interconnected needs of women and their children. Last, but not least, the set of problems in this field underlines the need for sensible services able to support the various needs of women who are victims of domestic violence [2].

It is important that during the intervention process one should insist on rebuilding the relationship between mother and children through various activities aiming at building self-esteem, helping children to identify and talk about feelings, strengthen their communication with their mothers and talk about aspects of their lives, which were considered secret in the past.

In the intervention process an important part is held by social workers and psychologists who must identify and value both the mothers' and their children's strengths in order for the former to work with them. One must take into consideration that after family violence (aggressive and frequent attacks) problems arose in the mother-child relationship; these problems must be identified and dealt with in order to make a new attachment tie in this couple; specialists should also focus on the improvement of certainty and stability for children and their parents.

But for any intervention to be successful, it must attend to the family's economic and cultural context and needs, and build on the natural supports around the child and family [5].

Discussion and conclusions

The exposure of the mother-child couple to domestic violence can have profound and long-term effects on them; however, many of them have the ability to cope with it without specialized help, thus proving resilience even under extreme circumstances. In this case we refer, first of all, to mother' resilience, which is actually "her ability to develop and become a parent who is good enough for her own children despite events and unfavourable circumstances to which she has been exposed" [15], but also to the protective factors holding an important part in a healthy development of children exposed to domestic violence. Therefore, the child's resilience, once shaped, reflects his/her capacity to adapt, change, cope with continuous stress concerning both the way in which he/she sees the world and the way he/she unfolds his/her life in it. The support provided via specialized intervention must offer ways and resources meant to support the development of mother-child couple, to minimize the risks they have been exposed to, emotionally support abused children and mothers, support and encourage positive change. Also, an important resource-oriented strategy is supporting ill-treated women and children to shape social networks, which aim at reducing isolation associated with family violence.

The role of the social work as professional factor in resilience building in the human traffic phenomenon

Goian C., Runcan P. L.

West University of Timisoara, Romania,
cosmin.goian@e-uvt.ro, patyruncan@yahoo.com

Abstract

This paper argues the links between the social worker as catalyzer in the process of building resistance in multidisciplinary intervention for beneficiaries who are victims of human trafficking. Starting from the social workers roles as stated by Federico (1973), of the principles of the deontological code of the National College of the Social Workers, of the ethical code published by the National Association of Social Workers (USA), but also of the manuals created by the National Agency Against Human Trafficking form Romania, the authors will make an inventory of a set of useful information in the process stated in the papers' title. Also, a documenting of the responsibilities and professional results of the social worker who activate at the Regional Center Timisoara in the frame of the National Agency Against Human Trafficking and of the professionals from the field who activate in NGOs (Young Generation Association). The results of the theoretic and on field documentation in Timisoara will be presented in the second part of the paper as professional factors in building resilience with direct referral to the responsibilities of the social workers in the frame of individual intervention or as member of a multidisciplinary team.

Key-words: social worker, assisted resilience, human trafficking, multidisciplinary team.

Introduction.

From the beginning of this study we must admit the reality occurring to which in the case of persons who were victims of human trafficking we can not accept the existence of a process of natural resilience processes. Due to the intensity and longevity of the traumas in time of the beneficiaries of these services we can merely use the term assisted resilience as it is explained in a recently published book in Romanian language edited by Editura Trei [1].

The Statistics of the Integrated System of Assessment and Monitoring of the victims of human trafficking for the period 01.01.2013-30.06.2013 has registered a total number of 501 identified victims, out of which 35% have been trafficked in the same period of time. The large number of persons victims of human trafficking In Romanian in 2014 leads to the necessity of well organized and efficient psycho-social services. We must admit that the professional field of the services for the victims of is one in which the fundamental role of the social worker is recognized in specific interdisciplinary activities with these categories of beneficiaries. In a paper published in 2008 the psychologist Mihai Şerban admits the role of the social worker as a case manager in the intervening multidisciplinary team in case of victims of human trafficking [4]. WE agree with this opinion because the social worker reunites in his professional practice a number of knowledge, abilities and values that may contribute essentially in the process of gaining resilience by the victims of human trafficking.

Discussions

Starting from the definition of the term resilience as it is explained in the field literature [3][1]in this paper we will try to make an inventory of the role of the social worker as facilitator in obtaining resilience through all his actions made through the support of the beneficiaries.

We will now present the responsibilities of the social worker in individual professional activities as well as in multidisciplinary teams from the perspective of the scientific papers from the general field, but also of the manuals written by the National agency Against Human Trafficking. WE will associate these information with the data we have from the interviews with a sample of 5 social workers who work with beneficiaries form the above mentioned category.

In a first description we note the model of Federico from 1973, cited by Ch. Zastrow in 1986 [5] who identifies roles of the social worker which we consider can be transposed also in his activities with the victims of human trafficking:

- The role of outreach worker – the professionals who go into the community in order to identify a need and the references given in the context of the work will follow. The social worker makes assessments and social enquiries at the homes of the victims of human trafficking. The obtained data gathered through this filed work is relevant for the process of help and integration of these persons in the family and community they come from.
- The role of the broker – who knows the available services and insures that those in need get to the service they are in need of. In their quality of case manager the social worker can use effectively this role of intermediate.
- The role of advocate – Helping specific clients to obtain certain services which normally would be rejected, help extend the services for people in need. The victims of human trafficking are part of the category of beneficiaries who can be stigmatized due to their past and the connections they had with organized crime networks. This category of beneficiaries must know that social workers are professionals who support them in these situations. Also, the professionals is the one who makes the administrative paper work necessary to prevent the social exclusion of the victims of human trafficking both during the assistance process and during the monitoring post intervention.
- Evaluation role – evaluating the needs and resources, generating alternatives for accomplishing the needs and taking decisions. In the activities with the persons who are the victims of human trafficking the social worker can have the evaluating responsibilities both individually and as member of the multidisciplinary team.
- Teacher role – teaches facts and abilities that can be useful for the beneficiaries in the process of gaining resilience.
- Mobilizer role – helps developing new services, this is a role that can be activated together with that of the advocate.
  The role of the person who determines behavioral changes – changes some parts of the behavior of the clients which can be useful also in the process of gaining resilience. The traumas of these categories of beneficiaries can create them self-destructive behaviors, non-trustful attitudes and isolation [2]
- Consultant role – works with other professionals in order to help them to be more efficient in assuring services.
- Community planner role – helps groups of the community to plan efficiently the social needs of the respective community.
- Care giver role – insures services of caregiving for those who are unable to solve completely alone their own problems and needs.
- Data manager role – collects and analysis information with the purpose to be able to take decisions.
- Administrator role – carries out activities necessary to plan and implement service programs (Federico from 1973, cited by Ch. Zastrow [5])

We consider that these roles reflect important components of the social workers activity and rise by applying them the efficiency of the professional work. When speaking about these roles in the interdisciplinary team caring for the victims of human trafficking we consider that the social worker is an important actor who can take over the attributions of a case manager.

We will now present the attributions of the case manager in the activities with the victims of human trafficking after a paper of ANITP who's author is the psychologist Mihai Şerban:

- assessing the victim's needs;
- establishing the priorities of intervention;
- assessing the available resources that can be mobilized for the process of assisting the victim;
- inventorying the accredited services form the local and regional network which can answer to the needs of the victim;
- constructing an individualized intervention and service plan;
- establishing the victim's connection with the selected services;
- offering the services;
-progressive monitoring of the intervention;
- assessing the intervention results;
- closing the case;
- post-intervention monitoring. [4]

It is obvious that in the unfolding of the above stages the activity of a multidisciplinary team is necessary. The phases of case management have the purpose of reestablishing the functionality of the person

who was the victim of human trafficking. This bio-psycho-social functioning represents the capacity to fulfil responsibilities towards one's own, the own family and the society. It is important that the beneficiary integrates on the labor market or in an educative system.

Besides the professional roles and methods offered by the knowledge and ability of the professionals an important role have also the professional values which establish a set of deontological norms. These may offer the social workers attitudes that insure a correct behavior towards the beneficiaries and contribute to the increase of mutual trust in the professional help process. In this way the Deontological Code of the Social Worker Profession in Romania published in the "Monitorul Oficial" from March 2008 it is stated in the articles 18-30 that the professional relationships with the beneficiaries must be based on honesty and confidentiality, respecting the principles of self-determination and maintaining the access to resources through a protective attitude. WE remarked here that article 14 writes that the social worker has the following responsibilities : to plead for the improving of the social conditions with the purpose of satisfying the basic human needs and promoting social justice; to act in order to facilitate the specific services and the possibility for vulnerable, disadvantaged or persons who are in difficulty to choose, to promote conditions which encourage the respect of social and cultural diversity; to promote the politics and practices that encourage awareness and respect of the human diversity; to facilitate and to inform the public about the participation at the communitarian life and social changes that intervene; to insure professional services in emergency situations , in the frame of the law and of the norms of the social work professional; to admit the fundamental importance of inter-human relationships and to promote them in the practical progression, to encourage the relationships between people with the purpose to promote, remake, maintain or improve life quality; to ensure the respecting of the basic human rights of men and of the laws Romania has adhered to.

The social worker treats all the cases given into assistance, based on the conclusions of risk, need and resource evaluation. The social worker will deal with priority the cases of minors in difficulty being activated automatically the principle of the child's best interest in the terms of the UNO Convention regarding the child rights. The social worker will always consider that his own behavior represents a model for the community members, acting in accordance, (Article 14 from the Deontological Code of the Social Workers of Romanian published in M.O.173 from 6.03.2008). In the same idea we have referrals to the professional values of the social worker in the Ethical Code of the national Association of The Social Workers of the USA (NASW) which promotes values like social justice, respecting dignity, integrity and human diversity. We consider that respecting these professional values creates the trust-based relationships in the interaction between social worker-beneficiary, reducing communication difficulties between the two parties. Respecting the association between principles and the implementation of competitive work techniques in the interaction with the victims of human trafficking can be factors in the process of assistant resilience.

We will now present a set of factors that can insure the resilience of the victims of human trafficking contributing to the success of professional intervention. These factors represent the synthesis of the theoretical elements but also of the results of five interviews applied on a sample of social workers from Timisoara who work with victims of human trafficking. The factors associated with social work that may favors resilience at these beneficiaries are the following:

- realizing a professional relationship based on trust between specialist and beneficiary;
- placing the beneficiary in a secure environment;
- introducing the beneficiary in a specialized counseling program;
- offering the victim the opportunity to beneficiate from a permanent contact with professionals of the support team;
- a real access of the beneficiary to the services established through the service plan;
- the existence of a continuous monitoring methodology of the beneficiaries situation, the registered progresses and of their needs;
- assuring the conditions of educational or professional reintegration of the victims of human trafficking.

Conclusions

Our study has succeeded in identifying from theoretical and applied point of view elements of the Romanian social workers activity that can produce in assisted manner resilience from the victims of human trafficking. The arguments presented in this paper indicate a reality in accordance to which the work methodology of the social worker and the professionals competencies contain elements that facilitate the resilience of beneficiaries of the social services. In conclusion the social work through his abilities, knowledge and professional values can contribute in a fundamental manner to resilience whether activating individually or in frame of a multidisciplinary team.

In the aftermath of family violence: lifeworlds of resilient adolescents. Are resilient adolescents really over the edge“?

Kassis W.[1], Artz S.[2]

Abstract

Questionnaire data from a cross-sectional study of a randomly selected sample of 5,149 middle-school students from four EU-countries (Austria, Germany, Slovenia, and Spain) was used to explore the effects of family violence on resilient adolescents. We used variance analysis to compare social and personal characteristics of non-violent/non-depressive students without family violence experiences and resilient (non-violent/non-depressive) students despite family violence experiences.

Our results indicate that a positive resilience status isn't a sufficient indicator for a positive social and personal development. Resilient students showed significant higher levels of social and personal risks and lower levels of social and personal protective characteristics than students without family violence experiences.

Additionally we were able to confirm the hypothesis, that despite the positive resilience status, the higher the experienced level of violence family was, the higher the risk characteristics and the lower the protective characteristics of the resilient students were.

Keywords: Aggression, family violence, depression, resilience, protective factors, risk factors.

Theoretical introduction

In the Western industrialized world between 28-31% of children and youth experience violence in their families. For example, in Canada, in 2010, the total number of police-reported family violence crimes (including dating violence) constituted 39% of all violent crime for that year. More than 63% of the victims of these crimes were female [1]. Further, almost 28% of adolescents in the US-National Longitudinal Study of Adolescent Health reported physical abuse by caregivers during childhood [2]. Exposure to violence in the family, especially to intimate partner violence, may well be the most common form of abuse affecting children and youth that we know [3]. This kind of violence is deeply implicated in multiple social problems, including poor physical and mental health, addiction, poor academic outcomes, problematic behavioral issues including delinquency and criminality and poor employment outcomes [4].

Aggression and depression are two social problems that have long been linked physical maltreatment by parents (e.g. [5], [2]) and witnessing physical or psychological aggression between parents (e.g. [6], [7]). Overall, violence exposure is certainly an established risk factor for the development of violent behaviour and depression in adolescence (e.g. [8], [5], [2], [9], [6], [7], [10]. Further, converging new evidence shows that early-onset exposure to domestic violence is associated with maladaptive life courses for children culminating in a less optimal outlook through the entire lifespan (e.g. [3], [11]). The extent of this widespread social problem begs the questions: How resilient are the young people who are exposed to violence in their families? What promotes and supports their resilience?

Methods and Results

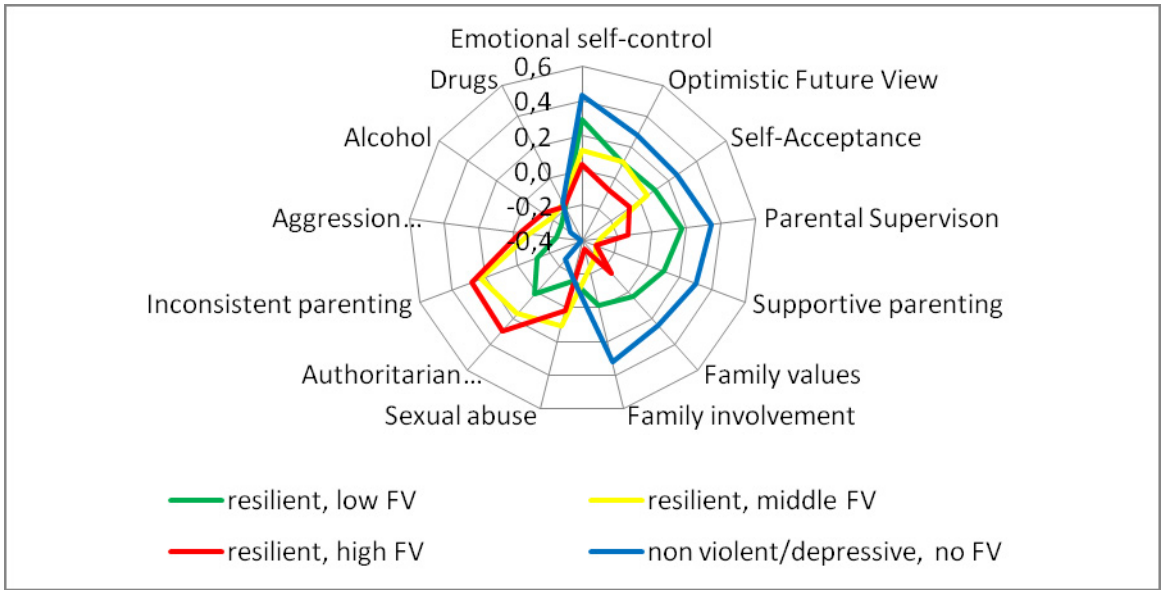
The data were collected in spring of 2009 from a **random sample** of 5,149 eighth graders in four EU-countries (Austria n = 724, Germany n = 2,832, Slovenia n = 726 and Spain n = 867) who completed a **questionnaire anonymously in class**.

Our study provides us with alarming results: of the 5,149 participating adolescents with an average age of 4.5 years, 1,644, that is, 31.9% reported experiencing violence in their families with 23% reporting physical parental abuse and 17% reporting witnessing physical spousal abuse. Consistent with the findings of (e.g. [12],

[13]; [7]), we detected a robust significant overlap (r = .475**) between the two reported family violence indicators. To examine the family burden, all 1,644 respondents who indicated they were exposed to some form of family violence were included in a subsample, family burden., The z-standardized-scores of this scale were trichotomized into the groups, low (n = 644), middle (n = 568), high (n = 432) levels of family violence. In order to identify the resilient youth, we created a composite resilience variable that included all participants' self-reports about their use of aggression and their depressive tendencies: The students who reported no use of aggression and who additionally had depression scores below the middle of our depression scale were coded as resilient (n = 510 /1,644) 31%). Students who reported use of and/or an above middle of the scale tendency to depression were coded as "non-resilient" (n = 1,134/1,644, 69.0%)

Our central question was: Is a positive resilience status a sufficient indicator for positive social and personal development? To answer this we conducted contextualized resilience analyses by computing the average protective and risk factors scores in the three resilience-groups and compared the means of the specific protective and risk factors (self-concept, family, school, peers) per group. Using variance analysis post hoc test (Bonferroni test) we found robust and reliable differences between the three resilience-groups (see Fig.1). The results of the variance analysis indicate that the average scores of the resilient adolescents' risk factors (the post-hoc tests between all risk groups are significant) increase and the average scores of the protective factors decreases as family burden level increases. Thus our central result is that higher levels of family burden, even in the case of resilient adolescents' are still strongly correlated with fewer protective and significantly more risk factors. This crucial finding about the lifeworlds of resilient adolescents' supports not only the finding of comorbidity of risk factors on higher family violence levels but also the parallel lack of protective factors. For those students who were exposed to high levels of violence in their families, the risk factors far outweighed the protective factors even if some reliance remained. These findings suggest that in order to promote resilience, controlling the level of family violence experiences is the most effective strategy.

Figure 1: Comparison of the protective and risk factors of resilient adolescents



Discussion

If we continue to structure our analysis of resilience only in terms of the absence or presence of core personal positive criteria (e.g. non-violent and non-depressive despite family violence), we continue to run the risk turning back to the individual as the sole source of explanations for why resilience is not achieved [12]. We call resilience conceptualizations based on single personal positive criteria as "first level resilience". We contend therefore, that resilience research should also examine the relationship between core positive resilience criteria (first level resilience) and further individual and social factors for modelling a contextualized and holistic resilience approach (second level resilience). Thus, a positive single criteria success as being non-violent and non-depressive despite family violence has been contextualized in our study not only on individual factors, but also on a range of ecological factors like family, school, and peers.

While we were encouraged to find that among the young people who had been exposed to violence, there were still many who exhibited resilience, this resilience came with limitations. However, our results indicate that a positive resilience status is not a sufficient indicator for positive development. Resilient students

showed significantly higher levels of social and personal risks such as significantly higher levels of aggression supportive beliefs, alcohol consumption, drug use verbal aggression towards and from teachers, and use of indirect aggression and lower levels of social and personal protective characteristics such as self-acceptance, emotional self-control, optimism about the future, seeking help form other and positive relations with parents and teachers, than students without family violence experiences. Resilience is not an on-off characteristic. As our results showed: The higher the experienced level of violence family was, the higher the risk factors and the lower the protective factors of the resilient students were. Our findings therefore suggest that in order to promote resilience, controlling the risks is of great importance that promoting protective factors because the weight of the risks diminishes the power of any protective factors that remain even though protective factors still play a significant role for all three levels of family burden. Exposure to aggressive parents and verbally aggressive teachers can create conditions where even an optimistic outlook is not enough to preserve resilience. Ultimately, we conclude that the level of family burden [14], and the accumulation of risk factors (e.g. [15], [16]) are central to resilience status and should therefore be the prime targets for prevention and intervention.

The research that we are report on here is part of a larger study, the STAMINA-project Formation of non-violent behaviour in school and during leisure time among young adults from violent families[1], funded from 2009-2011 by the European Commission Daphne III Programme. The STAMINA project investigated the social (family, school, peers) and individual (self-concept, attitudes, behaviour) characteristics of adolescents.

Psychological aspects of trauma and resiliency in victims of human trafficking

Muntean A.

Abstract

The human trafficking is a social phenomenon with pathological aspects and with a large variety of manifestation within the contemporary world. Notwithstanding of the goal and the personal characteristics of the victims, within the human trafficking we always find the relationship between the owner and the slave. Human trafficking is a relationship based on two poles: the perpetrator and the victim.

When the perpetrator is in the focus of the law, the victim is in need of complex rehabilitation. This rehabilitation starts with the enforcement of human rights and the circumscription of the victim within the framework which protects the human dignity and it continues with the efforts to understand the bio-psycho-socio-cultural aspects of the trauma and the enhancement of person's resiliency.

Human trafficking raises the costs and the threats of the democracy in the contemporary world. During the last years, the increased attention to the phenomenon, as well as the International, European and national social policies and the special structures aimed to implement the policies come together on the objective to stop the phenomenon.

Our presentation will be focused on the psychological aspects of the victim and the victim's family. We also intend to present the dynamic and the types of manifestations of the phenomenon during the last years.

The objective of this paper is to raise the attention of participants at the psychological trauma and PTSD's aspects involved in human trafficking as well as to the possible resilience of some victims.

Key words: trauma, PTSD, victim, perpetrator, resilience, human trafficking.

Introduction

The last decades brought to the professionals and researchers in the field of psycho-social sciences lot of information regarding the human development and functioning within aversive conditions. The entire literature in neurobiology shows the effects of trauma on human development. Recent researches following the focus on traumatic conditions and trauma's consequences discovered the differences in human functioning within difficult existential circumstances. The concept of resilience born and it's glorious carrier brought us today here. The pervasive violence of human being developed within different historical periods a variety of tuff and cruel adversities. "Homo hominis lupus" is just as old as the known beginnings of Roman Empire. The innate violence of humans shared with mammals defined very often within the human relationships two different roles: the role of the victim and the role of perpetrator. Traffic of human beings is one of the oldest types of the social phenomenon generated by human violence and defining the roles mentioned: victim and perpetrator.

In order to develop our presentation we need some basic definition about the concept which we are going to use:

1. **Psychological Trauma** is a type of damage that occurs as a result of a severely distressing event. The event can be either a single experience, or an enduring or repeating event or events, that completely overwhelm the individual's ability to cope or integrate the ideas and emotions involved with that experience. The effcts of the overwhelming experience can be delayed by weeks, months, or even years. Psychological trauma can lead to serious long-term negative consequences mostly named post-traumatic stress disorder (PTSD). Unfortunately often the symptomes of PTSD are ignored even by mental health professionals: "If clinicians fail to look through a trauma lens and to conceptualize client problems as related possibly to current or past trauma, they may fail to see that trauma victims, young and old, organize much of their lives around repetitive patterns of reliving and warding off traumatic memories, reminders, and affects." [1].
   Psychological trauma may accompany physical trauma but may also exist independently of it. Psychological trauma can occure due to terrifyng events such as: violent attacks such as mugging, rape or

torture; harassment, sexual abuse, employment discrimination, police brutality, bullying, domestic violence, indoctrination, living with an alcoholic parent, the threat of either, or the witnessing of either, particularly in childhood, life-threatening medical conditions, medication-induced trauma. Catastrophic events such as earthquakes, floods, and volcanic eruptions, car or train wrecks ; war or other mass violence can also cause psychological trauma. Long-term exposure to situations such as extreme poverty or milder forms of abuse, such as verbal abuse, can be traumatic.

There are theories suggesting that childhood trauma can lead to violent behavior in adulthood due to the lack of capacity to cope with stressful situations.

2. **The consequence of trauma: post-traumatic stress disorder (PTSD)**: is a mental condition that can develop following the type of events described above. People with PTSD have persistent frightening thoughts and flashbacks and feel emotionally numb. PTSD was first brought to public attention by war veterans and victims of rape.

   People with PTSD may experience sleep problems, nightmares, feel detached or numb, or are permanently alert. They lose interest in things they used to enjoy and have trouble feeling affectionate. They may feel irritable, more aggressive than before, or even violent. Neutral things or situations can be triggers reviving to them the trauma, which could lead them to avoid certain places or situations.

   Women are more likely than men to develop PTSD. PTSD can occur at any age, including childhood, and there is some evidence that susceptibility to PTSD may run in families. The disorder is often accompanied by depression, substance abuse, or one or more other anxiety disorders. In severe cases, the person may have trouble working, keeping the affectional relations with significant others including children, or socializing.

   The great theories in psychology (psychoanalysis, attachment theory, behavioral theory) bring the concept of trauma and its influences on human development and functioning. It is only later-on when Diagnostic and Statistical Manual of Mental Disorders (DSM), second edition, [2] issued by American Psychiatric Association included trauma and the post traumatic stress disorder as one of the diagnosis and launch an instrument for evaluation of PTSD. DSM is a non-theoretical and pragmatic approach of psychiatric diseases.

[3] DSM 5th edition (2013) reconsider the criteria included in the previous editions and expanded some aspects for diagnosis of PTSD:

Criterion B: intrusion symptoms

The traumatic event is persistently re-experienced in the following way(s): **(one required)**

1. Recurrent, involuntary, and intrusive memories. Note: Children older than six may express this symptom in repetitive play.
2. Traumatic nightmares. Note: Children may have frightening dreams without content related to the trauma(s).
3. Dissociative reactions (e.g., flashbacks) which may occur on a continuum from brief episodes to complete loss of consciousness. Note: Children may reenact the event in play.
4. Intense or prolonged distress after exposure to traumatic reminders.
5. Marked physiologic reactivity after exposure to trauma-related stimuli.

Criterion C: avoidance

Persistent effortful avoidance of distressing trauma-related stimuli after the event:
(One required)

1. Trauma-related thoughts or feelings.
2. Trauma-related external reminders (e.g., people, places, conversations, activities, objects, or situations).

Criterion D: negative alterations in cognitions and mood

Negative alterations in cognitions and mood that began or worsened after the traumatic event: **(two required)**

1. Inability to recall key features of the traumatic event (usually dissociative amnesia; not due to head injury, alcohol, or drugs).
2. Persistent (and often distorted) negative beliefs and expectations about oneself or the world (e.g., "I am bad," "The world is completely dangerous").
3. Persistent distorted blame of self or others for causing the traumatic event or for resulting consequences.
4. Persistent negative trauma-related emotions (e.g., fear horror, anger, guilt, or shame).

5. Markedly diminished interest in (pre-traumatic) significant activities.
6. Feeling alienated from others (e.g., detachment or estrangement).
7. Constricted affect: persistent inability to experience positive emotions.

Criterion E: alterations in arousal and reactivity

Trauma-related alterations in arousal and reactivity that began or worsened after the traumatic event: **(two required)**

1. Irritable or aggressive behavior
2. Self-destructive or reckless behavior
3. Hyper vigilance
4. Exaggerated startle response
5. Problems in concentration
6. Sleep disturbance

Criterion F: duration

Persistence of symptoms (in Criteria B, C, D, and E) for more than one month.

Criterion G: functional significance

Significant symptom-related distress or functional impairment (e.g., social, occupational).

Criterion H: exclusion

Disturbance is not due to medication, substance use, or other illness.
Specify if: With dissociative symptoms.

In addition to meeting criteria for diagnosis, an individual experiences high levels of either of the following in reaction to trauma-related stimuli:

1. **Depersonalization**: experience of being an outside observer of or detached from oneself (e.g., feeling as if "this is not happening to me" or one were in a dream).
2. **Derealization**: experience of unreality, distance, or distortion (e.g., "things are not real").

Specify if: With delayed expression.

Full diagnosis is not met until at least **six months** after the trauma(s), although onset of symptoms may occur immediately.

The new clinical orientation talks about complex trauma, specific for childhood. The [3] DSM 5th describes the trauma in childhood (0-6 years old). Above this age, the PTSD symptoms are similar, as mentioned above.

PTSD can be understood only when we take in account the social consequences [4].

Trauma gives like a new vision on the human development.

Psychological trauma is tightly connected with neurobiology. The way in which our brain is functioning within stressful circumstances brings the explanation for the consequences of traumatic experiences.

When facing traumatic event the individual reactions have a variety of manifestations going from the pathological development of PTSD to a resilient reaction.

3. **Resilience:** Different people will react differently to similar events. One person may experience an event as traumatic while another person might not. In other words, not all people who experience a potentially traumatic event will actually become psychologically traumatized.

Resilience is a 'dynamic' process in place only in relation to adverse conditions. Based on the large existing literature, [5] mentioned "two critical conditions: (1) exposure to significant threat or severe adversity; and (2) the achievement of positive adaptation despite major assaults on the developmental process." [5]. Etymologically, the word 'resilience' comes from the Latin 'salire' (to spring, spring up) and 'resilire' (spring back). This means that resilience can be regarded as the capacity to recover or spring back. There are considerable variations in the way in which resilience is defined in the literature . This makes it difficult to interpret the research into resilience. Moreover, research into resilience often employs a wide range of measuring tools that are only partly connected with resilience. This causes problems in assessing and comparing the results [6]. Resilience and posttraumatic growth as protective factors are assumed to decrease the likelihood of PTSD among victims.

Children's resilience is based on the protective factors, including the genetic aspects [7], [8] listed the protective factors building-up the resilience of children: some aspects belong to the child (personal resources) and others refer to social resources (within the family, within the educational units or within other social environments).

The recent talks and investigations on the field of Resiliency expand the concept at the family and community.

The resilience is proved by the reaction and personal story of the person fallowing the stressful event. [9] talks about three main kind of resilient development after confrontation with traumatic event: the attitude toward himself; the attitude towards others; the attitude toward life.

There are different instruments used to evaluate the resilience.

More recently, [10] launched the concept of assisted resilience.

4. **Social phenomenon:** defined by [11] "Social phenomena are considered as including all behavior which influences or is influenced by organisms sufficiently alive to respond to one another. This includes influences from past generations."
5. **Traffic of human beings:** Human trafficking is the trade in humans, most commonly for the purpose of sexual slavery, forced labor or commercial sexual exploitation for the trafficker or others, or for the extraction of organs or tissues, including surrogacy and ova removal. Human trafficking can occur within a country or trans-nationally. Human trafficking is a crime because involving coercion and commercial exploitation. Sometimes human trafficking involve the movement of the person to another location. Human trafficking is an illegal international trade estimated at $650 billion per annum in 2010. Human trafficking is condemned as a violation of human rights by international conventions. In addition, human trafficking is subject to a directive in the European Union.

   Human trafficking is by all the circumstancies and aspects inducing psychological trauma. It means dislocation of people, being kidnapped or held captive, violence and threat, verbal and physical abuse, harassment and all kind of violation of human rights of the person. Human trafficking induces to victims the feeling of being powerless, totally confused, betrayed and exposed to any kind violence thretening the life.
6. **Victim**: Anyone who is harmed by another person, the perpetrator. The victim is the disadvantaged party in a crime (e.g. swindle.). A person who suffers any other injury, loss, or damage as a result of a voluntary undertaking. An unfortunate person who suffers from a disaster or other adverse circumstance. A person who is conquered or manipulated by a villain.There is an orientation which attributes complicity to the person who is harmed by the social phenomena. This orientation is known as victim blaming. The Social Work Dictionary [12] mentions: „For example, a woman who is raped or sexually harassed is accused of seducing the attacker;...". This is unfortunately, very often the case for the victims of human trafficking. There is an interdisciplinary scientific domain: the victimologie, which is focused on the victims conditions and the context of victimization.
7. **Perpetrator:** it is always associated with crime. A perpetrator is often a suspect until it has been proven that he or she carried out the offense. The word usually describes someone who's committed a crime, but any wrongdoing will do.

As a theoretical conclusion we can say that human traffiking is a social phenomena occuring within specific socio-economic context, generated by perpetrators very often connected among them in network all over de world and involving trauma and PTSD as well as the resilience of victims.

The objective of our presentation is to raise the attention of the participants to the traumatic aspects of human trafficking and to initiate a debate on the opportunities to assist the resilience of the victims.

Statistics on human trafficking

Bellow we give some figures regarding human trafficking in the West Region of the country. The figures are provided by National Agency against Trafficking in Person – Regional Centre Timisoara.

Table 1: Demographic aspects of victims during 2011, in the West Region of the country

2011	Age of victims		Gender		Area of recruitment		Type of exploitation					Place		Total
	minor	adults	f	m	R/	U	sex	lab	beg	por	rob	Ex	int

Case study

A phone call from police office in Bucharest advertised and asked for assistance to a NGO in Timisoara (Society for children and parents/ SCOP). A girl, 16 years old, with her nuclear family (mother and father) were moving from a city in the south of the country to Timisoara. The story of the girl (named: A) was unbelievable: she was unique adopted child of the family M. She was in the high school and started a relationship with a boy in the same city. Family M. was very welcoming this friendship as the boy's family was very rich. Soon A. moved into the boy's family and house with the approval of her parents. A continue to attend the school but little by little she accumulated truancies in a class. The parents saw her regularly but not each day. They did not feel comfortable to visit the boy's family despite the fact that they agreed with the relationship between the teens. After a period of a week when the girl did not contacted them, neither by telephone nor visiting, they tried to get in touch with her and made phone calls to the boy's family. They found that the teens went in Greece together and they are well. This was strange to parents as the school was on. They wait for few days hoping that the girl will be back. As nothing happened after several contacts with boy's family, and after the visit home of the boy, they went to the police asking the support in order to find the girl. They were aware not having a great impact to the police office as the boy's family had friends everywhere in the administration of the city. Eventually the girl's parents succeeded to send a letter to the President of the country complaining about the situation and asking for support. The police in Bucharest took over the story and found the girl who was sold as a prostitute in another country. The police in Bucharest decided to ask the support of a NGO known as having activities for preventing human trafficking. The NGO could shelter and work with A. and the family could move from their city in order to protect them self and the girl. Very few information were disclosed by the police to the worker in the NGO. The girl was sheltered for 6 month and the psychologist and social worker worked together with her and her family. Both the girl who could not speak about her experience and the parents who had a permanent angered attitude were deeply traumatized by the entire situation in which not only that the girl had passed through terrible situations but they had to be dislocated from their place and to try to leave with very little resources in another city. After 6 months they moved to another city in the north of the country where the girl was again enrolled in a high school. A couple of months following their move to the next city, the mother made a desperate phone call to SCOP and she complained that the girl is again captured by the network. They were persuaded by a new relationship of the girl with a policeman in the city. As the first time they accused the police as being involved in the network of which the girl was victim, this time they were sure that the policeman who is playing as a boyfriend of A. is involved in the criminal network. The psychologist in SCOP tried to calm down the mother and take another appointment at the telephone two days after. Two days after the psychologist called the number she had from mother but nobody answer and such number was not in use. She called several times in Bucharest, the police office, but she could not get in touch with the police officer who referred the case. Apparently nobody knew there about the case.

Conclusions

Being a criminal activity the human trafficking is wrapped in secrecy. The secrecy is always damaging the human being, at any age. Human trafficking is producing lot of money for perpetrators. That is why usually they work in international network. These networks promote all kind of criminals activities: drugs, weapons, corruption, smuggling and deceiving people who become victims. When a person becomes victim to get out of the network is almost impossible. When the victim can get out this is not sure that she will not be again captured. What is the resilience in such a situation?

In case of human trafficking as well as regarding any risk factors there are circumstances which push the development of the events and make a predisposition of a person to become victim. In case of an adult, the decision taken one moment enchained the final situation in which she or he find him/herself as being the victim. The cascade theory is very evident functioning in such a situation.

When the victim is a child the responsibility of the entire situation is on the shoulder of the adults caring of him/her.

The ignorance is always, in both cases of victims, part of the picture.

The reverse of ignorance, the education is always the strongest protective factors. In human trafficking as well as regarding other unhealthy or toxic stressful situations prevention is much more possible and costless than interventions. The efficiency of education, supporting the resilience of the person victim, depends on many contextual aspects.

Abstract

In 2001, the valley of the Somme (Picardie, France) has experienced significant flooding. This study aims to evaluate the relationship between the manifestations of traumatic experience and the attachment to habitat of flooded people. Ten participants (age ≈ 64 ± 8 years, sex ratio = 1; owners) have agreed to answer first to a semi-structured interview covering both the experienced flooding and attachment to the habitat, then to the self-administered questionnaires: impact of Event Scale - Revised (IES-R)by Weiss and Marmar (1997) and a questionnaire collecting socio-demographic data. The interviews were conducted in participants' homes, in conditions which ensure the confidentiality of what is said. The results indicate that, for a significant probability of trauma (n = 5), there is a considerable habitat attachment (n = 4) or significant (n = 1). If attachment to the habitat does not appear exclusively decisive for the occurrence of trauma, however it clearly stains the manifestations of traumatic experience. Not enough generalizing, these results contribute to our understanding of the relationship between an individual and his habitat and the impact of the habitat to the traumatic experience related to flooding. This study raises the perspective of specific research on the relationship between attachment style of individuals and the one concerning their habitat. These elements could also be explored through other traumatic events affecting the habitat; likely to improve on the one hand, our understanding of trauma in specific situations, and on the other to highlight additional data on attachment to the habitat. Finally, this type of work is an interesting relay through interfaces as the site memoiredescatastrophes.org which aims to support the stories of individual trauma; for the purpose of appropriation of individual and collective trauma and at the same time promoting resilience.

Keywords: Habitat attachment, trauma, resilience, flood, natural disaster

Introduction

L'interface de l'habitat revêt une certaine complexité. Les représentations conscientes ou inconscientes associées à l'habitat varient pour chacun à travers l'organisation des propriétés du Moi. Si l'habitat reflète dans une certaine mesure notre monde interne, ce dernier ne noue de liens d'intimité avec cet espace qu'au gré d'expériences nourrissant notre vie, d'expériences qui modèlent le monde dans lequel nous tenons. Les réalisations personnelles au niveau familial, social, professionnel sont autant d'événements qui, au moins temporellement, peuvent être associées au point de référence spatial qu'est le domicile. Les liens qui se tissent entre le sujet et l'habitat peuvent prendre alors une certaine consistance. Notre expérience clinique a soulevé de nombreuses questions: que représente l'habitat pour le sujet ? Quelle place y tient-il au regard de sa famille, de

ses proches, au regard de la société ? Dans quelle mesure s'y sent-il chez lui ? Quelle place occupe l'habitat dans la mémoire du sujet et dans celle de son entourage ? Dans quelle mesure l'habitat est-il nécessaire au sujet pour sa réalisation dans le monde ?

Un certain nombre de repères théoriques ont été établis et permettant d'envisager les conséquences cliniques et psychopathologiques potentielles, suite à une séparation d'avec le domicile. Cette question qui sera explorée ici à travers l'étude du vécu de l'inondation en 2001 de la vallée de la Somme (Picardie, France) chez 10 sinistrés.

1.1 Étymologie et sémantique

L'*habitat* dérive du latin *habitatus*, signifiant « domicile » ou « action de demeurer ». Ce terme est issu du verbe *habiter* ou en latin *habitare*, lui-même étant dérivé de *habere* signifiant « avoir » [1]. Notons d'emblée qu'à la racine du terme *habitat*, se situe un verbe d'état employé en français dans deux perspectives inverses : d'une part, dans un rapport à la possession (exemple : « Henri *a* une maison ») et d'autre part dans un sens d'appartenance (exemple : « La maison *est à* Henri ») [2].

Par ailleurs, Liiceanu [3,4] nous fait observer qu'en grec, les verbes se rapportant à l'habitat : *oikein, naein, demein*, etc., renvoient au fait d'exister. Ces verbes étaient les seuls à pouvoir commuter entièrement avec le verbe « être », constituant dès lors de véritables synonymes. Les rapports étroits entre les verbes « être » et « habiter » sont mis également en lumière par Heidegger [5] lequel nous fait remarquer qu'en vieux-haut-allemand, le verbe *Buan* signifiait à la fois *bâtir, habiter* mais aussi « *[...] la manière dont nous autres hommes sommes sur terre [...]* ». Par leur racine commune, les verbes allemands *buan* et *bin* (signifiant respectivement *habiter* et *suis*) sont employés dans un sens commun, à tel point que « j'habite » vint à signifier « je suis » ou « la façon dont je suis » et vice-versa.

La langue française comporte de nombreux termes se rapportant à l'action d'habiter : demeurer, loger, occuper, résider, séjourner, vivre, crécher, hanter, etc. En toile de fond, la *durée* et la *stabilité* apparaissent comme des propriétés attachées au sens de ces verbes. Certains d'entre eux révèlent l'analogie entre l'habitat et la personne. Par exemple, le corps se constitue en habitat lorsqu'une personne est habitée, hantée par un esprit ; ou encore, le terme de « demeuré » qui désigne à son origine celui qui faute de moyens psychiques suffisants, n'a pu quitter la demeure familiale [6]. De même, ne dit-on pas avoir une « araignée logée au plafond » pour désigner une personne au comportement et aux réflexions incongrus ?

D'autre part, le sens de « déménager » peut être entendu comme un mouvement déstructurant, faisant perdre ses repères au sujet, au regard par exemple de l'expression « ça déménage » ou encore de « il déménage » qui renvoie à celui qui déraisonne.

L'observation montre que l'intensité du lien entre un individu et son habitat est variable. Cette intensité dépend de la propension de chacun, à faire d'un habitat un *chez-soi*. Cette expression dont le « chez » (du latin *casa* signifiant « maison » [1]) complété du pronom « soi », soulève la notion d'ancrage identitaire. Celle-ci met en exergue le lien indéfectible entre l'habitat du sujet et l'inscription de son être dans le monde [7]. Au regard de ces éléments, nous dégagerons les processus qui participent à l'élaboration de ce lien singulier.

1.2 Les représentations et fonctions de l'habitat

1.2.1 *Spatialité et temporalité*

L'individu construit depuis sa naissance un référentiel spatial à partir des coordonnées de son corps et celles de son environnement. La représentation du corps, délimité entre autres, à partir de l'espace dans lequel il évolue, est également support de l'investissement de cet espace [8]. Le référentiel spatial évoqué plus haut, se fonde sur l'image du corps et sa représentation consciente. C'est à partir de celui-ci et par le biais de mécanismes projectifs, que l'espace environnant prend un sens pour le sujet. Néanmoins, au-delà de la représentation du corps, c'est son incarnation, c'est-à-dire la spatialité du sujet, qui lui permet d'agir sur le monde et d'investir l'espace [4]. L'espace de l'habitat est le lieu privilégié à la fois de projections psychiques et de la pénétration du corps : *« c'est la spatialité du sujet qui permet d'appréhender l'espace habité plutôt que sa représentation »* ([4], p.4) .

1.2.2 *L'analogie des fonctions de l'habitat et du Moi*

De manière similaire à la construction du Moi, l'habitat est l'objet de projections de l'image que nous avons de notre corps [6]. D'ailleurs, Anzieu [9] prolonge l'idée du Moi Freudien avec le concept de « Moi-peau ». Celui-ci nous permet alors de penser un habitat soumis à ses projections et d'y envisager une structure et des fonctions aux propriétés analogues.

Les fonctions du Moi-peau décrites par Anzieu [9] sont au nombre de huit : *maintenance, contenance, pare-excitation, individuation, intersensorialité, soutien de l'excitation sexuelle, recharge libidinale, inscription*

des traces. Eiguer [6] quant à lui décrit cinq fonctions de l'habitat : *contenance, identification, continuité historique, créatrice et esthétique*. Les recoupements des fonctions attribuées d'une part au Moi-peau et d'autre part à l'habitat sont remarquables. En effet, l'habitat par sa fonction de *contenance* maintient l'individu dans une enveloppe stable et rassurante offrant du même coup un caractère de *maintenance* et de *pare-excitation*. La fonction d'*identification* de l'habitat, soutient la singularité du sujet dans le partage et les échanges des espaces ; et renvoie aux fonctions d'*individuation* et d'*intersensorialité* du Moi-peau. Ces échanges, par l'action d'une mémoire liante, permettent le maintien d'une *continuité historique* par l'*inscription de traces* communes positionnant l'individu dans un groupe d'appartenance. Cette appartenance au groupe est soumise à la *créativité* et l'*esthétique* : agencement du salon ou association de bijoux, de vêtements ; pour « *le plaisir de tous* »... En ce sens, le Moi-peau comme l'habitat est une interface avec le monde.

1.3 L'appropriation de l'habitat

1.3.1 *Un processus d'identification*

L'individu, porteur de son intimité propre, s'installe dans un habitat pour en prendre possession. Cette intimité est nourrie par une vie familiale, domestique, par des secrets, des arrangements privés, etc. Elle s'infiltre et imprègne les murs de l'habitat par un processus dynamique. « *La notion d'intimité traduit le sens et l'expérience même de l'habitat* » ([10], p. 6). Les processus psychiques évoqués (mécanismes projectifs), correspondent dans une certaine mesure au *processus actif* de l'appropriation de l'habitat soulevé par Bonetti [11], Djaoui, [[12] ou encore Serfaty-Garzon [10], pour lesquels il s'agit du « *projet d'engager l'espace habité comme la construction de soi* ».

1.3.2 *La réification de l'intime*

Investi de représentations diverses, l'habitat contient un intérieur particulier : une intimité. Intérieur et intime se rapportent à un dedans circonscrit dans les limites de l'habitat ou du corps. Néanmoins, l'*intime*, superlatif d'*intérieur*, désigne : « *ce qui est le plus à l'intérieur* » ([10], p. 6). Il est nourri de notre *identité*, de ses secrets, aspirations, regrets, malheurs ou encore de ses forces ou de ses angoisses ; mais il fait état aussi de nos liens d'*appartenance* familiaux, professionnels, sociaux, etc. Ce sont ces données de l'intimité de l'individu qui se matérialisent dans l'habitat investi. Certains auteurs n'hésitent pas d'ailleurs à user de métaphores éloquentes concernant cette symbolisation du *for intérieur*. Bachelard [13] propose celle d'un *être vertical* où les pôles de la cave et du grenier se rapporteraient respectivement aux espaces de l'inconscient et du conscient ; ou encore Goffman [14] qui parle d'un *espace narcissique*, équivalent de « *prothèse psychique* ». Il existe également une idée d'extension de l'intime vers l'intérieur de l'habitat lorsque par exemple Djaoui [12] parle de *pseudopode* du Moi de l'habitant ; il en va de même pour les objets possédés, parfois considérés comme des prolongements de la personne ou des membres de la famille [15]. En ce sens, l'intérieur de l'habitat révèle au gré d'un processus d'appropriation, une forme de réification de l'intimité du sujet. Au sein de cet espace familier, le sujet peut se manifester de manière authentique, s'autoriser à être lui-même, et laisser tomber les masques que lui imposent la vie en société. L'habitat permet de se ressourcer dans un univers intime, gratifiant, favorisant l'intégration des expériences du monde extérieur plus ou moins éprouvantes [12].

1.4 L'habitat : un point d'ancrage pour une ouverture sur le monde

La dynamique d'appropriation de l'habitat met en évidence les nouages complexes entre les dimensions du monde interne du sujet et celles de son habitat. Qu'en est-il des nouages avec le monde extérieur ? À l'instar du sujet qui observe et écoute à partir de sa subjectivité, l'habitat, en tant que prolongement de l'intime, et à travers ses analogies au Moi-Peau, symbolise une *interface du sujet avec le monde*. L'individu construit un chez-soi, qui devient ainsi un point d'ancrage, à partir duquel se dessinera une organisation du maillage de ses liens avec le monde. L'habitat serait dans une certaine mesure, à la fois le reflet de la trame de ce maillage, mais également celui qui permet de maintenir cette trame en tension afin que ce tissu ne s'effiloche. Une de ces lignes de tension est représentée par la famille comme groupe principal d'appartenance. Dans cette perspective, l'habitat n'est pas seulement le miroir (ou narcissisme) du sujet mais il est également celui de ses habitants et des liens qui les relient entre eux (qu'ils soient intenses, ténus, conflictuels, etc.). De manière plus intuitive, l'habitat est un instrument à partir duquel nous décidons de ce que nous souhaitons montrer, ou pas, de nous-même. L'habitat peut mettre en scène notre créativité, nos goûts, nos convictions religieuses, la confiance que nous inspirons, notre unité familiale, notre volonté d'intégration ; mais aussi notre souffrance ou notre solitude, etc. L'habitat permet de communiquer au dehors de ses murs, à la fois des formes d'expression de ses habitants mais également les corps de ceux-ci.

Cet ancrage dans l'habitat peut se perpétuer au-delà même de la présence de ses habitants en ses murs. L'habitat est dans ce cas « hanté » par la mémoire de son ancien occupant. À l'extrême, l'habitat peut s'élever en mémorial ou encore en sanctuaire, voué à l'immortalité [12].

1.5 L'habitat : un objet d'attachement

L'habitat est potentiellement au confluent d'investissements individuels, familiaux et sociaux. S'il symbolise l'intime, les liens entre ses habitants, un lieu de rencontre avec le dehors, il n'en demeure pas moins que selon les époques, les cultures et ses habitants, ces dimensions varient pour former la singularité du lien d'attachement qui relie un individu à son habitat. Cova & Giannelloni [7] résument différentes dimensions, reprenant en substance le cadre proposé par Oswald & Wahl [16]. Ainsi, les auteurs dénombrent les dimensions *personnelle* : identité, familiarité, intimité, refuge, héritage, sécurité, etc. ; *familiale et sociale* : statut social, socialisation intérieure, extérieure, etc. ; *économique* : efforts, investissement, héritage, etc. ; *spatiales et temporelles intérieures* : fonctionnalité, confort, équipement, etc. ; *spatiales et temporelles extérieures* : insertion dans l'espace urbain, nature, présence de commerces, de services, etc. La complexité de ce lien d'attachement est mis en lumière par la multitude des variables qui le composent.

Dans cette étude nous avons analysé le vécu qu'ont eu les inondés de la vallée de la Somme, à travers l'attachement des sinistrés à leur habitat.

Méthode

Notre population d'étude a été constituée de 10 sujets dont les caractéristiques sont présentées dans le Tableau 1.

Tableau 1. Description de la population de l'étude

	Hommes	**Femmes**
Nombre de sujet	5	5
Âge	M= 64,4 (DS=5,0)	M=63,8 (DS=10,1)
État civil	Marié (n=4) Veuf (n=0) Union libre (n=0) Célibataire (n=1)	Mariée (n=2) Veuve (n=2) Union libre (n=1) Célibataire (n=0)
Situation professionnelle	Retraité (n=4) Employé (n=0) Cadre (n=1)	Retraité (n=4) Employée (n=1) Cadre (n=0)
Propriétaires	5	5

M = Moyenne ; DS = Déviation Standard

Notre étude a nécessité la construction d'une trame d'entretien semi-directif ayant pour but d'évaluer l'attachement à l'habitat des sujets concernés par l'inondation de 2001 ainsi que le vécu subjectif associé à cet événement. Nous avons également utilisé un auto-questionnaire : l'échelle révisée d'impact de l'événement (IES-R de Weiss et Marmar, 1997) permettant d'évaluer l'impact actuel du vécu traumatique associé à cette inondation. Les résultats de celui-ci étaient croisés avec les données recueillies via l'entretien semi-directif.

Chaque sujet a été rencontré une fois, à l'occasion de sa passation. Avant chaque passation, le sujet a reçu un courrier présentant la recherche et recueillant leur consentement éclairé.

Résultats

Les résultats indiquent que pour une probabilité de trauma non négligeable (n=5), on retrouve un attachement à l'habitat *considérable* (n=4) ou *non négligeable* (n=1). À première vue, la probabilité de trauma *non négligeable* semble associée à un attachement à l'habitat relativement important mais l'inverse ne semble pas évident. Les symptômes de trauma les plus fréquents étaient ceux du « syndrome de répétition ou de reviviscence » [17].

Pour illustrer ces résultats, il nous a semblé pertinent de présenter le cas d'un participant afin de mieux rendre compte de l'existence de liens entre attachement à l'habitat et trauma lié à une inondation. Nous allons donc aborder la situation de Corinne K., âgée de 66 ans.

Corinne K. a acheté une maison avec son mari suite à « un coup de cœur ». Cette maison représente pour elle un prolongement de sa maison d'enfance. Il s'agit d'un lieu accueillant pour la famille et les amis. En tant que directrice d'école, elle est très connue dans le quartier. Corine a une appropriation de sa maison très importante. Notons qu'elle y vit seule depuis le suicide de son mari, qui s'est noyé dans les eaux de la Somme quelques années auparavant.

Au début de l'inondation, l'école dont elle est la directrice est touchée, puis l'eau apparaît aux portes de la maison, ce qui génère une très grande appréhension soulagée lorsque l'eau entrera dans la maison. Le rez de chaussé est alors complètement inondé, les portes ne ferment plus et l'armée se positionne dans les rues. Malgré une grande angoisse, et l'absence d'eau courante Corinne souhaite néanmoins rester dans sa maison.

Rapidement, l'espace refuge que représente sa maison se retrouve réduit à sa chambre, où Corinne tente de reconstituer une enveloppe pare-excitatoire suffisante. La tension anxieuse demeurera importante malgré un éloignement du domicile conseillé par ses filles pour que Corinne K. se repose. Durant l'inondation, Corinne se saisit de son entourage pour supporter le quotidien, en se faisant inviter à manger, pour faire sa toilette, etc. Par ailleurs, elle apprend au cours de l'inondation que sa petite fille ne supporte plus de se baigner, considérant l'eau comme un danger. Cet élément fait écho a posteriori au suicide du mari de Corinne par noyade et à la souffrance qui est associé à cet événement. Ces souvenirs réactualisés renvoient au retour de la réalité angoissante qu'induit cette inondation. De manière générale, Corinne se défend face à cette inondation d'abord avec déni puis par un activisme, avec humour, une hypervigilance. Au décours de l'inondation, on note pendant un certain temps une hypervigilance ainsi que des troubles de la conscience et de la mémoire.

Cette inondation a nécessité le réaménagement du mobilier et notamment des affaires de son mari qui étaient restées en place depuis son décès il y a quelques années. En tant que Directrice de l'école primaire, Corinne fut médiatisée et s'engagea dans plusieurs actions associatives.

Pour résumé, Corinne a subi l'inondation d'un espace pleinement investi. Cette atteinte à l'habitat fait potentiellement écho à une effraction fantasmatique de l'enveloppe de contenance (que l'on peut envisager comme une matrice maternelle, selon Alberto Eiguer, 2004). Cette effraction renvoie à celle du moi-peau, générant ainsi des angoisses archaïques.

Malgré la tentative de reconstitution d'une enveloppe dans la chambre par le rassemblement d'objets familiers appartenant à son quotidien, il demeure une porosité de l'enveloppe pare-excitatoire. Néanmoins, cette inondation a permis de retravailler le deuil de son mari et de surcroît la présence de sa mémoire dans les murs.

Sur le plan psychique, Corinne a fait face à l'événement en mobilisant de nombreuses défenses maniaques parfois dépassées et nécessitant l'emploi de défenses psychotiques comme en témoignent les phénomènes dissociatifs qu'elle décrit (déréalisation, dépersonnalisation). Néanmoins au long cours elle rapporte son vécu en mettant en évidence une objectalisation de sa blessure narcissique. Cela lui ayant permis de faire le lien de manière intéressante entre d'une part l'inondation et ses conséquences matérielles et d'autre part son histoire et ce qu'elle a éprouvé dans l'intimité.

En somme, nous pouvons avancer que les manifestations traumatiques liées à l'inondation et sa manière d'y faire face dépendent de l'attachement qu'éprouve le sujet envers sa maison.

Discussion

Les participants à l'étude ont chacun subi une inondation différente tant dans le déroulement de celle-ci que dans les conséquences. Celles-ci ne présagent pas de la probabilité d'un trauma. C'est bel et bien la confrontation de l'événement aux capacités de représentation du sujet qui conditionnera ses possibilités de subjectivation concernant l'événement, et l'éventualité d'un trauma. Pour les cas où nous avons considéré la probabilité de trauma comme non négligeable, son expression s'est traduite à travers le contenu et la forme du récit, et non par l'expression directe d'émotions ; les douze années écoulées depuis ont probablement favorisé la métabolisation psychique de l'événement, permettant d'introduire plus aisément un sens par le verbe et la métaphore. En ce sens, le trauma est présent en particulier par sa probabilité à être réactualisé.

Globalement, les participants pour lesquels nous avons évalué l'attachement général à l'habitat comme *considérable*, présentent une intensité d'attachement élevée pour la plupart des dimensions. Cette qualification ne saurait se résumer à l'addition des valeurs attribuées pour chaque dimension. En effet, un même sujet peut présenter un attachement nul ou faible dans deux dimensions et s'avérer être considérablement attaché à son habitat. C'est le cas par exemple de Corine K. pour qui la dimension "héritage" est faible et celle "efforts et/ou renoncements" est nulle. Or, l'intensité des autres dimensions est telle que l'attachement général à l'habitat apparaît très important. D'ailleurs, sur une échelle verbale analogique, Corinne évalue au maximum l'attachement à sa maison. Les résultats ont également mis en évidence une position variable donnée à l'habitat au sein du référentiel (personnel, familial, social, etc.) dans lequel ils évoluent. L'habitat participe pour certains au socle qui

les maintient dans le monde. Ce point est soulevé notamment, par l'incapacité de certains participants à se projeter dans un éventuel déménagement. Cet aspect est parfois inenvisageable et d'autres fois il est déduit lorsque nous percevons qu'un tel projet nécessiterait des aménagements considérables au risque sinon pour le sujet de perdre pied. L'habitat prend donc une place relative vis-à-vis des liens du sujet à son monde.

Ainsi, il convient de considérer au cas par cas, les rapports entre l'intensité de l'attachement à l'habitat et celle du trauma.

Au sein de notre population, nous observons que les participants évalués avec une probabilité de trauma *non négligeable* présentaient un attachement à leur habitat *considérable*, sauf un pour qui cet attachement était considéré comme *non négligeable*. Dans le cas des 10 participants, la perspective de perdre ce qui représente l'histoire d'une vie entière semble avoir participé au vécu traumatique. À cela s'ajoute le fait de vivre dans une maison où les fondations deviennent douteuses, où le sous-sol, de tout temps non investi, devient un lieu obscur, susceptible de faire disparaître les corps, de générer l'angoisse de *« s'enfoncer »*. Le sentiment de friabilité de la maison semble renvoyer à la fragilisation du Moi dont les assises narcissiques sont fissurées. Pour chacun de ces participants, le vécu traumatique lié à la rencontre de l'inondation avec l'habitat est singulier, par exemple : le retrait de l'eau, qui pour un autre participant, révèle un paysage de désolation, où règne uniquement la mort de ce qu'elle a créé et entretenu (fleurs, arbres, etc.) ; ou encore, pour un autre sinistré, la perte transitoire mais relativement longue de l'habitat, lieu refuge confortant le sentiment d'unité familiale ; ou bien, dans un contexte différent, l'inondation du cabanon, détruisant tous les outils, ces derniers permettant à son habitant de s'inscrire, de se positionner et de s'épanouir au sein de son habitat ; et enfin pour Corinne K., les portes maintenues ouvertes par la force de l'eau, nécessitant la protection de la maison par l'armée et générant du même coup un sentiment d'enfermement au sein d'un lieu habituellement porteur d'une grande intimité, celle-ci étant alors à découvert, à la vue de tous.

Bien que les manifestations du vécu traumatique semblent liées à de nombreux paramètres, le type d'attachement à l'habitat colore de manière substantielle le vécu traumatique.

Conclusion

L'habitat est un lieu qui touche à ce qu'on est en tant que sujet. Le lien qui se tisse entre l'habitat et son habitant se réalise, entre autres, par le concours de ce qui structure le sujet, et de l'écho, dans le temps, que cet habitat est susceptible de renvoyer à son habitant. Les inondés de la vallée de la Somme de 2001 ont, dans une certaine mesure, été touchés à travers l'atteinte de leur domicile : l'attachement à l'habitat joue sur l'expression du vécu traumatique lié à cette inondation. Ces données alimentent nos connaissances sur les liens qui relient le sujet à son monde intime, familial et social.

Par ailleurs, ce travail soutient l'intérêt de l'existence d'interfaces comme le site *memoiredescatastrophes.org*, qui permet à toute personne de raconter une catastrophe vécue collectivement. Avec cet outil, c'est à travers la subjectivité du récit singulier qu'est permise une appropriation d'un événement potentiellement traumatique. Cette appropriation se réalise pour celui qui témoigne mais également pour celui qui lit ce témoignage, celui-ci étant ainsi renvoyé à son propre vécu. En cela, l'Institut d'Histoire et de Mémoire des Catastrophes (Ihmec) constitue un outil intéressant pour la résilience de victimes de catastrophes.

Abstract

Natural disasters are for children in emergency state, the source for multiple traumatic events in their proximity and at representational level of their world. That can be perceived as endangering also their meaningful relationships [1,2] Recognition of psychological symptoms (including the possible post traumatic stress disorder (PTSD) is an issue also for adults in their environment ,due to special circumstances and developmental related (limited or special)expressivity in childhood. The cumulative risk factors should be acknowledged, to avoid more intrusive action in emergency situation and for preventive intervention in mental health [1].Attachment theory offer better understanding of behaviors observed in stress as base for early empathic intervention ,play therapy and lather in time story-making ,story breaking therapy .Resilience can be built through supportive relationships which help to make sense of what has happened .Actor-network theory refering at action that serves to reassembling the social in special ways can be useful in Romanian situation

The steering team, targeted 130 children, their families and a rural community in research-action projects, initiated during floods in 2005 in Western part of Romania ,for diagnosis of psychological reactive symptoms and screening for possible PTSD .Observation methods ,videotapes , drawings ,play ,focus groups, semi-structured interviews adjusted at developmental level engaged creativity and competences and tutoring processes at all levels.

Save the Children Organization, was committed, when pioneering the field, to emphasize the need for certain ethics and techniques for intervention in mental health services for children .Promoting United Nation Convention on Child's Rights (UN-CRC) it generated a practical guide that was enriched in time by experience that included children's opinion for those acting as volunteers in floods.

The specific volunteer involvement of academics from Timisoara's universities, governmental structures and other NGOs, in assisting (as professionals/supervisors)as volunteers in networking processes was focused to promote resilience at multiple levels. The strategic plan was focused on human relations as resources to increase resilience. Lessons learned in initial processes promoted resilience factors and changed practices and attitudes influencing local mentalities concerning children at risk.

Key words: floods ,research-action ,PTSD in childhood screening, resilience, UN-CRC principles

Introduction

In 2005, the floods in the Western part of Romania, in emergency involved "Save the Children" volunteers to deliver humanitarian aid in the immediate aftermath (providing food and shelter, medical supplies) for most affected communities in Timis district in four villages: Foeni, Otelec, Cruceni, Ionel. The aim was also to identify best ways to support local competence for recovering and facilitate feelings of being in control of the multiple processes that can lead finally to local to resilience. In order to empower communities to support themselves, (fighting through the pain of losing their possessions and houses), focus groups were conducted aftermath to set priorities of agenda of actions, with residents and local authorities, assisted by psychologists as leading volunteers in ONG. The initial assessment of children's needs was done on direct contact with local

schools directors and teachers concerned by children. Aiming to support complex processes immediately after the disaster, to promote resilience, on local groups were involved meaningful adults to make them available for children and their needs and rights. As result, in one of the villages, local consultative council decided as priority, to rebuild the school. That was considered meaningful by Save the Children Timis because already placed children as most important value in their agenda for action. Actor-network theory refering at action that serves to reassembling the social in special ways applied the social firld at that time in Romanian. Agency was regarded as a dispersed competence In contrast to classical approaches, actions were not simply an outcome of the interests, motivations, intentions and capabilities of actors. Instead, the realisation of actions was explained by exploring the points where an actor's dispositions meet the opportunities to act provided by concrete situations, contexts or constellations[7].

Material and methods

In Romanian was a lack of available literature in mental health, education, psychology or social work concerning psychological symptoms generated by perceived trauma during floods The specific issues connected with early recognition of possible Post Traumatic Stress Disorder (PTSD) in children victims of floods were quasi unknown It was designed an observational guide ,an interview guide, age specific for stages of development, concerning perception of events according to their unpredictability. Questions refer at different occurring moments: before, during, immediately after floods and lather in time, targeted on level of stress generated by perceived disaster. It was translated to be accessible for Hungarian speakers also in the region.

Diagnosis and intervention project was drafted in order to promote resilience at multiple levels (targeting also the youth group of Save the Children's volunteers). Mixed teams 36 participants as professionals specialized in psychology, social work, psychiatry, pedagogy, from universities, child protection agencies and school inspectorate's educational structures, (motivates also as adult volunteers for Save the Children) were coordinated and connected for common strategic plan and intervention. Brainstorming meetings with main actors in research and intervention took place in each institution (involving Save the children coordinators as team). They shared a basic knowledge about research - action and training intervention process ,attachment theory, PTSD diagnostic criteria in children . Special attention was done in training on observational skills necessary for capturing emotional verbal and nonverbal language to recognize and refer individuals with certain symptoms for psychiatric examination . For the steering team acting in training and supervision of students, exposed in their interaction with those confronted with floods, a special approach was also necessary. The drafted plan was known, and questions from interview and observational tools were discussed and enriched from different perspectives. Qualified mental health direct services were finally delivered for local community in mixed teams with local actors for only 3 children with clear PTSD symptoms ,and 4 with .

The level of perceived trauma was important to be correlated with perceived social support in the target group of 130 children from Foieni village.For children above 15 years it was applied an interview and an observational guide. For children between 10 - 15 years a special version of interview and observation guide was conceived. In the situation of children smaller than 10 years an interview about the child was held with the parent or principal caregiver..The interview at home was done for all 130 children focused on possible impact of events before, during, and after floods and in the following time. The observation of meaningful interactions and perceived social support took place in peer groups in kindergarten and school. The results of interviews indicated by adults were their feelings of distress regarding not only the lost of possessions, houses and animals in floods, but also concerns about the disruption of family life as washing, cooking, sleeping long time after. Some of the parents perceived the displacement much difficult because separation from peers or family members. The older children were worried about the additional stress factors for their parents and may choose to hide their emotions from them or teachers. Dealing with a "loss experience" as pets, toys, possessions, social isolation after moving to another accommodation place, changing life style that are recurring themes. Behavioral problems described by parents included tantrums and sleeping problems, as nightmares, enuresis since the floods - similar with what was found in the literature [7]. Poor academic performance can be a result of stress in family relations during the flood recovery process but also may be felt through disruption of routines and isolations from friends. The attachment to concrete places and/or their meaning is important to be focused in appreciation of consequences in disasters. When school was affected by floods some of the children perceived as double flooding trauma (and school was particularly challenging). Moving to a new school can increase the preexisting vulnerabilities (as having special educational needs). The lack of places for homework or overcrowded conditions in new places to live were perceived as added in time to the initial stress and important to be taken into consideration. The building of school as safe place in Foieni was considered as well as source of resilience and focusing attention to this aspect in future interventions was successfully promoted in this respect. In the case of neglected children school can be a source of consistency and continuity that can be assimilate to "the safe haven". The recent literature confirms our findings [9]. When teachers themselves, were personally impacted by flood experience it was challenging to deal with pressure added by their emotionality attendance to the children they were working

with [7]. Sentimental items that were lost when they, or the adults have to make, quick decisions in time were sometimes harmful feelings, the different life style after disaster induced the discomfort: loose of everyday routine as free time with family, with friends when it took long time to travel to and from the school[9]There are key themes when working with children and young people survivors of floods that were in focus for volunteers.

Results

Through interviews, (films and tape recordings) of play activities in school, 3 months after floods it was possible to have positive interactions and evaluate behaviors in all 130 children belonging to that community, called Foieni. Their perception and initial attitude towards floods (with tools adjusted to the age group, at home, at school and in the same age group) feelings were expressed verbally or through drawings of hand work in clay and ceramics under known adult's supervision. Narratives about events were listening with empathy from children and adult's as individual or family life stories. Teachers from local community (sometime working on the front line to protect children in classrooms or distribute emergency first aids) described their self-perception of social support and meaning ascribed necessary in the event. Those aspects were also analyzed together with conceptualized intervention, performing surveys, interviews, focus group. Finally was drafted a guide for strategic action, preserving child mental health and rights in emergency situation that can promote resilience. It was subsequently used by the volunteers in the counties of Dolj, Suceava, Iasi, facing floods in the following years. It was the starting point to involve children and youth volunteers in processing and elaborate strategies and presenting their perspectives in making plans to confront disasters in „Child Led - Disasters Risk Reduction"project(2009) It was considered of importance the transformation of the unpredictable in predictable. Understanding and using knowledge, mapping the resources in their proximity it helped in coping with situations and trusting relations to increase resilience

Discussions

Since the beginning, the lack of specific tools for diagnosis of PTSD in children victims of floods, generated the need for training for all participants in the project, to become familiar with diagnostic criteria and to recognize possible specific disorders in childhood, when acting as volunteers in different NGO's in emergencies generated by natural disaster. The studies identified from the literature have been divided according to whether they examined a single flooding event, or multiple events[7] The following self-reported psychological health effects were describe by those who had been flooded : anxiety, increased stress levels, sleeping problems, depression, panic attacks, flashbacks to flood, difficulty concentrating on everyday tasks,lack of energy, feelings of isolation, , nightmares, anger/tantrums, mood swings/bad moods, increased tensions in relationships (e.g. more arguing), thoughts of suicide. Research has identified a range of factors which were associated with higher levels of vulnerability including family income, age, ethnicity, pre-existing poor health and family structure[9] .

Risk factors associated with posttraumatic stress syndrome PTSD (elements were taken into account both the construction of the interview with the child and adults interview): age, sex, ethnicity, developmental stage of the child, pre-existing psychopathology (family, child), Special events/traumatic events in the last 3-5 years. Before, during, after the flood we studied at preschool children in kindergarten and family adaptive behavior and active search of social support as was remembered or illustrate in their narratives.

Adversity is part of the human experience. The program in action needed strong theories and clear guidelines for data collection, concerning children, their families and school. Symptoms that can elicit specific intervention from psychological diagnosis to psychiatric intervention needed to be known for those who assisted the processes of adjustment. For short and long term recovery in mental health it was important to be pro-active in involving multilevel perspectives and co-create strategies for each person's life span looking at their developmental level to grow across time as well at family group and community level.

Building on strengths and improving problem solving skills promotes feelings of self worth and increases overall capacity to deal with life challenge at all levels of actors participating in intervention. Different contexts will require guidelines to structured interventions but also specific responses.

The project methodology shows the importance of creating spaces (as time and places) where people can share their experiences in a way that enables them to learn from and support each other. Using participatory approach to empower local communities in their efforts to make sustainable livelihoods bring ethical concerns that need to be explicit from the very beginning and translate to local culture, that should be highly respected. Valuing diversity, working in multidisciplinary teams and volunteer ship as principle in action can increase the awareness concerning mental health and promote the principles of CRC.

This study supports the conclusions of other research [9] on disaster management. It may emerge from more informal working practices when is promoted a greater flexibility in terms of both institutional roles and individual job descriptions. Capability and capacity also emerge through facilitating and funding a broader,

community-based resilience approach, where there is cooperation between formal organizations and community groups.

Abstract

This study surveyed the mental and health condition of primary and junior high school children within severe tsunami disaster areas three years after 11th March, 2011. We conducted a survey of *Yogo* teachers who combine the function of school teachers and health care and education specialists in primary and junior high schools in two cities affected by the tsunami. We sent questionnaires by mail to all *Yogo* teachers in primary and junior high schools to ask about the condition of children in their schools. Almost three years after the disaster, this study has discovered several new problems about children's condition. First is an increase in the incidence of physical problems related to a lowering of immunity levels Next is the problem of family crises. High risk families tend to show a decrease in the function of child rearing, due to pressure caused by economic problems and social disparities.

Keywords: natural disaster, resilience, children, school teachers, psychosocial supports.

Purpose

This study surveyed the mental and health condition of primary and junior high school students within areas of Miyagi prefecture two and half years after suffering severe damage from the tsunami of 11th March, 2011. We conducted a survey of *Yogo* teachers in primary and junior high schools in two cities affected by the tsunami. *Yogo* teachers combine the roles of school teachers, and of health care and education specialists, which puts them in a unique position to assess the condition of children. This study started in 2012, and will be continued until 2014.

The ecological background of this study is as follows. The population of Miyagi is around 2,203,000. Miyagi is the economic and political center of the Tohoku region. In the disaster of 2011, Miyagi recorded the highest number of dead and missing people. Many schools located along the coast of Miyagi suffered severe damage. These schools also were designated as relief centers after the disaster. From the result of our prelimary study in 2012, we discovered the following facts and problems;

- The result of questionnaires showed that most school children had adapted successfully at schools.
- We found the unexpected results that the number of children with severe psychological problems from the disaster itself was remarkably low.
- However, teacher training programs based on the assumption that many children would get PTSD left teachers with a haunting fear of an impending 'epidemic' of PTSD. Too much PTSD was incapacitating teachers, creating a clinical-psychologist-made problem.
- The ratio of answers that children had not adapted successfully shows a correspondence to the mortality ratio for school children.
- In this presentation, we would like show the results for 2013.

Method

We sent unsigned questionnaires by mail to all the *Yogo* teachers in the same primary and junior high schools as in 2012 to ask about the condition of children in their schools.

The ratio of collection at the time of writing is over 70%. The questionnaire contained the same questions that we asked in 2012, asking teachers to choose from a group of alternative expressions about the health and mental condition of children and describe their concerns about children in a section for free description. We excluded the responses of teachers who had moved in from other areas in 2012.

In conducting this study, we had to work under some methodological restraints. The first restraint was that the Ministry of Education, Culture, Sports, Science and Technology has issued a directive asking researchers to refrain from collecting data from school children within the disaster areas. Secondly, ethical commonsense also dictates that any researcher should be sensitive to the side-effects of probing questions into the disaster and its after affects.

It is important to understand the methodological restraints under which we worked, and how this affects our data. It is under these restraints that we chose to collect data indirectly through *Yogo* teachers in schools within the disaster areas.

This study was approved by the ethics comittee of Yamagata University in 2012.

Results

Table 1 shows the ecological outline of the two cities studied.

Table 1 The ecological outlines of the cities surveryed

	City A	City B
Population	68,000	40,000
The frequency of disasters in the last hundred years	Frequent	Rare
Features of each city	Depressed area, mostly primary industry	A commuter town

Table 2 A comparison of the results of the questionnaire between the two cities

		City A	City B
The ratio of severely damaged schools		71%	60%
The ratio of collection	2012 2013	71% 76%	74% 70%
The mortality of school aged children		Almost 0.1%	Almost 1%
The ratio of *Yogo* teachers who answered the children did not adapt successfully.	2012 2013	10% 0%	40% 15%

Table 2 shows a comarison of the results of the questionaire between two cities in 2012 and 2013.

According to our results of 2012, only 10% of *Yogo* teachers of City A where 70% of all schools were affected severely, answered that children had not adapted successfully. In contrast, 40 % of *Yogo* teachers of City B where the mortality ratio of children was high answered that the children had not adapted successfully, even though the rate of severely affected schools was lower than City A.

The results of 2013 show that there were no *Yogo* teachers who answered that the children had not adapted successfully in City A. On the contrary, in City B, 15% of *Yogo* teachers still thought that there were children who had not adapted successfully.

Table 3. The concerns of Yogo teachers about children's problems in the free description section

	City A 2012→2013	City B 2012→2013
PTSD	0→0	1%→0
Afraid of aftershocks	10%→0	3.4%→0
The influences of family crises (unemployment, divorce, suicide, temporary housing stress, neglect)	17%→43%	30%→0
Truancy, school refusal	0→8%	3.4%→0
Deterioration of existing developmental problems	10%→4%	3.4%→10%
Obesity, Injury, fracture, dermatitis	14%→4%	13%→33%
Unidentified complains	3%→4%	3.4%→55%
Stress related to physical changes of school environment	20%→43%	6%→22%

Table 3 shows the changes between 2012 and 2013 in the number of *Yogo* teachers expressing concerns about children in the free description section.

According to the results for City A, *Yogo* teachers' concerns in 2012 that some children showed tendencies of obesity, skin diseases, or appeared to be increasingly accident and injury prone had decreased in 2013. However, some teachers were now reporting that certain individual children in high risk families (economically disadvantaged or in temporary housing) showed more serious psychological and physical problems compared to 2012. Some teachers reported that the tendency of truancy and school refusal is increasing because of a rise in children's apathy in high risk families.

Conclusion

In 2013, over 90% of the teachers reported that their children overall appeared to have adapted successfully. The resilience of children to the damage caused by the tsunami itself was remarkably high. However, we also found that in City B, not all the children had adapted successfully to the tsunami experience. The biggest difference in tsunami-related damage between City B and A is that the mortality ratio for school children was higher in City B. Some children still showed the same tendencies of obesity, skin diseases, or appeared to be still increasingly accident and injury prone as in 2012.

However, in City A where the majority of children had already adapted to the tsunami itself, by 2013, some teachers were beginning to report that certain individual children in high risk families (economically disadvantaged or in temporary housing) were showing a new range of psychological problems. The economic depression and damage caused by the tsunami to communities and families was evincing itself in pupil apathy and other social problems.

Our findings suggest that as Rutter argued, "it is necessary to focus on risk mechanisms and not on risk factors." According to the results of City A of 2012, children in that area showed better resilience than we expected. However, two and half years after the disaster, psychosocial risk has started to negatively affect some children caught in high risk environments.

Abstract

The research is focus on three neighbourhoods of Port-au-Prince.

Objective: to measure psychological state of art of 3-6 years' old children after 2010 earthquake in Haiti.

Research method: two standardised questionnaires PSYCa 3-6 applied to parents at home by end 2011 and beginning of 2012.

Results: Young children are the most vulnerable. Boys are most exposed than girls to psychological disturbances. Size and rank in brothers increase the score of psychological disturbance. The neighbourhood and perception of environment violence have a considerable impact on range of psychological perturbation.

Significant scores improvement between the first and second ones emphasised an increase resilience whose main factors are social support received by the family, rapid re-entrance to school, faith and religions practique.

Key words: Haïti, earthquake, assessment, psychological perturbation, PSYCa 3-6

Introduction

Quatre ans après un séisme dévastateur qui a fait 300 milles morts, des dizaines de milliers de personnes restent parqués dans des abris de fortune. La pauvreté, la mortalité infantile et maternelle, les inégalités sociales, la violence et la corruption restent relativement inchangées. Une nouvelle gouvernance a peu modifié l'incurie ou l'inexistence des services publics. Il n'y a pas de politique de planification et très peu de ressources pour la santé mentale. En milieu urbain la population est confrontée à des niveaux élevés de criminalité et de violence. En fin 2010, une épidémie de choléra avait touché plusieurs centaines de milliers de personnes, provoquant plus de 8000 décès.

Méthodologie

1.1 Les outils

Il existe peu d'outils d'évaluation psychologique transculturelle généraliste des jeunes enfants permettant une identification rapide des enfants les plus en difficultés. Nous utilisons Le PSYCa 3-6 version simplifiée et adaptée du QGE [6]. Avec désormais une adaptation et une validation transculturelle et la structuration du guide d'utilisation (Marquer & al, 2012). Le PSYCa 3-6 propose une mesure globale de la détresse psychologique plutôt que de viser un trouble ou un symptôme spécifique. Le questionnaire est rempli sur place par l'évaluateur, plusieurs études soulignent la validité des informations parentales ou du caregiver sur l'enfant [3].

Le PSYCa 3-6 est constituée en première partie, d'une base de 22 questions peu saturée en facteurs culturels avec une cotation en intensité. En fin d'administration, les scores vont de 0 à 44, les scores les plus élevés soulignant des perturbations importantes. Les différentes validations transculturelles indiquent un seuil de perturbation à partir d'un score de 9. La seconde partie du questionnaire cible les caractéristiques sociodémographiques et doit être adapté à chaque contexte.

1.2 Adaptation

L'utilisation transculturelle d'un outil d'évaluation psychologique nécessite son adaptation au contexte culturel, social et linguistique avec un travail de traduction et rétro-traduction en s'assurant des équivalence sémantiques des termes employés. Le créole haïtien (Kreyòl) est la langue maternelle de la très grande majorité de la population haïtienne.

Les terrains de l'enquête se situent dans les secteurs populaires de trois quartiers de Port-au-Prince : Cité Soleil, Fontamara et Delmas. L'échantillon a été choisi parmi les familles des quartiers où intervient déjà l'équipe psychosociale de l'institution partenaire ID Microfinance. Les critères d'inclusion étaient les familles d'enfants de 3 à 6 ans qui avait signé un formulaire de consentement en créole, également lu par l'évaluateur pour s'assurer de la bonne compréhension. Les critères d'exclusion étaient des troubles envahissants du développement massifs et des déficits intellectuels profonds que les évaluateurs étudiants en psychologie avaient été formés à prendre en compte.

1.3 Partenariat avec ID Microfinance, objectifs, déroulement

Après le séisme, un programme d'appui psychosocial qui s'adresse à des familles présentes dans les zones ayant été fortement touché par le séisme.

A travers deux passations du questionnaire, fin 2011 et début 2013, nos objectifs partagés avec les psychologues de l'équipe psychosociale étaient d'une part : identifier les enfants les plus en difficultés psychologiques, sensibiliser les familles à la santé mentale et au rôle du psychologue, mettre en place une prise en charge adaptée en cas de besoin. Et d'autre part, à travers la seconde passation une année plus tard, avoir une indication de l'évolution des scores de perturbation psychologiques des jeunes enfants sur un axe vulnérabilité/résilience. La visite à domicile permettait de dépister les troubles psychologiques au sein d'une population qui ne rend pas non plus dans les centres de soins communautaires.

Résultats

La première passation Temps 0 (T0) concerne 166 enfants, la seconde passation Temps 1 (T1) concerne 49 enfants, les mobilités, relogements, déménagements, etc., n'ont pas permis de retrouver l'ensemble des enfants évalués à T0.

1.1 Première passation

Pour la première passation, fin 2011 qui concerne 166 enfants, il n'y a pas eu de refus. Sur les 166 enfants participants à l'étude, il y a 44 % de garçons et 56 % de filles avec une moyenne d'âge de 58 mois. La répartition des enfants par quartier est de 61 soit 36.75 % pour Cité Soleil, 60 soit 36.14 % pour Delmas, 45 soit 27.11 % pour Fontamara. 165 enfants ont été directement témoin et/ou victime du tremblement de terre et 30 % ont eu des morts ou des blessés dans la famille proche. Pour 47 % d'entre-eux, la famille a remarqué un changement notable affectant, le caractère, le comportement ou la personnalité de l'enfant à partir de l'évènement. 30% des personnes interrogées ont été contrainte de changer de domicile après le séisme. La moyenne des fratries de notre échantillon est de 3 enfants, 30 % sont enfants aînés, 25 % sont seconds et 18 % sont troisième. 97 % des enfants sont scolarisés. 98 % des familles se déclarent catholiques ou protestants ; 36 % catholiques, 62 % protestants, 2% autres ou vodouisants. Le nombre moyen d'habitant par foyer est de six et peut aller jusqu'à 13.

1.2 Scores indicatifs de perturbation psychologique à la première passation

Nous avons retenu un seuil de difficultés psychologique défini à 9 préconisé pour les trois études de validation transculturelle avec gold-standart au Niger, en Colombie et au Kenya et confirmé pour Haïti avec la CGI.

Proportion d'enfants avec un score PSYCa 3–6 >= 9 (égal ou supérieur à 9)

– au Niger; 12.5% (n=31/255)
– en Colombie; 7.3% (n=8/109)
– au Kenya;11.5% (n=14/121)
– en Haiti fin 2011, à TO, 59% des enfants au-dessus d'un seuil de 9 et 33 % au dessus d'un seuil de 12.

Le score de perturbation psychologique est très important mais corroboré avec d'autres recherches sur la situation psychologique des victimes de catastrophes naturelles.

1.3 Score et religion

Il n'y a pas de différences significatives entre les affiliations religieuses.

1.4 Score et genre

On constate une différence significative entre les filles et les garçons, ce qui diffère de la littérature internationale cependant ces études portent le plus souvent sur des enfants au-dessus de 7 ans.

- 62,6 % des filles ont un score de 1 à 10 et 38,7 % ont un score élevé de 11 à 27.
- 37,4 % des garçons ont un score de1 à 10 et 52 % des garçons ont un score de 11 à 27.

1.5 Score et âge

Bien que le résultat reste non significatif sur le plan statistique le groupe des plus jeunes enfants paraît plus vulnérable.

1.6 Score et perception de la violence environnementale

Plus de 53% des familles ont la perception d'une violence environnementale pour la globalité des 3 quartiers, mais cette perception est bien plus importante pour un des quartiers, Cité Soleil ou près de 80% des familles ont la perception de la violence environnementale. Le fait de percevoir et/ou de subir la violence au quotidien entraine une hausse significative du score au PsyCa 3-6 chez les enfants.

1.7 Score et fratrie

Le score de perturbation est plus important avec une fratrie nombreuse égale ou supérieure à 4 enfants. En fonction du rang dans la fratrie, de façon significative, les aînées ou les seconds ont un score de perturbation moins important que les cadets.

Seconde passation

La seconde passation concerne 49 enfants connus à la première passation. Il y a une différence significative entre les scores à Temps 0 (première passation) et Temps 1 (seconde passation) Les enfants ont significativement amélioré leur score. Certains enfants ont vu leur score augmenter, mais l'évolution générale est à la baisse. Le score médian est passé de 10 à 8

Il existe une différence statistiquement significative entre les évolutions relative dans le quartier cité soleil, les scores ont globalement augmenté (médiane supérieure à 0), alors que dans les deux autres quartiers les scores ont baissé. Ce qui est bien corrélé à la violence perçue à Cité Soleil.

Discussion

Le score de perturbation psychologique apparaît considérable à Port-au-Prince, cependant, il reste corroboré avec d'autres recherches sur la situation psychologique des victimes de catastrophes naturelles. De nombreuses études soulignent l'impact psychologique considérable des catastrophes naturelles sur les enfants, bien qu'elles ne portent pas sur les jeunes enfants. Dans l'étude de Osofsky & al, (2009), après le passage de l'ouragan Katrina à la Nouvelle-Orléans en 2005, 49.1 % des sujets atteignent un score de perturbation psychologique nécessitant des soins en santé mentale.

Le score élevé de perturbation psychologique en Haïti doit aussi être corrélé à la vulnérabilité globale de la population étudiée associée à d'autres paramètres liés au contexte socio-démographique, aux antécédents traumatiques, à l'environnement pré et post-catastrophe.

Réflexion et conclusion provisoire

L'étude souligne certains facteurs de risque ou de protection pour les enfants de trois à six ans. Les enfants les plus jeunes semblent plus vulnérables. Les garçons sont davantage exposés aux perturbations psychologiques que les filles. La taille et le rang dans la fratrie augmentent le score de perturbation psychologique. Le quartier et la perception de la violence environnementale ont une incidence considérable sur le score de perturbation psychologique. Une vulnérabilité accrue est en lien avec un environnement violent et ces corolaires de pauvreté et de précarité.

L'amélioration sensible des scores entre la première et la seconde passation met modérément en relief une résilience que l'on peut aussi définir comme résistance ou comme réduction de la vulnérabilité. Les entretiens qualitatifs avec les familles mettent en relief la foi et la pratique religieuse et une forme de relation personnelle avec un Dieu, ici perçu ou définit comme "Dieu" bienveillant et digne de confiance. En termes psychologiques une présence internalisée, secourable et toujours disponible dans les moments de détresse et dont on peut imaginer qu'elle est un facteur de protection pour la maman et pour ses enfants. Foi et pratiques font partie des ressources après le séisme de 2010. Les entretiens qualitatifs avec les familles soulignent l'importance de l'accompagnement psycho-social de l'institution ID Microfinance. Dans le volet psychosocial, les psychologues proposaient une guidance de plusieurs mois, des groupes de parole réguliers, des prises en charge pour un parent ou les enfants en cas de besoin.

Le pain des morts, les mots des revenants: recits de resilience dans les camps de concentration

Benestroff C.

Psychologue clinicienne, Etablissement public de santé de Ville-Evrard- Université Paris8 (FRANCE)
benestroff.c@orange.fr

Abstract

Testimonial literature is rich in including clinical lessons on establishing resilience process in extreme situations. Indeed, the testimonies of Levi, Semprun, Tillion, Lusseyran, as well as many others, support the idea of assisted resilience (Ionescu) starting with spontaneous help to organised solidarity, where the bread of dead save the live ones.

If this assisted resilience well supports the survival in the camp, she also plays an essential role in the oral collective experience. Starting with this point, the process of identified risk and protection factors is based on the study of link between individual and collective traumatisms, and rolls played. Concerning the latter, links between living and the dead ones support this „making grand narratives" represented by History according with Cyrulnik et Peschanski.

We will approach the connection between different memorial regimes and their influences on the resilience establishment. How current society welcomes the words of ghosts? What does the clinician with this data? Which therapeutic tools could be developed?

Key words: assisted resilience, stories, concentration camps, History.

Introduction

Rappelons quelques éléments. Le système concentrationnaire nazi s'organise autour de deux axes, la déportation de persécution celle de répression. L'entreprise totalitaire, fondée sur l'idéologie d'une hiérarchie entre les races, vise à l'élimination des individus considérés comme des « parasites » et à la répression des opposants au régime. La mise ne œuvre de cette politique se fait au sein de nombreuses infrastructures dans tous les territoires occupés, dont les camps de concentration et camps de concentration avec centres de mises à mort [1], [2].(Camps de concentration avec centre de mise à mort: Chelmno, Treblinka,Sobibor,Belzec, Lublin-Maïdeneck, Auschwitz-Birkenau. 5 à 6 millions de Juifs et 250 000 Tsiganes ont été exterminés. Au départ de la France: 165 000 déportés.76 000 déportés de persécution (110 000 enfants), 3% sont revenus. 85 000 déportés de répréssion dont 60% sont revenus.)

Dans ces situations extrêmes, toutes les stratégies de survie cherchent à contrecarrer la déshumanisation imposée visant la destruction. Après le traumatisme du *Grand voyage* [3], commence pour le déporté, un cycle d'effractions (deshabillage, désinfection, rasage, immatriculation, quarantaine), visant à l'animaliser, avant de le transformer en *Stück* (chose).Soumis à l'arbitraire absolu, affamé, il doit effectuer un travail harassant dans des conditions désastreuses. L'horreur devient l'ordinaire, l'exposition à l'effroi est permanente. Le détenu est expulsé du sentiment d'appartenance à l'espèce humaine [4].

Du traumatisme à la résilience section

Ainsi, comme le note Boder, qui a réalisé en 1946, 120 entretiens avec des rescapés, tous ont été soumis à des expériences formant un « indice traumatique » [5], décrivant des violences physiques et psychiques, et la rupture des cadres sociaux. On retrouve dans la liste de Boder tous les signes d'une effraction continue inscrite dans une dimension collective.car, si l'expérience est vécue de façon unique et singulière par chaque individu, elle prend en raison même de sa nature de mort de masse, une dimension collective. Boder met la *déculturation* au centre de son analyse, « l'amputation progressive d'un être humain pour l'adapter aux camps » [5]. En forgeant cet antonyme du mot *acculturation* (incorporation de l'individu dans le groupe) [5], Boder annule la séparation entre traumatisme individuel et collectif. En effet, si certains facteurs (âge, condition physique, métier, compétences linguistiques), influent sur les possibilités de survie ils sont dépendants du contexte historiquement déterminé : date et motif de la déportation, camp d'affectation, nature du travail. Ces données

augmentent ou diminuent les probabilités de survie. Ces dernières ne peuvent être étudiées qu'à travers une analyse systémique et contextualisé. Qu'en est-il pour la résilience ?

1.1 Instauration des processus de résilience dans les camps

Dans ce contexte de terreur organisée, chaque détenu mobilise des stratégies conscientes et inconscientes, des habiletés et compétences, pour ne pas succomber à l'effroi. L'hypervigilance et l'hyperesthésie permettent de décrypter cet « univers ubuesque », évoqué par Rousset, pour en déceler les pièges (Repérer les meilleurs outils, les endroits les moins exposés, localiser les SS, éviter d'être isolé.) [6].Cette mobilisation intrapsychique concerne aussi des activités mentales, capacité de rêverie, d'abstraction, permettant de s'abstraire de l'environnement terrifiant. Mais, dans ce contexte, l'environnement est primordial car on ne peut survivre seul. Les caractéristiques et potentialités individuelles ne peuvent se déployer, qu'avec et grâce aux autres, ce qui installe d'emblée la primauté des tuteurs de résilience comme agents et vecteurs de la survie et des processus de résilience .La présence et les actions spontanées ou organisées de ces tuteurs suturent la brèche traumatique, facilitent la reprise de l'activité mentale, suspendent la condamnation à mort.

Tous les témoignages font état de ces présences miraculeuses offrant gestes et paroles qui sauvent : un camarade répare les lunettes d'Antelme [4], un autre soulage de Saint Marc d'une part de travail [5]. « Trouver un personne amie, c'était le salut », écrit Levi [8]. Ces gestes viennent rompre le facteur de risque qu'est l'isolement, ils forment cette « coalition de l'amitié » à laquelle Tillion [9] rattache sa survie. Mais, le réconfort vient aussi parfois du fait d'être encore vivants ensemble, il faut rester groupés, explique Rousset [10].Grouper, pour reconstituer, non seulement une identité collective, mais même selon Lusseyran, une identité unique « faisant de nous tous une personne -une seule » [11]. Ainsi, on voit comme le souligne Rutter [12], qu'un facteur de risque (la promiscuité), peut devenir un facteur de protection. Fédérer de telles actions, pour que chacun devienne le tuteur de l'autre, est un des axes du programme de la Résistance dans les camps, programme que l'on pourrait qualifier de résilience assistée appliquée.

1.1.1 Résilience assistée et Résistance

Le concept de résilience assistée élaboré par Ionescu [12] s'inscrit dans une perspective intégrative englobant les caractéristiques individuelles et le réseau d'interactions avec l'environnement. Le terme *assisté* souligne le fait que : « les professionnels ne font que seconder, accompagner, le sujet dans ce processus » [13].C'est une « intervention basée sur les forces » [13], et non sur les troubles et dysfonctionnements. Ces préceptes se retrouvent dans le monde concentrationnaire, qui montre une série de similitudes entre résilience assistée et Résistance, où l'on voit par exemple que, grâce au réseau relationnel, le coping centré sur l'action et celui centré sur l'émotion ne s'opposent pas, mais au contraire, se complètent.

1.1.2 Des forces pour la vie

« Résister dans un camp d'extermination, c'est protéger des vies », écrit Langbein [14]. Les gestes d'humanités ne pouvant suffire, dans tous les camps, les détenus ont mis en place des stratégies de survie : accueil et éducation des arrivants, repérage des compétences (linguistiques, manuelles, artistiques), amélioration du quotidien, organisation des activités culturelles et éducatives (conférences, écriture, spectacles), soutien des groupes défavorisés et des plus démunis, etc. On retrouve donc toutes les caractéristiques d'une *intervention basée sur les forces*. Prenons un exemple : la *solidarité*, où les morts secourent les vivants.

1.1.3 La solidarité ou le pain des morts

La *solidarité* désigne une pratique de partage des rations alimentaires. Un prélèvement est effectué sur les rares colis reçus par certains détenus, sur les rations distribuées. On utilise aussi les aliments « organisés » (volés ou troqués), et le trucage des listes de détenus. Des collectes sont organisées dans les blocks et à l'infirmerie, où les infirmiers conservent les rations des morts de la nuit. Mais, pour réaliser cet exploit, les morts devenus tuteurs de résilience doivent être montés sur la place d'appel, où les SS font les comptes. Les morts sont « soutenus par des mains invisibles » [3].Comptabiliser les morts comme vivants permet de conserver le même nombre de rations : « avec le pain des morts […] les copains faisaient un fonds de nourriture pour venir en aide aux plus faibles, aux malades », écrit Semprun [3]. Ces actes sont passibles d'une exécution immédiate.(Les bénéficiaires sont les blessés, les malades, les jeunes, les vieillards, les *musulmans,* terme d'origine inconnue désignant ceux qui ne luttent plus pour survivre)

1.1.4 L'assistance organisée

On voit ici que ces actions requièrent un haut niveau d'organisation : fédération du groupe, mobilisation de compétences diverses (observation, rapidité, sang-froid, aptitudes relationnelles, coordination), bref, une

longue chaîne d'interactions, toutes tendues vers un but commun, ce qui légitime la transgression. Dans ce cas, désobéir est plus qu'une vertu, c'est la réaffirmation de son humanité par le dépassement de soi, une *sublimation en acte*, selon la définition de Lagache [15].Le besoin de se nourrir est transcendé par celui d'aider l'autre [16]. Ce faisant, l'autre aussi affaibli soit-il, réanime l'aidant, le rend riche de son don. (Steinberg parle « d'assistance mutuelle »)Au sein du collectif, luttant contre la violence, animé par des valeurs communes, chaque individu devient un tuteur de résilience, comme on le voit chez Lusseyran : « Nous étions […] emboîtés les uns dans les autres, l'un protégeant l'autre, l'autre protégeant l'un, dans une circulation d'espérances communes » [11]. Ainsi, avec cet exemple, on peut dire que la résistance met promeut un programme de résilience assistée, tel que le définit Ionescu [13], programme qui soutient des personnes à risque, dépiste les ressources existantes dans l'entourage (tuteurs), crée et active de nouveaux réseaux.

Ce programme préventif et thérapeutique, mobilisant les forces pour la vie en utilisant toutes les ressources de chacun, se trouve au cœur des témoignages des déportés, où le pain des morts, cette solidarité inouïe, est l'emblème d'une coalition pour la survie.

« CrÉer, c'est rÉsister » [17]

La solidarité alimentaire illustre la réinstallation d'un contrat social basé sur la reconnaissance des individualités et des compétences de chacun, dans la mutualité des échanges. Si la priorité va aux actions assurant la survie immédiate, la promotion de l'expression des pensées et des émotions est au cœur du dispositif d'entraide. Toutes les activités- dessin, écriture, théâtre, musique, etc.-, facilitant le récit du ressenti sous des formes éphémères ou durables sont encouragées. (De nombreuses œuvres nous sont parvenues : dessins de Taslitzky, opérette de Tillion, poèmes rassemblés par Verdet et bien d'autres.) Elles répondent au besoin primordial de donner un sens et une cohésion aux pensées et aux émotions. Parce qu'elles s'inscrivent dans la relation à autrui, sans qui elles ne pourraient exister, ces productions servent, dit Taslitzky, à « éloigner l'homme du désespoir » [18], jusque dans l'après-coup du retour.

1.1 Récits de résilience

Véritable aire transitionnelle, les récits des revenants refondent le dialogue, de soi à soi, et de soi avec les autres, et contribuent à cette « fabrique des grands récits » qu'est l'Histoire, comme l'ont montré Cyrulnik et Peschanski [19]. Ce sont des documents, dont l'élaboration à commencer dans les camps. Mais, ils sont aussi des livres mémoriaux, qui rendent hommage aux camarades de déportation, à leurs actions, et aux effets de ces dernières. Ces récits hybrides, étranges et inclassables sont des passerelles entre les vivants et les morts.

De plus, derrière la liste des faits et évènements, ils dévoilent l'arrière-scène du théâtre intime, l'expérience effroyable en train de se vivre. Encore plus que dans la vie ordinaire, « l'histoire de vie se compose avec une multitude d'autres histoires de vie », comme l'écrit Ricœur [20]. Ainsi, le *Je* du témoin décrit bien l'expérience ontologique d'un individu, mais il donne également corps et voix, aux compagnons de détresse et aux disparus, ce qui amène l'expression d'un *Je* pluriel et polymorphe né dans le camp.

1.2 Les métamorphoses du moi

Si les métamorphoses du moi sont liées au traumatisme, elles ont aussi à voir avec les processus de résilience qui ont permis la sauvegarde psychique. Le moi réanimé par la présence et la fréquentation d'autrui, se découvre des potentialités insoupçonnées, de nouvelles compétences. Les exemples abondent. Lusseyran, aveugle, détecte les mouchards grâce à sa sensibilité. Steinberg, s'improvise chimiste, il trompe les SS parce qu'il a appris par cœur un livre de chimie. Ces réussites inattendues agissent au long cours, elles forment les axes des récits, témoignent de la métamorphose opérée. Ainsi, les récits de ces transformations participent de la sortie du trauma, ils sont la trace d'une « cicatrisation réactionnelle » [21] assurant la réparation du moi blessé, permettent par la médiation narrative de retrouver le monde des vivants.

Mais, les informations données, souvent qualifiées d'indicibles, sont le plus souvent inaudibles pour les destinataires. Pourquoi ? Parce que ces informations paradoxales, bouleversent notre rapport au monde, nos conceptions habituelles, nos cadres de pensée établis, nos catégories nosographiques.

Les mots des revenants : une langue Énigmatique

Les récits des revenants furent accueillis de façon très variable, souvent problématique, obligeant certains d'entre eux à se taire [22], ou à retarder le témoignage. En plus de l'horreur et de l'inimaginable qu'ils véhiculaient, ces récits n'ont pu s'inscrire dans le discours familial et social qu'en fonction de moments historiques correspondant aux différents régimes de mémorialisation [23], mettant en avant différentes catégories

de déportés. Pour être entendu, un récit doit avoir une fonction sociale. Même sur le plan historique, ces récits, en raison de leur diversité et de leur variabilité, en font des documents difficiles à exploiter.

Ces éléments se retrouvent au niveau clinique. Si le syndrome concentrationnaire a été très vite décrit [24], bon nombre de déportés ont été en butte à l'incompréhension, à une « psychiatrisation » de leur état, leurs récits étant assimilés à du délire. Le retour a souvent été une épreuve supplémentaire. Pour toutes ces raisons, la langue énigmatique des revenants a suscité de nombreux malentendus, alors qu'ils sont riches d'enseignements cliniques sur le traumatisme, la résilience et le fonctionnement humain en général.

1.1 Leçons cliniques

La mémoire est composite, sensorielle, synesthésique [25], plastique [26], les souvenirs sont « enveloppés » [27], les détails servent métonymiquement d'accroche aux souvenirs, la dimension collective est centrale, elle englobe les souvenirs des autres. Le temps est réversible, éclaté. Le moi est polymorphe, pluriel, rhizomatique, en développement. Ces caractéristiques permettent de mieux comprendre l'Etat de Stress Post Traumatique, de le considérer, non dans une catégorie figée, mais dans une perspective dynamique, phénoménologique et développementale, qui remet en cause des idées classiques. Les frontières entre le normal et le pathologique sont remises en cause.

Les symptômes et la maladie peuvent sauver de l'effroi : « la maladie m'avait sauvé de la peur […] sans elle, je n'aurai pas vécu », dit Lusseyran [11]. Dans l'après-coup, les troubles, bien qu'ils fassent souffrir, sont des étapes de la cicatrisation. Le *flash-back* est aussi une tentative de contrôle et de recherche de sens à donner à l'évènement.ces éléments nous apportent aussi des leçons sur la résilience.

1.2 Sur la résilience

Les exemples donnés sur l'instauration des processus de résilience dans la situation extrême de la vie concentrationnaire apportent une vision dynamique et intégrative de la résilience. Ils mettent l'accent sur :

- La notion de développement avec des phases de progrédientes et régrédientes
- La variabilité des effets des facteurs de risque
- La positivation d'éléments habituellement perçus comme négatifs (transgression, désobéissance, etc.
- La plasticité du moi et de la mémoire
- L'importance des liens sociaux qui maintiennent l'identification à autrui et l'empathie
- L'importance des mécanismes de défense de type primaire que sont le clivage, et le déni et le rôle central étudié par Vaillant [28] des mécanismes de défense de type secondaire, comme l'intellectualisation et l'humour, selon Jourdan-Ionescu [29]. L'utilisation des deux séries facilite l'adaptation à un environnement anormal et violent. Intriquées, elles deviennent des facteurs de protection. La fonction essentielle de la sublimation est confirmée, car le recours aux valeurs idéales culturelles, morales, politiques, religieuses, est déterminant, ainsi que l'a montré Veyssière [30] dans son étude des déportés résistants français.

1.3 Vers une résilience assistée

Ces enseignements concourent à promouvoir la résilience assistée dans la pratique clinique, même quand il ne s'agita pas de situation extrême. Les récits des déportés peuvent nous aider, car ils font état de centrés sur l'action, animées par un idéal et intégrant les émotions. Elles mobilisent toutes les compétences, sans les hiérarchiser. Ainsi, l'habileté manuelle a autant de valeur que les connaissances intellectuelles, un manchot peut secourir un aveugle, qui lui-même aide les autres grâce à sa connaissance de l'allemand. Les apprentissages sont mutualisés, ils reposent sur l'échange des savoirs et des compétences, la pédagogie se fait par l'exemple (les anciens détenus éduquaient les nouveaux). Le rôle des tuteurs est essentiel, l'accent est mis sur les potentialités et non sur les manques.

L'amélioration des conditions matérielles forme un projet, elle conditionne la mobilisation des stratégies adaptatives et rend possible les activités sublimatoires indispensables à la survie. On voit que les concentrationnaires résistants ont installé empiriquement un dispositif de résilience assistée, repris par les associations de déportés, dont nous pouvons nous inspirer.

Ces exemples sont un éloge de la différence (physique, culturelle, sociale) considérée comme une richesse et non seulement comme un handicap. Cela vaut au plan individuel comme au plan collectif, on sait que l'Europe est née dans le creuset linguistique et culturel des camps.

À la lumière de ce constat, nous pouvons nous interroger sur l'organisation de notre système sociétal, éducatif et de soins, qui trop souvent isole, et enferme dans des catégories rigides. La pauvreté, la précarité sont des facteurs de risque [13] rarement considérés dans leur dimension traumatique. Sur le plan éducatif, le cloisonnement et la hiérarchisation des apprentissages creuse les inégalités. En clinique, l'hyperspécialisation, si elle permet des avancées spectaculaires, a aussi des inconvénients. Le patient est parfois suivi, sans prise en

charge globale, par une armée de spécialistes, la maladie finissant par cacher le malade, la souffrance étant évacuée du tableau clinique.

Conclusion

De fait, les enseignements restent à étudier précisément, mais d'ores et déjà, ils nous apportent une vision de l'ordre de la « complexité » [32], qui s'enrichit de nos incertitudes, et pense la résilience dans sa dimension éthique [33]. Ils nous montrent que dans l'adversité, « les petites choses » [34] sont souvent essentielles, que la persistance d'un futur possible est le moteur de l'action. En somme, en nous confrontant à l'existence du Mal, ces récits nous montrent aussi la part de liberté humaine, le souci pour l'autre dans la détresse. Ce faisant, ils nous transforment à notre tour [35], nous incitent à ne pas désespérer, à tenter modestement de réaliser les rêves des revenants.

Resilient communities, historical trauma and narrative reconstruction of identity

Gavreliuc A.

West University of Timisoara (ROMANIA)
alin.gavreliuc@e-uvt.ro

Abstract

In our research we have analysed 31 oral history interviews (1720 pages of transcript the manuscripts) as part of the documentary sources constituted by the Archive of the Group of Cultural Anthropology and Oral History of "The Third Europe Foundation", Timisoara, Romania. In the methodological design we have used a content analysis combined with values scale realized by M. Rokeach for a sample of subjects confronted with a traumatic event (deportation in the Second World War or in the Communist period). In the content analysis register we have indentified some constants of remembrances (the so-called discursive anchors) and the mechanisms of identitary discourses depending on certain imaginary nuclei of reference, grouped around the "family" symbolic anchor, which renders evident the social construction of identity. In the values scales register, out of over 2700 axiological references, we can distinguish the predominance of the values which would integrate in the register of "to be", to the detriment of the "to have" values. "Destiny", as well as "history", have deprived the investigated subjects of wealth, stability, social position, but all the existential breakings and all the discriminations they have lived are but the motives of a superior understanding of life, of the lasting and authentic friendships acquired, of the special achievements of their children. Therefore, these acquisitions in the register of "to be", which prove stronger than the misfortunes of fate, have activated the features of resilient communities.

Key-words: resilient communities, oral history, trauma, values.

Life history and the traumatic self – a qualitative approach of social identities

At the beginning of the 2000s I have started a series of studies concerning the analysis of the Banatian imaginary identitary, especially for ordinary people who experienced traumatic events (like deportation), through the methodology of oral history. Years later, I had accumulated significant qualitative data around these narrative identities, and in the following pages I would like to briefly resume my previous attempt to outline the image of the memorial Banat [1]. The topic of traumatic identity has been followed, attempting to enlarge the horizon of the identitary knowledge toward the realm of the *silent world*, toward the second-plan actors of history, so often ignored when self-reflexive surveys have been carried out and only *the pursuit of the forefront actors* has been preferred. I am referring to approaching the simple world, which has refused the forestage of the social, a generation that has fully assumed the traumas of the last century, beginning with the great conflagrations, deportations and dramatic readjustments to postdecembriste hopes. A generation that has accumulated so many unspoken aspirations and disillusionment and has lived each new challenge of the moment so intensely that, at last, is now insisting on being listening to. I will resort to a privileged way of identitary journey – "the life history" – regarded as a genuine way of *producing identity live* [2], in which *the confessing subject becomes a kind of concentrate of the social world*, with all its hopes and failing. It is proper to abandon the so-called break between the objective and subjective by understanding the social and interactive nature of the identitary construction. Consequently, he who approaches this world is forced to understand that he enters a *three-pole game* [2]. It implies the researcher's empathic participation, the enjoyment and almost therapeutic unburden of the subject, and the living and permanently rebuilt relationships with his life, that becomes an identitary belonging for he who produces the discourse as well as for the one who is listening to him. There is no more place for epistemological detaching, self-sufficiency or superior considerations.

Thus, *the meaning can be understood only in relation with the other* who is properly considered not as a localizable and classifiable object, but also as a partner in the mutual negotiation of identity. He becomes an active subject who communicates, by means of shared symbols, with another equal subject, beside whom he starts getting used to the "taste of the journey" among the interwoven destinies. In this way, I will briefly outline the itinerary of such an identitary journey by a sample of interviews taken from the *Archive of the Cultural*

Anthropology and Oral History Group of "The Third Europe" Foundation in Timişoara, investigated over the last decade. It has offered us the opportunity to meet such a rich and ardent world by which we shall strive to catch a collective portrait of a generation that has faced so many breakings of history. Certainly, *this portrait has rather a heuristic value,* because of the limited samples and the inevitability of catching only one Romanian cultural area – Banat – and only one generation – adults born after 1930. We will try to clear up the tone and the essence of this journey toward the "self" and the "other" alike by examining the resources of memory's source.

Retrieving these fragments of life reunited in a coherent ensemble, to which the subject confers referential values and significance, we will have access, by means specific to oral history, to *the formation of the self as a process* in this confrontation with the conditionings, often tragic of the social background and history. The life story will be looked upon as a remarkable resource of revealing the social frames of memory around which the alchemies of identity articulate. As T. Todorov was underlining, "the representation of the past is not only the constituent part of the individual identity – the person present being, in a way, <built> of his own self-images – but also of collective identity". Thus, "the majority of human beings need to feel they belong to a group, this being the most accessible means of obtaining the recognition of their existence, which is essential to any person" [3]. As the American interactionism has also asserted, the narrative structure hides an argumentative structure in which the identitary discourse folds on dialogue logic. The life story assigns a part to the individual in the arena of life and also to the larger groups that have participated in the shaping of the personal destiny. Being an *ultimately founding discourse*, the life story constitutes a defining staging of the individual and group identity, which projects the ideology, mentality and communitarian standards and values into a new and clarifying light [4].

In other respects, following the manner in which the clarification of the self is achieved in this social game, K. Gergen introduces the term *self-narrative*, by which the subject remakes his past, assembling his past experience in a whole, as balanced as possible. Becoming a narrator of his own life, the subject acquires a feeling of his unity and establishes a network of referential events by which the present identity appears as a dénouement of his life story [5]. We do not have only a monologic formulation of discursive coherence. The identitary discourse is always a discourse addressed to *the other who is listening to us*. In the reading scale suggested by the symbolic interactionism, in which *people act according to the significance* different social objects have for them, their significance is *constructed socially* within their mutual interaction and is transmitted, being reshaped and renewed through the process of *interpretation* to which social objects are submitted to and through *root-images*, a kind of primary constitutive elements of any semantic elaboration (interaction, the actor as a social subject and activated roles). The discovery of these deep images will constitute the main goal of the approaches I have resumed here.

This way, D. Bertaux reveals us the valences *le récit de vie* acquires in the knowledge of the social world or of the social situations built in the field of interactions generated by the memorial narrative. Firstly, the French anthropologist remarks the simultaneous presence of three orders of reality [6]: *the proper socio-historical reality*, with the whole ensemble of "objective" facts; *the semantic reality*, reuniting what the subject has acquired cognitively throughout his life, the sum of the retrospective rationalization and evaluation; *the discursive reality*, which the subject formulates about his existential journey constitutes a product of a dialogue relation with one's "self" and the "other". The discursive reality takes the aspect of the *story* achieved depending on a series of *frames* (for example, the scheme of the *Saviour*, or of a *Conspiration*, supported by much more elaborated mythological structures belonging to the social imaginary. Thus, an intermediary level is interposed between the sensitive facts experienced and their telling, called by D. Bertaux the level of *subjective totalization*, a dynamic register, permanently made actual again, made up of the ensemble of mental conglomerations which the subject mobilizes in order to produce a story (memories, reflections and evaluations, perspectives, ideological elements).

But particularly, at the end of an oral history approach, the access to the understanding of the functioning mechanism of a group's memory opens to us. It represents the clarifying instance of the definitions of realities, through which we can follow the way the transfer from individual memory to the collective memory is achieved and the social identity is outlined.

Description of the research – the methodological design

Since we have made an analysis of the classical content, correlated with the application of a value scale through the matrix technique, we have covered the following research stages of the archive social documents [7]:

- 1. Choosing the research theme and establishing the material for analysis aims at catching the image of the "self" / the "other" of the Banatians. The documentary sources we have resorted to are those constituted by the Archive of the Group of Cultural Anthropology and Oral History of "The Third Europe Foundation".
- 2. The sampling permitted the selection of the most relevant and complex interviews, both in terms of their extent, therefore information, and also in terms of the intensity of the story, out of the 400 interviews

currently contained by the archive. The selection has stopped at 31 interviews, including approximately 1720 pages of transcript the manuscripts.

- 3. Choosing the units of analysis and carrying on the research: implies the operationalization of M. Rokeach's social value scale, supplemented by a content analysis [8]. Thus, a series of parallel value portraits of the population investigated may be constructed (according to different criteria: level of instruction, age-group, ethnicity etc), facilitating the access toward a multi-thematic comparative approach. The quantitative processing has constituted only the primary stage of data interpretation. Thus the main *referential criteria* of the retrospective discourse have been isolated, localized in 20 included categories which in their turn have been regrouped into 3 large thematic areas: Individual, Community / Society, Culture <see table 1>.

Table 1 Referential criteria

INDIVIDUAL	COMMUNITY / SOCIETY	CULTURE
S =„self". EmV = major events in life (birth, baptism, marriage, moving house, employment, retirement, death, burial). P = personalities (a member of the family – individualized -; friend, priest, teacher, mayor)). C = the "other" ethnic (German, Hungarian, Bulgarian, Gipsy, …); regional (Moldavian, Oltenian, Bessarabian…). Ac = „home". Căl = journey. D = destiny. EvTr = traumatic events (deportation, emigration, prison, exile). LR =reference places (village / town, district, street, public house). M = work.	Fam = „family" (as a group or as a relation with a member of the family group). CatS = social categories (peasant, clerk, craftsman, dealer, intellectual, student, officer). SfEc = economic sphere (craftsmanship, commerce). Aut = authority (army, police, security, town hall, prefect's office). CatP = political categories (communist, iron-guardist, liberal, national-peasant, social-democrat, SS-ist). DsP = political and social discriminations (exploitation, collectivisation, class struggle).	Sb = celebrations ("rugă", "chirvai", "nedee", "fărşang"). Rel = religion (church, religious practice, faith). VCt = quotidian life (entertainment, dance, ball, fashion, sport, club, evening party, performance, film, theatre, music, choir, brass band). Ed = education ("school;" and educational code, kindergarten, school with private teachers, primary / secondary / high school, university).

The referential criteria have been correlated with the three-level value categories of Rokeach's social value scale <see table 2>. The relative frequency constitutes the local influence of the variable, taking into account its orientation, and it is obtained by differentiating between the frequency of appearance of the positively orientated variable and the negatively orientated one.

The mentions of values as part of the discourse have been kept, achieving a hierarchical system, as well as a combination with the main referential criteria, aiming at the *association affinities* between the two registers (axiological / referential). We have also associated the technique of the content analysis with the expert group technique.

Table 2 The Rokeach value scale is structured on three levels, as follows:

Value categories			Values: V_i
Level			
I	II	III	
VI	F	Fo	1-5
		Fe	6-10
	R	Rd	11-15
		Ra	16-20
VF	A	Av	21-25
		Ae	26-30
	S	Se	31-35
		Sd	36-40

Note: we have the following axiological structure:

- values of maximum generality *(level I):* VI = instrumental values; VF = finality values; - *average generality values* (level II): F (faber) = action values; R = social relation values; A = affective satisfaction values; S = affective satisfaction values.	- low generality values, depending on the latent potential or manifest of the respective value *(level III):* Fo = orientative action values; Fe = effective action values; Rd = disposition relation values; Ra = active relation values; Av = self-achieved values aimed at; Ae = effective self-achievement values; Se = expected affective values; Sd = acquired affective satisfaction values.

Discussion

In explaining the articulation mechanisms of the "self" / the "other" images we have chosen an association between the quantitative and qualitative methods. In a primary interpretation of data, our attention is drawn by the predominant positive tonality of the retrospective excursus (589 mentions for the positive values and only 423 for the negative values), despite the traumatic character of the destinies evoked in most narratives. The resulted group image reveals us a pole dispute between the values of "being engaged in activity, of work" (v6), much appreciated (influence point/threshold pi>110), and those which express "suffering" (v37, pi>70), perceived as extremely present. The influence threshold 60 is also reached by other two negative values, "sabotage of the other" (v16) and "unpretentious conditions, poverty" (v21), but the total of the other value influences determines the prevailing of the positive tone discourse. The tonality of referential criteria shows us, on the superior generality level, the prevailing of the criteria centred on the "Individual", to the detriment of those focused on "Community / Society", "Culture" respectively.

At the subordinated generality level we can observe the way the nucleus of the social representation is built around the discursive anchor of "the family" with the most numerous positive references (pi>130); the only criteria which can compete with family being the "self" criterion (pi>110), and the "other" criterion (pi>100) respectively, both oriented positive, and the criterion oriented negative – predictable through its memorial charge – "traumatic events", where pi>110. If we treat these criteria distinctly, we can observe the positive projections on the "self", confirming the egocentric construction of personality in a group context, although the collective actor investigated writes his retrospective scenario in the dramatic register. The above mentioned observation confirms the research in the field of social experimental psychology, which renders evident the role of appreciative projects on the "self", with a view to acquire and preserve self-esteem (Baumeister, Tice, 1986; Higgins, 1989).

At the same time the "other" remains a strongly polarized criterion, in which the positive and negative evaluations exceed the pi>90 threshold, which suggested us the need of shading the criterion in the future stages of the research; in the present form, the criterion is not sufficiently relevant. In other words, the "other" category

is too diverse to be included in only one variable. Thus, it has been observed that a significant differentiation occurs between the "other" ethnic ("German", "Hungarian", "Jew", "Bulgarian" etc) and the "other" regional ("Oltenian", "Moldavian", "Bessarabian"), the appreciations being, surprisingly, more positive in the first case. Another differentiation is also distinguished between the generic "other" (defined in global, mediated terms) and the individual "other" (defined in specific, not mediated terms). These findings led us toward the two subsequent shadings which would be proper to apply to this referential criterion.

The less fortunate retrospective perception is achieved, predictably, around "traumatic events" and is partially compensated by the positive influence in the global portrait of valuing "work". It is interesting to note the observation according to which all the political referentials ("authority", "political categories", "political discriminations") are perceived negatively, suggesting that the whole traumatic existential line is associated with a political element appreciated as disturbing and discriminating, generating strong rejection. A last remark that should be made is that the general field of "culture", although less influent, produces a positive global tonality – the positive referential values being more numerous than the negative ones with all referential criteria. Such a remark suggests that the private space, the space of celebrations and school space, which give substance to this field, are looked upon as a kind of "refuge" space from the aggressions of history, with its public register, impersonal and institutionalised.

All previous findings strengthen the initial suppositions, according to which the historical and social dynamic significantly affects the discursive contextualization (therefore the corresponding articulation of referential criteria) of life stories.

We start the discussion on one of the resources which has a remarkable heuristic charge offered by the methodology adopted – value portraits associated with referential criteria by examining the most relevant identitary profiles which later superposed and considered in their depth, will permit to catch the global self-image of the population investigated. However, there is often a "diurnal other", serene, and a "nocturnal" one, threatening, but these two categories do not superpose. The boundary that separates them is not an ethnic one, as we supposed, but rather a regional one, as well as one imposed by the image level structuring (generic / particular). One of the most solid referential criteria – through the number of evocations and valuations – remains the "family", with a preponderant positive tonality. It is significant that the area dominated by positive values is the area of instrumental values (vi=1-20). The area in which the negative values are more present is that of finality values (vi=21-40). The message transmitted by the lines of this portrait seems to suggest that the family constitutes a knot of the social identitary representation. Such a conclusion stresses a fact ascertained by a previous field study, conducted in Belinţ, which discovered family as a "source of stability and permanence" [1], in an environment perceived as hostile, through which the community can survive the earthquakes of history.

The relative level II values reconfirm the importance conferred to *faber* values, but they regroup the self-fulfilling in another register. If *Ae* was on the second position as influence at level II, the structure of level II value categories undergo modifications, only slightly positive, giving way to relation values. Anyhow, all previous findings flagrantly contradict the ethic stereotype of the "Romanian passiveness", bringing into forefront the responsible commitment and work values.

We have realized a comparison among the finality values, which once acquired introduce the social actor in the register of "*to have*" and the instrumental values, focused on the register of "*to be*". We observe that the continuous presence of work and of assuming one's destiny – represented by the territory of "to be" – is more extensive than the territory which places the subject in the register of "to have", stressing an important reconstruction of the existential paradigm for those confronted with a threatening and unsettled history. Quite often in the retrospective discourse, the memory becomes a support for the rehabilitation of the identitary type, and the recovery takes place rather symbolically and, in any case, in another dimension. Several subjects affirmed in an unburdening refrain, even if "we have lost everything" – goods, houses, lands, a life's acquisition, "our children achieved themselves", becoming over years doctors, engineers, professors. Thus, the dispossession in the register of "to be", suggests a change of the orientation frame of the identitary nucleus, which is now valued through another attitude and value opening. The analysis of the relative level I values presents us an overwhelming prevalence of the instrumental values, stressing the previous finding according to which the pressures of history do not determine only a weak retort of its subjects but also an engaging and responsible one, which rather hypostatises the struggle with history and destiny, than their passive and inert acceptance. Thus, the vocation of communities to mobilize real identitary strategies when confronting with an unfavourable social context is reconfirmed [9], precisely to confer coherence to its own existential line and to master the contextual determinations, activating communitarian resilience [10]. We are stressing that in the extenso form of the research we can also follow the articulations of the "other" image through the portraits of each ethnic group or regional identity, and we can examine the construction of the diachronic identitary dimension by revealing the contrast between the accomplished "Banat of yesterday" and "the Banat of today" perceived as disappointing [1].

Conclusions regarding self narrative strategies in traumatically events

Starting with an initial intuition, offered by the construction of a field in Belinţ village in 1996-1997, on the traces of the Banat-Crişana Social Institute team of the 1930s, and achieving a comparative analysis of the two researches, we can render evident an unexpected constancy of social attitudes confronted by the main communitarian and institutionalised instances (from the same pattern of the distribution of authority within the family, to the same reference type of the "institutional other": priest, mayor, clerk), even if the composition of the community has been changed throughout all these decades. Similar social conduits suggest the presence of a mental matrix which has not modified its dominants concerning its defining features. Therefore we have tried to direct our analysis to the territory of Banat, regarded as a collective character, which has preserved its profound mentality to a *longue durée* in the confrontation with the waves of history of this cultural area, which has succeeded in transgressing all the conjunctural cleavages.

The complexity of such a territory of investigation imposes an adequate methodology as well. We have chosen the study, through content analysis, of a sample from the Archive of the Cultural Anthropology and Oral History Group, being aware that we will be able to catch only *a tendentious portrait*. We have localized three large thematic registers, centred on the individual, community-society and culture, which in their turn are grouped around the "self", around the images of "home", the "other", "family", celebrations", "traumatic events" "political discriminations" and so on. At the same time, we have applied a multilevel value scale to such a discursive thematic destructuring, which differentiates between the instrumental and the finality values. From the retrospective discourses, in the thematic area of the "individual", the "self" constructs itself a positive identity, confirming the theories of the social identity, which argue the decisive role of self-respect in the interpersonal balance and the seeking of a positive social identity within the affiliation group [11]. Such a strategy is mainly achieved by out-group differentiation, the "other" oscillating between the radical alterity ("it is another world") and total similarity ("they are like us"). Along the discourses, the profile of a *traumatic identity* is born, which finds its refuge in the nucleus of the family. The "family" appears most frequently mentioned in discourses, reuniting, at the same time, most of the positive valuations of all the referential criteria, facing a contorted history, but over which is capable of projecting a serene light resulting from a superior retrospective understanding which acquires a new meaning. The *self-narrative* evoked by K. Gergen [5] is outlined, conferring coherence to the past and teaching the social actor to look upon the existential drama serenely and to heal through words, as well.

At the level of social representation of the memorial identity, the "family" references are imposed in a symbolic confrontation with categories associated with "trauma". Thus, the narrative anchors related to "family" become the most influent categories of memorial discourses, representing the core of self-identification in biographical overview. As for the value scale, out of over 2700 axiological references, we can distinguish the predominance of the values which would integrate in the register of "to be", to the detriment of the "to have" values. Even if "destiny", as well as "history", have deprived the discursive actors of wealth, stability, social position, but all the existential breakings and all the discriminations they have lived are but the motives of a superior understanding of life, of the lasting and authentic friendships acquired, of the special achievements of their children, therefore, of certain acquisitions in the register of "to be", which prove stronger than the misfortunes of fate.

Abstract

Resilience is a process shaped by the interaction of risk and protective factors operating across the different layers of child's social ecology. This paper examines the overall adjustment of 159 Syrian refugees children, living in collective shelters in different area of Lebanon, through investigating the variety of multi-layered stressors and protective processes impacting their mental health, from individual characteristics to environmental mediators. The sample is divided into 4 groups according to the region where they are located: Akkar, the Bekka, Mount Lebanon and Beirut. The methodology employed combines qualitative and quantitative measures. Symptoms of child post-traumatic stress disorder and co-morbidity and psychosocial functioning, are collected through self report scales for children, parents and social workers, validated in Arabic language. Resilience measure includes items based on key actors perceptions of children needs and main resources. Specific drawing tools are employed in order to take into account children's own perception of risk and protective factors in their life. Results enable to define good practices of "assisted resilience", in orienting and optimising NGO psycho-social interventions with refugees children, families and community. In particular the awareness of protective process, allow practitioners to identify the main resources which can be improved and reinforced through psycho-social interventions. Risk factors lead to define criteria for detecting and monitoring more vulnerable cases.

Keywords: Resilience, PTSD, Children, War, Refugees.

Introduction

Since the beginning of the civil war in Syria in March 2011, nearly 2.5 million people were forced to be displaced [1]. Lebanon has welcomed more than 900.000 Syrian refugees (36% of all Syrian refugees) [2], [3]. Shelter is a serious problem for this large population and more refugees are gathering in informal settlements like camps which present extremely critical life conditions [3], [4]. These conditions accrue the deep sufferance caused by the traumatic experiences of war, violence and forced displacement.

War experience can generate a variety of psychological and psychiatric consequences, which could range from adaptive responses to diagnosable psychiatric disorders [5]. Researches on mental health of youth victim of war and displacement have revealed a high presence of post traumatic stress disorder [6], [7], [8], [9], [10], [11], [12].

Resilience is the capacity of a dynamic system to recover from traumatic experiences which threaten its development [13]. It is shaped by the interaction of risk and protective factors operating across the various ecological systems of child's social ecology [14]. Risk factors, lead to increased likelihood of maladaptation. Protective factors are predictors of lower levels of psychological symptoms [15].

In the last three decades resilience paradigm has been guiding research and practice focused on mental health of children victims of armed conflict and displacement aimed at understanding and improving the adaptation of children victims of extreme adversities [15].

Intelligence, self regulations skills, meaning and hope in life, agency, religious beliefs that finds meaning in suffering, adaptability, temperament and self-esteem appear to be the main individual protective factors [13], [15], [7], [16], [17].

Family cohesion, support and communication, secure trust, strong bond between the primary caregiver and the child, child's trust in their parent's abilities to protect them against danger, parental psychological health and parent's educational level result key family protective factors [13].

Community support, particularly available in peers networks and in school, are considered vital environmental protective factor for individuals [5], [15], [18], [19].

The main risk factors detected in children victims of war and displacement are the number of traumatic experiences before arrival in the new countries and stressful events after arrival [6], [20]. Recent war exposure, being a victim or witnessing violent acts, being exposed to violent shelling or combat, personal life threat and life threat to loved ones, deaths of family member, being separated from parents and forced displacement emerged as the most traumatic experiences [21], [22], [23], [24], [25].

Stakeholders are particularly concerned with the impact of extreme adversities in children [13]. Risk and protective factors can become targets of intervention [19]. In this perspective, intervention research is designed by both field and research experts, with the goal of exploring capacities, at individual, family and community level, that allows to foster resilience in young victims.

Important recommendations emerged from studies in this field. Researchers suggest a better interaction between qualitative and quantitative methodology to reinforce the selection and adaption of resilience predictors and outcomes [15].

Secondly they affirm that in child adaption process analyses it is important to refer to different developmental domains, such as psychopathology and psycho-social wellbeing [13], [26], [27].

Furthermore, the importance of providing input from multiple informants has been stated [13], in order to pursuit an "ecologically informed study of children's adaptation following trauma" [28]

Last recommendation concerns the importance of assuming child perspective, which should be distinguished and integrated with the adult's one [29], [30], [31].

"Above all, we need to listen to children. They can tell us better than any professional expert what war does to the human spirit. They have witnessed it, close up and defenceless. They have learned, as I did, that war is not good for children" [19].

Drawing represents an important media that allows children to express feelings and perception of their own internal world. A study on narration and drawings of Lebanese refugee children, victims of war, state that the origin of their own trauma wasn't the war itself. The traumatic experience was the disruption of what they call "collective envelope", which is "temporality", in terms of past memory and future projection, and cultural and symbolic references. Significant life spaces, such as the child's home, and the human affective environment, which has been forming his social context, got lost due to migration. At the same time, new places couldn't be invested by the children, who felt therefore stranger to the new context and depredated of a part of Self identity [32].

Methodology

1.1 Objective

This study is aimed at identifying significant risk and protective factors, that shape the overall adjustment in Syrian children victims of war and displacement living in collective shelters in different area of Lebanon.

1.2 Sample

The sample is composed by 4 groups of Syrian refugees children, hosted in: two tented settlements in the Bekka region, in Zahle (Fayda Afandi camp) and in Taanail (Ssou camp); a group of collective shelters in the town of Bebnine; homes located in Zaatrieh, a dangerous town run by drugs lords and arms dealers.

In the following tables the main characteristics of the sample are illustrated.

TABLE N° 1
DISTRIBUTION OF SAMPLE ON KEY DEMOGRAPHIC VARIABLES

Variables	%	Variables	%
Gender		**City of provenances**	
Boy	44,9	Idlb	13,3
Girls	55,1	Halab	25,9
Age		Cham	19,0
(X = 10,7 years)		Homs	30,4
7 years	0,6	Raqqa	6,3
8 years	17,1	Damascus	5,1
9 years	12,7	**City of residence**	
10 years	15,8	Zhale	13,3
11 years	13,3	Bebnine	59,5
12 years	19,6	Taanail	15,8
13 years	8,9	Zaaiterieh	11,4
14 years	11,4	**Type of dwelling**	
16 years	0,6	tented settlements	29,1
		Shelter	59,5
		House	11,4

1.3 Measures

The methodology employed combines qualitative and quantitative measures.

Symptoms of child post-traumatic stress disorder and co-morbidity are assessed through the Arabic version of the Post Traumatic Stress Reaction Checklist - Child version [33]. It presents three subscales, which correspond to the three main cluster of the PTSD in the DSM IV [34] Re-experiencing, Hyperarousal and Avoidance. The questionnaire is administrated together with the Child War Trauma Questionnaire [35], which assess children's exposure to war trauma. Both measures are child self-report.

Psychosocial functioning is measured through the Strengths and Difficulties Questionnaires (SDQ) [36], validated in Arabic language [37], [38]. It presents 5 subscales: Conduct problems; Inattention-hyperactivity; Emotional symptoms; Peer problems; Pro-social behaviours. It was completed by parents.

Resilience was assessed through the Child and Youth Resilience Measure-28 items (CYRM-28) [39], expressly translated in Arabic by the Lebanese team of research. The instrument's subscales are divided into individual resources, which includes individual personal skills, individual peer support, individual social skills; Care giver resources, composed by Physical Care giving and Psychological Care giving; Context resources divided into Spiritual, Educational and Cultural.

Socio-demographic characteristics concerning the child were collected.

Specific drawing ateliers, edited by the Team of the Resilience Research Unit of the Catholic University of Milan, have been employed in order to explore children's own perception of:

- the main risk and protective factors in their life (Under the Rain) [40]
- significant internal and external resources (The Self Bag) [41]
- the adaptation process to the new Lebanese reality in terms of significant places which the child has invested in Syria and in Lebanon (The Cardinals Points) [42] and in terms of what they felt they have left in Syria and what they have taken to Lebanon (My marks on the Earth) [43]
- past and life history in terms of positive and negative memories (Time line) [44]
- capability of projecting himself in the future (The wishes Chest) [45]

The drawings activities have been coded through ex post content analysis, which leads to a classification of units of analysis into a set of categories [46], [47]. Specific domains of study of resilience research oriented the definition of categories [48]. Criteria of exhaustivity, mutual exclusivity and homogeneity have been followed in defining categories. In order to ensure objectivity, different researchers have been included in the codify phase [49].

1.4 Procedure

The field workers team was composed by 2 psychologists from Himaya NGO. Sample families has been recruited for the study through local NGO, tribal leaders and directly during researchers visit to the settlements. Informed consent has been signed by parents.

The children were divided into groups, of approximately 20 subjects, following similar age criteria, guided by one researcher. The instruments have been administered through 6 2h30 hours sessions. The setting varied depending on the locations: in Zahle and Taanail in opens spaces of the camps, in Bebnine in the courtyard of the municipality, and in Zaaiterieh in the community centre "Voix de la femme".

Results

Results are organized in two parts. In the first one, we will explore the relations between the single scales of the four instruments described above: CWTQ [35]; PTSRC [33]; SDQ [34] and CYRM-28 [39]. In the second part, we will explore whether children who expressed specific contents in drawings ateliers, differed in scales measure comparing to the ones who didn't express them.

1.1 Relations inside the scales

CWTQ correlates positively with the three scales of the PTSRC: Re-experience .350 (p=.000); Avoidance .295 (p=000); Hyperarousal .326 (p=.000). It indicates, as hypothesized, that the Post Traumatic Stress Disorder is due, at least partly, to the frequency of negative war experiences. This scale correlates weakly with the scale Behavioural problems of the SDQ (,170; p=.033).

PTSR is related also with the scales Emotional symptoms (Experience .354, p=.000; Avoidance .251, p=002; Hyperarousal .276, p=.000) and Behavioural problems (Avoidance .158, p=048; Hyperarousal .221, p=.008) of the SDQ and negatively with the scale Contest Educational, the importance to study in our life (Avoidance -.267, p=001; Hyperarousal -.161, p=.045). No relations were found between CYRM and both SDQ and CWTQ.

1.2 Relations between the scales and the categories of drawings, memories or wishes differed

1.2.1 CWTQ

T-Student statistic has been used to estimate the significativity of the difference between subjects who express or not specific contents on each scales of the four instruments. The principals significant differences will be reported.

CWTQ Scale has a range between 0 and 1. In the following table we report the main results obtained by relating drawing categories with CWTQ scale. Children who indicated bad memories of grief and armed conflict and the ones who expressed the future wish of their family recover and well-being reported higher exposure to war trauma. While desires concerning future educational pathway were more frequent in children with less exposure to traumatic experience.

Table n° 2 Means comparison between children who express or not specific categories on cwtq

CWTQ	Atelier	Categories	Subcategories	Presence mean	Absences mean	Mean difference	Sig. (2-tailed)
Exposure to war traumas	Time line	Bad memories	Grief	,36	,25	,11	0,40
			Armed conflict	31	18	,13	0,00
	Cardinal points	Host. Country	Community centre	17	28	-,11	,009
	Wishes chest	Self	Education	20	28	-,79	,045
		Relation	Original Family	35	25	,10	,029

1.2.2 PTSRC

PTSRC Scale has a range between 0 and 1. In the following table we report the main results obtained by relating drawing categories with PTSRC subscales.

Children who expressed bad memories of grief and armed conflict had higher rates of the PTSD symptoms. While lower PTSD symptoms were typical of children who indicated self disappointment experiences as bad memories and community events as positive memories.

Children who reported as risk factors war and violence experiences, but no negative perception of current environment, presented higher symptomathology of PTSD in the three clusters.

The indication of school and places of worship in native country as significant places in child's life was typical of children with higher level of PTSD symptoms. While school, home and community centre in the host country appeared as significant places in the drawings of children with less PTSD sufferance.

Children with wishes concerning their own educational pathway showed lower level of PTSD, while the ones indicating wishes on their original family recovery and wellbeing reported higher PSTD complete symtpomathology.

Table n° 3 Means comparison between children who express or not specific categories on ptsrc

PTSRC	Atelier	Categories	Subcategories	Presence mean	Absences mean	Mean difference	Sig. (2-tailed)
Re-experiencing	Time line	Bad memories	Grief	60	43	,17	,031
			Armed conflict	52	31	,21	,001
			Self disappointment	34	49	,16	,017

1.2.3 CYRM

CYRM Scale has a range between 1 and 5. In the following table we report the main results obtained by relating drawing categories with CYRM subscales.

Children indicating grief negative experience presented less individual, family and context resources; armed conflict experience was reported by children with less physical care giving support and less educational resource.

Children recognizing their past and present environment as risk factors presented more individual, family and context resources. Children reporting their own house, school and community centre in Lebanon as significant places showed higher resources in the three levels. While those who indicate Syrian urban points as significant places reported lower level of individual resources.

Wishes concerning future education pathway were associated with higher family resources.

Table n° 4 Means comparison between children who express or not specific categories on crym

CRYM	Atelier	Categories	Subcategories	Presence mean	Absences mean	Mean difference	Sig. (2-tailed)

1.2.4 SDQ

SDQ Scale has a range between 0 and 2. In the following table we report the main results obtained by relating drawing categories with SDQ subscales.

Armed conflict experience was reported by children with lower level of pro-social behavior, and grief experience by the ones with higher peer relations problems.

Community as protective factors was frequent in children with higher level of pro-social behavior and with less behavioral problems and less difficulties in peer relations. Even school and beliefs or faith reported as protective factors was associated with less problematic peers relations and less hyperactivity.

Children who recognized their home, school and community centre as significant places show less behavioral problems and less emotional symptoms.

Future wishes linked to educational pathway were associated with lower emotional problems, while the ones concerning original families recover and well-being were typical of children with emotional problems.

Table n° 5 means comparison between children who express or not specific categories on sdq

SDQ	Atelier	Categories	Subcategories	Presence mean	Absences mean	Mean difference	Sig. (2-tailed)

Discussion

The strong relation between war-related experiences and Post Traumatic Stress Disorder symptoms show the relevance of the traumatic experience reported in the CWTQ. The correlation between Post Traumatic Stress Disorder and child psycho-social functioning, is consistent with the clinical description of traumatic symptomathology in children. The weak relations between resilience measures, war-related experiences and social functioning appears in contrast with the definition of resilience as positive outcome despite adversities.

Grief and armed conflict appear to be the main traumatic experiences as it correlates positively with symptomathology and negatively with resilience subscales. This results is coherent with the main risk factors illustrated by the literature [21], [22], [23], [24], [25]. The lower symptoms reported by children who indicated self disappointment experiences as bad memory can be due to one of the main peculiarity of traumatic experiences: they overwhelm the person, and induce the feeling of helplessness and hopelessness. Self-disappointment experiences are due to self failures; therefore controlled by the individual.

The second peculiarity of child war trauma that emerges through drawings ateliers is the disruption of his "collective envelope",[32] and the consequent chaos of space-time dimensions. Significant life spaces of past reality represent still an important reference for the child, but they got lost due to migration and new places of present reality cannot be invested. The traumatic overinvestment in past reality emerged in the perception of different sites in native country as significant places, which appearesd frequent in children with higher PTSD symptomathology and lower level of individual resources. While the recognition of school, home and community centre in the host country as significant places is typical of children with lower PTSD sufferance, less behavioral problems and less emotional symptoms.

Children who reported as risk factors war and violence experiences, but no negative perception of current environment, beside the several difficulties they are facing in the settlements, presented higher symptomathology of PTSD in the three clusters. The reason can be that traumatic events fixation doesn't allow the child to detach from the memory of the event and to move on with the present reality. Findings on the positive adaptation of children who reported community, school and beliefs as protective factors are coherent with the literature [5], [7], [15], [16], [18], [26], [32].

Presenting future wishes concerning personal educational pathway may show the child capability of projecting himself in the future, where he will grow up and develop and therefore it's frequent in children with less war exposure, lower level of PTSD symptomatology, resilient skills and less emotional problems. The high prevalence of psychological sufferance in children who reported future wishes of the original family recovery

and wellbeing may indicate that they are still focused on reparation process from the impact of traumatic experiences which they still feel very present.

Conclusion

This study presents typical limits of researches on extreme adversities, such as difficult availability of assessment tools suitable to the culture and situation, chaotic and hazardous settings due to the physical and political conditions, absence of pre-disaster baseline data, difficulties of engaging comparison groups and the lack of funds on this field [13]. And a very high rate of illiteracy among the children.

But at the same time results appear to have implications for interventions aimed at protecting children, mitigating risks and promoting resilience. It's important to be aware of the type of experiences lived by the child and to monitor the ones who has been exposed to high level of violence and grief.

Restoring a sense of agency in child and supporting his investment in the present reality, starting from the everyday concrete places, such as personal settlement, school and community centre are fundamental protective factor. Finally future project and wishes concerning the child are important protective factors, which should be supported. Community, school and personal beliefs play a central role in the resilient process.

Resilience throughout life: the narrative of a senior missionary kidnapped by renamo

Gonçalves M.

Instituto Universitário de Lisboa (ISCTE-IUL), Cis-IUL, Lisboa (PORTUGAL)
marta.goncalves@iscte.pt

Abstract

Active ageing is the process of allowing individuals to continue participating in social, economic, cultural, spiritual and civic issues independently of their age. Missionaries are members of a religious group sent to an area to do evangelism or other service ministries like education, literacy, social justice, health care and economic development. Based on a program we are experimenting in Portugal in order to develop individual active aging plans for missionaries who return from mission in retirement age, we will present a case study of a senior priest kidnapped by Renamo during his mission in Mozambique, Africa. Renamo (the Mozambican National Resistance) is a conservative political party in Mozambique, founded in 1975 following Mozambique's independence as an anti-communist political organisation, that fought against the FRELIMO in the Mozambican Civil War of 1980 and against the ZANU movement. We conducted 24 face to face sessions with this missionary, during which among others the priest wrote his life narrative. This narrative was subject of an analysis exploring stressors and resources. Being resilience the long-term capacity of a system to deal with change and continue to adapt and develop within critical thresholds, this case study brings an interesting insight to the actual uncertainty being again lived in Mozambique with several kidnappings.

Keywords: active ageing plan, missionaires, kidnapping, life narrative, stressors and ressources, case study

Introduction

Throughout life the human influences and is influenced by the environment. These influences and choices contribute to the quality of life at retirement age. Active ageing is the process of allowing individuals to participate in social, economic, cultural, spiritual and civic issues independently of their age [1]. The Model of Active Ageing presented by WHO [1] is influenced by several factors: personal (biological), behavioral (healthy lifestyles and active participation in the care of own health), economic policy (access to income and social protection), physical environment (safe neighborhood, safe food), social order (adequate social support, education) and social and health services (focusing on health promotion and prevention). This approach recognizes the importance of human rights of older people and the principles of independence, participation, dignity, care and self-actualization and encourages the responsibility of older persons in the exercise of participation in various aspects of their daily lives, based on health, security and social participation.

Missionaries are members of a religious group sent to an area to do evangelism or other service ministries like education, literacy, social justice, health care and economic development. To be a missionary implies having good interpersonal relationships, adaptability to other cultures and emotional stability [2]. Navarra & James [3] founded in a study with 76 missionaires that missionary acculturation follows a similar stress/coping model as other sojourner groups, though that religious orientations differentially predict perceived stress. When missionaires achieve a senior age, usually 30/40 years being abroad, they go back to their home country due usually to their health condition. When back, they see a different country from which they left, and they don't understand their actual role. Some show decreased mobility, others lack of motivation of continuing active.

As life narratives help seniors assign meaning to past action and events, sharing their knowlege with younger generations, this study aims to understand resilience throughout a life narrative of a senior missionary, identifying in each life stage stressors and ressources [4, 5, 6]. Based on a program we are experimenting in Portugal in order to develop individual active aging plans for missionaries who return from mission in retirement age, we will present a case study of a senior priest kidnapped by Renamo during his mission in Mozambique, Africa. Renamo, the Mozambican National Resistance, is a conservative political party in Mozambique, founded in 1975 following Mozambique's independence as an anti-communist political organisation, that fought against the FRELIMO in the Mozambican Civil War of 1980 and against the ZANU movement.

Methodology

We conducted 24 face to face sessions with this missionary, during which among others the priest wrote his life narrative. In session one an individual program was discussed and an agreement celebrated. Each session consisted of a one hour weekly meeting during which the psychologist read what the missionary wrote with pencil and paper, asked for more details and worked together age related doubts and anxieties as memory stimulation. The life narrative was subject of a content analysis exploring stressors and resources.

Results

The life narrative can be divided into 5 periods: 1. Childhood, 2. Adolescence, 3. Seminar in Portugal, 4. Studies in Rome, 5 Misison in Mozambique.

During childhood the main stressor we can find in the life narrative of this missionary is a punishment due to his bad behavior at school together with his classmates. As main childhood ressources we identify the priester invitation to the missionary to become his assistant at the church and his mother verbal approval after his decision to become a missionary. Now as senior, the missionary explains remembering these childhood moments that *"time eassembled everything in its place"* and that until today nothing could pull him from the road of being a missionary.

During adolescence the main stressor we can find in the life narrative of this missionary is the feeling that something was missing. As main adolescence ressources we identify the priester multiple iniciatives, including the invitation to visit two seminars. Now as senior, the missionary explains remembering these adolescence moments that thanks God every five years he can change his life and that Priester's words helped him overcome difficulties and uncertainties.

During the seminar in Portugal the main stressor we can find in the life narrative of this missionary is the fall from a tree and lost conscience. As main ressource during seminar in Portugal we identify the relationship with God. Now as senior, the missionary explains remembering these moments at the seminar in Portugal that it was the time he learned "*that a disease is for each of us a very important life moment as we are visibly more dependent of God with our most vivid hope waking up our faith"*.

During the studies in Rome we can find four stressors in the life narrative of this missionary: bad behavior in school room, difficult times due to Concil Vatican II, bike accident and bike theft. As main ressource during studies in Rome we identify the presence of his class mates. Now as senior, the missionary explains remembering these moments of studies in Rome that *"after all God does as He wants even after we have submitted plans for how we think about doing. It is a very useful teaching for each of us"*.

During the mission in Mozambique the main stressor we can find in the life narrative of this missionary is his kidnapping by RENAMO. As main ressource during the mission in Mozambique we identify his job prior to the kidnapping - the creation of 44 communities and the respective leaders for each of them. Now as senior, the missionary explains remembering the kidnapping by RENAMO in Mozambique that at first we was afraid to dye but said "*Be what God wants"*. Though at the end he recognized the deep relationship of friendship between them and the military.

Table 1.: Stressors, Ressources and Resilience at each life narrative stage

Life Stage	Stressors	Ressources	Resilience
1. Childhood	school punishment due to behavior	Priester invitation to become his assistant mother's approval to become missionary	*"time eassembled everything in its place"* *"I got enthusiastic for this great ideal and until today nothing could pull me from this road"*
2. Adolescence	feeling that something was missing	Priester invitation to visit 2 Seminars priester multiple iniciatives	*"I thank God because in my life until today every five years I could change my life"* *"There were Priester's words that helped me overcome difficulties and uncertainties of the way"*
3. Seminar in Portugal	fall from a tree and lost conscience	relationship with God	*"It was also a special day where I learned that a disease is for each of us a very important life moment as we are visibly more dependent of God with our most vivid hope waking up our faith"*
4. Studies in Rome	bad behavior in school room difficult times due to Concil Vatican II bike accident bike theft	school mates	*"After all God does as He wants even after we have submitted plans for how we think about doing. It is a very useful teaching for each of us"*
5. Mission in Mozambique	Renamo kidnapping	prior great job: creation of 44 communities and leaders for each of them	*"We said: Be what God wants...In that moment I thought it was my last life moment...To conclude I would say that the sacrifice that we did together - missionarires and our friends the RENAMO military, generated deep friendship, the one that is not easy to separate from us. It was therefore difficult for each of us when it came the goodbye hour"*

Conclusions

The main aim of this study was to understand resilience throughout a life narrative of a senior missionary, identifying in each life stage stressors and ressources. The content analysis of the life narrative shows us that ressources are in all five life stages persons: priester, mother, God, class mates, communities/leaders. Stressors are therefore punishments, accidents and missings. Resilience is for this missionary related with time, ideal/road, change, words and faith/dependency of God. Being resilience the long-term capacity of a system to deal with change and continue to adapt and develop within critical thresholds, this case study brings an interesting insight to the actual uncertainty being again lived in Mozambique with several kidnappings.

Abstract

Studies of resilience in war-torn countries such as Uganda, Congo and Mozambique have broadened the field of resilience research [1, 2, 3, 4]. However "significant gaps in our knowledge about effective responses and factors associated with resilient outcomes and resilient trajectories" in these contexts prevail [5].

In 2013 ethnographic fieldwork was carried out among former child soldiers and ex-combatants from the rebel army The Lord's Resistance Army (LRA) in Northern Uganda, Acholiland to explore coping strategies, demobilization and resilience in a context of severe adversity. The LRA is known for methods of brutal torture and use of child soldiers in their war against the Ugandan government using similar means. This paper rests on in-depth descriptions and emic notions of individual ex-combatant's responses to such adversity. The responses associated with resilient trajectories and outcomes call for re-conceptualizations of resilience: In Acholiland `dissociation´, `avoidance´, and `silence´ and in some cases `appetitive aggression´ [6] seem key in resilient responses and coping. Thus resilience must be studied in a variety of contexts, based on what we know from resilience research [7, 8] but integrated with a culturally sensitive and individual differences perspective approach [9]. Not doing so puts the subjects we study at risk of being placed in confining categories of pathology, which in return puts scholars at risk of missing the opportunity to broaden and deepen our understanding of resilience.

Keywords: Resilience, dissociation, coping, ex-combatants, child soldiers, Northern Uganda.

Introduction

The paper derives from a study on resilience and coping strategies among former child soldiers (below 18 when abducted) and ex-combatants (above 18 when abducted or volunteering) from The Lords Resistance Army, originating from Acholiland, Northern Uganda.

The PhD is a qualitative study using ethnographic fieldwork methods such as participant observation and reflection [10], repetitive narrative life story interviews, semi-structured interviews as well as resilience scales and questionnaires assessing relevant protective factors such as perceived social support, locus of control and life orientation [11, 8, 12]. In some cases, where additional consent had been obtained, video recordings inspired by "A day in a life method" [13] were carried out when the researcher and the female or male interviewee found it appropriate. This paper however will only make use of the data obtained during participant observation and reflection, interviews and videos. (*N: 36.* Females: 18 Age 16 – 38. Males: 18 Age 19 – 39)

When constructs and categories do not capture what is on the ground

As explained in various articles resilience research originated from developmental studies of children growing up in chronically adverse environments [8, 14]. Since then the field has included studies of resilience as responses to singular traumatic events – in a recent paper referred to as `minimal-impact resilience´, which is

different from `emergent resilience´; indicating the chronicity of adversity to which resilient responses might emerge [14].

A gap in the literature [15] thus exist on research in populations where chronic adversity has become long-lasting, affecting children and adults throughout their lifespan, and where the adversity is defined by both re-occurring acute stressors such as attacks or violent conflicts in a region, as well as chronic adversity in the form of poverty and political turmoil. This study was conducted in such a context in Acholiland, Northern Uganda.

Our study of resilience among former child soldiers and ex-combatants from a context still struggling in its aftermath of war, has taken an explorative approach to identifying and defining what seems to be resilient coping in this context, precisely because the measurement tools and findings in resilience research at hand so far did not seem to adequately apply in this context of cumulative trauma and somewhat extreme adverse circumstances - and in some cases the data called for arguing against consensuses in trauma and resilience literature.

As a result we suggest a framework for identifying resilient coping strategies and resilient coping, which takes departure in the situated living conditions and culture asking: *What are the conditions for corresponding to established notions of resilience in this particular context?* Arguing that in some contexts, trauma is so severe and cumulative, and uncertainty in the forms of poverty and political instability is so prevalent, that conditions are too un-ordinary to make use of consensual and categorical trauma related disorders [15, 16] and resilience constructs arrived at in contexts far from the one represented in this study.

Along these lines our approach to researching resilience is particularly inspired by Bonanno and Burton [9] as well as Barber [15]. We aspire to their requests to pay increased attention to individual differences and providing detailed accounts of context. Bonanno and Mancini [7] in a groundbreaking article about ways forward in trauma and resilience research and beyond, critique traditional trauma theory for failing to grasp the full range of adjustment in the aftermath of potentially traumatizing events, and Bonanno and various co-writers in numerous articles describe studies (Mancini, Bonanno, & Clark, 2009, Curran & Hussong, 2003, Jung & Wickrama 2008, Múthen & Muthén, 2004 are referenced), which have "dramatically underscored the natural heterogeneity of human stress responding" [7 p. 76]. An additional important point set forth in the article is that studies of the latent structure of PTSD symptoms using taxometric analyses have consistently supported a dimensional rather than a categorical structure (Bonanno & Mancini 2012 referencing Broman-Fulks et al 2006, Ruscio, Ruscio & Keane, 2002). Thus: *"PTSD is best understood as a continuous dimension ranging from mild to severe trauma rather than as a discrete clinical category; thus, any diagnostic cutpoint we might use will to some extent be arbitrary."* [7, p. 75]. The fieldwork in which this paper has its foundation supports these findings and analyses.

Due to the context and population of this study, still rather uncommon in the resilience literature, our framework is eclectic and moves across approaches and paradigms in order to collect the most useful and applicable findings in the field of resilience research (O´Dougherty Wright, Masten & Narayan 2013, Masten 2011, Bonanno and Burton 2013, Bonanno and Dominich 2013, Betancourt and Williams 2009, Betancourt and Kahn 2008, Ungar and Liebenberg 2009, Carrey and Ungar 2007 to mention a few) to support our analyses of coping strategies and definitions of resilience as they emerged during the fieldwork among the female and male former child soldiers and ex-combatants in Acholiland.

We are greatly inspired by Klasen's term "posttraumatic resilience" [3] when defining resilience. Klasen et al research resilience in children (11-17) from Northern Uganda whom are former child Soldiers. Our study population is 16-41 years of age, with the vast majority above 18. The study is looking for detailed accounts of individual coping strategies rather than patterns across the study population. Thus our data calls for new conceptualizations and putting words and concepts to findings, we have not come across elsewhere in the resilience and trauma literature so far. Finally we focus on coping strategies, i.e. responses to the past cumulative PTE´s and present seemingly chronic adversity, which among other things characterize the Acholi context[1]. This has brought about the term "resilient coping". Our focus on coping strategies means that we empirically explore resilience by observing, inquiring about and co-reflecting with informants on mental and behavioral responses to adversity, with the goal of identifying what seem to be resilient responses. In other words; coping strategies are perceived as resilient if they entail relatively desirable and constructive outcomes in a challenging context with a study population with a severely challenging past. This means we consider and research both resilient processes (coping strategies) as well as resilient outcomes: By resilient coping we mean the outcome of the coping strategies which former child soldiers and ex-combatants more or less consciously and voluntarily engaged/engage in - and how these coping strategies have influenced/influence past, present and potentialities of the future for instance in terms of vicinity of resources (out of reach, moving closer or still out of hand?), mental states, self-efficacy, own evaluations of life quality, quality of social relationships. All of these factors, we stress,

[1] We favour Barber´s emphasis on contextualising resilience research. Publications in progress will provide lengthy accounts of the Acholi context; unfornuately it is beyond the scope of this congress paper to provide such.

are always influenced by situational and environmental cues such as political stability, climate, and states of poverty (see section 5 for elaboration).

Outline

The paper will present six markers we argue are crucial to paying attention to when researching resilience and if evaluating the resilience in responses to traumatic stress. The markers and the additional 5 criteria we use to define resilient coping are empirically based, but informed by existing literature on trauma and resilience research, as well as the gaps in the same literature we find essential to contribute to filling with empirically based knowledge. Due to the fact that 34 out of 36 informants were not part of any organization or NGO, which would address past trauma and facilitate interventions as part of a healing process; the data for the most part concerns mental coping strategies in general with dissociation, avoidance and silence as particular prevalent responses. This paper will conceptualize dissociation from diverging academic fields, to inform the empirical data and promote analysis of how dissociation, avoidance and silence in an Acholi context seem essential parts of resilient coping.

Relativity and traumatization: 6 markers that matter and complicate

Traumatization and resilient coping co-exist in Acholiland, and, we suggest, in many other contexts too. We are aware that the *experience* of how detrimental adversity or potentially traumatic events is to your functioning, to your system and life is relative and thus it does not take a context of war or extreme adversity like Acholiland to argue for a critical reflection in application of standardized measurement scales of resilience and adversity. What is extreme is relative too as is what is traumatizing and to what extent disturbances in functioning are disturbing enough to be viewed as pathology. Based on fieldwork data from Acholiland and findings in trauma and resilience literature [17, 18, 15, 13], we argue that how much a traumatic event affects you depend on

1. The prevalence of trauma in the surroundings society (family and societal context) of the person studied.
2. Occurrence of trauma (what type of trauma/number of PTE´s) in the individual person's life.
3. How emotionally sensitive the person is
4. How much support the person has and what kind of support

This also relates to cultural notions of suffering, coping and how to cope/heal/recover:

1. How much and how one is supposed to display emotional reactions to suffering, reflect on, talk about and share about pain and suffering (i.e. what is acceptable behaviour in a specific context? What can be talked about? What is taboo? Is rape? Is killing?)
2. What financial and social resources are available? If everyday life consists of either surroundings of privilege in a highly effective performance society, or a less privileged society equally busy with managing to meet primary needs and ensure survival - this influences what possibilities, social scripts, time available and resources one has to engage in ones coping process.

Clearly all these factors play a pivotal part in a dynamic complexity, which human beings exposed to adversity navigate more or less constructively and successfully. What is considered constructive and successful will vary too in relation to what cultural and socio-economic context is in focus, as well as the cultural and socio-economic context of the researcher influence what is noticed and how. In short; critical awareness of the ambiguity and shortcomings of resilience constructs and categorical diagnostic terms when describing and analysing responses to trauma in any given context is essential.

Five criteria for defining "Resilient coping"

With the stories and admirable struggles of Acholi females and males in mind, we propose 5 criteria for defining resilient coping, which we realize are not measurable, but none-the-less can serve as a guiding tool when exploring resilience in a context of cumulative PTE´s and chronic adversity. We have chosen to call them abilities, referring to "being able to". This connotes and promotes looking at actions and thus lived practices on the ground, which is a useful component when complementing, critiquing or revising measurement tools or diagnostic manuals. After these criteria we will use excerpts of elaborate case stories in order to serve our investigation of what coping strategies our informants have made use of (more or less voluntarily – this will be elaborated on) in order to enable resilient coping. We are aware that the following criteria as well as our perception of the coping strategies as relating to resilience can be provocative. We then again refer to the chronicity with which severe trauma occur in the context studied here.

1) *Ability to actually survive* through ambushes and a war known for its innate brutality and exploitation of the civil population in Acholiland. We realize that this also has to do with coincidence. But often stories of survival and escape spoke of tremendous courage, creativity, strategic planning, perseverance, self-control, and help from God, spirits or both, as well as avoidance, emotional numbing and compartmentalization.
2) *Ability to stay (relatively) sane through witnessing, carrying out or being target of ongoing atrocities such as repeated torture, rapes and killings.*
3) *Ability to maintain daily functioning despite having experienced severe trauma:* Relative maintenance of hope, will to live, self-efficacy, goals for the future. Ability to maintain ones daily functioning and ability to take care of primary needs. If a family caretaker; being able to feed and comfort children – unless poverty, present war and climate conditions inhibit one in doing so. Absence of chronic severe depression, re-occurring suicidal thoughts, absence of apathy, but not necessarily absence of PTSS, PTSD, DTD or for instance dissociative disorders. We argue that one can adapt to/learn to function with and despite eventual disorders and trauma-related symptoms.
4) *Ability to come to terms with a past, where one was both at the enforcing and receiving end of atrocities, through meaning or sense-making processes, decision-makings and navigation towards resources, which enable informants to live sustainable lives and continue the demobilization, which were initiated at escape or rescue from the Lord's Resistance Army*. This ability, like #2, 3 and 5, can be seen as operating on a continuum, but in this criteria #4 the continuum refers to having obtained more or less acceptance of one's past. One is not completely stuck in the past, but has an overall understanding, that the past belongs in the past and that now is something different. Due to the cumulative traumatic events the majority of the population in Acholiland has experienced, flash backs might occur (as they did to the majority of informants). This can seem as us being self-contradictory: Criteria # 4 stresses that one has an overall understanding that the past belongs in the past, since flashbacks is a distortion of the notion that past and present are separate time entities. However, referring to criteria 3, we would again argue that alterations in memory due to traumatization is a different matter than appraisals and meaning making of one's past and how ones past affects one's present and future. Even if suffering from flashbacks, one can maintain functioning on various levels and might be able to establish constructive and healthy notions of one's identity, even if this notion has to draw on imagination or altered beliefs in order to enable identifying with an identity that is bearable.
5) *To live relatively peaceful in co-existence with family and wider home community* (occasions of domestic violence between men and women, as well as village fights between the men in the community especially in combination with the consumption of alcohol is very frequent in many areas of Northern Uganda, and in this Acholi context should not be seen as something extraordinary, but rather "a given" (conversations with numerous families, men as well as women and NGO´s in Acholiland).

This last criteria in between the lines holds a premise that demobilizing is considered constructive and resilient, and in addition "a morally acknowledgeable thing to do". However this is complex. The vast majority of male former child soldiers and ex-combatants whom took part in this study say they would remobilize if "things got worst"; that is if war should break out again, if their life was threatened, or simply if poverty and unemployment got too detrimental to maintain daily functioning and, when being the caretaker of a family, to ensure survival of children and wife. Thus remobilization cannot always be considered "a choice to join violent networks because one seeks the violence, revenge or one has an urge to act violently, is radical etc". Though very critical of the government, most informants would join the government army if war should break out again, because they consider it to be "the winning side". This points to the fact that survival is not taken for granted, but has been chronically threatened in Acholiland. It is to all of us, but the threat to survival is kept very much alive in the history as well as in the minds and the present day life of many Acholi people. Thus, using Zimbardo´s words "What is available, dominates what is right and just" from studies in social psychology [19] as well as theories from evolutionary psychology [20, 21]: Most of us would choose to harm, and ultimately kill others, in order to ensure the survival of our own community. If joining combat was the only way to save our children, how many of us would pick up the gun and start shooting at the enemy literally attacking our daughters and sons? This is what has been at stake for many Acholis. Now that the war is over, to some informants, boredom, lack of belonging and lack of a sustainable future ensure (re)mobilization into the ranks. To a final few it is addiction to violence and an urge to kill that would make them take up arms again. Our data consists of stories on how this addiction came about as well as stories of how one managed through remarkable courage, perseverance, creativity and resilience to lose his addiction to killing. With the above mentioning of alterations and imagination we go on to define dissociation and shortly present the empirical basis for why dissociation is part of strategies enabling resilient coping.

Defining "dissociation"

1.1 Defining "dissociation" from within psychiatry and psychology

In the data from Acholiland "escape" is synonymous for various terms describing mental processes of coping; "dissociation" being the most important one. Dissociation is a term or concept often described in psychology, psychiatry and anthropology. However the various fields define dissociation in very different ways: In the American Diagnostic and Statistical Manual of Mental Disorders (DSM 4), dissociation is defined as: "Disruption in the usually integrated functions of consciousness, memory, identity, or perception of the environment. Among the most commonly described dissociative experiences are `depersonalization´ (an altered perception of self) and `derealization´ (an altered perception of ones surroundings)." [22, p. 649].

1.2 Dissociation in psycho-analysis: Into the `crypt´.

Rosenblum, inspired by Torok (1968) and French avantgarde author Perec writes about "The crypt": A space where that, which is too painful to live with, is hidden away, concealed, confined. The detrimental risk of opening the crypt, which is the premise on which psychoanalysis and other, more recently developed methods of therapy such as for instance Narrative Exposure Therapy rest, is what Rosenblum reflects on in "Postponing Trauma: The Dangers of Telling": "Perec feels that crypts obey a binary logic; they allow one modification and one only. They hold or they break. Crypts immobilize the dynamics of the unconscious" [23, p. 1333].

Perec's and Rosenblum's words resonate with numerous writings on reactions to trauma and how repression, dissociation and splitting are ways of coping with what are experiences of extreme suffering or shock: "Not only do traumatized subjects succeed in distancing, denying, erasing the shock, but what is erased is sometimes much more than the affective experience or subjective recognition that an unbearable event took place. Sometimes what is erased is the traumatic event itself and together with it, whole segments of reality." [23, ibid].

When defined from within fields of psychiatry and psychology, dissociation is a common response to double bind situations, trauma and other situations of severe stress [24, 25, 22] – a link which was first made in writings by Freud and in other theories of hysteria [24, 25]. In the double bind theory by Bateson and colleagues [28], and in additional writings [29, 30] the word `escape´ is often used synonymously with dissociation [23, 22, 26]. Bateson and colleagues wrote about the challenges of being in a double bind situation: *"but in an impossible situation it is better to shift and become somebody else, or shift and insist that he is somewhere else. Then the double bind cannot work on the victim, because it isn´t he and besides he is in a different place."* [28 p. 210]. The events leading to dissociation, whether singular and immediate or chronic are closely related to the building of the crypt, described by Rosenblum. The dissociation is the escape response to what is too painful to be fully conscious of; hence the building of the crypt. We shall return to both terms in the analyses.

In summary "dissociation" is both used as a term to describe *immediate reactions* to severe, and or shocking stressful events in the actual moment of the stressor occurring, and thus as a natural human reaction to severe stress, shock or trauma. And dissociation refers to a symptom of re-occurring or chronic patterns of alterations of consciousness, memory, identity or perception of environment and self, related to past trauma now reoccurring because the stressful event/shock or trauma has resulted in traumatization, and thus what in psychology and psychiatry is often referred to as trauma – and/or dissociation disorders.

1.3 Dissociation in anthropology

Contemporary anthropological analyses of dissociation, often referred to as trance, spirit possession and as processes, which are part of rituals, tend to "concentrate on its function as a way of articulating certain self-states in a manner that resonates with local cultural notions of personhood" [27, p. 42].

Thus anthropological approaches to describing dissociation tend to do so emphasizing meaning and structure by focusing on how dissociation contributes to the cultural constructions of self and personhood, and how dissociative processes articulate, confirm, break away from or maintain personal, social and moral order within the local cosmology. Thus, dissociation when described with an anthropological perspective seems to be expected, culturally appropriate, desired, even joyful and promoting good health. In contrast dissociation within the field of psychiatry and psychology might be described as expected in the sense that it is a mechanism; i.e. a bio-physiological response to a traumatic event, but culturally inappropriate, promoting ill health, viewed as a state of pathology.

1.4 Emic notions of dissociation in Acholiland: `Cen´ and `Ajiji´

A majority of ex-combatants mentioned spirit possession, or more specifically, *cen* when sharing their stories. In Acholiland *cen* is defined as "the vengeful spirit of a dead person" a spirit capable of possessing places where killings have been carried out, or anyone involved with the killing, including family members to the one who has killed [31, p. 59 and notes from fieldwork]. Cen and other notions of spirits would intertwine with other explanation - or belief systems in Acholiland. The majority of Acholis I came to know during fieldwork would integrate beliefs in both ancestral spirits, Acholi ritualistic healing, witch doctors, God, prayer and pills.

In the Acholi tradition people expect certain behaviors from a person who has killed. The person might be possessed by *cen* and furthermore a traditional healer clarifies: "If a person has killed someone and has not told his people at home, people would begin to know it through his bad deeds for he would be filled with the heart of doing harm. Especially when *cen* has taken control of him, like when he is drunk, he would be filled with the heart of doing bad things and even kill." [31, p. 61]. Cen is related to `ajiji´ meaning "the urge to kill". Such urge was a severe challenge to two of the informants in this study.

Signs of àjiji´ are nightmares, shouting, trembling, not able to think straight, and loosing strength – referred to as "strong fear" [31, p. 62-63]. The signs are thought to disappear over time without any healing processes, however it is recognized that `ajiji´ can lead to "madness" (*apoya* or *bal pa wic*). In the Acholi cosmology "madness" shows itself in "severe nightmares, `visions´ during which people vividly see what has happened in the past, overly aggressive behaviour, excessive shouting, talking about things that are not related to what is currently happening in the person´s surroundings, moving around in long an aimless walks." [31, p. 63].

As mentioned in the beginning of this section dissociation in this paper is simply perceived as ways of coping. Thus in the remaining when the terms of "dissociation", "repression", "crypt" [30], "erasure" or "disintegration" is used, they refer to the "escape" Bateson in articles and books [26] argues is a logical response to adversity. Thus the connection "escapes as coping" emerged as a common characteristic in coping strategies in Acholiland. Now, rather than determining from which paradigm dissociation should be defined, and where on a continuum from `culturally perceived healthy reaction´ to` pathological response´ to `psychosis´ and `schizophrenia´ the dissociative states presented in this paper should be placed, we have briefly presented different perceptions of what dissociation means. This will serve as a foundation to deeper and more poignant analyses of the routes of escape two informants, Janus and Martin walk down - or rather dissociate into. The following story about Janus exemplifies how this seems to be the case.

Analysis: On the first time Janus killed

Janus was ten years old, when he was abducted by the LRA. Janus had attended school, and so the LRA quickly gave him the position of attending the wounded, because he could read the labels on the medicine made accessible to the LRA in the bush by collaborators, corruption, looting and attacks. Janus has seen babies being bashed against trees, and "weak rebels" pushed off cliffs. Janus was around eleven when he killed for the first time. Janus tells very different stories of the first time he killed. In one of them he takes up the narrator voice of a fierce fighter, "shooting out the brains of the other man", "stealing his gun", stating: "*And that was the end. I would never fear anything anymore*". His voice is deep, his intonation abrupt, his body language big and harsh.

In other versions of the first time Janus killed, his voice is lower; he speaks of crying when thinking about "that man". Of waking up, seeing the face of the man, thinking about why he killed him and reflecting on that "God says we should not kill one another". In other stories intertwining with that of the fierce soldier, and of the one haunted by images of the man killed, Janus narrates in a way that allows him to appear a hero. In one particular conversation, documented on video, Janus, without neither the performance of a fierce soldier, nor a victim, simply says: "*There were very many small children in the rebel army. So many. Small, small children. So many…"* and in a rare, brief moment, Janus sits there, vulnerable and just is. His shoulders rounded, his right arm wrapped around himself. Shortly after, he breaks out of the vulnerable state of being in order to again become someone else; a someone more endurable: "*That is why very many are so grateful to me. Many from the bush they see me and they say `thank you, thank you´. Because I helped A LOT of children in the army, I helped A LOT!* ". Janus himself was twelve years old, when he managed to escape the LRA.

Martin is an ex-combatant in his early forties who is stuck in a limbo between longing for his past as a commander in the LRA and being haunted by the past. What complicates Martin´s present life is that his longing exceeds the haunting; Martin when we meet, regularly expresses feeling "the urge to kill". However, Martin at the same time expresses that he wishes to be at peace *in* the present. Janus too lives in a limbo, running around between various identities, of which none offers him at place to rest in terms of a sense of "a self" he can accept, and pursue a sustainable future through. Janus is unemployed, separated from his family because of poverty and

stigma and turns to wishful thinking, that some call lies, in order to identify with a bearable, desirable identity and his persistent ambition to "be more than this".

1.1 The urge to kill

There are many things Janus and Martin have had to mentally escape from to cope due to the atrocities which have been committed against and by them. One is the guilt that accompanies killing - or is considered as *supposed to* accompany killing. Martin has partly succeeded in this great escape. Only in nightmares do the faces of the ones he has killed, tortured and the bodies he has desecrated come to haunt him. About killings and rapes he has committed during his time as an, according to himself, highly valued and skilled LRA commander, he says: "*Back then it was good*". Whether Martin never felt guilt, or whether he has had to erase it in order to function today, is not clear (more thorough analyses of this theme is in progress in a forthcoming article on coping strategies). Martin describes his experience without any traces of emotion, describes it as thinking (not feeling) *"If this is work, let it be work"*. To this day, Martin says, what he misses the most about being with the LRA "is killing" and he elaborates without any encouragement: *"Seeing blood makes me feel so strong, makes me feel such a strong moral. Makes me want to go and kill even more"*.

On scales developed far from the battlefields Martin fought, Martin has the highest score possible on "The Appetitive aggression Scale" (AAS) [6]. The scale is a measurement tool based on research in contexts of mass-violence, where psychologists found that the form of aggression described as part of combat testimonies from 2. World War, The Congo, The Genocide in Rwanda and in Northern Uganda, differed from other descriptions of aggression theory and aggression studies in the field. According to the researchers "Appetitive aggression" is defined as: *"... the perpetration of violence and/or the infliction of harm on a victim for the purpose of experiencing violence-related enjoyment.*" [32, p.24-25].

1.2 Appetitive aggression – a protective factor?

Martin describes how he would be on the lookout for the opportunity to be violent, if battles for some reason had not been fought for a few days in the bush. He explains how the urge to kill calls him. He says about rape and killing that *"back then it was good"*. But he also says: *"If my wife knew what I did in the bush, she would leave me."* Martin knows that in the present life what he did can be viewed as "not good". Martin says; *"one has to consider oneself a hero – otherwise there will be a problem. If you do not see yourself as a hero, you will be the one who is dead."* Martin survived. He considers himself a hero, a good soldier. His statements of violence being "not good", is not just pure obliged rhetoric, but speaks of a desire to find peace in the present by continuing to live with his wife and children in the quiet village.

Weisterstall and colleagues argue that appetitive aggression seems to have a protective role against trauma-related illness. They have shown in studies among Rwandan genocide perpetrators and Ugandan Child Soldiers that "those who reported a greater propensity to appetitive aggression were more resilient towards the development of PTSD" [32, p. 2, 33]. All the men and women I spoke to in the village where Martin lives had been screened for PTSD by an international NGO working in the area together with locally trained counselors, and results were that the persons screened did not suffer from PTSD. Emotionally charging reactions in general, in Martins case, were somehow ungraspable, because they were rarely displayed.

All informants spoke about their time in the bush as a time to completely repress (they would use the word `erase´ or `forget´) their emotions of for instance longing for home, grieving over the loss of loved ones, or feeling devastated after being forced to kill.

This was a strategy of survival displayed empirically throughout every story shared in fieldwork, as well as the repression of emotions as a coping strategy when facing and coping with severe trauma is richly described empirically and theoretically across paradigmatic preferences in psychology and psychiatry [31, 29, 34]. We have just used the terms "coping strategy" and "survival strategy" interchangeably although well aware of the fact that they are theoretically two separate entities. In Acholiland however, when with the LRA, the ability to repress emotions was at that time a necessary strategy: Completely distancing oneself, separating oneself, or dissociating oneself from the pain, disgust, fear or sad emotions one feels is as effective as it is necessary if one is to survive in the bush: In addition to the daily death threats and witnessing of killings, which were part of bush life, there is a strong tendency among ex-combatants to believe that commanders in general in the LRA, and the LRA leader Joseph Kony in particular, have mythical or spiritual powers. Thus we argue that what initially was a survival strategy during war, captivation and combat, has been carried into the present as a coping strategy: *"They literally know how to read your thoughts, so you just have to stop thinking about home. The first week, you think about home. But the second week… No… they can read your mind. So it is like that. Yah."* (Janus about his first weeks into the abduction).

Concluding reflections: Escape, erasure, survival

Most of the men and women we met during this fieldwork were children or adolescents when they were abducted. During the abduction incident or the shortly following initiation rituals, other abductees, sometimes including loved ones, were tortured, and often killed. Each and every one we spent time with during both fieldworks had been told to "not show sad emotions" in the bush". "To not look miserable, to not cry", "to not long for home" – or they would be killed, severely tortured, or forced to kill. Such a context, we argue, calls for careful conceptualizations of what resilience is and how one can or is forced to act in order to survive and/or to cope resiliently with severe, cumulative and chronic adversity of different kinds.

We have made an empirically driven exploration of resilience by looking at coping strategies as they emerged during observations of actions and as they were narrated and reflected on during fieldwork. We have fused our analysis by eclecticism across disciplines to show how *coping* strategies during the years where the war ravaged the Acholiland were equivalent to *survival* strategies, and, to some extent, still are.

1.1 Forced resilience

In contexts of severe, threatening adversity, which we argue, is not isolated to Acholiland, but can include various contexts, resilience does not necessarily relate to choice, choosing one's strategy etc. In some cases, and intense moments, we argue, the term best describing what resilience is when displayed in such a specific situation is "*forced resilience*". Like Janus explained, thoughts about home were soon avoided, completely repressed or abandoned, and so were the showing of emotions or sad thoughts, because the commanders of the LRA are believed to be "mind readers" – and because experience in the bush quickly taught Janus and his many fellow child soldiers and ex-combatants, that showing signs of weakness; showing any kind of emotions considered relating to vulnerability, would get you killed.

"Avoidance" within the field of psychology and psychiatry is defined as a *symptom* of Posttraumatic Stress Disorder. However, in Acholiland the ability to avoid certain thoughts and emotional reactions to the extent where emotions are disintegrated from subjective experience; e.g. the ability to stop thinking about home, seem to have been carried through to today as a present coping strategy.

It is beyond doubt that many of the ex-combatants we spoke to were traumatized to some extent. But what forced them to abandon thoughts about home and emotions of sadness and suffering in the bush, referred to in this paper as dissociation, repression, and avoidance/escape, seems to be working as an effective coping strategy in most cases in this study. This ability offers escape where there is none, and a way to move forward by moving away from the severely violent domination that many Acholis have suffered, which creates intrusive memories, stuckness and confinement in Acholiland on a collective as well as on an individual level.

1.2 Silence intensifies when coming home

The silence which seems to so naturally accompany avoidance intensified once the former child soldiers and ex-combatants in our study came home from the bush. In the bush silence was enforced as a necessary survival strategy. But once reaching home, stories of what happened in the LRA might very well be stories of killing, torture and abduction that sons, husbands and daughters often do not wish to burden their siblings, parents or partners with. And quite possibly so the telling of the stories of killing, torture and abduction are likely to shatter the fragile post-war rebuilding of a community equilibrium, because sons, daughters, cousins and husbands are still missing, or are dead – because the perpetrators of these atrocities in many cases are the very same persons, whom are now returning after their own abduction and share of various forms of hardships while in the bush. Silence bandages help keeping together the ties of the wounded in many villages in Acholiland, as well as silence and avoidance with Rosenblum's words serve as bandages holding together the crypt on an individual level too; keeping it from breaking and Janus from staying too long in vulnerable states and identities undesirable, or unbearable, to him – and his home community.

Not so few grew up in the bush, made friends, new families, grew through the ranks in the LRA, and into a sense of belonging.

Very few of them shared stories of experiencing growing fond of killing, but some did. Whatever balance between being traumatized or thrilled by the battlefields, silence seems the safest and more effective coping strategy to obtain communal mercy, or at least lessen the fierce stigmatization, which most often follows a homecoming. One's pride as an LRA soldier or commander, as in the case with Martin, does not have much space, if any, in neither the local, nor the global communities [35].

There are few exceptions among the Acholis whom we followed who had returned from the LRA where silence had been replaced by sharing of stories and with openly confronting taboos of atrocities committed. 3 out of the 4 whom had shared their stories, were encouraged or told to do so while with an NGO, or when being sponsored or taken care of by one of the many European aid-workers whom have passed through Gulu town over the years. One young man, Jason, who in many ways stood out in remarkable ways and whom never passed

through any reception centre or NGO was abducted as a 12 year old boy from his local village and quickly rose through the ranks with the LRA. A common strategy in the LRA is to send soldiers, often child soldiers, back to their local villages to loot, abduct and in some cases cause terror by committing very graphic torture and killings. This also happened in Jasons case. Jason decided to abandon his post as a commander in the LRA and upon homecoming, one of the first things he did was to walk up to the family, from where he abducted three boys while with the LRA - two of them still missing - to let them know he was the abductor and ask for forgiveness. The family responded that they had known Jason as a child, that they knew him as a "good and gentle boy", and that they would forgive him. Further unfolding of Jason's story must resume elsewhere, but this is the only story we have heard of where silence at a returnees own initiative turned into sharing and confrontation of taboos during 2006 and 2012/2013 fieldwork periods. This study, of course, points to the differentiation between whom one is supposed to silence ones past to, and where exceptions to this collective rule are allowed or encouraged. As a few among many European researchers and NGO workers visiting before us, we were safe to share stories with, because we did not have sons or daughters, or other relatives whom the informants could have abducted, tortured or killed during their own years of abduction/or years with the LRA. In the urban areas talking to "wazungus" like us, could potentially be beneficial in terms of material resources, however in this case it was made clear that this would not be the case.

Lacking in our material is data on bodily reactions; remnants of memories, which we would in some cases with female former child soldiers, inquire gently about, but would not get verbal accounts of, although body language too is indeed informative in its own right. The stories shared by female former child soldiers and their coping with pasts of repeated rape and violence support the strategies of dissociation, avoidance and silence, which we conclude are the most prevalent coping strategies in our data. In this paper however we have chosen primarily to focus on two male informants, and will elaborate on the female former child soldiers elsewhere.

The mental escapes into something better than what the past, present or future has to offer the two men, are in both Martin and Janus' case mostly walked alone. The atrocities of the past are silenced, due to taboo and fierce stigmatization in the local community due the intertribal character of the conflict in Acholiland. However stigmatized or lonely, Martin and Janus do share a collective response carried out by many Acholis: Silencing and being silenced in order to avoid a horrific past to take up too much space, in order to obtain a sense of control, and thus leaving a more endurable image of the future in Acholiland.

The outro is not rosy-red. Janus is hungry, literally and existentially, and Martin says the only reason he does not return to violence, to killing, is that he does not have a gun. Is there a limit to how long one can endure stuckness without reacting in ways that are destructive to self and/or other? History nods. Martin and Janus have both lost lives of loved ones and taken lives. They have argued (Martin consistently, Janus only when taking up the position of fierce soldier), that doing the latter was right. To provide a rich account and exhaustive reflections on what place moral has in the Acholi context is beyond the scope of this paper. Deutch [36] seems to be even more at point than Zimbardo when trying to explain why gross human rights violations at times are believed to be the right thing to do: "Once a boundary between `us´ and `them´ has been established, and `them´ are gradually excluded from the moral community, one can consider oneself moral for engaging in otherwise `depraved´ actions" [36. P. 24]. Going along with Deutch´s thoughts on inclusion and exclusion: A judgment is present when creating the ultimate exclusion; a killing. And a judgment is present in the creating of the crypt, and when going into shock while experiencing trauma because it necessitates a subliminal and/or cognitive appraisal in the form of the judgment of something being too painful to fully and openly embrace in its totality.

Many would have broken down, many would and do appear in studies on the prevalence of PTSD, DTD or other disorders from the Acholi region [37, 38, 39, 40]. Many others merge into new constellations of militias or private security markets [41, 42], cadreship [43] or strike up fights in the many loud bars and liqueur sheds around Gulu town. The borrowed terms from psychiatry and psychology can categorize Janus as suffering from PTSS and split personality disorder, and Martin as one that is placed so far out on the continuum of dissociation and on the scale of appetitive aggression that it serves him as a protective factor against the breaking of the crypt, at the brink of who knows what? Time will tell what will become available to Martin and Janus. For now, coping strategies of dissociation, avoidance, silence and compartmentalization allow some to be heroes and to maintain the hope of one day to become "more than this".

1.3 The situated constructive-destructive continuum

The last point to end the concluding reflections is that before trauma or adversity related mental illnesses progress so far out on the continuum we will call `the situated constructive-destructive continuum´ that it *does* belong within a category of pathology, there once was and might still be a meaningful response in the behaviour, which was at the time necessary and helpful because one had to deal with adversity or even immediate and life-threatening danger.

We call it the situated constructive-destructive continuum rather than the `normal-abnormal´, `normal-deviant´, or `normal-pathology´ continuum most often operationalized within diagnostic disciplines, because we

hold onto our initial argument, that in a context like Northern Uganda, and other war torn contexts or dysfunctional families where traumatic events are cumulative and crisis become chronic, adaptation processes take place too. Resilience and traumatology research is very familiar with and attentive towards adaption and how influential adaptation is to coping, resilience and thus dealing with or overcoming adversity and trauma. We however, like Bonanno and Barber, request more studies focusing on the myriad of, individual differences in, and detailed accounts of coping with/responses to adversity, PTE´s and/or trauma whether cumulative/chronic or single/acute.

For example a study exploring resilience among Palestinians in the Ghaza strip, or child soldiers in Northern Uganda in combination with assessing resilience using the validated scales will, we argue, benefit from adding to their study questions about what meaning making processes (or lack thereof – see [44]) exist on the ground about how to overcome trauma, what notions of victimhood exist in the specific context and culture, and; when a trauma is collective and embedded in decades and possibly centuries of a community´s or nations history, how does this possibly influence such measures?

To be specific one could ask what happens, when atrocities become norm? Is the one committing the atrocity and the one whom the atrocity is committed against still related to feelings of shame, shaming or taboos? Is the reaction as severe? We are not asking these questions to diminish the destructiveness one who has killed has carried out, nor the suffering this has inflicted on the dead and his or her relatives, whom have lost a loved one. But in the pursuit of understanding coping strategies and resilience and how these are affected by the kind of social fabric, history, structure, rituals and culturally influenced expectations to "how one/we are supposed or can react to suffering in this particular context" we argue that when atrocities and trauma become collective as well as cumulative, in the case of Acholiland less attention, less "right to mourning", and less time and energy was spent on "feeling" the suffering. Less blame was put on killing.

Because the circumstances were in some areas and villages that *the majority* of young men had killed - some even killed kin - and *the majority* of young women - girls even - had been raped. Majority matters, because what is the norm matters. This matters because it seems universally human to compare oneself to ones surroundings and to want to feel a sense of belonging, a sense of fitting in. Several experiments in social psychology and neuropsychology has shown that conformity is a powerful structuralizing principle [19]. Atrocities hurt. But if you are the only one experiencing this, it becomes more of a taboo than if there is a shared understanding; a knowledge of that "this happened to us" - even if this knowledge is silenced.

1.4 The absence of the word "victim" – and of "victimhood"

An important note is that interestingly the word "victim" or "victimhood" [45], does not exist in the Acholi language, nor does a synonym. This stands in great opposition to the discourses, campaigns and interventions carried out by many of the numerous NGOs, which travelled to Northern Uganda to provide aid, and psycho-social interventions to help the Acholi population in the years where the war took its greatest tolls. The lack of the word "victim" in the Acholi language - and the fact that none of the female and male former child soldiers, and/or ex-combatants whom shared their stories identified with a victim-position - stands in strong opposition to reports and psychology and psychiatry research articles published from the region [46, 47, 37, 38, 39, 40]. NGO and human rights based discourses, practices and articles stressing the importance of "claiming the right to victimhood" or "speaking through your trauma in order to be able to heal" is in most cases full of good intentions, sometimes based on evidence [48, 49] when arguing that this is the most constructive trajectory to healing, but not necessarily taking into account the individual, socio-cultural and historical influences marking a specific context. For the children, women and men this study encountered, knowing what is your right seems crucial. But if the resources are not there to ensure that rights are fulfilled - if, for various reasons, the system, the financial resources and the human resources it takes to inform about, advocate for and make sure rights are given, met and followed are not obtainable, one can feel even more powerless by having learned about that "everyone has the right to…" not go through, what the vast majority of the Acholi population and many more around the globe unfortunately have had to endure for years.

Resilience and segregation on post-communist romanian labour market

Istrate M., Bănică A.

Abstract

During the last two decades Romania has experienced major social and economic changes, influencing the structure and dynamics of the labour market: decreasing number of active and working population, increasing unemployment, the growing risk poverty and rising vulnerability of certain socio-professional groups. This approach studies the labour force in Romania from the perspective of the relation between resilience and segregation. The purpose is to identify regional convergences and disparities, shaped by the adaptation of the labour force in post-communist Romania, in the general context of international selective migration of population, economic crisis and recent application of new employment policies, in accordance with the European regulation. Based on the activity rate indicators and segregation indexes applied to different sectors and economic activities, the paper analysis the spatial differentiations marked by modernization processes of the social structures or by the perpetuation of the traditional regional disparities. The results demonstrate that Romania has entered a new social and economic paradigm while the issue of effective utilisation of labour force remains one of the main challenges of the future.

Keywords: labour force, regional disparities, segregation index, occupational mutations, social modernisation, labour market policies.

Introduction

In numerous studies dedicated to resilience in different fields (biology, psychology, engineering etc.) there are references to the capacity of a system to adapt when subject to external perturbations. Therefore, resilience expresses mainly the capacity of a system, region, community or person of responding and adapting to a quick change, of absorbing external shocks without attenuating their impact, so that sudden strains may not necessarily lead to a long-term decline, but to the fastest possible recovery [1], [2], [3]. The summarization of the characteristics of resilience in all these subjects have inspired and enriched the conceptualization on this topic, the varied approach of this term opening a wide range of interpretations, including in the field of the labour market analysis [4].

Generally, the *labour market* notion includes all the institutions and policies governing the labour force flows, as well as rules influencing employment, mobility, competences acquisition and continuous education, income distribution etc. The sudden changes during the past 24 years in Romania, as well as the broader structural transformations (higher flexibility, instability of jobs, changing working and salary conditions etc) are both opportunities and challenges for the labour market [5], [6].

The labour force resilience may be explained by reviewing the 4 stages characteristic to a system subject to external influences: *challenge, context, response and outcome* (fig. 1).

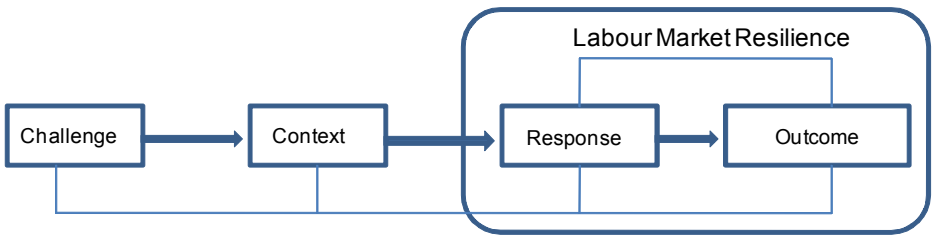

Fig.1 : Labour market resilience – conceptual framework (After Bigos et al., 2011, pp. 19)

First, the *perturbation* or *initial shock* triggers certain response mechanisms. For Romania, such thresholds can be identified in the sudden change of the political regime at the end of 1989, the beginning of the privatization of the large industrial enterprises in 1997 or the economic crisis in 2008. These events seriously affected the labour market by generating a decrease of both employment rate and national economic stability. The *context* refers to the fundamental structures that shape the labour market, namely the state politics, the functioning of the decision-making institutions, the demographic overall situation and the socio-economic context. Passing from a centrally planned economy to a transition economy and, subsequently, to a market economy (especially after 2007) implied the introduction to reforms hard to assimilate by a large part of the active population. The *response* should be understood as an adaptation, namely the ability of the labour force of dealing with the innovative challenges and the re-arrangement of the institutional structures. Finally, the *outcome* is either preservation of the initial pre-shock situation or the improvement of system's functionality. In other words, the labour force either was deeply affected or gained by minimizing the social costs and maximizing the citizens' welfare (decreasing the unemployment rate, changing the income distribution, improving life quality etc.).

A feature that can be put in relation to labour force resilience is occupational segregation that consists in the unequal distribution of the various work posts between two groups considered to be different. If we consider gender segregation of the workforce, one should notice that it is a multidimensional process that refers to the fact that men and women work in different occupations, economic sectors and have different contractual terms.

Objectives and methodology

The present approach studies the labour force in Romania from the perspective of the theoretical and methodological ensemble of resilience and segregation. Our first objective would be the estimation of the resilience of the labour force system components, the identification of the problems it faces, as well as the analysis of multiple relations contributing to the resilience of this system. Taking into account previous researches [7], [8], [9], [10] and using the available data, we built a composite index of the labour force resilience.

Consequently, the capacity of the labour force to adapt to the new economic conditions was analysed based on six indicators: ***st_p*** –the relation between the active population employed in industrial and services activities reported to the population employed in the primary sector; ***castig*** – the average monthly gross salary earnings per counties; ***som*** – unemployment rate; ***edu_sup_act*** – the percentage of the highly educated population out of the total population; ***migr_comp*** – the migration compensation indicator i.e. the rate between the arrived and the departed for each year of the considered period; ***intrGDP*** – the economic performance derived from the number of active companies, gross national product, related to the country population.

The TEMPO chronologic data series (1990-2012) from the National Institute of Statistics [11] was used in order to calculate the average value (***med***) and the average annual growth rhythm (***rtm***). The data were standardized, normalized and used within an ascendant hierarchic classification (cluster) in order to obtain typologies regarding the status and degree of adaptability of the labour force in every county.

The same variables were integrated within a principal component analysis (PCA) able to reveal the different importance of each indicator and the relative weight within the final resilience index.

The second objective was the identification of the existence of segregation per genders and activity sectors of the employed population and the estimation of segregation as regards the income distribution. We calculated an index of gender dissimilarity (ID) [12] of the employed population of each county, in relation to the active population. Eventually, a correlation between the resilience index and the dissimilarity index assessed the extent to which a higher degree of adaptability of the labour force is explained by the equal participation of women and men in economic activities.

Results

1.1 Evaluating workforce resilience

The recent major perturbations in the labour force system were determined first of all by the change of the political and economic system at the end of 1989, followed by a series of events that accelerated the system dynamics: the privatization and the deindustrialization of Romania (the shut-down of the great industrial units) which generated an important mass of officially unemployed persons but also unemployment under the mask of anticipated retirements, the restitution of agricultural properties, the migration of the labour force to Western Europe (especially after 2001), the accession of Romania to the European Union and the necessity of aligning to the European policies (including the labour force policy), and last but not least the world economic crisis (starting from 2008).

The '90s were marked by a continuous decrease of employees and an explosive increase in the unemployment rate. The climax was reached between 1998 and 2000, when the number of unemployed persons exceeded 1 million persons. Due to the limited possibilities of employment, part of the labour force left the labour market, another part was oriented towards agriculture and another towards the black labour market. From 2000, the phenomenon started to decline and was reactivated after the emergence of the economic crisis in 2008, when a new increase in the unemployment rate was reported.

If one refers to the adaptation cycle [13], the labour force system is currently passing through a *reorganization phase* marked by its resizing, the reduction of the secondary sector and diversification of the tertiary activities. According to the theoretic ensemble of resilience, this phase is characterized by the emergence opportunities that could easily reform the system, either by interventions from the upper hierarchic levels or by accumulating changes from the lower levels [14]. Nevertheless, future *malfunctions* might occur, given that the age-related structure of the population is more and more unbalanced, and the employees-retiring people ratio is clearly to the disadvantage of the first category. At the same time, the increasing *vulnerability* of certain segments of the active population (young men, unemployed, people with a low level of education etc.) highlights the importance of the horizontal and vertical relations between components while the political and legislative incoherence and instability diminish the resilience of the labour force.

1.2 Resilience assessment at county level. Cluster analysis

Based on these assumptions and taking into account the afore mentioned indicators, we applied a cluster analysis (ascendant hierarchic classification) and identified five classes that express the differentiated evolution of the labour force and its more or less resilient character in Romania, at county level (fig. 2).

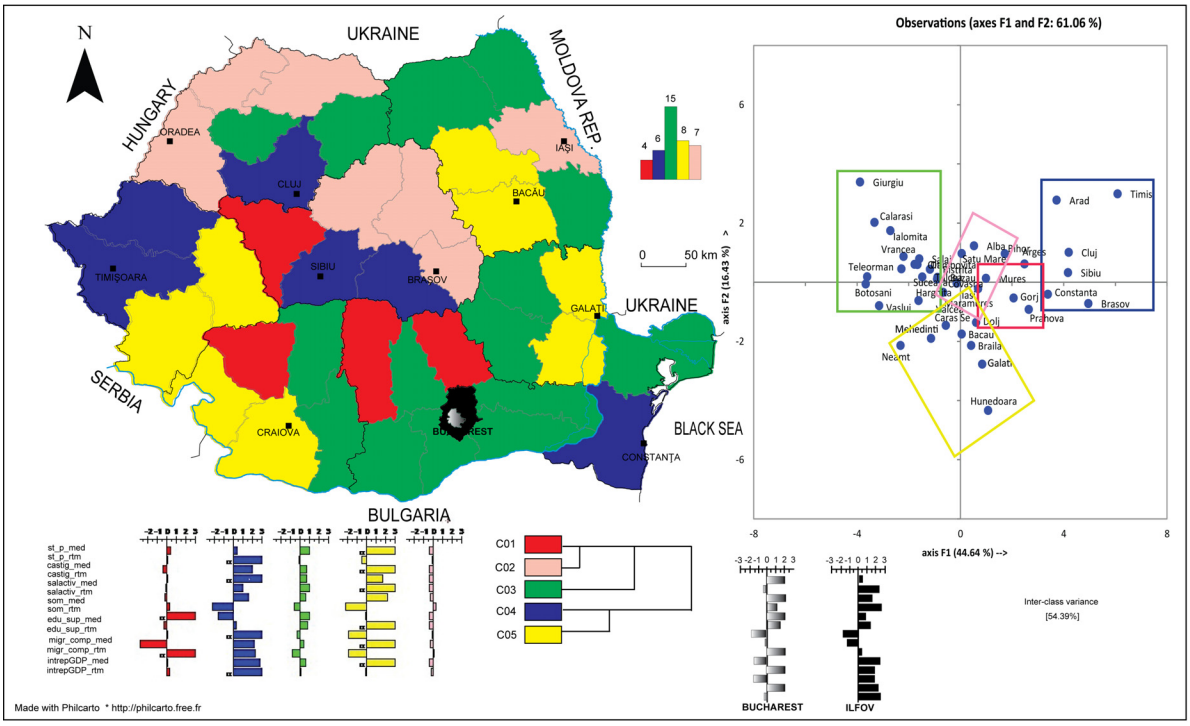

Fig. 2 Workforce resilience- typology at county level

Class 1 includes counties (Alba, Gorj, Argeş, Prahova) characterised by strong industrialization during the communist period, which managed to a certain extent to maintain their activities in the secondary sector; after 1989 they went through critical moments, marked by a high unemployment rate and high emigration rate, but, currently the tendencies seem positive, especially through the consolidation of their tertiary profile;

Class 2 is the most resilient; it includes counties economically strong, which had a quick recovery after 1990, benefiting from important re-technologizing investments, tightly connected to their favourable geographic position, to the superior infrastructure or long tradition of industrial development (Cluj, Constanţa, Braşov etc.).

Class 3 is the most comprehensive, occupying large areas east or south-east, but also in the Carpathian domain (Suceava, Botoşani, Buzău, Teleorman, Olt, Sălaj ş.a.); it includes counties with an important agricultural and natural potential, but with a relatively low degree of urbanization and modernization; though

they have been identified for a long time as areas of emigration of the labour force par excellence, their current counterurbanization and growth of the productivity in the agricultural activities seem to maintain a certain stability.

Class 4 includes counties (Galați, Bacău, Hunedoara etc.) that are currently in the phase of reorganization, namely of replacing an unprofitable industrial activity implanted in the communist period with more competitive fields. Their "inherited" professional structure, as regards the qualification level, is an advantage for economic restructuration and modernisation.

Class 5 has a profile close to the national average, includes apparently unbalanced counties, either because of the weak subordination of the rural space to one major city (Iași, Oradea), either due to the lack of such an important nucleus that may polarize efficiently the surrounding areas (Covasna); they are contrasting counties, where the adaptation and modernization of a part of the labour force coexist with the resistance to change of another part.

1.3 Segregation assessment

We have analysed both *horizontal segregation*, dividing females and males workers per activity sectors (primary, secondary, tertiary), and *vertical segregation*, dividing employees according to the income level [15].

If we take into account *horizontal segregation* in 2012, women predominate within the population occupied in social services (education 69%, healthcare and social work 79%, administration 57.5%), activities much more stable than the industry or private services [16], [17]. Nevertheless the issue of reduced access of women to the leading functions and the smaller earnings of women compared to men remain current. Employed men predominated in all the other economic activities, holding overwhelming proportions in transportation and storing activities (84.4%), construction works (84.1%) and extractive industry (83.3%).

While the first ten years after the revolution were characterized by economic instability, strongly influenced by the level and evolution of inflation, the second decade was marked by the end of the period of transition to the market economy, a positive evolution being reported in all the economic branches except for agriculture, revived only after 2007. From the viewpoint of the gender-related segregation, certain activities stand out due to a higher degree of feminization (healthcare, education, administration). As regards the agricultural and processing industry sector, segregation is much lower, on the background of a much more turbulent evolution of these activities (Table 1).

Table 1: Share of women in same major sectors of activity and their dynamics
(Source : National Institute of Statistics in Romania, TEMPO Database, Accessed in January 2014)

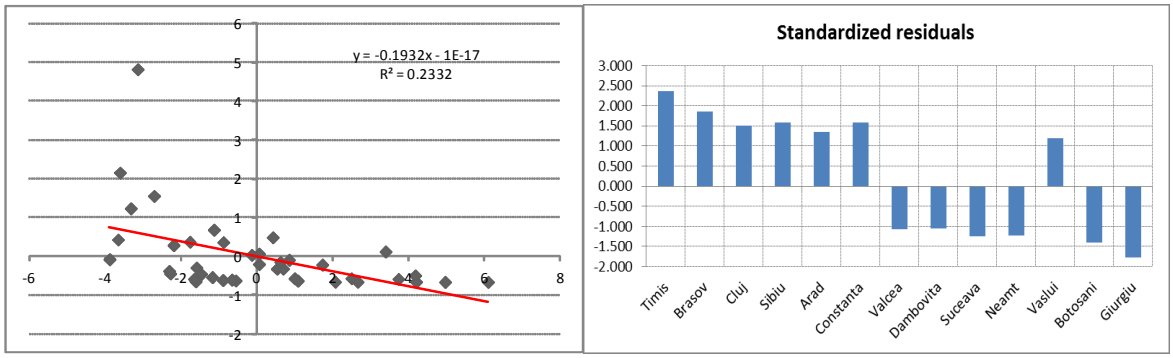
	1992_1996		1997_2001		2002_2006		2007_2012	
	% women	*sector_dynamic 96_92*	*% women*	*sector_dynamic 01_97*	*% women*	*sector_dynamic 06_02*	*% women*	*sector_dynamic 12_07*
Health	73.8	0.67	76.6	0.56	78.4	0.37	78.9	-0.06
Education	67.1	0.45	67.9	0.11	68.7	0.24	69.5	-0.13
Administration	49.6	0.26	57.0	0.22	57.9	0.46	55.0	-0.08
Manufacturing	45.1	-3.75	46.5	-3.07	46.4	-0.08	43.2	-1.56
Agriculture	51.5	1.6	51.0	3.2	52.3	-5.8	53.4	3.0
Constructions	12.1	-0.42	12.2	-1.02	11.9	1.56	12.5	0.82

The income-related segregation can be explained by a gender-related segregation between activity sectors, professions, jobs and hierarchic positions. Even if the salary gap between women and men is rather small and decreasing in the last years, men are better anchored in extra-family activities and consider their job more important, in exchange women are more traditionalistic and more attached to the household. The concentration of women mainly on certain activity sectors determines a decrease in their salaries (crowding effect). During the analysed period, the average gross salary of men was constantly higher than the national average, reaching its maximum value in 2001 (9.3% higher than the national average), but this percentage has been slightly decreasing for the past years. Nevertheless the average gross salary earned by women had an ascendant evolution, reaching 89.2% in 2001 and approximately 96% in 2008, after which it went back to 93%.

As regards the distribution of employees into salary categories, the gender-related segregation is more than obvious [18]. Women hold a high percentage in the categories of very low salaries (under RON 670). In the average salary group (up to RON 4,000), the gender-related distribution of employees is more homogeneous, but in the category of high and very high salaries, the percentage of men is much higher. Therefore, the differences in qualification level, job and hierarchic position influence the income level for the men and women working in different activities of the national economy.

1.4 The relation between resilience and segregation of workforce

If we take into account the correlation of the resilience index previously obtained and of the gender-related segregation degree on the labour market (described above and calculated as dissimilarity index for all Romanian counties), we notice a firm connection between the two. Each of them has a different basis: resilience is grounded on a set of factors seen from the point of view of their evolution, while segregation is centred only on the presence of the active population corresponding to the two genders on the labour market. However, a strong segregation, namely a much higher employment rate in men in comparison to women reveals a traditionalistic, sometimes retrograde, behaviour, which may be interpreted as a weak adaptation of the labour force to current realities (fig. 3).



(a) *(b)*

Fig. 3 (a) Correlation between resilience and dissimilarity indexes. (b) The highest values for regression's residuals

The tightest relation between gender-related segregation of the employed and the recent efforts of restructuring the socioeconomic system under the need for adaptation to the requirements of the market economy is most visible in the counties Alba, Satu Mare, Mureş, Bacău, Iaşi, as well as Hunedoara, Mehedinţi and Dolj. Still, there are administrative units whose clearly superior economic performance has different explanations, less connected to the gender-related structure of the labour force. This is the case of the capital and Ilfov, as well as counties Timiş, Braşov, Cluj, Sibiu, Arad and Constanţa. On the other hand, there are counties whose labour force is mostly exodynamic and apparently less adapted to the requirements of the inner market (although many times these are counties where a large part of the activities is insufficiently transparent or taxed), but where the gender-related segregation index is low. A particular case is Vaslui County, where though the lowest percentage of women in the employed population destabilizes the professional structure, it is not translated by a complete lack of capacity of resilience of the labour force.

Conclusions

The analysis of resilience within the workforce system highlights that recent social-economic were unequally resented by different areas in Romania, a fact that was reflected by the employment rate in dynamic economic sectors, the unemployment ratio or the level of salary earnings. The adaptation capacity is in direct relation to the quality of human capital and to the capacity of economic agents to innovate and increase their performance, both contributing to the attractiveness of each region or county. The composed workforce resilience index at county level is well correlated with the gender segregation of the occupied population which shows that increasing the integration of women in certain economic sectors is a mark for the capacity of territorial systems to adapt to the modern society's requirements.

Abstract

Introduction: In the circumstances of emotional delicacy and fragility in children, family separation endangers the quality and homogeneity of its development, exposing the child to several risks. The phenomenon of migration is not new, however the contemporary provides a few characteristics that know no valences in the afore societies. Objectives: Identifying protective factors in behavior, cognitive and emotional development in children with parents working abroad due to the economical needs. Methodology: The study includes children aged 6-10 years divided into two groups. The study group is formed out of children from families in which parents, both or only one of them have migrated abroad. And, the control group formed of children with parents at home. In the area of investigating the behavior, emotional and cognitive development, we used projective techniques - drawing techniques: Tree test, Draw-a-Person test (DAP), SDQ questionnaires (The Strengths and Difficulties Questionnaires) completed by parents/caregivers to assess emotional and behavioral problems in children. Results and conclusions: The results argue for the development of resilience in the presence of several protective factors resulting from workshops within curricular and extracurricular educational activity as a counterbalance for a resilience risk factor, that of having a parent/both parents migrated.

Key words: children, resilience, protective factors, risk factors, migration.

Introduction

In assessing the Romanian migration phenomenon periodization was used in order to highlight changes in type, destination and intensity of this phenomenon.

At the beginning of the 90s migration became a social phenomenon of great importance that crosses several phases [1,2]. Thus, if at first migration was done to reunify families; later on it was based upon labor, due to economic needs and shortly became fundamental in this respect[3,4].

Migration as a phenomenon generates unfavorable consequences both at micro- and macro-social levels. One of these consequences reflects upon family integrity, hence the *de novo* appearance of labels that have been ingrained in the form of "home alone generation"[5].

Parents, one or both, under economic pressure migrate abroad aiming a better life for their offsprings.

In an interview conducted with one of the mothers, which after a long period of time abroad, came back home for a few days, said: *"Afore, I could barely nourish him, now I can send him to school and assure a decent life"*.

Ritual is the very first formula for a coherent and general concept in life[6].

In the mythical world the child without is attributed several meanings, being found in various Romanian and South-Eastern stories. In one of the Romanian legends following the mother's sacrifice, the child is approved as deity, seizing to exist as human; it is cared for by fairies, rocked by the wind and bathed by rain. The child is one, single, unique and through him/her worlds arise. He/she arises directly from the heart of the elements: water, rain, wind. The child without parents is subject of Romanian folkloric creations being attributed deity traits, and his/her tragic fate determines the later heroic vocation.

However, in the context of the child's emotional delicacy and fragility, family segregation threatens its evolutive traits and homogeneity, exposing him/her to various risks.

Resilience research is based upon understanding the reason for which some children are more vulnerable than others when facing adverse effects of the unfavorable environment.

Resilience is better revealed when approached from the developmental processes point of view. Certainly, resilience comprises and is based upon multiple and various factors: from biological to life events, cognitive factors and coping mechanisms[7].

The plurality of factors eventually leads to a resilience structure with inherent characteristics.

Known, is the fact that the current social environment makes it more difficult to the parents to develop skills for stress endurance.

Several terms are to be fulfilled in order to develop the ability to resiliate to stress: early attachment and parental interaction – the base for child's morality; development of educational intimacy – that conducts to immunity in front of existential trauma; proper educational environment.

Given the impact on children all over Romania of parental absence through migration, we aim to emphasize the resilience of children from Calan, a town in Hunedoara County, Romania. This town is a representative example of decreasing socio-economic levels and thus a high rate of labor migration. Thereby, within Calan several children are raised by only one parent, grandparents or an outer family caregiver, however they benefit from curricular and extracurricular programs within their schools[7].

Material and methods

During its industrial activity, Calan a town located in the Hunedoara County of Romania, encountered several national and international premieres: the statute of the largest furnace in Romania (the late XIXth century), the world first industrial plant for coke and semi-coke production through fluidization, use of furnace blowers produced and designed by Romanian specialists and the manufacturing of casting machine for steelworks straight from Romanian first fusion cast iron.

Currently, due to nearly complete cessation of the former industrial platform, upon which the population depended almost entirely, along with the dismissal of most employees; unemployment rates exploded, thus Calan faces serious economic and social problems. Moreover, according to the census conducted in 2011 the city population amounted 11,279 decreasing from the previous census conducted in 2002, when there were recorded 13,030 people[8,9].

Given the socio-economic problems that welcome new generations, local schools have organized various activities within the Children's club: Drama, Children Theatre, Decorative Art, Dance, Soccer, Computer World Traveling, The Art of Behaving, Classes of English and Spanish, Personal Development and Psycho-Behavioral groups for Children and Preadolescents; and trainings for parents and caregivers.

Thereby, this study was conducted in Calan, Hunedoara County within two Elementary Schools under the patronage of Ovidiu Densusianu Technological High School, in between 01. 12. 2013-14. 02. 2014. There were included 50 children aged between 6-10 years. They were randomly selected from the abovementioned schools and were divided into two equal groups (N=25). The control group comprised children from well-organized families, whereas the study group comprised children with a background of dysfunctional family. The term of dysfunctional family refers to families in which one/both parents is/are migrant/s as a result of low economic standards, thus arising the need to provide adequate financial support to the family left behind. Each of the groups includes 11 male children and 14 female children.

Within the study, we applied projective techniques (the drawing technique: Tree test, Draw-a-Pearson test and the SDQ Questionnaire - The Strengths and Difficulties Questionnaires) on both parents/caregivers and their children, with the purpose of assessing the children's cognitive, emotional and behavioral levels. These techniques were applied within an organized Creative workshop.

Both parents and children were prior informed about the workshop and this study through brochures, in which the purpose, terms and form of the study were explained. Afterwards, semi-structured interviews were applied in 15 of the 50 parents that gave their consent to participate in the study. The other parents could not be present at the interview on the established dates and hours. The tests were applied by a Child and Adolescent Psychiatrist, who in a joint collaboration with the Professor – Head of the Children's Club and the Elementary Schools' Psychologist provided supervision within the workshop.

At the end of the workshop, the material was gathered for interpretation by the Child and Adolescent Psychiatrist and a psychologist.

The data thus collected was organized in a Microsoft Excel 2007 data base, comprising of the following fields: identification data (name, initials), demographics (age, gender), type of caregiver (parent, grandparent and outer family caregivers), SDQ Questionnaire (divided into – emotional symptoms, conduct problems, hyperactivity, peer problems, prosocial behavior and SDQ total), the Draw-a-Pearson test (score and interpretation) and the Tree test analysis that was divided into traits of adaptability, personality and

environmental relations, together with general traits defined as E1, E2, E3, E4, E5. Data analysis was performed using SPSS (Statistical Package for the Social Sciences) version 17.0 and EpiInfo 7. The groups were compared using unpaired t-tests or the χ^2 test. $p<0,05$ was considered significant.

The study was approved by the Ethics and Research Committees of each School included and of Louis Turcanu Children's Emergency Hospital – Department of Child and Adolescent Psychiatry.

Results and discusions

This study was conducted on a total of 50 children and implied the: SDQ test analysis, Draw-a-Pearson test analysis, tree test analysis and correlation analysis.

1.1 SDQ analysis

Following data acquisition and SDQ tests interpretation the following values were returned: normal, borderline and abnormal for both each of the SDQ subcategories (emotional symptoms, conduct problems, hyperactivity, peer problems, prosocial behavior) and SDQ total. Data analysis in this respect returned no significant differences among the two groups (study and control) (Table 1, 2). Fact, justified by the presence of resilience protective factors, such as: secure attachment, the presence of a carer within the family, above average intelligence. These findings are similar to Jordan and Graham's findings published in 2012 [10].

Table 1. SDQ tests

	SDQ emotional symptoms					SDQ hyperactivity			
	Control	Study	χ^2	P		Control	Study	χ^2	p
Normal	64%	52%			Normal	80%	92%		
Borderline	20%	8%	4,17	0,12	Borderline	8%	4%	1,54	0,46
Abnormal	16%	40%			Abnormal	12%	4%		
	SDQ conduct problems					SDQ peer problems			
	Control	Study	χ^2	P		Control	Study	χ^2	p
Normal	76%	52%			Normal	64%	52%		
Borderline	12%	16%	3,54	0,17	Borderline	20%	12%	2,73	0,25
Abnormal	12%	32%			Abnormal	16%	36%		
	SDQ prosocial behavoiur					Total SDQ			
	Control	Study	χ^2	P		Control	Study	χ^2	p
Normal	80%	72%			Normal	64%	52%		
Borderline	20%	24%	1,20	0,55	Borderline	20%	12%	2,73	0,25
Abnormal	0%	4%			Abnormal	16%	36%		

Draw-a-Pearson test analysis

In terms of the Draw-a-Pearson test, which aims cognitive assessment, again differences were not significant within the two studied groups. Thus we identified children with: normal intellectual functioning in proportion of 76% in both groups, borderline intellectual functioning in proportion of 8% for the control group and 12% for the study group; and mild mental retardation in 12% for the study group and 16% for the control group (χ^2= 0,34, p = 0,84) (Table 2). This is justified by the presence of competent trainers, a friendly teaching-learning environment, active methods of teaching and learning, continuous stimulation through curricular and extracurricular programs within schools[11,12].

Table 2. Numerical data analysis

T-Test	Mean		SD		P
	Control	Study	Control	Study	
Draw-a-Pearson Test	21.16	20.24	5.14	4.79	0.51
SDQ Total	10.4	13	5.3	7.05	0.14

1.1 Tree test analysis

The tree test interpretation was divided into traits of adaptability, personality and environmental relations, together with general traits defined as E1, E2, E3, E4, E5. Within each category of traits a number of key elements were highlighted. Thus, statistical significance between the two groups was found within adaptability traits (χ^2=5.82, p=0.016), which translates into a reduced capacity to adapt in children coming from dysfunctional families. Also notable, were elements of conformity, timidity, mental trauma, narcissism and tenderness as shown in Table 3. Noteworthy is the low incidence of these latter elements I the study group. All these are justified by the presence of competent trainers; a friendly teaching-learning environment; active methods of teaching and learning; providing high availability; usage of until then unexplored; dormant resources and abilities; new skills and resources acquisition[12].

1.2 Correlation analysis within the study group

In this part of the study we tried to highlight the global correlations between the studied fields. So, the study revealed a direct correlation between the Draw-a-Pearson test and the children's age (p=0.001) – explained by a direct relation between cognitive development and age. Another important element is the increased frequency in traits of independence and extroversion in the presence of an outer family caregiver (p=0,04), facts of protective factors regarding resilience also enounced by Chen and George in 2005[13].

Moreover, Emotional Symptoms SDQ correlates with conduct problems SDQ, as evidenced by the increased frequency of abnormal emotional status related to an increase in conduct behavior disorders (p=0,005).

Another direct correlation (p=0,04), relates traits like: the need for affection, passivity and prudence to normal and borderline Conduct problems SDQ results, as compared to abnormal Conduct problems SDQ results, where these traits are almost unmentioned within the analyzed drawings. Direct correlation between Prosocial behavior SDQ and Peer problems SDQ (p=0,005), is translated by the Prosocial behavior SDQ tendency to borderline-abnormal traits together with Peer problems SDQ to abnormal, these being risk factors for resilience, as resilient children are described to be capable of social and emotional normal traits by Dobrescu[11].

Regarding Prosocial behavior SDQ as borderline, it relates to Tree analysis General traits E2 as vivacity (p=0,004). Fact justified by the presence of negative factors, socio-economic status and the absence of one or both parents.

In Peer Problems SDQ normal results tend to be correlated with traits of fantasy and opportunism (p=0,03) as mentioned to be protective factors by Ionescu[12]. Whereas, elements of psychological trauma and vivacity are more frequent in children with normal intellectual functioning compared to those with borderline intellectual functioning and mild mental retardation (p=0,04). Normal intellectual functioning is more frequently associated with traits of fantasy and opportunism in the children comprising the study group (p=0,035). And, the older the child gets (p=0,01) less evident are the psychological trauma traits and vivacity traits in the tree test interpretation, thus resilience protective factors dressed up a education, workshops within curricular and extracurricular workshops help in a positive mental development as enounced by Ionescu[12].

Conclusions

Resilience is a novel theme of great interest throughout Child and Adolescent Psychiatric World. Thus, our study supports the promotion of health and wellbeing among children, centered upon positive emotions, thoughts, traits and behaviors. This was achieved by integrating special curricular and extracurricular workshops in schools with the purpose of giving and teaching both children and their family/caregivers how to cope with the absence of a parent/both parents by migration in terms of labor. Therefore using the results of our study and of similar studies to come, we hope to improve and create collaborative projects between medical and teaching staff aiming the composition of a system that moderates the effects of resilience risk factors, whereas nurtures protective factors.

The resilience of the second generation following the communism

Muntean A.[1], Ungureanu R.[2]

Abstract

Being violent towards human being, the communism is more and more recognized as responsible for inflecting to individuals and societies a special type of trauma. In Romania the communism had the worst face and the traumatic effects are still visible within the public and private space. Additionally, none of the strategies used in other former communist countries were used for improving the awareness of the people and for starting the healing process. In the absence of any general approach of trauma we suppose that the trauma of the parents passed to the second generations.

In order to follow the level of trauma as well as the resilience of the children of Romanian parent grown-up during the communism we evaluated about 150 students in psychology as well as 150 students in economics, within West University in Timisoara. The evaluations were done with specific instruments created by Şerban Ionescu and focused on the traumatic events and the resiliency. The work within West University in Timisoara was part of an international research on the societal trauma and resilience leaded by Şerban Ionescu, during 2010-2011.

Our investigations disclosed striking aspects, some of them in the same line as the literature as well as some of unexpected aspects. The papers will develop the conclusions based on the statistic work on the data.

Keywords: societal trauma, communism, resilience, protective factors, risk factors, respondents.

Introduction

The societal trauma is described in connection with significant stress factors which account for modifications of people behavior. The traumatic stress factor can be an intensive and unexpected unique event during which the persons have the feeling that their life or the life of significant ones will end or it can be an accumulation of multiple adverse factors, in a period of time, which overcome the energy and the coping capacity of individuals. The communism in Romania created the context for the achievement of the second type of trauma. The severe limitations of food, hitting, electricity and so on, jeopardized the wellbeing of people on the daily bases. These aspects induced new behaviors to people on the general level of the society. The new behaviors were aimed to facilitate the survival of individuals. They were useful during that harsh time but they lost any sense, 20 years after the fall of the communism. In Romania, where the communism had the worst face under Ceausescu's regime, nothing was envisaged as a national strategy in order to heal the societal trauma following the communism. The literature shows multiple ways in which the parental trauma is passed to their children if nothing is done for healing the post traumatic syndrome (PTSD). According with DSM, the 5th versions, there are several criteria which prove the PTSD.Criterion B: intrusion symptoms; Criterion C: avoidance; Criterion D: negative alterations in cognitions and mood; Criterion E: alterations in arousal and reactivity; Criterion F: duration; Criterion G: functional significance; Criterion H: exclusion/ differential diagnosis).

The real dimension of PTSD can be understood only when taking in account the social consequences [1]. When we talk about societal trauma, we can expect that the consequences of PTSD will invalidate the well functioning of the social systems. The parents' syndrom will pass to their off-springs through the child's rearing behavior which will create and bring the gosts in the bedrooms of children [2].

The reactions of people to the pervasive adverse factors were showing huge differences according with their resilience. This will give in tourn quantitative and qualitative differencies in the passage of parents' trauma to their offsprings. The resilience of the next generation can be identify as personal resilience as well as the resilience of parents who were directely exposed to the traumatic daily life context.

The context and the questions of our study

20 years following the fall of the communism in Romania, we are trying to see the trauma consequences as well as the resilience of the next generation, the children of the traumatized generation. The children are mostly born in the free world in Romania, installed in 1990. We found the 'next generation' among students at the West University in Timisoara. In the context of a multisite research conducted by Serban Ionescu within 8 different countries exposed to traumatic events, we collected our data having as respondent students of the second and third year of their studies in psychology and economics. The evaluation's tools were three questionnaires investigating the risk factors (alpha cronbach=.922), protective factors (alpha Cronbach=.694) and the resilience (alpha Cronbach=.860). Excepting the questionnaire for protective factors, the two questionnaires on resilience and risk factors have good internal consistency. The internal consistency between the resilience and the protective factors (alpha Cronbach=.863) and the resilience and risk factors (alpha cronbach= .879) are good. The questionnaires were set-up by Serban Ionescu and Colette Jourdan-Ionescu, based on a compilation of existing instruments.

We collected information through these 3 instruments on a sample of 134 students in psychology and 106 on students on economics, during the last month of 2010 and the first months of 2011. 34 questionnaires of respondents in psychology were invalidated due to multiple missing data.

Due to the specificity and differences of the studies within the two faculties, we expected to have differences on the resilience of the two categories of students.

The procedure to collect the information was based on a meeting the students within a seminar in the university and asking all of them at once to fulfill the questionnaires. This means that all the information we obtained was based on the self- report. The questionnaires on risk factors and resilience ask for responses based on a Likert scale choice. The questionnaire investigating the protective factors is asking for yes/no type of response.

Our questions are:

1. What is the prevalence of protective factors?
2. What is the prevalence of resilience?
3. What are the differences between the two samples regarding the risk and protective factors and the resilience?

Demographic aspects of the samples

In our research we can take in consideration three samples: the sample of students in psychology; the sample of students in economics; the total sample of students. We will provide the demographic aspects for the two specific samples: students in psychology and students in economics.

Tabel 1. Demographic description of the samples

Sample	Ages		Gender		Years of study		SES		Sibling		Partner		Time used to fulfill the 3 questionnaires	
	mean	st.d.	F	M	2nd	3rd	good	poor	yes	no	yes	no	mean	std.
Psychology	23	4,7	64	36	23	77	84	16	61	39	56	44	12,8	2,3
Economy	21	1,2	85	31	116	-	105	11	62	54	60	56	22,8	3,6
Total sample	22	3,5	149	67	139	77	189	27	123	93	116	100	18,22	5,8

Results

The resilience evaluation is done through the self-report based on Likert Scale on 7 dimensions, between total disagreement (1) and total agreement (7). We consider the middle value (4) as being non decisional; the 1-3, rejections; 5-7, agreements. There are 25 items asking for self-report expressed through this likert scale.

What is the prevalence of resilience?
What are the differences between the two samples regarding the resilience?

Running exploratory factorial analyses on the data we keep in consideration the 8 items which has the best communalities with the other factors and which can explain the resilience (value is >.70). The students in psychology are placed according to the 8 factors selected like in the table below:

Tabel 2. The resilience on students on economy: the items with best values in communalities

Nr/ importance	Question	1 (total disagreement)		2		3		4		5		6		7 (total agreement)	
		frec	%	frec	%	frec	%	frec	%	frec	%	frec	%	frec	%
1	Sometimes I push myself to do different things even I do not like it	3	3	5	5	11	11	20	20	19	19	32	32	10	10
2	I do not loose time with things which are out of my control	5	5	9	9	21	21	30	30	12	12	17	17	6	6
3	I like myself.	0	0	1	1	9	9	12	12	29	29	24	24	25	25
4	Usually I explore a situation from all perspectives.	0	0	1	1	1	1	17	17	25	25	38	38	18	18
5	For me is important to keep high interest for something.	0	0	0	0	2	2	5	5	12	12	37	37	44	44
6	I always find something to laugh.	1	1	3	3	8	8	11	11	20	20	31	31	26	26
7	The life has sense.	0	0	1	1	2	2	11	11	15	15	26	26	45	45
8	I trust my self and that is why I can overpass difficult periods.	0	0	4	4	8	8	12	12	22	22	34	34	20	20

If we rune the average on the less resilient behaviors, we find 12% of the sample as placed in this side; double of this, 24% are proving the best resilience. However, based on the same type of calculation, if we take in consideration the agreements 73% of the students in psychology are moving on the right and resilient direction. 15% does not show any direction on the scale of resilience.

The same statistical approach done on the data collected among the students in psychology, highlighted 5 factors which account for similar values as the values on psychology, regarding the communalities shared with other items. These factors are not the same as the ones found among the students in economy. In order of their communalities values, they are in the table below.

Table 3: The resilience on students on psychology: the items with best values in communalities

Nr/ importance	Question	1 (total disagreement)		2		3		4		5		6		7 (total agreement)	
		frec	%	frec	%	frec	%	frec	%	frec	%	frec	%	frec	%
1	For me is important to keep high interest for something.	0	0	0	0	4	3	6	5	21	18	33	28	52	45
2	If necessary, I can manage by myself.	0	0	0	0	0	0	2	2	9	8	44	38	61	53
3	When having some projects I can successfully go to the end	0	0	0	0	1	1	6	5	9	8	24	21	76	65
4	When I am in difficult circumstances usually I can find a solution	0	0	1	1	1	1	4	3	27	23	50	43	33	28
5	Sometimes I push myself to do different things even I do not like it	1	1	1	1	8	7	22	19	22	19	41	35	21	18

The prevalence of resilience is approximately=90 %, with undecided 7%, and 3%, disclosing un-resilient behavior.

The same calculation done on the entire sample is showing similar and different figures.

This time, the factorial analyze depicts less latent factors (7 instead of 8 as it was to the previous samples) which explain the variance of the data.

The communalities have only two indicators with similar values as in the previous cases (communalities>.70) as in the table below:

Table 4: The resilience on students on psychology and economy: the items with best values in communalities

Nr/ importance	Question	1 (total disagreement)		2		3		4		5		6		7 (total agreement)	
		frec	%	frec	%	frec	%	frec	%	frec	%	frec	%	frec	%
1	For me is important to keep high interest for something.	0	0	0	0	6	3	11	5	33	15	70	32	96	45
2	Sometimes I push myself to do different things even I do not like it	4	2	6	3	19	9	42	19	41	19	73	34	31	14

Continuing the work on the data we have 29,5% resilient students, but 79,5 % moving in the resilient direction and only 12% undecided, with 8,5 % un-resilient.

Table 5: The resilience of students in the research: comparing data

Type	Resilient		Moving toward resilient estate		Undecided		Un-resilient		Total	
	frec	%	frec	%	frec	%	frec	%	frec	%
psychology	24	24	49	49	15	15	12	12	100	100
economics	48	41	56	48	8	7	4	3	116	100
total/media	36	32,5	52,5	48,5	11,5	11	8	7,5	108	100

The students in economics are apparently more resilient and the prevalence of resilience is quite high among the second generation: 81%. There is 19 % who need support.

What is the prevalence of protective factors? What are the differences?

In the case of students in psychology, taking in account the data on the protective factors, in the same way, out of 33, there are 5factors accounting for more than .750 of all the indicators. For economics, there are about 10 factors accounting for more than .750. The protective factors on all the respondents get smaller values on communalities and if we keep the selection based on the same accounting value (75%). The protective factors highlight the difference between the students in psychology and those who are in economics.

Table 6: Protective factors: Economics

Nr.	Items	Yes		No	
1	I use very often the humor for making the things less difficult	96	83%	20	17%
2	I have a trustful relationship with my partner	60	52%	56	48%
3	I was raised-up in a loving atmosphere	107	92%	9	8%
4	I have an easy temperament	87	75%	29	25%
5	I have a good social network (friends, colleagues, members of my family to whom I am attached and from whom I can have a real support)	110	95%	6	5%
6	My family offered me good material conditions	105	91%	11	10%
7	I use to have or I have a pet	58	50%	58	50%
8	When I need help I know how to find it	111	96%	5	4%
9	I had the chance to meet a good mentor for me	61	53%	55	47%
10	The parents' expectations helped me to progress	91	78%	25	22%

On the students in psychology, the values on communalities are less high. There are only 5 items out of 33 which has the values higher than .750, as can be see bellow.

Table 7: the protective factors for students in Psychology

Nr.	Items	Yes		No	
1	I am useful to my community (for instance by doing voluntary work)	64	64%	34	34%
2	I have efficient strategy when facing the difficulties (I talk to other persons, I do sport, I take decisions)	84	84%	16	16%
3	I was raised-up in a loving atmosphere	79	79%	21	21%
4	I am happy to belong to my community (I share values, traditions, etc.)	76	76%	24	24%
5	I had and I have interesting leisure time activities	78	78%	22	22%

Discussions

The samples which we compare here are not homogeneous neither comparing the number, the gender, nor comparing the age and the year of the study of the respondents. Despite these disparities to put side by side the results as well as the work on the total sample gives interesting image about the resilience of the next generation of the old communist people in Romania. The way in which we work on the data, based on the communalities is just a half a way to real analyses on the data, which can be done. Communalities reveal just the saturation of each item with other items in the tool. Choosing the highest values in communalities we were trying to catch the superficial factors which account the best for the resilience, protective and risk factors.

Conclusions

Is the second generation already healthy following the societal trauma brought by the communism? If we look at the results among students in economics, the sample answer is yes, in a great dimension (89% are showing good resilience or moving toward resiliency). We have to add that this generation is also capable to search for remedies. We consider the students in psychology (resiliency: 24%, moving toward resiliency:49%), in a great proportion as choosing to attend this study based on their own motivation to understand them self better and to repair the damages brought in their previous life by the adversities encountered including in relation to their parents and family. This idea is not new and several researchers found that the motivation underlying the career choice of mental health professionals may include a desire to resolve personal psychological distress from childhood or the need to continue the caretaking role hold in the family [3]; [4]; [5]. "An unsatisfactory childhood resulting from family dysfunction frequently leaves the children confused, empty, battling their own inner difficulties. As they attempt to come to terms with their own childhood, they may begin the study of psychology or social work. Indeed, the need to understand the self is one of the most frequent motivations cited when social service students are questioned about their interest in the field [6]." [5].

If we compare the resiliency's indicators as well as the protective factors there are significant differences between the two samples.

The respondents, who are students in economy, are more homogeneous as a group (age, year of study) and more consistent in their answers. The factors with high communalities in the resilient questionnaire are also privileged within the protective factors questionnaire (like humor, good social network, good atmosphere in the family, good self-esteem). These items are mentioned within the literature on resiliency as being important for facing difficult circumstances: the humor, the capacity to ask for support, the good social network, as well as enjoying leisure time activities and having dear pets.

The students in psychology show less homogeneous aspects as a group (age, year of study) and less consistent responses to the questionnaire on resilience and protective factors. There are only 5 items with high communalities in resilience investigation and they are different comparing with the items in protective factors.

This incongruence is probably also connected with the time spend for answering. A huge difference is evident on the table showing the time spent by students in doing their self-report. When the average time for students in psychology is 12,8 minutes (st.d.=2,3), the students in economy spend almost double time in average (m=22,8; st.d.=3,6). One of the specific aspects for PTSD is avoiding the memories of the traumatic or unpleasant events. When such event in the memories has to be avoided less time will be used to recall in the memory and to work on the answers in an honest way. When students have access to their memories, they take the time to explore them self and to give honest answers.

Knowing the common motivation for aspirants in psychology and taking in consideration our results some supportive device or services can be developed and should be developed for students in psychology.

The students in economy are more emotionally connected to their family, social networks, partner, pets and have better access to them self comparing with students in psychology who are more prone to experience different situation which can keep them active and participative. Participation has therapeutic effects. Again we can see the wised natural impulse on the way of healing process, at work.

The last aspect which we mention here is that for both categories of respondents the self-discipline is an important aspect for their resiliency.

Abstract

Orientation to failure was identified in an exploratory factor analysis carried on the responses at Five Factor Nonverbal Personality Questionnaire collected from a national representative sample of 1600 adult participants. We started to investigate around this factor pointing to a cultural specific personality trait of Romanian people, aiming to describe its psychological meaning and potential impact on resilience at a social level and in the same time to identify if a historical - social explanation is possible for. The investigation illustrates an interdisciplinary perspective creating bridges between a clinical psychological perspective and a social - historical one. The paper presents the results coming from a number of qualitative investigations, done using a group of experts from social sciences and humanities, in order to describe the meaning of identified personality factor and its impact on resilience. The paper is also focused on presenting the main arguments and conclusions of a historical investigation, which was done to explore if development of a reasonable explanation is possible at social and cultural level for Romanian people for the existence of the identified factor. Also, the paper focuses on methodological details of the subsequent investigations.

Keywords: personality, orientation to failure, interdisciplinary, historical perspective

Orientation to failure- a Romanian national trait

An exploratory factor analysis carried on the items of a nonverbal Big Five questionnaire – FF NPQ [1], revealed a structure of 6 meta-factors of personality. We used in analysis the answers coming from the Romanian normative sample of FFNPQ, consisting of 1800 participants (900 males & 900 females) and being representative for the Romanian population over the age of 12. Although other investigations pointed out the hypothesis of a 6 broad personality factors [2], [3], [4], in contradiction with the main assumption of the Big Five model, the 6th factor obtained in Romania differs also from the 6th described by HEXACO model [5], [6] in addition to Big Five and seems to be rather culturally specific. By considering the items contents, we named this factor Failure or Orientation to failure. The 6th factor obtained covers 6,49% of data variance and groups 2 items staying as facets: Intolerance to loss (item 3, loading .66) and Failure in learning (item 19, loading .75). It represents, from a standard Big Five perspective, an unexpected finding, being a factor that does not relate with any of the classical 5 dimensions. It is factor of failure on an interpersonal level, a failure in the desire of self-fulfilling, failure in learning and academic achievement. It identifies individuals with a high awareness for the concept of failure or otherwise negatively influenced by failure. Intolerance to loss is a facet emphasizing the difficulty in accepting the idea of loss in competitions, even though the stake matters. This facet identifies persons who do not enjoy losing and who display aggressive manifestations to loss. The item content is related to aggressive responses to loss in a sportive competition, loading also on Aggressiveness facet. The facet is not significantly loaded on any of the five Big Five dimensions. Failure in learning is a facet of failure in learning and academic achievement, with a content related to rejection due to failure. The factor has no significant meaning on any of the classical Big Five dimensions. Item 8, having the major loading on the Consciousness dimension, also load higher than .30 on the Failure. This item is supplementing the significance of the facet with a content related to failure in academic accomplishments.

The significance and validity of the 6th factor obtained was further explored by using a number of qualitative investigations with experts and a peer nomination procedure. The peer nomination procedure using a

group of 93 high school students demonstrated an average correlation coefficient of .26 between self-report scores and evaluations on the same constructs made by peers. The analysis on expert opinions leaded to the conclusion that a failure orientation factor has both psychological coherence, as well as historical and social resonance in the Romanian cultural context. This personality trait of Romanian people may significantly impact the general adaptation (e.g. resilience) and can play an explanatory role for different Romanian social realities. As we were able to bring proofs regarding the validity of our findings and in the same time as it is very likely that the presence of this trait is connected to some real historical and social moments of the Romanian people (it can be interpreted as an expression of a fatalist feature, present in Romanian personality after centuries of domination and oppression), we decided to search for a comprehensive historical explanation on it.

Historical Explanation

If cross-cultural research reveals a culturally specific dimension, variation on that dimension may be uniquely important within that culture's particular social context [7]. In order to explain this trait it must be taken into account the Romanians` historical experience. Just as an individual personality is structured during its developmental stages, the core personality of a nation we can assume is structured during its formation and evolution.

Romanians appeared as a result of an historical process not different from the one of other nations of Latin origins [8].The common element of these nations is the Roman component and the difference is due to other layers. For Romanians the ethnic base was the Geto-Dacians. All the ancient written sources highlight a main common trait of Geto-Dacians: *the powerful belief in their immortality*. This *serene acceptance of death* made them highly brave in battles as mentioned by Ponponius Mela and Emperor Iulian Apostatul (361-363 d. Hr.) [8]. Furthermore, after the Roman troops conquered Dacia in 106 AD, the king Decebal chose suicide than the captivity humiliation. Transforming Dacia in Roman province set off the Romanization - the essence of the acculturation process [9]. All the Dacians acquired the popular Latin language, which become the engine of the Romanization process.

From the late third century until the thirteenth century, the Romanians people had to face the migration era. The Slavs constituted the most important layer in the formation of the Romanian people whose contribution remained imprinted in the language. Also the Romanians assimilated several other migratory. The historians presented the Romanian people as „an enigma and a miracle", meaning that they managed to survive surrounded by a „sea of Slavs", without losing identity [10]. The people managed to diminish the migratory impact also by retreating in the woods and in the mountains - hence the popular saying "the wood is the brother of the Romanian". It seems that historical proofs indicate that the main objective for the people was survival. The Romanians` strength and durability in the migration era and the succeeding ones, was given by "the admirable Romanian village" [11]. Villages were the main organizational forms that assured the shaping and development of the Romanian civilization. The people ensured their existence through working the land and animal breeding. From the thirteenth century it began the formation of the fairs and cities as product distribution centers and, then as handicraft production units; thus the city dwellers category expressed other types of community relationships and behaviors different from the villagers. Moreover, the Romanian feudal states were formed which meant a long, difficult economic and military effort, with negative consequences for the economic and social development. Whether they fought the Turks, Poles, Tatars and Hungarians, the major objective was the defense of the political identity and the religious faith. The methods used to achieve these aims were battles and negotiations.

The most difficult and asymmetric conflict was the one with the Sublime Porte (the government of the Ottoman Empire) that took place for more than four centuries. The Romanian people maintained their autonomy and self-government in exchange for financial and material obligations. As the Ottoman domination enhanced, especially during the Phanariot rule (1711-1821), a new psycho-moral behavior appeared - the so-called "diplomacy of the tip" [12]. The Ottoman impact on the Romanian mentality manifested through some fundamental psychological aspects which continued even after the Empire`s disappearance: a powerful habit of bribery, a deep fear and distrust in authority, a strong sense of humility, compliance, obsequiousness or obedience. All this time, the vast majority of the population – the peasants – was the one that had to sustain all the financial debts through hard work and giving up their lands and freedom. They all lived in poverty, deprived of formal education and their main goal was survival.

In the first half of the nineteenth century the peasants` material and social situation remained dramatic. They lived in extreme poverty under barbarian physical punishments aimed to intimidate and compel them to the taxes payment. They were fleeing from the states representatives hiding in the woods and mountains [13] - the same strategy of resistance used in the migration era and also a survival strategy. In 1835, Helmuth von Holtke, a German Field-Marshal that had knew the country, described a generalized Romanian behavior: "Every well-dressed man makes an impression on the Romanian who considers him, fully entitled to command and to claim services from him... and in the same time he receives quietly the mistreatment. The Romanians lived in

miserable huts and were dressed in rags [14]. After the Treaty of Adrianople in 1829 which removed the Ottoman economic monopoly on Romanian Principalities` trade, the development of capitalism and its new social class – bourgeoisie - accelerated. From the late eighteenth century an acculturation phenomenon emerged in the Romanian Principalities. Part of the Romanian elite borrowed elements of French culture without having the bribery and favors practiced in the Phanariot era to be eradicated but even more amplified by the capitalism`s flaws.The year 1848 found the Romanians in the European revolution turmoil. Political programs and actions aimed major reforms for the Romanian society: unity, independence, rights and freedoms, empowerment and land reform. In Transylvania, the crucial issue was the struggle for national defense due to the condition imposed by the Austro-Hungarian nobility regime – even though they were the majority, the Romanians were considered tolerated. In a favorable European context the Principalities of Moldavia and Wallachia were united in 1859 under the rule of Al.I.Cuza. There had been implemented major reforms to modernize the Romanian society; the most positively remembered was the land reform that positively marked the peasants on the psychological level [15]. Removing Cuza in 1866 brought to the throne of Romania a stranger monarch – Carol I. His will, however powerful, hadn`t managed to change the Romanian mentality. Romania was essentially an agrarian and patriarchal society. The politicking, the cronyism and the counterproductive attitudes coming from the distant past have made the Romanian entire society`s modernization and change extremely slow.

The War of Independence of 1877-1878 meant some notable successes: the state independence from the Ottoman Empire and increased linkage to the European model. Regardless of these breakthroughs the Romanian economy has remained mostly agrarian. The vast majority of Romanians lived in archaic rural villages; they showed a lack of concern for industrial activities due their powerful belief that “the use of natural forces and tools (meaning industrialization) is the Evil`s invention that upsets God” [16]. On the other hand, the peasants lost their properties again (by division and inheritance) and in the early twentieth century the key issue was again the lack of land ownership.

The main drive for the Romania's participation in World War I (1916-1918) was the union of the territories there were still under the foreign rule of Austro-Hungarian and Tsarist Empires. In 1918 Romania succeeded to unite Basarabia, Bucovina and Transilvania to the main country and formed “The Great Romania”, an event sustained by all social classes from the peasants to the royal family. This opened new developmental prospects and the opportunity to implement the land reform and the election reform. Still the Romanian society preserved its past flaws: "blunted critical sense, bargaining, inversion of values, morbid passivity, acceptance of attacks, tolerance of injustice, old fatalism reverberation - all determining confused boundaries and evil in the public consciousness” [17] – that affected and diminished the hopes brought by the Great Union. The Romanian society as a whole entered in the new era as an organism marked by inner diseases but hidden by those who were meant to lead it [18]. In fact, the peasant psychology remained - as an individual the Romanian was interested in ensuring the daily existence and in the group, he was marked by “gregariousness” – the constant trait to obey the authorities till the loss of his individuality in the crowd he is part of [19]. Gregariousness saved the Romanians in the past but for the future it was a break for development; the progress for the people should be an intense differentiation of of skills and character among members of the society [20].

The geopolitical changes at the beginning of the World War II led to the collapse of Great Romania by ceding some essential territories to the revanchist states pressure (USSR, Germany, Italy, Hungary, Bulgaria). This situation has also been explained by the life concept of the epoch marked by "frivolity, luxury, idleness, truancy, favoritism, theft, etc.” [21] that didn`t create a natural collective reaction but an acceptance response to the situation. The geopolitical objective of the Romanian participation in the eastern campaign against URSSS failed in 1944 when Romania turned the weapons against the German and allied with the United Nation Coalition. As a consequence the Soviets occupied Romania and imposed an extremely harsh Stalinist regime. Following the Soviet model, the Romanian political elite and all those who were perceived dangerous regardless the social class have been incarcerated as a result of serious legal abuses.

The communist period, especially Ceausescu`s regime, was marked by several key aspects: the permanent surveillance and control of the people; multiple deprivations (food, water, electricity, warmth, information); the authoritarian regulation of personal and collective space (e.g. nationalization of buildings and lands); sexuality control (e.g. prohibition of any birth control methods); prohibition of any religious activities; prohibition of any relationships with foreign citizens; indoctrination with Marxist philosophy. Therefore there was little and timid resistance movements that were continuously suppressed by the secret police (securitate). The main instrument of political power was the terror [22] through violent oppression, abuses and numerous crimes [23]. Also, it`s essential to mention that any existing opposition was very difficult due to the intense admiration for Ceausescu`s policy expressed by the main powers in the world. The continuous life degradation, the country's isolation from the rest of the world, the constant propaganda for the dictator's family determined powerful frustrations that exploded in December 1989 in the context of the revolutionary changes in the neighboring countries and of the URSS` lack of involvement. The Romanian revolution was one of the few moments in their history in which the people publicly reacted together, expressed their discontentment and ruled in favor of a radical shift.

Reviewing the main historical experience of Romanians point some major patterns: their past has largely been determined by others; they had little opportunity to determine their own fate; the vast majority of the people almost constantly lived in fear, poverty and terror; they had little opportunities to evolve at an educational, economic level; they had to find some ways to survive in these aversive circumstances.

Psychological Explanation

The evolutionary perspective on the Big Five holds that humans have evolved "difference-detecting mechanisms" to perceive individual differences that are relevant to survival and reproduction [24]. Buss views personality as an "adaptive landscape" where the Big Five traits represent the most salient and important dimensions of the individual's survival needs. Briefly, people have mechanisms that currently exist because in the evolutionary past they have successfully solved specific adaptive problems. In a history marked by the domination of the big powers, Romanians have developed a trait that helped them adapt and ultimately to survive as a nation. Fatalism leads to resignation and passivity; it is the trait that helped them cope with aversive historical conditions.

The resilience model [25], [26] can further deepen the psychological explanation of the failure orientation`s structuring in the Romanian nation`s soul. What is (the existence of such personality factor in Romanians) has meaning only by framing it into the past and into the future. The interactions between vulnerability factors, the risk factors, the resilience and protective factors offer a complete and comprehensive perspective of the psychological functioning and recovery/healing of the Romanian people.

The first psychological trait that can be considered the foundation of the Romanian nation is the fundamental belief in the immortality of the soul. If this belief made the Dacians brave and fearless in battles, further, under the traumatic events in the Romanian history, it made the Romanians able to accept the adverse conditions. It should be mentioned that this ancestral belief has been further reinforced by the orthodox religion – where life is the God`s choice and judgment over people and justice would come into after-life. "Therefore, the Romanians almost don't personalize their feelings so that the Ego becomes dominant. They are ready to rise above the Ego, into a sort of Super-ego, philosophical and, implicitly, fatalist, that enables them to accept the reality with all its manifestations, because the Good as the Bad, when are considered predestined, can be easily and resent less accepted as parts of a divine schema" [27]. Secondly, philosophers and other scholars have mostly mentioned and discussed one trait of the Romanian people: the fatalism as a "national characteristic". Most of them perceived it in terms of Romanians` ancient and strongly anchored belief in eternity of life. For example, the well-known Romanian philosopher Mircea Vulcanescu explained the Romanian fatalism as an integration of a being into universality of existence [28]. The philosopher and poet Lucian Blaga, deeply preoccupied by the specificity and identity of every nation, introduced the concept of "stylistic matrix" to explain and analyze the deeper archetypal reality of a nation`s soul. Starting from the most emblematic folk-ballad for the Romanians - Miorita (The ewe-lamb) – Blaga draws the conclusion that the stylistic matrix for the Romanians is the "mioritic space", meaning that the transfiguration of death is a logical consequence of resignation and fatalism [29]. Thirdly, regardless the historical stage, the resistance (survival) of the Romanian nation seems to be the common central behavior and can be seen as a major over-compensatory mechanism in front of all the adverse conditions. The psychological consequences of the lived historical experience for the Romanians were: constant fear, helplessness and horror which can be framed as traumatized parts of the soul. The constant hiding of the people from different and numerous invaders is perceived by Cioran (1911-1925), writer and philosopher, as a search for safety [30].

The Romanian society has been constantly brutalized and became incapable of voicing a protest but passively accepting every ignominy that it is called upon to bear with monotonous regularity [31]. Somehow, maybe as sign of learned helplessness (a main mechanism of depression), Romanians seem to have internalized the belief that evil always wins and they are condemned to fatalism and contemplation. In a study on the main strategies used by Romanians to deal with the communist atrocities, the essential one mentioned was "the acceptance of the unacceptable" [23].

Mircea Eliade (1907-1986), Romanian historian of religion, writer, philosopher, and professor at the University of Chicago, thoroughly analyzing the so-called passivity of Romanians understands the resigned attitude as a more deeper existential decision: "one cannot protect himself from the destiny as one cannot protect from the enemy; all one can do is to impose a new meaning to the unavoidable consequences of a meant-to-be destiny. It is not fatalism, because the fatalist doesn`t consider himself capable to change the meaning of what was predestined [32].

This unconscious "choice for resistance" can also be considered the main resilience factor used by Romanians for a long period of time. In front of traumatic events, one can rely on what brings strength. Ernest H. Latham, the author of a paperwork published in the United States about the legendary ballad, perceives the fatalism of the people in a different manner: "sat by fate on the border of West and East, after two thousand years of harsh rule, barbarian invasions, greedy conquerors, by evil rulers, cholera and earthquakes gave the

Romanians the feeling of temporary and transitory qualities of things (...) Romanians possess the greatest ability to get relaxed blows of fate. They know how to fall with art, with every muscle and every joint soft and relaxed ... The secret art of falling is, of course, do not be afraid, and Romanians are not afraid, as the Westerners are. A long experience in survival taught them that every failure has unimagined opportunities and that, in one way or another, they`ll manage to put themselves together on the feet again" [33].

In the same time, what functioned as a coping mechanism for almost all Romanian history, nowadays – in a free, democratic regime – has proven to be a risk factor for developing pathological behavior. While today Romanians have the opportunity to choose their own fate, to evolve as a nation, the resistance continues (as if they are still under foreign occupation - in history, in a past already ended) and it has transformed itself into what we called orientation to failure. Today, Romanians as a whole, still don`t speak up for themselves, still don`t know their rights and still accept any injustice – and they cope with all in the same manner as before: with profound resignation and passivity. This lead to what William Wilkinson, British counsel at Bucharest from 1814 to 1818 long before called "intolerable servitude", "lack of hope for a better condition", "habitual depression of their minds that become natural stupor and apathy, which renders them indifferent to the enjoyments of life, and insensible to happiness, as to the pangs of anguish and affliction" [34]. Also, Felix Colson, secretary to the French consulate in Bucharest from 1835 to 1840, mentioned the Romanians as "humble, submissive and ready to endure anything; their hollow eyes, which they dare not raise, proclaim their slavery absence of well-being" [34].

These attitudes lead to specific behaviors that, in turn, today and in the future, have only one major consequence: failure. For example, the Romanian novelist Augustin Buzura clearly described this in-depth and generalized attitude of the people, as a mark for future failure: "The greatest catastrophe is that we have become accustomed to servility, that we no longer recognize it, that we have grown to tolerate it, that we allow ourselves to be transformed by it, that we have become accomplices to it, so we cannot shake off the image which it has bestowed upon us even when we are alone" [31].

What is to be done under such psychological grounds? Analogically with the healing process in a traumatized soul [35], the recovery and healing process of a nation follows the same path. The national acknowledgment of the psychological wounds and their consequences for this nation`s soul can be done through national programs and politics that aim: honesty in presenting the historical facts together with understanding of the psychological consequences - deep pain and need for survival of the common people. This can bring re-integration of the traumatic dissociated part of the nation. Along with this, the development of healthy parts of this nation should begin: the re-establishing of national self-esteem and authentic Romanian honor; developing the real power of decision and action "here-and-now"; developing the optimism and the ability to enjoy life; acknowledging the existence of the free-will. Of course, further suggestions are expected from the future investigations on the topic opened by the present paper.

Abstract

Alice lives her life normally. She is married. She works. Her children are growing and go to live their lives. Her husband dies, she must live alone. One day she falls. Thigh bone fracture. Not appropriate medical recovery, impossible to walk again. She becomes dependent. She should enter a special caring service for retired. The slipping syndrome is mention. A request was made by the team to a psychologist. He will assist her resilience. Then, Alisa starts to tell her ordinary life story and the past will repeat in the present: her survival after the bombing during their childhood.

Key words: assisted resilience, social theory of memory, survival

Syndrome de glissement ?

Pendant la seconde guerre mondiale, à 6 ans, Alice fuit sous les bombes, avec son père et son frère. Une bombe explose à proximité. Alice est enterrée vivante ! *Elle ne peut pas bouger, elle est coincée, elle est sous la terre, et pratiquement asphyxiée, elle se sent mourir*. Une deuxième bombe souffle la terre déposée par la précédente. Alice reprend sa respiration, se relève et voit à côté d'elle les cadavres allongés de son père et de son frère ! Elle est désormais *une survivante*.

Entre Ulysse et Alice, quels points communs ? Jean-Pierre Vernant raconte Ulysse au retour de la Guerre de Troie, guerre meurtrière : Il évite de rentrer immédiatement chez lui, vu le sort du chef de l'expédition, Agamemnon, assassiné par sa femme Clytemnestre et son amant. Ulysse accomplit alors un long voyage ordalique et expiatoire. Il y perd son nom, ses compagnons, il visite les confins de la terre et de la vie, il parle avec les héros qui, tel Achille depuis l'enfer, l'invitent à prendre le chemin de la vie plutôt que celui de la mort, fût-elle glorieuse. Au bout de vingt ans d'errance, enfin, il retrouve son Ithaque. Prudent, il s'y présente vieux, méconnaissable. À l'inverse de Clytemnestre, Pénélope a cultivé l'absence de son époux et refusé de saturer le vide physique laissé par son départ, prendre un amant ou un nouveau mari, bien qu'elle eût mis un enfant au monde, conçu quelques mois avant le début de l'expédition. Les nombreux prétendants présents au palais festoient, se servent allègrement des biens et des richesses de l'absent, déciment et dévorent ses troupeaux.

Transformé en vieillard hideux, Ulysse se déguise en mendiant. Une de ces ruses de guerre qui lui ont maintes fois sauvé la vie. Alice quant à elle fait sa vie, sans qu'apparaissent de séquelles visibles de l'incident critique qui a failli la tuer, comme son frère et son père. Elle se marie. Elle a des enfants. Devenue veuve, elle demeure dans la maison jusqu'au moment où une chute lui fracture le fémur. Impossible de demeurer seule chez elle. La décision médicale s'impose : elle doit rentrer en maison de retraite, pour une longue et difficile rééducation. L'enfermement l'immobilisation forcée, la dépendance aux autres, côtoyer les personnes âgées dont certaines vont mourir, c'est insupportable ! Elle s'enfonce dans une dépression d'allure mélancolique. Alice repousse les aides, ne mange plus, refuse la rééducation. Elle se laisse mourir. Un syndrome de glissement ?

1.1 Assistances

L'équipe s'alarme et demande l'aide d'un psychologue. Il travaille également aux urgences de l'hôpital voisin où il rencontre des personnes choquées, traumatisées. Son travail consiste à générer une situation d'interlocution afin d'aider les victimes à sortir de leur mutisme, de leur terreur. Il adopte une méthode active, empathique, adaptée pour les personnes impuissantes à surmonter seules l'effondrement consécutif aux événements critiques, lorsqu'elles ont vécu la mort.

La seule trace d'Ulysse en Ithaque réside en creux dans l'attente de son retour. Il doit d'abord lutter contre le mendiant habituel, irrité par la concurrence. Il doit trouver des alliés qui vont l'informer et l'assister pour retrouver sa place, son identité. Seul, il est impossible d'y parvenir. Sa vieille nourrice, ayant mission d'accueillir tous ceux qui entrent dans la ville et seraient susceptibles d'apporter des nouvelles d'Ulysse, le

reconnait en premier. Par un détail insignifiant à d'autres : une cicatrice au mollet, faite par un sanglier lors de son initiation de jeune guerrier. Elle sait qui il est et il comprend qu'elle sait. Avant qu'elle puisse crier sa surprise, il lui met la main devant la bouche pour l'empêcher d'éventer la ruse. Sa nourrice retrouve en lui l'enfant et le jeune homme blessé. Télémaque, né après son départ, n'a pas connu de père et son père n'a jusqu'alors jamais joué ce rôle auprès de lui. C'est chose faite aussitôt qu'Ulysse lui intime d'autorité l'ordre de le croire sans discussion quand il lui affirme son nom.

Ulysse devient père au moment même où Télémaque devient fils. Ils naissent l'un à l'autre en un seul instant par l'établissement de la relation d'autorité. L'assemblage de la constellation des identités relationnelles se poursuit.

De la mémoire sociale à la résilience assistée

Le psychologue aborde Alice selon cette technique adaptée, prenant le temps d'être une présence identifiée, de se faire accepter, de faire naître la confiance et le transfert. Alice s'habitue et se met petit à petit à lui parler. Son vécu d'impuissance physique et son enfermement actuels la replacent dans des conditions analogues à celles du bombardement : un enterrement avant l'heure ! Cette concordance rend manifeste le vécu traumatique de poly-victimisation. Elle revit corporellement son expérience d'enfance et la raconte dans le même instant d'interlocution. Son appareil psychique construit simultanément du souvenir, du passé, du présent sur le modèle de la mémoire comme objet social selon Pierre Janet. Ce dernier expliquait qu'un témoin engendre le temps de l'humain en récapitulant son expérience sous la forme d'un récit adressé à un autre, légitimement institué comme référence, par son métier, sa pratique, son statut social. Janet annonce une théorie possible de la résilience assistée par interlocution et abréaction.

Il expose une *théorie sociale de la mémoire*. Que veut-il dire par là ? La mémoire humaine s'inscrit dans un scénario relationnel voisin de celui du théâtre : les lieux, les actions, les personnages, la durée et sa structuration, le déroulement et la conclusion forment un ensemble cohérent et nécessaire. Ainsi, le guetteur d'une tribu préhistorique est-il, par son chef, chargé de veiller, d'observer, de donner l'alerte si un danger menace, et de faire le rapport le lendemain. La dramatisation, la scénarisation, les relations sociales interviennent pour mettre en souvenir ce qui le jour suivant sera restitué sous forme de récit adressé au chef. Par délégation, le veilleur de nuit doit être attentif à ce qui pourrait se passer. Il sélectionne les éléments à observer car *a priori* ce n'est pas le nuage qui passe devant la lune qui intéresse le destinataire du rapport à venir. Le déjà attendu, avant même que rien ne se fasse ni ne se passe, introduit par anticipation ce qui dans l'après du jour suivant deviendra le récit du présent de la nuit passée. Récapitulation faite dans le rapport à celui qui s'est physiquement absenté, mais dont la demande agit toute la nuit comme anticipation dans l'esprit du veilleur et mobilise son attention. La délégation de responsabilité permet l'absence physique du chef et oriente le devenir car le récit lui sera adressé au moment voulu, à son retour. C'est l'architecture de la formation du souvenir selon la théorie sociale de la mémoire. Nous y ajoutons des éléments théoriques de *la psychologie historique* proposée par Ignace Meyerson, reprise et illustrée par Jean-Pierre Vernant, insistant par l'exemple d'Ulysse sur la nécessité de réinvestir des rôles relationnels pour exister.

Les techniques de la résilience assistée s'appuient sur la structuration du temps et des rôles sociaux. Dans l'après coup des événements critiques paralysant l'appareil psychique, le cadre proposé soutient la formation du souvenir par le récit adressé. En effet, la brutalité, l'imprévisibilité, la sidération empêchent la mobilisation spontanée des ressources résilientes pour traiter l'événement. L'avenir n'est pas possible. La rupture de la continuité chronologique génère l'effondrement de l'histoire et de la géographie humaine, partielle ou totale, de l'Être. Il n'y a plus d'autre, sinon mort. Le petit théâtre social de la mise en scène du monde réel sous forme de représentation ne se construit pas dans l'instant. De même, lorsque la personne affectée de troubles post traumatiques forge le discours qu'elle adresse au thérapeute, la participation active de ce dernier dans le cours du traitement contribue à sélectionner ce qui doit se dire. Les paramètres de la communication inter humaine sont sollicités. D'où l'intérêt de l'architecture psychosociale de la mise en scène.

Alice, la résilience assistée et les autres

À partir du moment où Alice a pu verbaliser/représenter/signifier cette expérience, la raconter sous forme d'un récit adressé au psychologue patenté, elle a pu accepter de surmonter son handicap du moment, accepter aussi des aides, accepter qu'il y ait une amélioration possible, être partenaire du projet de soins et être meilleure actrice dans la rééducation. Le temps du passé étant advenu, le temps du présent peut reprendre son cours et Alice peut reconquérir ses rôles sociaux actuels.

À la différence de ces nombreuses personnes âgées qui répètent indéfiniment la même séquence de leur vie, mais que personne n'entend comme manifestation post traumatique à travailler comme telle par résilience assistée. Ce n'est pas entendu comme *un récit en souffrance*, et par voie de conséquence, ce n'est pas un récit. Au mieux une récitation lassante pour les destinataires qui ne se reconnaissent pas dans ce rôle et dont les

répliques sont décalées : *mais Madame, vous savez bien que votre mari est mort ! Il ne peut pas vous entendre lorsque vous criez, enfin ! On vous l'a déjà dit.* Se méprenant sur l'intrigue de la pièce, ils font bifurquer le scénario. Les cris risquent alors d'être entendus comme la manifestation d'un comportement troublé chez une personne désorientée dans le temps, qui a perdu la mémoire, avec des conséquences médicamenteuses possibles, circonstances aggravantes. D'autres personnages s'immiscent en la scène qui se joue, sans imaginer le traitement post traumatique. L'atelier mémoire sera d'un piètre recours.

1.1 Ulysse revient à lui-même

Ulysse, advenu père vingt après la naissance de Télémaque simultanément devenu son fils, redevient également le fils de son père, retiré dans une ferme à l'écart de la ville, affligé par tout ce qui se passe dans le palais dont il fut autrefois le maître. L'identité d'Ulysse se reconstruit au fur et à mesure qu'il peut habiter à nouveau les rôles déterminés par les relations personnelles, uniques et identitaires, entretenues avec sa nourrice, son fils, son père, puis bientôt sa femme qui l'attend et l'espère, mais ne le reconnaît pas encore en ce vieillard : il doit revisiter au préalable le rôle du fiancé. Pénélope donne alors le signal de l'épreuve qui doit départager les prétendants.

Il s'agira d'utiliser l'arc dont seul Ulysse parvenait à se servir. Celui qui atteindra la cible sera digne de rejoindre la couche de la reine. Tous s'y essayent. Personne n'y parvient. Le mendiant demande à son tour de tenter l'expérience. Tous les vaillants jeunes hommes dépités se font des gorges chaudes à l'expression de cette prétention sénile. Néanmoins il lui est accordé le droit d'essayer. Il bande l'arc, contre toute attente, mais, toujours aussi rusé, il fait mine de manquer la cible. La flèche atteint mortellement un premier prétendant. Il recommence et manque encore la cible officielle. Puis avec l'aide de Télémaque, du porcher, du bouvier, les cent prétendants sont immolés malgré leur volonté de fuir. Le calme revient, la salle est nettoyée, purifiée du sang versé.

Ce vieillard est bien singulier ! Mais Pénélope n'y reconnaît pas l'homme jeune qu'était son mari parti pour la Guerre de Troie. Ulysse doit encore, dernière épreuve identificatoire, résoudre une énigme piégée. Sera-t-il, lui le guerrier rusé, capable d'échapper à la dernière ruse de Pénélope ? Elle propose de déménager le lit conjugal dans une autre pièce avant de sceller leur union, s'il est bien cet Ulysse qu'il prétend être. Elle sait, et elle seule sait, que seul le véritable Ulysse connaît aussi la réponse. *Non*, dit-il, *le lit ne sera pas déménagé*. Et pour une raison simple : c'est lui, Ulysse qui l'a fabriqué de ses propres mains. Et il n'est pas possible de le déplacer car un olivier enraciné fait office de quatrième pied. Il doit donc demeurer, ce lit, immuable, à l'endroit où il a été fabriqué. L'arbre, faisant lien entre la Terre des hommes et le Ciel des dieux. Il est bien Ulysse !

Échapper à la fausse résilience

Alice reprend aussi le cours de sa vie. Elle participe activement à sa rééducation, s'intéresse à son environnement, propose son aide serviable aux personnes qui manquent d'autonomie. Elle joue son rôle social au présent. Le travail de résilience assistée lui a permis de sortir de la fausse résilience qui avait suivi le bombardement. Elle avait continué de vivre sans séquelles apparentes. Cela n'a pas empêché un travail souterrain de production de traumatisme. L'incubation a pris des années et le déclenchement fortuit de sa présence en a révélé les ravages. Pendant tout le temps de l'apparence victorieuse, elle a réussi sa vie. Comme Œdipe avait aussi réussi en apparence, après avoir tué son père et épousé sa mère. Il avait débarrassé sa ville affaiblie par la Sphynge mangeuse d'hommes jeunes en résolvant l'énigme de l'Homme.

Faussement résilient, Œdipe franchit victorieusement l'épreuve du mariage, sans séquelles apparentes. Ce que la suite de l'histoire va contredire. Le malheur va à nouveau s'abattre, sur la ville, et sur lui par son insistance à vouloir connaître la vérité sur ce forfait accompli par cet homme qui a tué son père, épousé sa mère dont il a eu des enfants. Il cherche la vérité et trouve sa propre vérité, aveuglante, qui lui crève littéralement les yeux.

Le malheur des Atrides tient à ce que la matrice de l'architecture des vies et des morts, des filiations, des préférences sexuelles, des mariages, est torsadée. L'histoire et la géographie deviennent incohérentes, accidentogènes. Laïos, le père d'Œdipe, momentanément écarté du pouvoir à Thèbes et réfugié à Corinthe, était tombé amoureux de Chrysippe, le fils du roi Pélops. Il avait tenté d'obtenir une relation sexuelle non consentie. Chrysippe s'en était suicidé. Accidents en chaîne sur trois générations : Œdipe, fils de Laïos, épouse sa mère Jocaste et lui fait des enfants qui seront à eux-mêmes des ennemis plutôt que d'être fraternels. Les rôles sociaux sont brouillés. À la différence d'Ulysse pour qui le fils est fils, l'épouse est épouse, le nourrisson est bien le jeune homme, le mari est bien le mari. Fausse résilience chez Œdipe et Laïos, résilience assistée réussie pour Ulysse.

Conclusion

La fausse résilience nourrit un chancre intime qui dévore les forces vives de l'hôte, à la manière des prétendants au trône d'Ulysse qui épuisaient ses ressources domestiques en son absence. Après la crise, à l'issue de l'assistance à la résilience, Alice reprend le cours de la nouvelle vie. Elle a réintégré l'autre dans son rôle d'autre à qui le récit de vie est adressé.

L'expression de la resilience en milieu traditionnel a l'ile de la reunion.

Payet Sinaman F.

Doctorante en psychologie clinique (France)
Sous la direction du PR JF HAMON
Université de la Réunion - CIRCI

Abstract

The presentation is focus on resilience from the cultural point of view as express on Reunion Island. We adapt a phenomenology approach of resilience based on its three components: treatment, process and result. Out goal is to contribute to the theory of this phenomenon collectively described and presented by individuals of this society. The paper is based on a qualitative analysis of collective representations starting with popular writings. This analyse emphasises that resilience is part of a long continuum of struggling to resistance till spiritual transcendence. Ordinary language shows a way to face life challenges based on a socio historic traumatic past including slavery. The lexicology analysis shows a resilient type of personality, psyche-soma solidarity in the process of resilience and achieving a spiritual dimension as a sign of resilience as result.

Key words: resilience, cultures, traditions societies, spirituality, language

Introduction

Si la psychologie met l'accent sur l'histoire individuelle d'un sujet, Derrivois (2011) que « les ressources individuelles s'activent toujours sur fond de ressources collectives ». Dans le contexte traditionnel de la Réunion, on observe une omniprésence du religieux, du spirituel, d'un système de pensées complexes, des croyances persistantes dans la psyché individuelle et groupale et des pratiques cultuelles vivaces. Comment ces éléments interviennent-ils dans la construction de la résilience ? Quelles contributions la recherche en milieu traditionnel peut-elle apporter à l'enrichissement conceptuel de la résilience et à sa compréhension? Afin d' obtenir une compréhension indigène dans une "configuration traditionnelle" (B.Champion, 2010), j' ai adopté une démarche empirique à partir de la langue dans une visée exploratoire. Ce procédé se justifie par deux principaux obstacles .L'un d'ordre théorique concernant l'ambiguité conceptuelle de la résilience et l'autre méthodologique. Selon M.UNGAR (2010), l'appréhension de la résilience au niveau conceptuel est obscurcie par les influences contextuelles. D'autre part, poursuit cet auteur, l'approche étique a été privilégiée dans beaucoup d'études. Des biais ont été démontrés rendant problématiques voire contestables, certains résultats. Aussi, une voie possible consiste à envisager en complémentarité une perspective émique. Dans cette optique, partir de ce disent et pensent les personnes concernées, par l'examen de la langue courante, notamment du lexique référentiel, est une piste pertinente. En effet, le lexique permet la création d'un rapport symbolique entre le locuteur et le monde. Mais également entre le locuteur et la société, la culture dans laquelle il vit. Son rôle est essentiel dans l'élaboration de la pensée, de l'identité de l'individu dans son milieu. J'ai effectué un repérage non exaustif des expressions, mots, locutions et des proverbes en usage dans la langue courante à partir de textes chantés populaires. Ceux- ci véhiculés au sein du grand public révèlent la représentation collective du mal être psychologique, du traumatisme et des moyens pour parvenir à les dépasser. Ils témoignent également des traces traumatiques profondes enfouies dans l'inconscient collectif. Ce choix se justifie par le souci d'une plus grande proximité avec la représentation collective traditionnelle accordée au bien être psychique, à un développement réussi. Le but étant de saisir un sens contextuel tel qu'il s'exprime dans une oralité conservée et non pas de rechercher la traduction du concept de résilience. Dans l'univers traditionnel réunionnais pour parler du développement, en Créole, un individu dit « mwin la grandi dedan » (littéralement, « j'ai grandi dedans ») pour signifier ce qui l'a façonné, fabriqué, ce qui l'habite et laisse voir sa vision du monde. Aussi, le mal être psychologique, les obstacles, les situations délétères, les traumatismes, les moyens pour les dépasser s'appréhendent avec une conception empreinte d'un sens religieux. Mon hypothèse est qu'en configuration traditionnelle, la résilience trait, processus et résultat s'inscrirait le long d'un continuum qui va d'une résistance-lutte jusqu' à une transcendance spirituelle. En complémentarité à l'analyse lexicale, afin d'appréhender cet

éthos et d'éviter un biais ethnocentré, j'ai procédé à une analyse cognitivo discursive d'un discours émanant de plusieurs internautes à propos de la diffusion sur internet d'une cérémonie sacrée. Le problème posé à l'origine de cette discussion est la réaction controversée quant au dévoilement médiatique de ce type de rituel. Dans un premier temps je donnerai une brève présentation des données théoriques et méthodologiques en privilégiant la perspective culturelle. Puis, je présenterai la conception traditionnelle des trois composantes de la résilience (trait-processus et résultat) à travers l'analyse lexicale qualitative issue des écrits populaires en y intégrant les résultats de l' analyse du discours.

Considérations théoriques et méthodologiques

L 'île de la Réunion, située dans l' Océan Indien, à sept cent kilomètres de la côte est de Madagascar réunit sur sa terre une variété d'habitants issus de son peuplement originel. De l' interaction de ces peuples différentes, facilitée par une plurireligiosité, a fini par naitre, au fil des générations, une pensée sociale et religieuse spécifiquement réunionnaise, élaborée à partir des catégories communes appartenant à chaque système religieux" (F. DUMAS-CHAMPION, 2008).Différentes visions du monde se côtoient dans un contact permanent contribuant à vivifier et dynamiser l' éthos culturel réunionnais. Discourir sur la résilience culturelle dans ce milieu revient à l'envisager dans une perspective plurielle, complexe en intégrant différents niveaux d'analyse. Les données de la littérature montrent qu'il existe au moins quatre voies possibles concernant les contributions que la recherche peut apporter quant aux relations entre culture et résilience. D'abord, l'étude des racines culturelles, les dispositifs traditionnels de soins, les sociétés soumises au stress et à l'acculturation des sociétés dominantes et enfin l 'étude des facteurs culturels de protection IONESCU (2011), UNGAR (2010). Ces pistes de recherche récentes font partie de la quatrième vague d'études sur la résilience qui l'inscrivent dans une perspective culturelle. Brièvement, en psychologie, les trois vagues d'études antérieures ont sucessivement mis l'accent sur la résilience comme trait, processus et résultat. De nombreuses interrogations demeurent au sujet de ce concept aussi bien au niveau théorique que méthodologique. Ainsi, M.UNGAR (2010) pointe l'un des obstacles important est la manière d'envisager la recherche sur la résilience et de l'évaluer rendent difficile la recherche empirique. En effet, étant un construit culture bound euro centré, il a été appliqué à d'autres contextes. (KAGITCIBASI, 2006 cité par UNGAR, 2010).D'autre part, un biais l'affecte fortement: "*l'attachement au discours scientifique objectif*". Cet auteur préconise alors l'étude des sociétés hors contexte occidental en l'envisageant dans une perspective écologique.

1.1 Conception traditionnelle de la résilience en milieu créole : la langue, support d'analyse du façonnage de la résilience.

1.1.1 Le lexique, premier niveau d'analyse

Dans un contexte écologique traditionnel, il est pertinent d'envisager le renversement épistémologique proposé par DERRIVOIS (2011) qui postule « une résilience de l'Esprit et des esprits » soumettant ainsi ce concept dans la perspective d'un nouveau débat .En effet, les racines culturelles de la résilience à la Réunion puisent dans un éthos particulier fortement marqué de plurireligiosité. Comme le souligne BRANDIBAS (2003) « cette terre créole a façonné ses enfants, fabriqués avec des pensées, des mots, des histoires familiales, des cultures marquées par les ruptures et les traumatismes ». L'ile de la Réunion est passée successivement du statut de colonie, puis de département à Région française. Cette société s'est construite dans la survie, la résistance, et la souffrance pour large majorité des habitants, chaque époque apportant son lot de difficultés. C 'est dans cette configuration, qu' est née le Créole réunionnais. Il s'est crée et développé dans la nécessité d'un vivre ensemble soumise à la domination et à l'acculturation de la langue Française. Il a été tout à tour, interdit dans les espaces officiels, objet de lutte contre l'indifférenciation et pour sa permanence. A présent, cette langue s'écrit, est prise en compte dans l'enseignement, est source de créativité s'exprimant sans complexe dans les écrits populaires. Aussi, je risque l'analogie en parlant *d'une langue résiliente.* 98% du lexique de la langue Créole est à base lexicale Française. Le Créole réunionnais a conservé et véhicule de nombreuses références à la spiritualité. J'ai effectué un relevé de certaines catégories verbales dans un corpus de textes chantés populaires, en puisant dans le répertoire du maloya (chant traditionnel sacré et/ou profane) et du dancehall, style musical moderne de la jeune génération. Ainsi, la manière d'envisager une situation délétère détermine l'intensité et l'impact que cette situation aura sur l'individu. De même que le locus de contrôle (ROTTER, 1954) reste prédictif dans la manière de vivre cette expérience. J'ai examiné la relation entre une situation délétère et le locus de contrôle. La grille d' analyse élaborée à postériori détermine trois catégories:

1/ La première catégorie se subdivise en trois sous catégories: un impact sur le corps seul, un impact psychique uniquement et un impact affectant à la fois la psyché et le soma. Le locus de contrôle peut être interne et/ou externe.

2/ Une deuxième catégorie dans laquelle la situation délétère induit l'idée d'expiation, de châtiment. Cet évènement n 'est pas généré par l'individu mais il est amené à vivre cette expérience car il doit en retirer une leçon. Le locus de contrôle est interne.

3/ La dernière catégorie se subdivise en deux sous catégories: situation délétère causée par des agents visibles (les humains) ou des agents invisibles (les esprits). L 'évènement est un coup du sort relevant du destin. Le locus de contrôle est externe.

1.1.2 Le discours des sujets, deuxième niveau d'analyse

J'ai effectué une analyse cognitivo discursive à l'aide de TROPES (P.MOLETTE, A.LANDRE, R. GHIGLIONE, 2013) d'un discours émanant d'un groupe d'internautes recueilli sur le site d'un journal électronique local[1]. Ce support permet une double distanciation : une mise à distance d'un dispositif expérimental physique et les biais relatifs. Puis, la production d'un discours plus ou moins authentique (non censuré) des sujets. Le discours est composé d'un total de 47 échanges. 3 sujets interviennent en plusieurs fois. Le style général du texte est argumentatif. 40 propositions remarquables ont été retenues ainsi que 8 épisodes détectés. Les mises en scène montrent que les internautes discutent, comparent et critiquent. Ils se passionnent (153 mots soit 34.3% pour les modélisateurs d'intensité) mais se mettent également à distance pour raisonner. Ainsi, le taux des adjectifs subjectifs 45.7% (79 mots) avoisine le taux des adjectifs objectifs 43.4% (75 mots) pour la totalité du discours. Leurs propos sont assumés et ils s'engagent personnellement dans la discussion. Le pronom dominant est le « je » (32.9%).On observe également le pronom « on » (15.8%) qui est concentré dans chaque épisode au début et/ou au milieu du discours mais tend à faiblir à la fin de discours. Basé sur des critères normatifs, un discours entendu, les sujets finissent par s'influencer mutuellement (modélisateurs la cause obtient 18.4%, l'opposition 16.3%) et se faire une propre opinion. On observe pour les modélisateurs 0.0% pour doute. Sur un total de 1013 verbes, les verbes statifs, exprimant des états ou des notions de possession obtiennent le score le plus élevé avec 405 mots (40%).

Discussion

Traditionnellement, l'homme anthropomorphise tout. Il projette sur son milieu sa manière spécifique de dire son propre corps (BADGIONNI, 2002). A la Réunion, des catégories verbales spécifiques désignent des maux, des malaises, des maladies du corps. D'autres réfèrent au psychisme seul. Dans ce cas, la tête le symbolise, elle est synonyme d'esprit. L'individu est tourmenté et/ atteints de troubles psychiatriques. D'autres catégories encore expriment une solidarité soma-psyché. Ainsi, le corps peut désigner l'individu lui-même servir de barrière contre l'envahissement et/ou l'anéantissement psychique. Il symbolise la puissance « Kaf na sept peaux », « na la peau dyr [2]» et a par analogie une fonction de protection du psychisme « l'esprit i vive dan le kor[3] ». De cette analyse, on peut brosser le profil d'une personnalité résiliente. L'individu a un « lespri for » (une force mentale), "un for tampéraman" (BRANDIBAS, 2003).A l'opposé, un vulnérable a "lespri feb" (une faiblesse de caractère). Le résilient possède un mental d' acier ("lé rézistan"), une force spirituelle propre ("na un gayar","lé kador", "na tét dyr") .Il est sage et un devoir d'aide. Il cumule les caractéritiques théoriques de la "personnalité hardie" telle conçue par leurs auteurs (KOBASA et MADI, 1977).Il s'agit d'une caractéritique de "la personnalité se rapportant à des croyances, des sentiments, des valeurs qui s'expriment par une constellation de trois dimensions inter reliées, soit, le sens de l'engagement, le sens de la maîtrise, et le sens du défi". Ce Type d' individu est un "zarboutan"[4], il est fiable, fonctionne comme un garant. Le locus de contrôle de cette personnalité est interne.

Face à une situation délétère, la première attitude d'une personne est qu'elle « *pran son problème* », De nombreuses références sont associées à la main. Faut-il y voir la trace dans l'inconscient collectif de cet outil majeur de survie dans l'ancien temps ? Une fois la situation empoignée, on la rend solidaire du corps, médium indispensable : « i tienbo ansamb », « i larg (lach) pa lo kor », « i rézist »[5]. Le sujet pour aller mieux, doit « batay », « sobat » « lyter »[6]. Ce processus est une lutte- résistance. Ceci se traduit par un mouvement physique car si l'engagement est d' abord physique, celui-ci conditionne le mental, on « mange ou on port la douleur » (manger ou porter la douleur) pour se lever et se mettre debout. Ce processus est graduel car on sait que c'est « ti

[1] Article du 08/12/2009 : "on appelle les esprits pour protéger la famille", site du journal zinfos 974

[2] Expression signifiant littéralement « le Cafre a sept peaux ». Le cafre désigne à la fois les descendants des Malgaches et d'Africains.

[3] Signifie: l' esprit habite le corps.

[4] Ce terme designe les vieux artistes qui ont milité pour la reconnaissance et la sauvegarde du maloya, la musique traditionnelle de la Réunion. Ce sont des figures emblématiques et ont un rôle d' ainé et de guide.

[5] Signifie successivement « tenir ensemble » et « ne pas lâcher le corps » « résister ».

[6] Dans ce contexte, tout le champ lexical de la lutte et du combat peut être évoqué.

pa ti pa », « ti lamp ti lamp »[7] qu'on s'en sort. L'espoir et la foi en soi sont sous jacents à ce processus. Il existe beaucoup de proverbes dans la langue Créole enseignant l'acceptation et la patience comme facteurs de protection.

Pour marquer la fin de cette lutte- résistance et désigner le recouvrement après une expérience délétère, des catégories verbales traduisent le retour à un nouvel état. On dit d'un sujet, que « *li la* ensort a li » ou « li lé bien koméla »[8].Cette personne s'est dégagée d'un problème antérieur, le résultat est manifeste. Ainsi, « li lé libéré » (il est libéré), « li la levé » (il est debout) et peut continuer son cheminement. Certains mots et locutions évoquent aussi, au bout de ce parcours de lutte, l'idée d'une métamorphose, d'une transformation comme dans « li la refé ». Autrement dit, il devenu autre. Bien souvent, c'est suite à une nouvelle affiliation ou ré affiliation au sein d'un groupe culturel donné ou une rencontre spirituelle que cette transformation a lieu. Le résultat est une élévation de l'âme[9]. A la Réunion, les réalités existentielles s'interprétent dans une perspective baignant dans le mysticisme chrétien et/ou animiste. Les thèmes qui ont une forte occurence sont la famille, la religion, la tradition, le groupe social, les sentiments, la mort et le temps. Les valeurs traditionnelles, comme le respect des pratiques ancestrales des uns et des autres, le respect des aînés, des morts, la tolérance, la recherche de spiritualité imprégnent fortement ce discours. Selon Dumas-Champion (2008), dans le contexte réunionnais l'interprétation des maladies sert de base pour penser le religieux en général.

Conclusion

Cet exposé avait pour objectif de montrer qu' au delà des débats entourant la résilience, les obstacles d'ordre méthodologiques et théoriques peuvent s'aplanir. Des précautions doivent cependant être prises. Les effets contextuels sont puissants, il est difficile de les ignorer. D'autre part, se focaliser sur ce qu' UNGAR (2010) appelle "l' attachement au discours théorique objectif" constitue une entrave supplémentaire à l 'appréhension de ce concept. Une voie alternative reste la recherche empirique et une méthodologie créative et mixte. Dans la configuration traditionnelle étudiée ici, le phénomène se conçoit dans un cadre autorisant un saut épistémologique préconisant une résilience de l' Esprit (DERIVOIS, 2011).La résilience s'exprime dans une langue concrète, imagée mais qui soutient une pensée, une vision du monde complexe, multi et trans culturelle. Dès lors les caractéristiques individuelles ne peuvent être étudiées sans le processus qui a permis à un sujet dont l'identité culturelle est fortement subordonnée à son affiliation à un groupe déterminé. Celui-ci lui offre l 'étayage en cas de nécessité. Il peut acceder à d' autres groupes pour trouver son bien être et continuer à se développer. De sorte que le résultat issu de cette quête devient à son tour dépendant des deux autres éléments. L' atteinte d'une spiritualité signe le résultat de la résilience. L'analyse des écrits populaires montre une évolution et une différence dans l'esprit véhiculé dans la représentation collective. Autant le traditionnel emploie un langage de résistance, de lutte et de survie, autant la jeune génération s'exprime, clame de ne pas céder aux difficultés, de cultiver l'espoir, de s'élever, et croire en une divinité, prône la conscience collective et l'unité tout en conservant la multiplicité.

Narrative constructs of resilience in post-apartheid South Africa

Abstract

The concept of resilience is a multidimensional construct which has been defined in various ways and from multiple perspectives. A common element to most conceptualisations is represented by the adverse context in which resilience can be developed. This paper aims to identify specific constructs of resilience used by survivors of political violence in their narratives of recovery after serious trauma. The study adopted a thematic narrative analysis of twenty life narratives, taking into consideration the use of language, structure, sequence of events, chronology, plot and the meaning participants ascribed to various experiences. Results showed that stories of resilience have specific characteristics in terms of structure, language and content compared to stories of non-resilience. The analysis highlighted the following constructs of resilience: defining the self as survivor, fighter and hero, purpose and commitment towards fulfilling a goal, ability to access internal and external resources, healthy relationships and meaningful engagement with the social world.

Keywords: Resilience, narratives, *self*, thematic narrative analysis, post-apartheid, political violence

Introduction

The psychological impact of political violence during apartheid in South Africa has been extensively analysed through research, conceptual analyses and discussions during various academic events. Numerous research studies have emphasised the traumatic nature of political repression which had a negative impact on the Black and White population who were actively involved in the struggle against the oppressive regime. [1] [2] [3] [4] After the collapse of apartheid, former victims of political violence started to embark on a journey to psychological, relational, social and economic recovery. As expected, their experiences of the recovery process have been rather different. Some were able to rebuild their lives, developing resilience and even growth as a result of their traumatic experience. Others, on the contrary, were not able to make much progress as their continuous suffering increased their sense of helplessness and bitterness.

Several research studies have pointed out that a majority of survivors of gross human rights violations during apartheid have become more resilient as a result of their trauma. [3] [4] [5] The research methodology employed by researchers to analyse life trajectories in the aftermath of trauma used a combination of methods (quantitative, qualitative and mixed) in order to create space for more complex interpretations in the process of analysis. As part of the qualitative methods, it is commonly acknowledged that life narratives represent insightful ways through which one can gain a better understanding of the story teller's reality. [6] Regarding research in the field of psychology, narratives are usually used in the form of "extended accounts of lives in context that developed over the course of single or multiple research interviews of therapeutic conversations".[7] The political and cultural context shapes the narratives of individuals and groups in society. Narratives of war, genocide, mass-killings and refugees cannot be understood in the absence of a historical and political framework. Most studies on trauma and recovery processes have worked with life narratives of suffering, conflict and healing. [8]

In her book on narrative inquiry, Reissman identified specific elements and functions of narrative analysis, which are at the core of this research method. An important feature of narrative is its constructive and performative character. [9] Narratives do not convey unmediated facts and events since they rely fundamentally on language, memory, interpretation and human subjectivity. Consequently, narratives are not simple reconstructions of empirical past events, but ways in which past events are used by people in the present to make sense of their experiences and construct their individual and collective identities. [10] Narratives are part of the collective through the way protagonists shape their stories and use language. According to Antze & Lambeck (1996), narratives also contribute to the construction of collective experience and meaning in the present. [11]

The significant link between narratives and the self is emphasised by Paul Ricoeur (1992) in his book *Oneself as Another*. [12] He argues that people define themselves as being distinct from others through a continuous narrative process in which past and present events are organised into actions, motives and situations. [11] People construct identities through their stories, which fulfil multiple functions in the process. Riessman showed how narratives serve various purposes depending on who the speakers and the audience are. [7] For example groups and communities make use of narratives to mobilize masses into action, to protest against injustice and to contribute to positive social change. Narratives operate in a linguistic universe in which structures of language confer coherence, order and meaning to representations of events, experiences, characters and actions. Although language is the vehicle of representations in narrative structures, the meaning of events is not restricted by inflexible linguistic boundaries. In this vein, Scott argues that "experience is a linguistic event (it doesn't happen outside established meanings), but neither is it confined to a fixed order of meaning. Since discourse is by definition shared, experience is collective as well as individual". [13]

Therefore, such characteristics of life narratives are relevant for the analysis of resilient processes that might be present in survivors' stories included in this study. As a theoretical framework for conceptualizing resilience, Ungar's (2008) [14] model seems to be more complex and holistic than previous approaches [15], [16], [17], as it takes into consideration both individual and contextual aspects. These are reflected in the following dimensions: (1) access to material resources (personal agency, self-esteem), (2) relationships, (3) identity, (4) power and control, (5) cultural adherence, (6) social justice and (7) cohesion. [14]

Methodology

This analysis is part of a more complex research study that took place at the University of Cape Town in South Africa, during 2008-2011. [18] The study sample included twenty survivors of gross human rights violations who suffered: detention, torture, police harassment, displacement, shootings, or the loss of a significant other. Interviews were conducted during 2009 - 2010, involving participants from a diversity of race groups, ages, gender and socio-economic status. General areas of exploration were: (hi)story of suffering under apartheid, impact of traumatic events, ways of coping with negative effects, helpful and hindering aspects of their journey after trauma, present situation and views about the future. Interviews were recorded and transcribed for analysis. The study used qualitative research methods and thematic narrative analysis. The conceptual framework of the study was informed by contextual and narrative approaches to understanding trauma and recovery. Moving beyond a mere medical approach, the analysis highlighted complex articulations of trauma reconstructions and multiple pathways to recovery which emphasise resilient life trajectories.

Results and Discussion

Silverman suggests that while performing the narrative analysis, researchers should move beyond their data in order to find explanations. This means to move from "commonplace observations to a social science analysis" [6]. It is also what Braun and Clark (2006) defined as a search for *latent meanings,* a process considered to be more than a mere description of phenomena. Important questions to bear in mind at this stage would be: "What is the purpose of participants' descriptions in this study and what are their intentions in structuring their stories in a certain form?" and "What is the meaning of these stories and why are people telling these stories?" [19]

By examining survivors' narratives with a focus on these particular questions, the analysis process was able to access new and multiple levels of meaning in which social expectations, cultural values, language structures and identity constructs interact in sophisticated ways to shape the structure and meaning of narratives. Observing closely the life trajectories of survivors, clear differences were distinguished in the area of survivors' journeys after trauma up to the present time. Some narratives follow progressive pathways while others, on the contrary, show stagnation and regression which may point towards a condition of *continuous traumatic stress* following previous experiences of trauma. [20] Participants actively use language structures and metaphors to interpret and construct various meanings about their selves and the world in which they live. Thus, some participants in this study reconstruct themselves as survivors, heroes, successful, able to cope with challenges, resilient and in control of life events. Others, on the contrary, describe themselves still as victims, helpless, angry, bitter, defeated and disillusioned. The next section will discuss some of these features comparatively.

1.1 Two polarised worlds: narratives of resilience and helplessness

The use of language in the form of passive or active verbs, the use of personal pronouns as well as metaphors and symbols suggest a means for understanding intention and meaning in narratives [6] [7]. For example, in resilient stories, one can easily notice the extensive use of the "I" pronoun, active verbs and detailed descriptions about achievements and personal efforts. Such stories do not talk to a great extent about trauma and

its psychological impact, but rather describe positive coping mechanisms and how survivors succeeded in overcoming the negative effects. Through the construction of these stories, the self emerges as being in control of his/her life, as an agent of change and being engaged with social realities.

In the following quote, on only one page of transcript, the pronoun "I" is used over 50 times and the pronoun "my" 26 times. The paragraph shows how the language shapes the narrative form:

*And so this great fear almost apprehended you and these things welled up on the inside and **I** needed to deal with those things because **I** couldn't allow **my** greatest fear to restrict what **I** thought **I** needed in order to make a contribution. And so in dealing with this **I** needed to create within **myself** the opportunity to explore and internalise this great hope that whatever **I** went through had an expiry date. That is, it will end. That was **my** greatest hope. **I** just couldn't determine when it would end. But this hope was inside of **me** and so part of **my** answer to the solution was **my** hope. Hope is a fickle thing and very often disappoints you. Because of the struggles that **I** went through and the fact that **I** was born out of struggle as it were, **I** felt **I** had endured enough struggles to be able to carry on hoping this would be better. And **I** said to **myself:** this was only a transitory phase in **my** life. **I** am destined for greater things. That is what kept **me** alive, that is how **I** kept sane amidst all the insanity (P1).*

The quote shows how the use of active verbs (deal with, create, explore, internalise, determine, endure) and metaphors ("*I was born out of struggle*") create the idea of agency and control, which are important elements of progressive narratives. In addition, resilient narratives are more elaborate and descriptive, using a variety of language structures and vocabulary. One can feel that the narrator has a voice and something important to tell. [21]

On the contrary, the majority of Black participants who still live in townships and continue to struggle with poverty, unemployment, illness and crime have used a different type of language structure. They also considered it more important to talk about their past, their suffering under the apartheid and the impact of their sacrifice for the good cause. [22] They expanded on the impact that multiple types of trauma had on themselves as individuals as well as on their families and communities in which they lived. Their language reflects extensive use of verbs used passively (taken, put, beaten, carried) and of the pronoun "they".

***They** caught me and put chains around my legs. I was full of blood on my face. **They** threw me in the back of the van and took me to John Vester Square in Joburg at the 10th floor, room 1026. **They** tortured me, beating me and asking me all sorts of questions. **They** put a handkerchief in my mouth, cover my mouth with a plaster, put my hands at the back with handcuffs and **they** chained my legs. Then **they** covered my head with a wet bag. While I was struggling breathing **they** electrocuted me. I don´t know how many times. When **they** cool it out, I was very numb… (P2)*

Participants make extensive use of metaphors in their stories. This is highly visible, especially when they try to reconstruct their pain and negative feelings. Metaphors, comparisons and personifications become useful tools in participants' attempt to find the right language to describe their suffering. For example, one survivor (P5) describes herself in the light of past and current victimisation through a powerful metaphor: *"I'm a vandalised person by the apartheid"*. Another participant (P7) describes himself in the present as a *"mental wreck", "a laughing stock"* and *"a joke"*. Similarly, when talking about his recovery after trauma with regard to his family, one participant (P12) concludes: *"We cannot be recovered… we are just mingling around in mist"*. In addition, when talking about current attitudes of people in black communities, one participant used a powerful comparison: *"It is such a sense of poverty and our people is nesting it like a baby. Poverty is their baby. They should say, no! Go out! Don't stay with me! You are not my friend! I'm fighting with you! You are the devil!"*

All these elements point towards what Silverman termed the puzzle, arguing that it has to be assembled piece by piece in the process of analysis. [6] A major task at this stage was to find explanations for the intention behind the use of language in the narratives. Within this context, Silverman's indication is to search for data outside the confines of the study. Therefore, we complemented existing information with findings from similar and broader social contexts by searching deeper with regard to the moral and cultural worlds of the two types of narratives, whose protagonists were former victims of repressive structures of apartheid. On the one side, it was the universe of those who "have made it" or who "are climbing the mountain" and are at various levels of height. On the other side are those who "are still struggling" or have not made much progress in climbing the mountain. The metaphor can go on with regard to why the second category of people were not able to climb the mountain, whether because of lack of the right equipment (education and personal resources) or fear of difficulties (lack of skills and social support) or because of trying to find an easier way around the mountain (avoidance/passivity). However, although such presuppositions may carry with them some psychological truth, there is a need for a more profound analysis and interpretation both in the context of the study's further findings and previous theoretical concepts.

1.2 Dimensions of resilience in post-apartheid

A common element of resilient life trajectories is the success and achievements experienced by survivors throughout their lives after trauma. Considered by various researchers as positive outcomes in the

process of recovery and development of resilience, such constructs represent important elements in survivors' journey of defining meaning of their selves and the world in which they live. [23] There is clear evidence that participants in this category define themselves in positive terms. They display their identities emphasising their strengths, success and achievements, situating themselves in contrast with people who do not possess such qualities. They seem fully aware of the victimising connotation inferred through the victim label and prefer to call themselves survivors instead of victims (*I am very strong, I'm a survivor, I can take anything! I helped many people. Other people become morbid, depressed, depending on tablets to make them sleep, tablets to wake them up. I'm not that way, I'm not that way! I find means of getting stronger because my faith is strong and I won't allow anybody to diminish my mind. Most of the time, I try my best to be the person that I am. P5)*

One of the most important aspects regarding the ways in which participants in this category rebuilt their selves concerns the development of constructive coping skills. An important role in this process was played by an individual's ability to access internal and external resources and to pursue higher goals. Personal qualities and talent were considered by survivors an important resource in dealing with the impact of trauma and a way of creating new meanings in life. These attributes together with positive perceptions about the *self* have been considered important elements in the construction of resilience and posttraumatic growth. [24] [14]

As was observed in people's narratives, the way to developing good coping has been paved with great effort and mixed feelings. For example, one survivor expressed the struggle, loneliness and confusion she experienced in the process of finding meaning. Art became her "*escape*" and "*shelter*":

You can be alone in the fight because you cannot express yourself, sometimes you don't know what you really want and you try to find what you really want. My art became an escape, it gave me shelter. I didn't have good schooling, good academic skills. I dropped out of school but I always felt there was nothing I could do without having good education, good family structures. I can give to other people. I felt I had that gift that I can give to other people. (P18)

Her words clearly show how the self is rebuilt and paradoxically enriched by giving to others, a fact that supports the relational dimension of the self. [12] [25]

Another important step for participants in developing good coping skills was to refuse passivity and victimisation (*"I was not given many opportunities, but (...) I was not going to blame the legacy of apartheid or to be marginalised." P 11).* Pursuing and fulfilling goals (not only setting goals) was also mentioned by most participants as an important aspect of their successful life trajectories (*"I was going to pursue this at whatever cost. I have already pursued other things in my life and the cost was nearly my life. So, why would I now hold back on my life in terms of shaping direction?"*) In defining coping strategies, resilient participants expressed several beliefs: (1) good decisions have to be followed by actions *("when I make up my mind about something then I go all out for it"*), (2) there are important lessons that can be learnt from mistakes *("I see failure as a growth process"*), (3) one needs to assume risks in life *("If I hadn't taken the risk, I wouldn't have accomplished what I needed to accomplish"*) and (4) failure is not an end but "*another stepping stone towards getting to where I needed to go"*. According to Bonano's (2004) theory of resilience, these characteristics describe hardiness - a concept considered to be one of the "multiple and sometimes unexpected pathways to resilience". [26]

Last but not least, the anchoring of the self on religion and faith appeared to be a constant element in the struggle against the destructive legacy of the totalitarian political context of apartheid. Religion and religious beliefs, as fundamental markers of identity, can offer solid ground for building resilience in times of political crisis and conflicts. [27] As one survivor mentioned: "*I think it has everything to do with my faith that I have. I strongly believe that we are a purpose-driven creation"*. For him, the spiritual dimension is not just another facet of the self but rather the transcendental framework in which all the other dimensions of the self (as caring, loving, capable, successful and forgiving) make sense and are able to draw their energy from.

In terms of perceptions about current contextual realities, most participants emphasised the importance of continuously engaging with the context in which one lives by assuming responsibility in relating to others and defining the social context. One participant perceived it as a daily struggle as "*dealing with people in the world, there will always be things taking you back in that situation. Each time when you wake up you have to say: Ok, I'm going out in the world today and I don't know what is gonna come. Today I don't know who I am going to meet"*. However, social change in the context of transition depends on multiple interacting factors. The intersection between identity, race and economic inequality is evident in participants' perceptions of current contextual concerns.

Finally, being engaged in the social context did not mean only expressing positive views but also openly addressing issues of social concern. The slow change regarding the issue of poor housing conditions in black communities made one survivor affirm that "*apartheid is still there, townships are still there. If the ANC will be sincere, they will do something about townships, try to put people together…"* Being disappointed with the current economic and political situation is arguably understandable in the context of participants' personal investment and traumatic experiences in the struggle against apartheid. One the one hand, this aspect supports Crossley's (2000) idea of the self as being constructed through "historical and social structure". [28] On the

other hand, it highlights Taylor's (1989) concept of a "moral universe" as a context in which the self reflectively makes sense of what is "good" through responsible engagement with the world. [25]

Conclusions

Summing up the main findings of the narrative analysis, one can easily notice that resilient life trajectories have distinct characteristics compared to non-resilient stories of recovery. Taking into consideration the structure, language, tone, content and meaning of the narratives, it can be assessed that resilient stories convey more agency (through the use of active verbs and the pronoun "I"), are more present and future oriented, have a more optimistic tone and are more concerned with the rebuilding process than with the damage caused by traumatic events. The multiple ways in which survivors have developed resilience in their journey to recovery were related to various aspects such as good coping skills, agency and control, positive self-concepts, healthy relationships with others, spiritual development and active engagement in communities. This situation confirms Bonano's (2005) statement that resilience is more common than is often believed and that it can be achieved through multiple pathways. [26] Furthermore, resilient narratives celebrate the success and ability of individuals, families and communities to repair what trauma had destroyed in their lives. Obstacles are seen not as failures but as important lessons for the future. However, resilience is not an end in itself but a continuous process of making meaning and rebuilding oneself, *others* and communities. Since its rebirth after the collapse of apartheid, the rainbow nation of South Africa is continuously learning to develop resilience, growth and transformation.

Abstract

The paper discusses aspects referring to the organizational resilience in the mining field within the Valea Jiului area. The restructuring of the mining sector, following the institutional reformation undergone by Romania during the transition period, entails a rethinking of the mining field, in order for the actors involved in the resilience process to assimilate new action models.

The complex problematic of the social and economic reality in the Valea Jiului area has aggravated the decline of the area in all areas of life. This entails a sociological approach that underlines the understanding of the interaction between the institutional subsystems, when the decline of one of them generates a dysfunction in the other interposed subsystems. The paper focuses on analyzing the social and demographical tendencies, the strategies and the social and professional behaviours in the Valea Jiului area, as adaptive means through which people perceive and overcome certain structural changes, in the context of post-December institutional and organizational reformation. The presentation of such tendencies is objectively supported by the evidence of statistic data recorded during 1990-2011 and reflected on a subjective level in the perception, attitude towards or assessment of the problem studied. In this context, that of a difficult social and economic period, such as the current one, organizational resilience plays an important role in the institutional recovery process conducted within the Valea Jiului area, which will lead to a revitalization plan for the area. The importance of social knowledge is given by the outlining of the major tendencies that support adaptation and the drafting of sectorial policies and strategies that would correspond to the current local social and economic realities, as well as that would generate the desired effects. These have to be harmonized and correlated with the existent regional and national policies and strategies, by sketching the priority problems and their degree of social utility.

Key words: resilience of organizations in the mining industry, contemporary economic and social crisis, institutional restructuring and adaptation, organizational sociology.

Introduction

In our paper, we have tried to approach aspects referring to the organizational resilience in the mining field within the Valea Jiului area, from the perspective of the restructuring of the mining field, as a result of the institutional reformation undergone by Romania in the post-December period. This has entailed a rethinking of the sector, in order for the actors involved in lead resilience to assimilate new action models. This study is based on the perception the employees from the institutional mining system in the Valea Jiului area have on the institutional and organizational capacity to adapt to the post ’89 social, economic and political changes.

The problematic of an ample transformation of the old centralized economic system into a functional market economy, following 1990, marks the beginning of a long and difficult road that has led to important mutations within all the aspects of the economic and social life, the knowledge of the economic and social reality becoming an essential factor and requiring the joint participation of specialists in interdisciplinary fields: sociology, economy, anthropology, history, demography, as well as other branches of science. Institutional fluidity (therefore the absence of institutional crystallization) and institutional rarity are the first characteristics of the macro-social transition space. [7] The institutionalization processes initiated during the first transaction years have targeted especially the social “periphery”, meaning the areas in which social complexity could be reduced through simple mechanisms.

Taking into account the complexity of the processes and the phenomena, determined by the multitude of features and characteristics of these organizational mutations, there is the need of a deeper knowledge of the resources involved and of the effects generated by the activity analyzed. At the same time, it must allow for the

objective selection of the most efficient manner to adapt to the new organizational structures. [8] According to the field literature, it has been deemed that the manner in which public organizations can be made more efficient is by being taken over by private management. [4] Management is a set of beliefs and practices developed within organizations as a strategy for improving performances. As Peter Drucker used to say, "managers and management make institutions perform".

The analysis of the institutional process as a system leads to identifying certain **qualitative characteristics**, because institutional reorganization, through the dynamics of the restructuring operated on an institutional level aims to make the institutional system more **flexible and more efficient**. Due to its nature, the process of institutional reformation accomplishes a **function of structural adaptation** to the European requirements. As a system for the extraction and processing of mineral resources, dimensioned from the point of view of material and human resources, according to the efficiency objectives and criteria, the production process fulfils the economic function. At the same time, as a form of social work, and as a place in which human personality is moulded, it also fulfils a social and human function. In this meaning, Peter Drucker says that the social reasons have priority, because the institutions are born to serve individual and collective interests of the collectivity, and not the other way around. From the point of view of this process of constant adaptation of the mining units to the market requirements, institutional reorganization plays an important role in the organizational resilience within the Valea Jiului area.

The optimization of the institutional system, from the point of view of the mining activity, is the fundamental element for creating new work places, both within the system, as well as within other interdependent ones, and can generate, in turn, a regeneration of the regional social space.

The adequate and efficient usage of work force in reasonable economic and social conditions, entail that the division of work, the expansion of the professional profile and of service areas be conducted in adequate development conditions or be based on the Valea Jiului area's capacity of institutional recovery, because the complex problematic of the social and economic reality in the Valea Jiului area has aggravated the decline of the area in all areas of life. This situation entails a sociological approach that underlines the understanding of the interaction between the institutional sub-systems, when the decline of one of them generates a dysfunction in the other interposed subsystems. Taking all of the above into consideration, this paper aims to study the organizational resilience in the mining sector of the Valea Jiului area, by analyzing the perception of the employees of the mining units within the Valea Jiului area. The capacity to adapt to the new conditions within the mining sector in the area contributes to the development process of the area, and is at the same time a factor of economic and social balance of the area.

The research methodology

This paper lists several aspects related to the **results obtained,** following the research conducted within my doctoral thesis entitled "Institutional birth rate and death rate – a sociological perspective on mining". A social inquiry was conducted, having as its research tool the questionnaire, applied within the National Pit Coal Society of Petroşani (SNH). Both elements related to the objective situation of the mining unit, correlated with the local social and demographical tendencies, as well as aspects related to the subjective state of the employees within SNH, as well as subordinated units were subjected to social analysis, in order to outline an image as faithful as possible to the current 2013 reality of the mining sector within the Valea Jiului area, as a fundamental activity in the area.

Taking into account the **high number of employees** (5,166), it was necessary to resort to a **pool** that would faithfully reproduce the shares held by the following variables: the ***mining units*** subordinated to SNH and the ***gender structure***. As a pool scheme, we have opted for the "share" pool. The volume of the pool was **5%** of the total population, which has led to a pool of 258 employees, and after rounding it up where necessary we have reached a pool volume of **273** subjects.

The distribution of the subjects according to mining units was as follows: "EH Lupeni" (29.30%) followed by EH Lonea (21.25%), EH Livezeni (20.88%) and EH Vulcan (15.38%). For the other three units, the percentages are significantly lower, and put together they barely exceed 10%. Due to the fact that mining is a difficult activity that entails effort and physical force, meant mainly for men, we found that the male gender has the largest share (80.22%).

The subjects' assessment of the changes occurred within the mining sector

The social and economic effects of the restructuring process occurred within the mining sector have been felt strongly by the population in the area and require well-elaborated social measures in order to create a favourable context, needed in order to develop the business environment and a competitive economic spirit that would entail a favourable perspective for the development of a functional market economy, in order to elaborate

a viable decisional alternative on the optimization of the social and economic structures within the Valea Jiului area.

The evolution of the mining sector within the Valea Jiului area, throughout time, has known an ascension prior to 1990, generating a significant increase of population in the area, due to the migration of the work force from more or less surrounding areas. The policies promoted before 1989 gave birth to the development of an oversized mono-industrial centre, with a concentration of mono-qualified work force dependent at the same time on the evolution of the mining activity within the area. Within the context of national political, economic and social changes, the post-December period is characterized by an obvious downfall of this economic sector.

The transition period has generated, among the population, the uncertainty of a work place, thus conditioning the withdrawal of a significant mass of population from this activity. This situation was even more inevitable in the Valea Jiului area, because this area was included in the national program for restructuring and orienting the industrialized areas towards an economically competitive market.

An overview of the average number of employees shows that this remains relatively constant during 1991 – 1996 and then decreases significantly during 1997 – 1999, due to the restructuring of the mining activity, in each of the localities within the Valea Jiului area. After 1999, the average number of employees remains relatively constant, until 2011, except for Petroşani. As of 1997, the average number of employees decreases by 45% during a period of time of only 3 years. This decrease is explained through the layoffs occurred in the mining sector during that period, and by the fact that the extractive industry plays a primordial role within the entire industry of the Valea Jiului area. From 1999 to 2008, the number of employees remains constant, and following 2008, it begins to decrease again due to the onset of the economic crisis. In the Valea Jiului area, the average number of employees has decreased from 71,217 employees in 1991 to 28,448 în 2011. Therefore, within 20 years, the number of employees in the area has decreased by 42,769 employees.

The results obtained following the sociologic inquiry conducted on the employees of the National Pit Coal Society shows the subjective side of the institutional mining system within the Valea Jiului area. The main aspects observed by the research, as a result of the institutional reformation, focus on the subjects' opinion regarding the causes that led to the restructuring of the mining sector and the current situation of the mining sector, as well as an evaluation of the measures related to the personnel layoffs and the institutional reorganizations conducted. We have also touched upon aspects related to the perception of the subjects on the institutional future of affiliations within the energetic complex envisaged, as well as their opinion on the possible solutions to improve the mining sector within the Valea Jiului area in general.

The measures taken in order to render the institutional system more efficient and more flexible have affected both the employees who were laid-off, as well as those who remained within the system. The employees' assessment of the financial situation and the current work conditions shows to a certain extent the degree of contentment or lack of contentment of the subjects with the current work conditions.

In order to analyze the effects produced by the changes occurred due to the restructuring of the mining sector, we have to see how these transformations influenced the life of the employees in particular and that of the company in general. First of all, the changes brought about by the national reformations have strongly influenced the financial situation of the population in general. Moreover, the financial situation can be evaluated from the point of view of various salary losses. Almost three quarters of the people interviewed believe that their financial situation has been greatly affected.

The stagnation of salaries has been attributed to a lack of state subsidies, as well as to factors related to the productivity of work. During 1990 -1994, any salary claim would be satisfied, and if not, it would be peacefully supported through certain forms of manifestation, until reaching a consensus satisfactory for those claiming their rights. Following 1997, such protest forms were attempted again, but the financial and material incentives diminished. With the onset of the economic crisis, which affected the entire world, the incomes became insufficient to support one's family and to ensure minimal decent living conditions. All these aspects have affected the situation of each employee. At the same time, we notice that the majority share of respondents incline towards a deterioration of the mining sector following 1997. That years is taken as a reference year, because it represents the beginning of the process of enforcing the politics on the restructuring of the mining field, by applying OUG 22/1997 on personnel layoffs, when the percentage of layoffs in 1997 reached 48%, according to the analysis of the data on personnel layoffs recorded during 1990 – 2011, within the National Coal Company.

Therefore, the poignant limitation of the coal production during the second half of the 90's is not so much the result of the implementation of a coherent restructuring and efficiency strategy, which should have been applied immediately following 1989.

It was necessary to adapt the system to a market economy, from both a structural and a functional point of view, because a system based on a free market economy is built on competitiveness, efficiency, competition and hierarchy of values, while a system with a planned centralized economy promotes non-compliance with the hierarchy of values and a more reduced efficiency. When referring to the dynamics of

transforming a centralized system into a free economy one, professor Krausz Septimiu points out two directions for the incongruities related to the first reparatory measures applied during the 1990's, which should have engaged a more correct understanding of the need for a change. (134) These measures could have been justified by the frustrations generated by the system with a planned economy, which believed in the collective mentality that a person with modest qualifications could be supported by society through the fact that they benefitted from the privilege of becoming unemployed. The other direction refers to the exaggeration of the claims promoted, during the first post-December years, regarding working hours, salary or retirement age. These subjective aspects have slowed down the creation and implementation of certain adaptation mechanisms of the institutional structures to a working and efficient system. We find that the predominance of answers given to another question targeting the current problems within the Valea Jiului area is overwhelming in what concerns the absence of alternatives for the absorption of work force (91.21%). Two thirds of the subjects believe that another problem, mainly due to the restructuring of the mining sector within the area, and to the layoff of a significant part of the work force, is the occurrence and establishment of unemployment.

The institutional reorganization of the industrial sector was one of the main premises for the reformation process, consisting of a series of measures and actions meant to create a mechanism that would ensure the national economy a sustainable functional structure that would function at a high performance level. In this context, the managerial experiences within the last years, regarding the organizational measures adopted within the institutional strategic framework including the company, have targeted mainly the invigoration of the activity in terms of economic performance that would lead to more efficient organizational structures and to an increase of work productivity. In this regard, the sociologic analysis, from the point of view of managerial experiences, is placed within the practice of industrial unit management. It was observed that almost a third of the subjects believe that institutional reorganization is "rather not" a solution for the future of viable mines in the process of institutional efficiency.

It is observed that the decrease in the usage of coal as an energy source is justified by the closing down of certain economic units that used part of the coal exploited to produce steel. The decreased usage of coal within the last few years is also explained by the decrease in the usage of energetic pit coal for electrical energy extracted within the area, due to the relatively high cost as compared to that of imported coal. The economic crisis represents a serious factor that should be taken into consideration, because it significantly contributes to the process of limiting certain activities both in the field of mining, as well as in other fields of activity, slowing down the functioning of the system or even interrupting the activity during a larger or smaller period of time. We observe that almost half of the subjects believe that the lack of investments is the greatest problem of the stagnation of mining, another great dysfunction in terms of mining being the absence of national field policies, followed by the much too obsolete technology and a faulty management, in the subjects' opinion. Almost half of the subjects believe that the lack of money for subsidies is the main cause that led to the restructuring of the mining sector, generating organizational and structural changes, personnel layoffs and the shutting down of numerous mining units. In the subjects' opinion, almost a third of them identified as another problem that has led to the mutations listed above the lack of outlets, and then a smaller percentage believe that the focusing on alternative and renewable resources would be another cause for the restructuring of the mining sector.

Conclusions and recommendations

The need to maintain a social and economic life within the Valea Jiului area, as well as a positive evolution of the area, mainly entails solutions meant to reduce the institutional death rate, as a means of awareness of the negative tendency of the Valea Jiului area. When the mining personnel layoff measures were implemented, the situation of the Valea Jiului area was aggravated. This measure, part of the institutional reforming process, has failed to prove its efficiency, because 20 years following the transition, the great problem of the Valea Jiului area, also supported by the majority of the subjects, is the lack of work places. This aspect shows the lack of a perspective based on sustainable development for other activity areas that would ensure a viable sustainable development alternative for the area. In what concerns the economic re-launch of the social space researched, the subjects listed the following alternatives:

The undergoing managerial restructuring should focus on creating new work places and on optimizing the conditions of professional expression for all professional segments in the mining sector. Therefore, the overcoming of the narrow economic vision on mining entails a re-evaluation of the entire situation, starting from the social parameter, respectively from the creation of new job opportunities for those who were laid-off, but also for the young generations to come, that may opt to continue the traditions within the Valea Jiului area.

The initiation of a strategic program meant to create alternative occupations for the population in the area. The envisioning of professional alternatives as a realistic perspective to capitalize on the professional potential of the area is another of the possible solutions meant to increase the employment rate and the economic optimization of the area. This prerogative represents the perception of the social actors subjected to the authority

of the regional and local decisions made. After analyzing the current 2013 situation of the area, a regeneration plan for the Valea Jiului area should be drafted, supported by certain and real propositions, which can be monitored and quantified into results.

From independence to strength: institutional resilience and coping mechanisms in ngos providing social services financed through public financing mechanisms

Baciu L.

West University of Timişoara (ROMANIA)
baciu.loreni@gmail.com

Abstract

The Public-Private Partnership (PPP), under its various forms (from privatization of public services to subsidies for private bodies) has been discussed in many occasions and found to be one of the most desirable methods for developing social services tailored on the needs of the communities.

What happens with the NGO once entered in such partnership and how its structure and form changes because of it, is an entirely different matter, which has not been discussed as much.

The current paper is focused on analysing the changes brought to the NGO (in terms of structure and function) by the experience of accessing and managing public financing and the struggle of these entities to remain independent, while passing through this experience. Local research at the level of Western region, Romania, showed the coping mechanisms used by the NGOs in their fighting for survival during the period of post-communist private donors' withdrawal. The implications of adopting the public funding solution are also analysed and discussed.

Keywords: public financing for NGOs; organizational autonomy, identity and development; institutional coping mechanisms.

The third sector organizations – alternatives or complements of the Governmental institutions?

After 1980, the third sector (represented by the non-governmental non-profit organizations) started to gain more and more public recognition at the level of the EU. Some of the delays, inconsistencies, and inertia periods [1] were counterbalanced by the various research initiatives focused on understanding the role and place of the third sector in a modern democratic state [2], thus making possible the current progress known by the third sector, which is now almost unanimously recognized in EU as an equal and reliable partner of the governmental institutions [3], the establishment of the European Economic and Social Committee (EESC) being just one of the numerous examples of the third sector`s current status in the EU.

Various authors [4, 5] consider that the recent and accelerated growth of the third sector organizations in Europe can be considered a sort of an institutionalized response to the market and state failure, generated by the dependency and universality embedded in the provision of the social services.

As compared to the public sector, the private sector (including non-profit organizations) has been analysed and found to be more flexible [6], more efficient [7] and productive [8], easier to manage and administer [6], and, at the same time, with relatively more motivated and satisfied employees [9]. Of course, many of these findings were highly debated [10].

The popularization of these results made possible for the third sector organizations to improve their public image and gain even more public support.

1.1 Public financing – opportunity but also a risk

The public financing mechanisms available for the NGOs are numerous and diverse as regarding their purpose, nature and administering procedures, varying from direct financing in the form of grants, subsidies or loans [11], to more indirect and subtle forms of assistance, as *tax exemptions on income or tax incentives on philanthropy* [12].

In a visionary article, published almost two decades ago, Bossuyt and Develtere [13], after reviewing and cataloguing the most important four approaches used in public financing mechanisms for the Northern NGOs (the famous „program", „project", „windows" and „Quango" approaches), make a very interesting point in highlighting the fact that, in their efforts to self-ensure a certain level of financial stability by accessing public funds, the NGOs risk losing in some extent either their autonomy (becoming dependent on the public financing bodies and adapting the structure and internal mechanisms to the requirements of those external factors) or their identity (becoming more market-oriented and losing touch with their initial mission and objectives).

Of course, both those risks could be prevented by not accessing and/or using public funding, but, in a time of shortage of private resources, this is a luxury that only a few NGOs can afford.

Study regarding the Influence of public financing on the structure and functioning of recipient NGOs

1.1 Methodology of the study

In 2010, a research was conducted on a sample of 28 NGOs accredited as social services providers in the Western Region of Romania (in Arad, Caraș-Severin, Hunedoara and Timiș counties). One of the objectives of the research was to establish if the public funding has an impact on the recipient NGO and, if so, what is this impact, in terms of autonomy, identity and development level.

This part of the study used the perspective of Bossuyt and Develtere [13] enounced earlier and was based on the assumptions that, in time, the public funding impacts the activity and identity of the recipient NGOs, (1) making them less autonomous, but (2) more developed and, at, the same time, (3) more market-oriented, derailing them from their initial mission.

Moreover, the horizontal assumption of this part of the study was that, these effects are directly proportional with the experience of the NGOs in accessing and managing public funds.

1.1.1 The method

The organizations were selected from the on-line database of the Ministry of Work, Family and Social protection and were all, at the time of the study, private accredited social services providers from the Western Region, Romania.

In order to collect the necessary information from the organizations, a questionnaire with 32 items was sent to the organizations` representatives. The items referred to different technical, operational, financial and statutory aspects of the organization`s activity within the last 3 calendar years (2007-2009). The answers collected were included in a database and their statistical interpretation was conducted with the SPSS program – version 12.00 for Windows.

1.1.2 Operationalization of concepts

Organization`s level of development (low, average and high) - its financial and operational capacity, expressed in five characteristics: total number of employees in the last 3 years; the percentage of qualified employees from the total number of employees, within the last 3 years; annual budget over the last 3 years; total number of projects implemented by the organization within the last 3 years; annual average number of beneficiaries over the last 3 years.

Autonomy of the NGO (low, average and high level) – its capacity to maintain the control of certain structural and functional organizational aspects, expressed through not altering the structure and functioning of the organization (mainly motivated by compliance with eligibility rules for accessing certain public financing programs) in regard to the following components: statute (mission and objectives), personnel structure, activities, target group, partnership network, reporting methodology, working methodologies within the financial/accounting department.

Experience regarding public funding (low, average and high level) – expressed by the percent of the public-financed projects in the total number of annual project implemented; number and type of applications submitted for public funding over the last 3 years; number and type of public funding obtained over the last 3 years.

Level of public financing (low, average and high level) – expressed through the percentage of public funding in the total annual budget.

Orientation towards a certain type of partnership structures (towards public partners, towards private partners and un-defined) – calculated based on the number of partnerships/collaborations the NGOs had established and the nature (public or private) of the partners.

1.1.3 The results

The results of the study confirm the initial assumptions in all three regards:

Indeed, there are strong evidences that the public financing impacts the recipient NGO in terms of autonomy, development level and identity, as shown below.

a) The influence of public funding over the autonomy level of the recipient NGO

The crosstabulation between the level of experience in managing public funding and level of autonomy of the organization show (Table 1) show that, the two characteristics find themselves in an inverse proportionality relationship: as the level of experience in managing public funds raises, the level of autonomy of the NGO decreases. Most of the NGOs that report a high level of autonomy (80%) are organizations with a low level of experience in managing public funding. Half (50%) of the organizations with a low level of autonomy are identified as organizations with high level of experience in managing public funding. Interestingly enough, an average level of autonomy relates more with a low level of public funding experience (67%) than with an average level of experience (33%). This situation, in our opinion, describes the NGOs that have been making all necessary efforts to access public funding, but still didn`t succeed.

*Table 1. The experience level in managing public funding * The level of autonomy Crosstabulation*

		Level of autonomy of the organization			Total
		Low	Average	High	
Level of experience in managing public funding	Low	3	4	8	15
	Average	3	2	1	6
	High	6	0	1	7
Total		12	6	10	28

These results are further confirmed, when the level of autonomy is put in connection with the level of public funding as a percentage in the total budget of the organization (Table 2). Thus, we can observe that the organizations which present a high level of public funding as percentage from their annual budget are those described by a low (80%) or average (20%) level of autonomy. None of them has registered a high level of autonomy. Moreover, all the organizations that present a high level of autonomy are described exclusively by a low level of public funding.

*Table 2. Level of autonomy * Level of public funding in the annual budget of the organization Crosstabulation*

		Level of public funding – Percentage from the annual budget			Total
		Low	Average	High	
Level of autonomy	Low	7	1	4	12
	Average	5	0	1	6
	High	10	0	0	10
Total		22	1	5	28

b) The influence of public funding over the development level of the recipient NGO

The organization`s general development level over the period 2007-2009 was put in relationship with two variables: the level of experience in managing public funding and the level of public funding as a percentage in the total budget of the organization (Table 3 and Table 4).

Both crosstabulations show us a consistent, although incomplete picture:

*Table 3. The general development level * Level of experience in managing public funding Crosstabulation*

		Level of experience in managing public funding			Total
		Low	Average	High	
General development level	Low	10	2	4	16
	Average	4	3	1	8
	High	1	1	2	4
Total		15	6	7	28

*Table 4. The general development level * Level of public funding in the annual budget of the organization Crosstabulation*

		Level of public funding in the annual budget of the organization			Total
		Low	Average	High	
General development level	Low	12	1	3	16
	Average	7	0	1	8
	High	3	0	1	4
Total		22	1	5	28

Thus, while both crosstabulations clearly indicate a consistent connection between the low level of general development and a low level of both experience in managing public funding and public funding as percentage in the annual budget, still, none of them is valid for the opposite: the high level development seems to have no connection with neither the level of experience in managing public funding nor the level of public funding as percentage in the annual budget.

This could be translated into the following conclusion: while the public funding does not necessarily guarantee the development and/or progress of the organization, still, it could be an efficient solution for overcoming the risk of decline or stagnation for an NGO.

Moreover, we can observe that the level of public funding in the annual budget of the organization is equally un-involved in inverse proportionality relations – the high-low connection is equally distributed (11%) between the organizations high level of general development and a low level of public funding in the annual budget and between the organizations that have a low level of general development in spite of their high level of public funding in the annual budget of the organization.

Once again, this draws attention on the inconsistent relation between public funding and organizational progress of NGOs. This means that the NGOs that manage to register progress over a certain period of time have a very well extended repertoire of solutions for facing the challenges in their development. We could surely say about these organizations that they have managed to be resilient to external negative impact factors (for example, the decrease in number of the private donors in the last years), but without using the very popular coping mechanism used by the large majority of NGOs to overcome financial difficulties - that of accessing public funding.

c) The influence of public funding over the identity of the recipient NGO

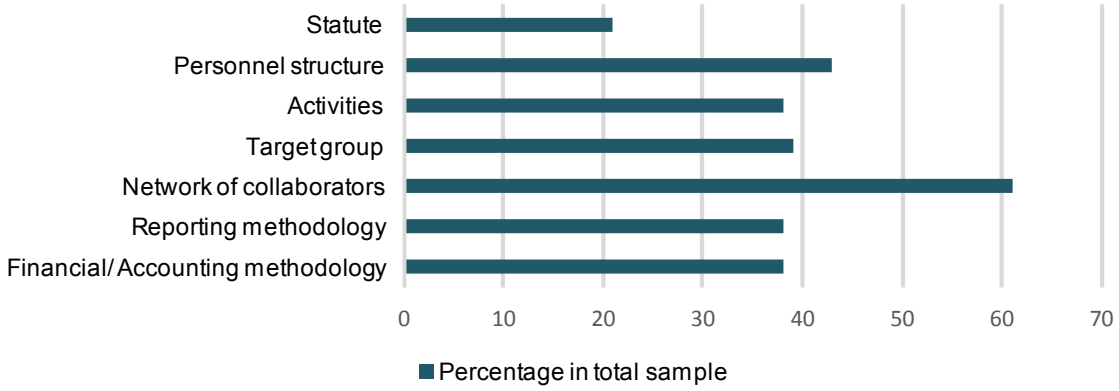
When crosstabulating the orientation of the NGO towards a certain kind of partner networks and its level of public funding as percentage in the annual budget (Table 5), we notice that the majority of the organizations that register a low level of public financing (59%) are more oriented towards collaborations with private partners, while most of the organizations with high levels of public funding (60%) are more oriented towards public partners and collaborations.

*Table 5. The orientation towards.... partnerships * Level of public funding as percentage of the annual budget Crosstabulation*

		Level of public funding in the annual budget of the organization			Total
		Low	Average	High	
The orientation towards.... partnerships	Private	13	0	1	14
	Public	7	1	3	11
	Un-defined	2	0	1	3
Total		22	1	5	28

If we add also to the picture the situation of the changes made by NGO representatives in the structure and functioning of their organizations, as a result of or in order to meet the eligibility requirements for public funding (Figure 1), that we have previously used for evaluating the organization`s autonomy level, but is also a good indicator for the organization`s capacity of keeping its identity over time, we can observe that, indeed, the access to public funding impacts the NGOs identity in notable ways. It would be very interesting to also have a feed-back on the public perception regarding this process of adjustment used by the NGOs to cope with the changes in their environment.

Fig. 1 Organizations that operated changes regarding the following dimensions, as a result of or in order to meet the eligibility requirements for public funding



1.2 Conclusions of the study

While it is clear enough that the public financing has its positive and negative effects over the recipient NGO, we cannot say for sure if the risks it encumbers are worth taking on.

After all, as we observed, the level of development in terms of progress seems in no way influenced by the use of public funds. On the contrary, if we were to analyse just the organizations that have registered overall progress over the last 3 years previous to the study, we would observe that most of them (60%) preferred other donors instead of public ones.

At the same time, we clearly see that the large majority of the organizations that were in trouble during this period (low development level) are organizations with low interest/experience in public funding.

In terms of impact on organizational development, this would make the public financing for the NGOs more a vaccine than a medicine – it will help prevent the disease, but it will not cure the patient.

As about the two other matters in discussion (autonomy and identity of the recipient NGO), we observed that they are both affected in case of long or intense exposure to the public funding of the recipient NGO. This involves two inter-related risks:

- firstly, the NGOs become in time more institution-like and, thus, more bureaucratic, losing the only feature the researchers agree it`s superior within NGOs than in public institutions – their flexibility;

- secondly, because of this „derailment" from their initial mission statement, the NGOs could lose the support of the community members, because, probably, these members have given their initial support to the NGO in first place because it represented an viable alternative to the public institutions that have failed to answer satisfy their trust.

Acting in these conditions and choosing a solution over another is really nothing else but a medium-versus-long-term thinking. We could say that it is probable for the long term perspective to be the winner in this case (the NGOs who choose to stand by their initial mission statement and avoid the traps of public funding), but at the same time we are very aware that this victory has very slim chances to take place in this advertising-ruled society, where the, currently, those most visible seem to be the most appreciated.

Resilience in humanitarian aid workers: understanding processes of development

Comoretto A.

London South Bank University (UK)
comoretto@gmail.com

Abstract

The objective of this study was to assess a conceptually based model of resilience development, centered on the interrelationship of three groups of protective factors (individual, cognitive, environmental), in a cohort of humanitarian workers deployed in the field. This was a mixed-method investigation incorporating a longitudinal survey design and qualitative interviews. A structured questionnaire composed of 11 different scales designed to measure key protective/adverse factors were administered to humanitarian aid workers (N= 56) pre- and post-deployment in the field. These questionnaires incorporated previously validated and widely used scales to measure resilience levels, work stress, coping skills, social support networks, general health, self-efficacy, and dispositional optimism/pessimism. Semi-structured interviews were subsequently conducted in a sub-group of participants (N= 15) to qualitatively explore the interrelationship of groups of protective factors. The presence of Post-Traumatic Stress Disorder, the use of mental disengagement as a coping technique, the age at which participants had left education, and the presence of social support networks significantly predicted changes in resilience over time. Dispositional and environmental protective factors interrelated and positively influenced the way humanitarian workers perceived and coped with mission stressors. The coping strategy of mental disengagement, affected by the stress domain, was found to negatively influence changes in resilience via a direct pathway. To conclude, the model tested in this investigation partially accounted for the explanation of mechanisms of resilience development suggesting a direct relationship between work environment and individuals' emotional and psychological well-being.

Keywords: resilience; humanitarian aid workers; longitudinal study; mixed methods; stress; coping

Introduction

Resilience describes the factors that promote wellbeing and strength in individuals who are undergoing unusually stressful life conditions. It concerns acutely traumatic experiences followed by positive psychological outcomes despite those experiences. [1] Over the past three decades the study of resilience has received increased attention. [2] The construct is relatively new, however, and issues such as generally accepted definitions are still in the process of development.

The international humanitarian aid workers literature is characterised by increasing attention towards workplace adversity. Thus a great deal of research attests to the organisational challenges currently facing humanitarian workers in many parts of the world. Even a brief review suggests that aid workers have to cope with a whole range of work-related challenges, such as occupational health and safety issues [3], concerns around re-entry stress [4], pre-existing problems such as earlier psychiatric treatment [5], in addition to the obvious stress of working in disaster and war situations, with continuous exposure to human suffering.

Protective factors in resilience research

Three overarching protective categories, applicable to populations at risk for stress (among which humanitarian aid workers) can be identified [6] : a) attributes of the individual (e.g. age, gender, physical health, etc.); b) cognitive features (e.g. motivation, locus of control, optimism, self-efficacy); and c) characteristics of the wider social environment (work colleagues, family, peers).

Because many aid workers often survive and thrive within very demanding organisational situations, the issue of why some people are able to thrive and continue to find satisfaction with their careers, while others are not, naturally arises. To answer this question, a mixed-method study was carried out with the aim of assessing which humanitarian workers would be more resilient than others, and therefore better equipped at coping with workplace adversity. It was hypothesised that the three key areas of protective factors (individual, cognitive, and

environmental) would interrelate and buffer the effects of stress, while at the same time favouring negative or positive changes in resilience.

An original theoretical model in in resilience research

An original theoretical model was developed to test several hypotheses about the origins of resilience in adult populations carrying out highly demanding jobs. It was theorised that positive or negative changes in resilience would be governed by dynamic relations among protective factors within the individual and the wider environment. More specifically, cognitive and environmental factors were thought to impact on individuals' psychological responses during stressful life experiences, at the same time mediating fixed dispositional markers. Thus, it was hypothesised that the interrelationship of these three domains could affect changes in resilience, which could be of two types: positive (increase in resilience) or negative (decrease in resilience). In addition, the relationship between dispositional resources and outcome was thought to mediate environmental constraints and perceived levels of threat (the stress domain). Fig. 1 is a graphic representation of this theoretical construct.

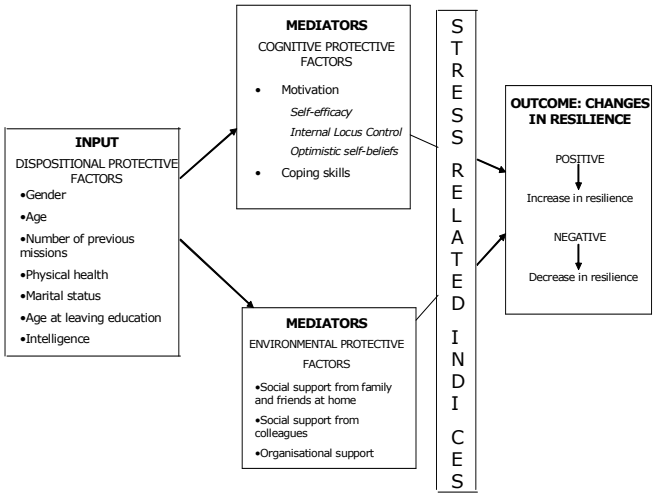

Figure 1 *A model of dispositional, cognitive and environmental factors developed from the literature and tested to examine changes in resilience*

Study design

To test the aforementioned model a mixed methods investigation was implemented in two phases: a longitudinal self-completion questionnaire survey (phase I) and a series of semi-structured qualitative interviews (phase II). In phase I self-report questionnaires were completed by expatriate staff members of a number of humanitarian agencies at two points in time. Baseline questionnaire administration (time 1) took place before participants were sent to the field; follow-up administration (time 2) began when humanitarian aid workers were back from the field. The survey provided extensive data, contextualised the interview phase (phase 2), and supplied a sampling frame for the interviews. The questionnaire incorporated different already validated and well-known scales: the Los Angeles Symptom Checklist (LASC) [7], the Maslach Burnout Inventory (MBI) [8], the COPE [9], the Generalised Self-Efficacy Scale (GSE) [10], a modified version of the Rotter's Internal-External Locus of Control Scale [11], the Life Orientation Test (LOT) [12], a modified version of the Social Provisions Scale (SPS) [13], and the Self-Report Questionnaire-20 items (SRQ-20) [14]. In addition, three resilience scales, the Ego Resiliency Scale (ER-89) [15], the Connor-Davidson Resilience Scale (CD-RISC) [16], and the Resilience Scale for Adults (RSA) [17] were included. In phase II the chosen methodology involved the use of qualitative interviews to investigate, participants' accounts of field experiences. A semi-structured question schedule was followed to allow themes surrounding resilience and the experience of humanitarian work to emerge. Moreover, it permitted the analysis of those existing social networks that positively affected the relation between exposure and reactions to trauma in participants.

Statistical analyses

To test the aforementioned model a mixed methods investigation was implemented in two phases: a Pearson correlations explored bivariate relationships among the questionnaire's scales and subscales at baseline and at follow-up. Moreover, independent samples t-tests were used to assess whether the individual protective factors in the model (i.e. age, gender, age at leaving education) could be associated to changes in resilience from baseline to follow-up. Multiple regression analysis examined whether changes in resilience from baseline to follow-up would be explained by the three sets of protective factors considered in the model. Path analysis provided quantitative estimates of the likely causal connections (path coefficients) between sets of predictor variables highlighted in the model. The qualitative data collection phase involved the conduction, coding and analysis of 15 interviews.

Results

A total of 56 people took part in the study: 23 were males (41.1%) and 33 females (58.9%). Females (r= -6.298, p< 0.001) and unmarried participants (r= 3.982, p< 0.05) were found to be more likely to experience positive changes in resilience from baseline to follow-up. Similarly, humanitarian workers with high self-efficacy levels (r= -0.429, p< 0.01), and people presenting with lower levels of depersonalisation before deployment (r= -0.940, p< 0.05), reported significant increases in resilience levels at follow-up. Social support (r= 0.454, p< 0.01), use of humor (r= 0.739, p< 0.01), and behavioural disengagement (r= -1.070, p< 0.01) as coping strategies, together with high levels of personal accomplishment (less burnout experienced) (r= -0.268, p< 0.05), positively influenced changes in resilience measured before deployment. Next, path analysis technique was used. Table 1 shows the four variables which, as a result of the initial regression, had beta coefficients that significantly predicted changes in resilience.

Table 1 ß coefficients for the four variables that significantly predicted changes in resilience

Independent variable	B	ß value
LASC total score	0.091***	0.605
Age at leaving education	-2.110**	-0.690
SPS total score	0.742*	0.401
COPE mental disengagement subscale	-1.679*	-0.330

Figure 2 shows a diagrammatic representation of the structural model achieved by the analysis.

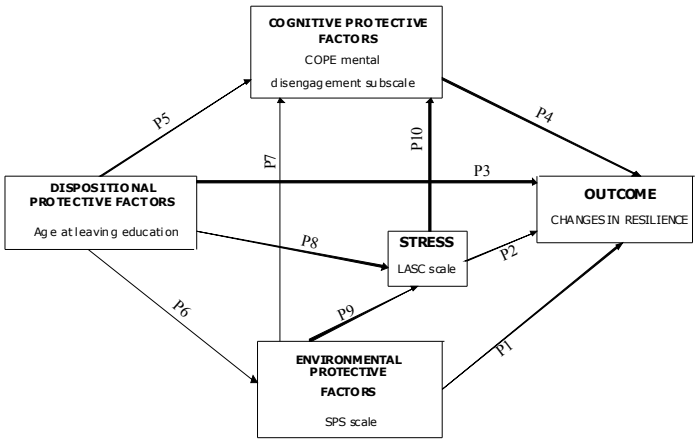

Figure 2 Model used to explain changes in resilience and its associated paths

Because this tested theoretical model could not be saturated due to the small number of participants in the study, the four variables included in the path analysis were chosen on the basis of theoretical reasons. First, age at leaving education represented the group of dispositional protective markers and was chosen over, for instance, age, gender and number of missions because it represented intelligence, one of the most critical features affecting the ability to cope with adversity. Second, the SPS scale highlighted the presence of environmental protective factors, which are thought to shield against stress. Third, the LASC was chosen to characterise perceived stress and was selected in preference to the Maslach Burnout Inventory (MBI) because it came out more frequently as an indicator of stress. Finally, the COPE mental disengagement subscale was selected to represent the area of cognitive protective factors because it significantly affected changes in resilience as measured by the CD-RISC, the resilience scale influenced by the highest number of variables representing the three protective factors groups. Table 2 displays the direct, indirect and spurious effects of each predictor of the dependent measure changes in resilience.

Table 2 *Direct, indirect and spurious path coefficients for each predictor variable, for each resilience scale*

CD-RISC scale	**Direct**	**Indirect**	**Spurious**	**Total effect**	**Zero order correlation coefficient (Pearson's r)**
Age at leaving education	-0.117 *(P3)*	-0.132	0	**r = -0.249**	-0.257
SPS scale	0.243 *(P1)*	-0.125	0.045	**r = 0.163**	0.164
LASC scale	0.362 *(P2)*	-0.004	-0.035	**r = 0.323**	0.336
COPE mental disengagem.	-0.229 *(P4)*	0	0.033	**r = -0.196**	-0.124
ER-89 scale	**Direct**	**Indirect**	**Spurious**	**Total effect**	**Zero order correlation coefficient (Pearson's r)**
Age at leaving education	-0.033 *(P3)*	-0.122	0	**r = -0.155**	-0.217
SPS scale	0.202 *(P1)*	-0.105	0.027	**r = 0.124**	0.132
LASC scale	0.294 *(P2)*	-0.001	-0.048	**r = 0.245**	0.264
COPE mental disengagem.	-0.064 *(P4)*	0	0.020	**r = -0.044**	-0.042
RSA scale	**Direct**	**Indirect**	**Spurious**	**Total effect**	**Zero order correlation coefficient (Pearson's r)**
Age at leaving education	-0.18 *(P3)*	-0.104	0	**r = -0.284**	-0.324
SPS scale	0.265 *(P1)*	-0.041	0.047	**r = 0.272**	0.287
LASC scale	0.1 *(P2)*	0.004	-0.001	**r = 0.102**	0.125
COPE mental disengagem.	0.195 *(P4)*	0	0.025	**r = 0.220**	0.133

Together table 2 and figure 2 show that the association between the LASC, assessing the severity of PTSD, and changes in resilience was determined mainly by a direct path, with little influence from intervening variables. People suffering from PTSD were therefore more likely to report negative changes in resilience than colleagues not affected by this mental health problem. The finding that participants employing mental disengagement coping techniques were characterised by negative changes in resilience was also best depicted by a direct causal link. Moreover, the relationship that people suffering from PTSD and employing mental disengagement coping strategies were less protected against negative changes in resilience was also dependent upon indirect links via age at which people had left education and the presence of social support, even though the social factor was the variable with the lowest impact on the outcome.

Mirroring the quantitative findings, the 15 qualitative interviews found that participants were characterised by several cognitive protective factors that helped them thrive despite difficulties. For instance, job satisfaction was one of the crucial elements in protecting individuals against stress. Similarly, internal locus of

control (LOC), namely the belief that outcomes and behaviours were largely within one's control, was related to positive changes in resilience. Moreover, high self-efficacy and optimism prevented people from developing work-related stress. The varying strengths and weaknesses of the social network relations available to aid workers were also highlighted during interviews. Participants talked about types of social support, but also about positive and negative social processes, as well as long-term consequences of humanitarian work on already existing social ties.

Discussion

This study hypothesised resilience as being influenced by dispositional, cognitive and environmental protective factors, which could substantially account for the development of post-mission resilience.

Female participants were more likely to experience positive modifications in resilience from baseline to follow-up. There have been a number of suggestions stressing the fact that gender may influence or modify responses to adversity. Social relationships may be the key to women's thriving. Women facing hardship, in fact, report that they have more support available than men, and that they are more likely to seek help in times of need. [18] Age at which participants had left education mediated the effects of stress on changes in resilience. Taylor and Frazer [19] observed a significant negative correlation between age and stress development in rescue workers handling dead bodies. Not only did those in the lower stress group tended to be older; they also demonstrated a quicker return to their normal pattern of eating, sleeping and feeling at task completion. An age effect explaining this reported behaviour was not excluded by the authors of the study.

The strengths of the social networks available to aid workers were explored both quantitatively and qualitatively. Path analysis results indicated that social support mediated the effects of both stress and maladaptive coping on changes in resilience. At the end of their study on the mental health of humanitarian aid workers in complex emergencies, Cardozo and Salama [20] concluded that family networks were essential in the lives of humanitarian personnel because these allowed staff to offset the stressors encountered during field deployment. Interviewed participants reported feeling psychologically vulnerable because of the stressful job demands endured during their mission. Yet the majority of them described themselves as resilient individuals, determined to go back to the field in spite of the difficulties experienced. This might indicate that participants were able to adapt and grow to the difficult tasks intrinsic to the mission despite the stressful environments in which they were operative.

Four markers significantly predicted changes in resilience from baseline to follow-up, namely participants' scores on the LASC, indicating levels of PTSD, the use of a specific coping strategy (mental disengagement), the age at which participants had left education, and the presence of social support networks. First of all, perceived stress, in the form of PTSD, was weakly and positively associated with the use of mental disengagement, which in turn was negatively associated with a positive outcome (positive changes in resilience). Coping strategies such as mental disengagement are aimed at avoiding active confrontation of the stressor, and in the literature they have been linked with more stress and less resilience. [21] Second, the mental disengagement coping technique was found to be directly related to changes in resilience in a negative way, which was congruent with the fact that this strategy is considered non-adaptive over the long-term. [9] Although disengaging from a goal is sometimes a highly adaptive response, this approach often impedes active coping. [22] Third, age at leaving education, used as an indicator of intelligence (i.e. the older people were when they left school, the more intelligent they were considered to be), was the second most significant predictor of post-deployment changes in resilience. Social support and mental disengagement partially mediated the effect of intelligence on resilience. At the same time, stress mediated the effect of both intelligence and social support on resilience. Age at leaving education was negatively associated with the use of mental disengagement and with the presence of PTSD symptoms, implying that people who had left school at a later stage were more likely to rely on functional techniques to deal with stress and to be more protected against the development of psychopathology. The positive relationship between intelligence and resilience has mainly been documented in children and adolescence literature, where this feature has been described as a key protective factor against adversity. [23] Finally, social support was the fourth statistically significant predictor of over-time changes in the outcome, mediating the effects of both stress and maladaptive coping. To conclude, contrary to what was predicted by the theoretical model, only two of the three domains of protective factors (the dispositional and the environmental one) seemed to interrelate and positively influence the way humanitarian workers perceived and coped with the stressors characterising field missions. The cognitive area, affected by the stress domain, was found to negatively influence changes in resilience via a direct pathway only.

Conclusion

This study on resilience processes in an adult population (humanitarian aid workers) was the first to combine a longitudinal survey with semi-structured qualitative interviews, a design which improved the

reliability of the study findings. Participants differed greatly from each other in terms of experience, age, and nationality, thus the generalisability of the project was enhanced.

A theoretical model was developed by taking into account three types of protective markers and by assessing how these interrelated with each other. Fixed dispositional protective factors were theorised to mediate environmental and cognitive variables, with the possibility of obtaining positive or negative changes in resilience. This relationship among dispositional, environmental and cognitive factors was considered to mediate perceived levels of stress. Luthar and colleagues [24] observed how exposure to stress may sometimes end up with positive individual growth and development rather than psychopathology. Tugade and Fredrickson [25] suggested that everyone has resilience potential, but its level is determined by interpersonal and cognitive characteristics, by the environment, and by each person's balance of risk and protective factors.

Aid workers are a very diverse group, ranging from school leavers to retired people, who may work alone, with a partner or as part of a team, in a conflict region or a peaceful area, for weeks or for decades. Some are involved with relief work, while others participate in development projects only. Some find the experience traumatic, while others enjoy it. There are a large number of variables which have not been considered in detail in this study, mainly because of the limited number of participants recruited, and which may warrant further investigation. For instance, further research could explore related topics, such as: a) the specific characteristics of resilience among non-Western international workers and national staff (employees working in their own countries), as well as the most appropriate way to maximise the development of resilience processes; b) the diversity of interrelationships present within humanitarian aid workers teams, as well as their positive and adverse impact on collective resilience; c) the real impact of more resilient aid workers on the population they come to serve, as well as on colleagues and organisations.

To conclude, humanitarian workers' occupational setting is likely to contain important elements of stress. Combating these adverse effects through minimising vulnerability and promoting resilience has the potential to impact positively on daily work experiences and to reduce post-mission morbidity. Although still much is to be learned about how individuals meet and adapt to adversity and stressful life events, this study contributes to understanding how resilience development can assist humanitarian workers to survive and thrive in their extremely challenging work environment.

Helping professionals - the bless and the burden of helping

Dârjan I., Tomita M.

West University of Timisoara, Romania
ioana.darjan@e-uvt.ro

Abstract

The experimentation of stress, either acute or prolonged, major stressful events or daily annoying and disturbing little facts, is a risk factor in developing psychopathology. The helping professionals, dealing directly with the lives of those in need, are particularly prone to burnout and exhaustion and secondary traumatic stress. When you work directly with those who you help, your compassion affects you both in positive and negative ways. Also, in educational, therapeutic and remedial settings, there are often crisis situations which could escalate into a conflict rapidly. Though the existence of a conflict is not always a bad things, while solving it effectively could bring personal and professional growth, the stress also cause many psychological and interpersonal problems. By solving conflict successfully, you may also solve many underlying problems that it has brought to the surface and obtain unexpected benefits for your personal and professional development. Conflict management skills are very important assets for helping professionals and for helped people.

A resilient factor for these professionals is theirs conflict management style, theirs ability to express assertively theirs emotions and to solve efficiently the conflictive situations. In this paper we intend to assess the impact of the life stressful events on the ability to cope with adverse circumstances and the relation between conflict management style and job satisfaction and burnout.

Key-words: job satisfaction, compassion, burnout, conflict management style

Theoretical background

Helping professions are at the same time and in various grades sources of great incentives and rewards, on one hand, and of desolating and sometimes devastating consequences and regrets. The rewarding and the consuming characteristics of these professions derive from the percent of different factors combing and defining job satisfaction.

1.1 Compassion: satisfaction and fatigue

Job satisfaction is an affective reaction to an individual's work situation [1], it can be defined as an overall feeling about one's job or career or in terms of specific facets of the job or career (e.g. compensation, autonomy, co-workers - Rice et al., 1991, in [1], and it can be associated with specific outcomes, for example efficacy, job persistence, turnover. In helping professions, job satisfaction can express the sense of a work well done, sens of self-efficacy [2], and positive impact on outcomes and on the lives of helped people. One model of explaining and investigating job satisfaction is the Job Demands-Resources Model (JD-R model) [3] is a theoretical approach that tries to explain the relationship between psycho-social working conditions and well-being. According to the JD-R model the work environment is characterized by two general categories: job demands and job resources [3]. The JD-R model was primarily developed to explain burnout and it is also useful to assess well-being at work and job satisfaction.

Job demands include those physical, social, or organizational aspects of work that require continuing physical and/or psychological effort (i.e. cognitive or emotional). For that reason job demands are associated with physiological and/or psychological costs, like exhaustion. Job demands are not necessary negative, but they may become job stressors when those demands exceed the employees' resources, generating job exhaustion and fatigue. Job demands of helping professionals include quantitative demands, time pressure, physical and emotional demands,) and demands for managing their own emotions.

Job resources refer to physical, social, or organizational aspects of the job that (1) are functional in achieving work-related goals, (2) reduce job demands and the associated physiological and psychological costs, and (3) stimulate personal growth and development [3]. These resources can be found at the level of the

organization at large, in interpersonal and social relations, in the ways of work organization, and in the specificity of tasks [4]. Job resources may foster employees' growth, learning and development.

The rewarding and the consuming side-effects of helping professions could be theorized in terms of Compassion Satisfaction (CS), representing the positive aspects of helping, and Compassion Fatigue (CF), representing the negative aspects of helping.

Stamm (2009)[5] proposes a theoretical model of satisfaction and fatigue related with the work of the helpers. Professional quality of life incorporates two aspects, the positive (Compassion Satisfaction) and the negative (Compassion Fatigue). Compassion fatigue breaks into two parts. The first part concerns things such like exhaustion, frustration, anger and depression typical of burnout. Secondary Traumatic Stress is a negative feeling driven by fear and work related trauma.

1.2 Conflict and conflict management style

Considerable amount of research has been done into determinants of job satisfaction, fewer investigated the relations between job satisfaction and people's conflict management style.

Gray & Starke (1984) define conflict as the behavior express by a person or group with the intention to inhibit the attainment of goals by another person or group [6]. Blake and Mouton (1964) [7] developed a two-dimensional conflict behavior model that is still referenced today. The two dimensional model of conflict includes: assertiveness, defined as a party's attempt to satisfy his own concerns, and cooperativeness, defined as attempts to satisfy the concerns of another person [8].

There are four main types of conflict in organizations: intraindividual conflict, interindividual conflict, intragroup conflict, and intergroup conflict [9][10][11], and the main motives for conflict in organizations are competition for limited resources, the need for autonomy, divergences in objectives [12][13].

According to the Ruble and Thomas' model of conflict behavior [8], employees have the ability to deal with conflict five different ways: by *avoiding* conflict all together (uncooperative and unassertive), by making too many *exceptions* (cooperative and unassertive), by *competing anytime* a conflict arises (assertive and uncooperative), or by *collaborating* (assertive and cooperative). Thomas-Kilmann' model (1977) [8] also has a fifth mode, *compromising*, which serves as a middle ground for both assertiveness and cooperativeness (Figure 1).

Fig. 1: Modes of conflict management (Thomas-Kilmann, 1976)

The objectives of the study

The purpose of this research was to investigate helping professionals' degrees of job satisfaction in correlation with theirs style of managing conflict, determining if this style of managing conflict represents a factor of resilience, viewed here as the ability to bounce back, to cope, to adapt, and to develop social competence despite adversity.

In this study we pursued two objectives. The first is a descriptive one: we tried to discover if there is a specific style of conflict management of helping professional from Romania as well as their professional satisfaction and burnout. For this objective we state the hypothesis that the helping professions have a specific culture of conflict management. Our hypothesis is that helping professionals engage a conflict management style based on collaboration instead of competition. The second objective was to analyze the relation between conflict management styles and professional satisfaction and burnout. Our hypothesis is that there are significant differences in professional satisfaction and burnout between professionals with different conflict management styles.

Participants and instruments

Our sample consists in 56 subjects in helping profession. Considering the gender distribution this sample is highly unbalanced with 91,2% female and only 8,2% male, but this distribution reflects the fact that helping professions in Romania are regarded as feminine. More specifically most of them are psychologists (46,4%) and teachers (35,7%) and the others are social workers (5,4%), medical staff (5,4) or others (6,4%). Their mean age is 35,8 years (s=7,62) and their experience is on average 9,8 years (s=6,33). Their clients are primary children (67,9%), but some are specialized in adults (7,1%) while others work with both children and adults (25%).

In order to measure the conflict management style we used a 15 item scale [14] that measures five different styles (collaborating, avoiding, competing, accommodating and compromising). The Romanian version has a good reliability (α=.738). The scale is Likert type with five levels and three items for each style. We used Professional quality of life scale (ProQOL) in order to measure the professional burnout and satisfaction. The scale is Likert type with five levels and has 10 items for each of the three measured dimensions (compassion satisfaction, burnout and secondary traumatic stress). The Romanian translated version has reliability coefficients close to the original scale (α=.748, compassion satisfaction α=.825, burnout α=.574 and secondary traumatic stress α=.724).

Results

The results showed that the preferred conflict management style is collaborating (mean=6,47, s=2,20) followed by a group of three styles (competing: mean =7,03, accommodating: mean=7,45 and compromising: mean= 7.87). The least frequent style is avoiding (mean= 9,40). However, the scale is allowing that a person to display two styles in the same time (the same score for two styles) so we compute the specific style for each subject. Only 41 subjects have a clear style of conflict management. From these group, 43,9% have a collaborating style, 31,7% have a competing style, and 14,6% have an accommodating style, while the avoiding and compromising styles have 4,9% each. From these results we could draw two conclusions: the helping professional are favoring an active, more assertive strategies of conflict management, either collaborative or competitive, instead of avoiding or compromising choices; although the mean of competing, accommodating and compromising styles are close, the last two are only secondary conflict management styles. Our hypothesis is only partially true. The professionals are more collaborative than competing, but the competing strategy is still important. We wanted to see if there are significant differences between different professionals and conflict management styles but the results were not supporting the hypothesis (chi square =17.97, p=.326).

We have measured the level of professional satisfaction and fatigue (assessed by two subscales: burnout and secondary traumatic stress). Our sample could be described by moderate to low job satisfaction, but also only moderate to low burnout and secondary traumatic stress. So, 94.8% percent of the subjects present moderate job satisfaction. Only 3.4% percent of the respondents reported high job satisfaction, but, at the same time, only 1.7% percent perceives low job satisfaction.

In terms of job fatigue, the subjects reported moderate to low burnout and secondary traumatic stress. Although 55.2% percent presented low burnout, it is interesting to notice that almost half of the sample (44.8%) experience moderate burnout. Secondary traumatic stress is experimented at moderate level by 34.5% percent of the subjects, while the main majority (65.6%) of the subjects has only low secondary traumatic stress. The results show that the majority of caring professionals are well adjusted to the workplace stress.

One objective was to assess if the conflict management style has an influence on job satisfaction and fatigue. In order to test the hypothesis we applied one-way ANOVA procedure in order to see if there are significant differences between the samples with different conflict management style in terms of their level of burnout and secondary traumatic stress. The overall results show that there are no significant differences in satisfaction (F (4,36)=2.274, p=.08) or burnout (F(4,36)=1,187, p=.333), but there is a significant difference on secondary traumatic stress (F(4, 36)= 3,06, p=.029). However, the post hoc comparison didn't highlight any significant differences between two groups, the most significant difference being between avoiding and collaborating styles.

Discussions and conclusions

Our hypotheses were that helping professional have particular ways to manage conflicts and that these managing styles have an influence on job satisfaction and burnout. Our findings were that caring professionals are indeed using specific styles of managing conflicts. We have predicted that they are using collaboration and compromising styles, but our findings prove that the second style of managing conflicts is competing. Consistently with our predictions is the fact that they use assertive styles instead of strategies of ignoring and avoiding solving the conflicts.

Our prediction that different conflict management styles are influencing the job satisfaction and levels of burnout was not supported. This doesn't mean that the conflict management style has no effect, but in our sample we couldn't highlight such relation. This could be the case that the level of burnout was quite homogenous as well as the conflict managing style. It is possible that those teachers which use avoidant strategies have a higher level of stress. The limited number of teachers with non-assertive style does not allow us to make a clear statement, but we think that the issue need further studies.

Helping professionals tend to involve in assertive ways of solving conflict, either collaborative or competitive. They are not usually ignoring or avoiding ambiguous or controversial issues, because the core of their professions stands for clarifying problems and for findings efficient solutions and strategies for these objectives.

In terms of job satisfaction and fatigue, although there is no impressive high job satisfaction, the moderate level of it, combined with moderate to low levels of burnout and secondary traumatic stress, allow us to conclude that this is a positive picture of investigated helping professionals. It means that the positive reinforcements they receive from their work exceed potentially bad outcomes (senses of inefficacy, job related irrational fears and worries). These results support the conclusions that these professionals are most likely good influences for their colleagues and their organizations, that they are liked by their clients/patients. This type of professionals benefits from engagement, opportunities for continuing education and career development [15].

These findings sustained the necessity of continuing education for helping professionals and the importance of their periodical (self)assessment and constant preoccupation for their well-being. For attaining these objectives, we consider that the supervision relations are crucial for these helping professionals, in order to debrief burdening issues and to learn how to understand, accept and solve work-related issues. Continuing education for helping professionals could focus on improving their abilities (for example, listening abilities) and on developing their assertive and collaborative ways of interactions and managing conflicts.

Abstract

The psychiatric unit is often a place of despair, hopelessness and tremendous pain. Resident psychiatrists get in touch with this world and need to find abilities and resources to cope with that on a daily basis for their whole professional life. The aim of this study is to establish and measure the professional quality of life (compassion satisfaction, compassion fatigue) and identify potential professional coping methods in resident psychiatrists. Using a sample of 108 resident psychiatrists (73.14% women) from 3 training centers in Romania, 2 scales were applied. Results show significant negative correlations between burnout/secondary traumatic stress and addressing a therapist and significant positive correlations between secondary stress and self-medicating. Also, the evaluated professional quality of life changes during the training years of resident psychiatrists, first years residents showing higher level of burnout and secondary traumatic stress than final years residents.

Keywords: compassion satisfaction, compassion fatigue, burnout, secondary traumatic stress, resident psychiatrists

Introduction

Compassion fatigue, compassion satisfaction

Compassion fatigue can be described as a disruptive, yet natural by-product of working with traumatized and troubled patients [1]. In 2010 Hudnall Stamm & al. describes symptoms such as exhaustion, frustration, anger and depression typical of burnout and a negative feeling driven by fear and work-related trauma called Secondary Traumatic Stress (Vicarious stress) [2]. But there is also a positive aspect of being in the position of helping patients: it is defined as compassion satisfaction. At this point burnout is considered to be a public health issue [3] and it is proven to determine serious health issues in those affected [4]. It has been of great interest for researchers, managers and clinicians in the last years due to its powerful impact on the quality of life of the individual, couple, family and organization.

Burnout in resident psychiatrists

For medical professionals, the seeds of burnout may be planted as early as medical school. The literature to date seems to support the notion that there are a variety of factors during medical school that contribute to burnout in physicians, and that burnout is a phenomenon that develops cumulatively over an extended time period [5], [6]. Several studies have explored possible reasons for burnout in residency training. In these studies, residents report that time demands, lack of control over time management, work planning, work organization, inherently difficult job situations, and interpersonal relationships are stressors that may contribute to burnout, especially in the first year of training [7], [8], [9]. In 2004, Martini et al. did a unique study that compared burnout rates among the different specialties using the Maslach Burnout Inventory [10]. Psychiatry residents had a burnout rate of 40% and were noted to have additional stressors including fear and exposure to patient violence and suicide. [11] Often residents step in for the physician (their coordinating psychiatrist), the

nurse, the social assistant, psychologist, therapist and become overloaded with paperwork, tests and physical activities.

Romanian resident psychiatrists

Being a resident in Romania means being a part of a suffering and suffocated health system dominated by a culture of learned helplessness as a constant source of discontent, bitterness, and doubt for themselves and their patients.[12] This is the consequence of nearly 25 years of reform without continuity nor clear objectives, a constant underfinancing of the healthcare sector, poor planning and management of the health workforce, and lately an 4 immigration epidemic of healthcare professionals. [13]

Coping Interventions

There are certain interventions that are effective in preventing compassion fatigue and thus encouraging compassion satisfaction. These interventions fall into 2 categories: workplace-driven interventions and individual-driven behavioral, social, and physical activities. More studies are needed to examine the applicability and utility of these interventions in resident physicians [14] (Ishak et al, 2009). This study explores some of the professional types of intervention the residents resident psychiatrist consider when confronted with burnout: addressing a therapist, consulting a psychiatrist, self-medication or joining a peer support group.

Objectives

The aim of this study is to measure the professional quality of life in resident psychiatrists in different training centers across Romania, compare the results with the existing data of peers and establish the intervention of choice in dealing with burnout. Also, we aim to point out the significant correlations between the professional quality of life in resident psychiatrists and professional types of intervention the resident psychiatrist consider when confronted with burnout (addressing a therapist, consulting a psychiatrist, self-medicating or joining a peer support group) and the significant differences by gender, age, year of residency and training centers.

Material and method

Participants and procedure

This study was conducted in three different academic centers: Timisoara, TirguMures and Bucuresti. We applied two questionnaires to 120 resident psychiatrists. Only 108 individual answers were taken in the analysis (90 % of the tests distributed) as some of the scales were not returned. The testing phase was done individually by paper and pencil questionnaires. The environment in which the participants answered the questionnaires was a suitable one (without noise or disturbance factors). Therefore, the sample consists of 108 participants (73.14% women) with a mean age of 28 years. Participants in the study were junior year residents (first and second year) 54,4 % and senior year residents (3-rd, 4-rd and 5-th year). Anonymity and confidentiality were guaranteed to participants under the research code of conduct requirements specified in the Romanian legislation.

Instruments used

The professional quality of life was measured with the (ProQOL) Version 5 (2009) 30 items questionnaire developed by B. HudnallStamm (2009). The ProQOL is the most commonly used measure of the negative and positive affects of helping others who experience suffering and trauma. The ProQOL has sub-scales for compassion satisfaction, burnout and secondary traumatic stress.

The measure has been in use since 1995. There have been several revisions. The ProQOL 5 is the current version. The scale showed adequate reliabilities for our sample (alpha scale reliability .76). All items were scored on a 5-point Lickert scale, ranging from (1) “very rare” to (5) “very often.”

The professional coping methods to job stress were assessed with 4 items that measure: addressing a therapist, consulting a psychiatrist, self-medicating or joining a peer support group. Participants were asked to score on a 5-point rating scale, ranging from 1 (“strongly disagree”) to 5 (“strongly agree”).

Results

Data was processed in SPSS program 12.00. Pearson coefficients were determined between the measured variables and t test for mean differences was calculated. The results are shown in the tables below. The

results have shown that there is a significant negative correlation between burnout, secondary traumatic stress and addressing a therapist as a coping intervention.

Table1 – Pearson correlation coefficient between burnout and addressing a therapist

		Therapy
Burnout	Pearson Correlation	-.204*
	Sig. (2-tailed)	.034
	N	108

Table 2 – Pearson correlation coefficient between secondary traumatic stress (STS) and addressing a therapist

		Therapy
STS	Pearson Correlation	-.166
	Sig. (1-tailed)	.041
	N	108

A significant positive correlation was revealed between secondary traumatic stress (STS) and self-medicating.

Table 3 – Pearson correlation coefficient between secondary traumatic stress (STS) and self-medicating (self-med)

		Self-med
STS	Pearson Correlation	.169
	Sig. (1-tailed)	.04
	N	108

Results show that first year residents have a significant lower level of burnout and Secondary Traumatic Stress than the last year residents.

Table 4 – Differences of burnout/STS in first year residents and last year residents

	Residency	Mean	Std. Deviation	Sig. (2-tailed)	t-test
Burnout	Group 1	20.98	4.536	.009	-2.64
	Group 2	23.26	4.266		
STS	Group 1	16.24	4.416	.039	-2.089
	Group 2	18.04	4.452		

Group 1: year of residency 1,2
Group 2: year of residency 3, 4, (5)
Also, age-related differences were highlighted: residents aged over 30 have a significant higher level of STS than the residents aged below 30.

Table 5 - Differences of STS in residents aged over 30 and below 30 years

	Age	Mean	Std. Deviation	Sig. (2-tailed)	t-test
STS	Group 1	16.34	4.005	.0179	-2.428
	Group 2	18.59	5.235		

Group 1: aged below 30
Group 2: aged over 30

Results show that residents from Timisoara declare a significant higher level of compassion satisfaction than the residents in Bucuresti. Also, residents in Timisoara would chose consulting a psychiatrist as a coping intervention when confronted with burnout.

There are no significant differences between residents studying in Timisoara and Tirgu Mures or the ones in Bucuresti and Tirgu Mures.

Table 6 Differences in level of compassion satisfaction and consulting a psychiatrist between Bucuresti and Timisoara training centers

	Training center	Mean	Std. Deviation	Sig. (2-tailed)	t-test
Satisfactie	Bucuresti	34.93	5.614	.05	-1.980
	Timisoara	37.57	4.727		
Psychiatrist	Bucuresti	3.20	1.271	.022	-2.331
	Timisoara	3.91	1.164		

Discussions

Our study shows that Romanian resident psychiatrists experience different levels of burnout and secondary traumatic stress but addressing a therapist is not the coping intervention they would consider. Although emotional awareness and emotional management abilities, time management, relaxation response techniques, focused breathing, meditation methods, mindfulness techniques, all of which are subjects of psychotherapy, have shown encouraging results in dealing with and preventing burnout [15], [16] the group we studied does not see addressing a therapist as a valid option. We can assume there is a matter of trust in the abilities of a therapist or a lack of trust in the power of the mentioned coping intervention. They nevertheless trust their own ability to use the proper medication if confronted with burnout syndrome. First year residents show a higher level of burnout and STS that last year residents. This aspect has been proven by other studies, where being in one's first year in residency was associated with increased likelihood to meet burnout criteria. [10] Residents in Timisoara have shown a higher level of compassion satisfaction than those in Bucuresti but not than those in Tirgu Mures. We can think of certain differences in the local culture, organization or community.

Conclusions

Current studies show that workplace-driven interventions like developing stress-reduction programs or increasing staff awareness of burnout and individual-driven behavioral, social, and physical activities are most efficient in dealing with professional stress. Our study shows that Romanian resident psychiatrist who are confronted with burnout would rather chose self-medication as a coping intervention. Raising awareness of burnout and multiple coping interventions for future psychiatrist is important for their own well-being but also to provide safe, high-quality patient care and should be considered when tailoring residency programs.

Towards an ecologically based intervention to grow professional resilience

Hudson C., Hart A., Dodds P.

[1]*School of Health Sciences, University of Brighton, UK*
cjl@brighton.ac.uk, A.Hart@brighton.ac.uk, P.Dodds@brighton.ac.uk

Abstract

Despite high levels of stress and burnout [1] and the recently reported, 'compassionate care' crisis [2], professional resilience as a strand of resilience research has received relatively little attention. Staff well-being is an antecedent to patient care [3] and this paper will explore the feasibility of a professional resilience intervention, to *'buffer'* the effect of work related stress [4].

Resilience research has begun to apply resilience-focused concepts to supporting professionals in various fields including education [5, 6], social work [4, 7], nursing and midwifery [8, 9, 10, 11 & 12]. However, much of this work is not sufficiently grounded in ecological theories of resilience, as described by Ungar [13]. Adamson, Beddoe and Davys [14] offer a conceptual framework of resilience in social work that is ecologically based, but this does not extend to an intervention, nor has it been applied to other professional groups.

This paper will present work in progress of a doctorate study, which links with the resilience work (http://www.boingboing.org.uk/) and the Health and Social Inequalities research programme, co-ordinated by Professor Angie Hart and collaborators. The aim of the thesis is to answer the question, '*What are the best approaches to support professional resilience*?' This paper will draw on the resilience literature across different professional groups, to define the construct of professional resilience, the nature of adversity and to propose an ecologically based intervention to grow professional resilience, otherwise termed as the, 'Growing Resilience Intervention Tool' (GRIT).

Keywords: Resilience, work-based, intervention, novice health professional, preceptor, support.

Introduction

Professional well-being has been inextricably linked to service user outcomes [3]. In the current 'compassionate care' crisis [2] professional resilience features as an important attribute. Research to explore an ecologically based approach to support novice professionals, otherwise termed as the, 'Growing Resilience Intervention Tool' (GRIT) is an important and timely contribution to the resilience literature.

The challenge to reviewing the literature is that over time, any concept analysis of resilience becomes dated [15]. Previous studies on professional resilience have tended to use an individualistic perspective. More recently, recommendations for increasing resilience in the health care curriculum [16] focus on a combination of individual and contextual factors and the interplay between individuals and the context is strongly emphasised [4, 17, 18].

Learnt adaptation over a period of professional life may inform an early career intervention to grow professional resilience. Adamson, Beddoe and Davys [14] offer a construct of resilience from the field of social work that is ecologically based (p 9). In this model, professionals can explore the interplay between the *self* (intrinsic) the *practice context* (extrinsic) [14] and the 'space inbetween', identified as mediating factors, of which 'supervision and peer support' is one. This paper draws on the 'space' inbetween to determine whether the, '*hypothesised mediators'* [19] are i) evident in other professional groups and ii) to determine the efficacy of developing an intervention (GRIT) to support 'supervision and peer support' in the preceptorship period.

1.1 Resilience across professional groups

Professional resilience is defined as, '*the ability to maintain personal and professional wellbeing in the face of on-going work stress and adversity'* [18 p 61]. In a review of resilience literature across five professional groups (nurses, social workers, psychologists, counsellors, medics) McCann et al [18] identified numerous individual and contextual mechanisms and distinguishing features. Only gender (more specifically, being female) and maintaining a work-life balance have been found to consistently relate to resilience across all the

professional groups studied. However, the complexity of comparing different groups and studies with different definitions and measurements of resilience has been acknowledged [18].

McCann et al's [18] study reveal similar findings to those featured in Adamson et al's [14] construct of resilience. Worklife balance which resides in the 'space' in between [14] is a defining attribute of professional resilience. Beliefs and spirituality reside predominantly in the self and are featured elsewhere [9]. Other dominant factors that relate to resilience in *four* of the five disciplines [18] are associated with the mediating factors in the 'resilience matrix' [14]: *Laughter and humour* fits with coping behaviours; *self-reflection and insight* as part of supervision and peer support, and *professional identity* is also prevalent in other studies [14, 20].

Factors predominantly reside in the mediating space, rather than the individual which fits with an ecological approach to professional resilience. McCann et al [18] also recognise a number of contextual factors which are predominantly relational, categorised in both personal (extrinsic to work) and professional. Of these, the dominant professional relational categories relate to i) work colleagues and mentors/role models and ii) client connectedness. This study will focus on the first category, intervening in co-worker/preceptor support. Studies that enhance client connectedness and its influence on resilience, is an area for future work.

Adamson et al's [14] construct of resilience is found to be congruent with the professional context, and to a number of professional groups [18]. Limited conclusions can be drawn about the transferability of these findings to other professions such as teachers, and this is another área for future work.

Growing Professional Resilience

An ecologically based resilience intervention relies on an appreciation of the i) *the exposure of adversity* and ii) *the positive adjustment outcomes* [19]. Sensitisation to stressors during professional development in the pre-qualifying years may influence novice professionals' resilience but this requires more longitudinal studies. Common stresses at the professional novice phase are recognised [21] and a period of preceptorship has been widely implemented in health and social care professionals to buffer the effect of early career stress [22]. However, evaluation of preceptorship has largely focused on the preceptees experience [23] and less on the support needs of preceptors to enact the role [24]. This paper will present evidence that supports the need to grow professional resilience (GRIT) by intervening in the preparation and support of preceptors.

1.1 The Adversity

There are a number of studies predominantly from Australia, New Zealand and the UK, which report adversity in the practice learning environment experienced by student nurses, including incivility and bullying [25, 26, 27], and some cases of overt racism by qualified staff and some non-professional staff. Students were seen to counteract the oppression, and as such learners' resilience was evident. The question remains as to i) Why this 'oppression' manifests itself, and to determine ii) what enables some students to independently and collectively resist the 'othering.'

Whilst acknowledging that this is not the case for all students, practice experience within the curriculum is reported to cause students the most stress. Overall levels of 'caseness' (stress) reported at 43% in social work students (n=240) [7] calls for effective resilience models, and attempts to build resilience in the pre-qualifying curriculum are being implemented [28]. McAllistair and McKinnon [16] make recommendations for embedding resilience and specific interventions in professional education to grow resilience have begun to emerge [10,11, 29].

1.2 Newly qualfied

These studies suggest that novice professionals may have been exposed to signifcant adversity during earlier practice experiences. Using a 'Growing Resilience Intervention Tool' (GRIT) at the outset of a professional career, is valid given the high levels of stress and role adjustment during this time [30, 31]. Experiences of 'covert' horizontal violence, including some significantly distressing incidents are reported at the early career phase [32]. Similar patterns of non allegiance with novice midwives, as with the women being cared for, reveals the negative sequelae on service users [33].

Interestingly, only a minority of participants reported positive outcomes in relation to the experiences described. These included, more assertiveness, inner strength, reassurance gained from support of other colleagues [32]. Vulnerable groups were identified, as follows: newly qualified and inexperienced professionals, those in poor health, or staff with roles which cross over different work environments [34, 32].

Ungar [35] emphasises that measuring resilience relies on a clear definition of what it is, but acknowledges that ambiguity exists. These studies would suggest that professional resilience is e*xceptional levels of functional adaptation in circumstances of heightened risk exposure* for a very small minority. For the

most vulnerable reported in these studies, professional resilience during early professional maturation is more aligned to *normative levels of coping in exceptionally difficult circumstances.*

1.3 The Context

Despite instigating prevention measures at an organisational level, including policies of zero tolerance, assertiveness training and encouraging the reporting of incidents, inappropriate behaviour and the existence of a hostile work context was sometimes tolerated in order to meet service demands [33]. It would appear that organisational processes and structures that exist are not always protective. 'Oppressors' are allowed to 'thrive' and shape a hostile work environment, at the expense of vulnerable individuals.

Perpetrators of bullying were found not only to be from management positions but from ther colleagues also, includng a minority of preceptors themselves [32]. Protective self-management, leading to self-withdrawal, and a perpetuation of a culture in which students can feel abandoned and unsupported by colleagues has been postulated [8] and Ungar warns against turning 'oppressors' into victims [35].

Preceptors narratives are under-reported in the literature. The need for preparation and organisational support for preceptors is advocated [36]. Choice in enacting the role is often over-ridden by organisational and professional requirements, and feelings of powerlessness have been reported by mentors supporting learners in practice [37]. The need to feel valued by the organisation and recommendations for a 'managerial support framework' [36] implies an ecological framework.

Growing professional resilience intervention tool (grit)

Despite studies recognising the challenges for preceptors, areas of concern continue to be unresolved, such as role strain caused by workload fatigue, lack of time and value afforded to the role [38]. Indeed, supervisors such as preceptors have been found to have high levels of stress which may compromise their ability to identify stress in novices as well as provide support [39].

1.1 Preceptor connectedness

Recommendations to strengthen resilience in nurses through strategies and mentorship programmes have been reported [9]. Preceptors who share and practice 'resilient moves' [40] as well as role model a positive identity and share sources of social support, coping skills and connectedness in the workplace have benefits in preparing pracititoners for the early stages of a professional career [41].

Exploration of what causes, 'distal space' in work contexts and conversely, supportive models that mitigate against organisational constraints, will inform an ecologically based intervention (GRIT) to grow professional resilience. Interventions to support preceptors to manage the 'space' [14] between their own context and practice experiences, and that of novice professionals fits with Ungars' [13] definition of resilience as the interplay between the individual and the environment as a '*place of possibility'* [42].

Acknowledgement of the importance of student: supervisor connectedness [42], positive supervision [43] and reciprocity gained through the relationship [44, 45] exist. In the early career phase, novices need 'relational connection' which includes: role models who practice in congruence with students' idealized view [31], positive peer relationships and continuity between clients and preceptors [46]. The doctorate study will specifically identify the pre-requisites for supportive preceptor preparation, as well as the preserving and protective processes to enhance the 'relational space' [47] between preceptors and novices.

This paper strengthens the argument for an ecologically based intervention that enhances the '*Supervisory interpersonal interaction'* [48]. Recognition of peer and supervisory support features in the professional resilience literature [14,18]. The doctorate study will develop a GRIT to enhance preceptor connectedness and will apply Ungars [17] four principles of an ecological resilience construct *decentrality, complexity, atypicality and cultural relativity* to further inform the professional resilience literature.

Conclusion

In summary, this paper offers a review of the contextual issues impacting on novice professional resilience. There is evidence of adversity, in terms of incivility and 'horizontal violence' impacting on novice professional resilience and in particular the complex relational and contextual aspects at play. Enhanced connectedness through the preceptorship relationship has been suggested as the basis of a GRIT.

Further work includes using an inequalities lens [49, 51] and in particular exploring the psychodynamics mechanisms including the, '*Effect of the professional ego' (*p502) [50]. In this respect, remuneration for preceptors; racism and bullying experienced by some novices and other inexperienced staff, those in poor health, and others can be viewed with an inequalities imagination [51].

Exposure to incivility in the workplace, has been predominantly described in studies on pre-qualifying and novice nurses and midwifes. An ecological intervention to avoid the 'sink or swim' [52 p382] phenomena will be extended to other professional groups and aim to counteract the organisational aggression, strengthen influential mediating factors and bolster individuals' positive connectedness. Growing professional resilience, using a GRIT in the supervisory relationship could have wide and far reaching application beyond the health and social care arena, extending to newly qualified teachers and beyond.

Resilience and public administration: implications for the "New Political Governance" in Canada

Milley P.[1], Jiwani F.[2]

Abstract

We live in an increasingly interconnected, complex world. Concerns have been raised about the capacity of governments to cope with the disruptions that emerge out of this context. The concept of resilience offers a credible strategy, but its potential contribution in light of increased complexity in governance contexts has not been widely researched. This article targets this gap in the knowledge base of public administration. It presents a theoretical perspective on resilience based on key concepts from an ecological model derived from complex adaptive systems theory. That lens is used to examine the New Political Governance in Canada, a set of reforms that have allowed ministers and political staff to increase their influence and direction over the public administration. The push for greater political control represents a particular kind of response to increased complexity. The analysis provided suggests there are numerous weak spots in this new governance strategy, which has the potential to reduce anticipative and adaptive capacities in government and society and to cause a 'regime shift' in the functioning and integrity of the public administration that could destabilize and make more vulnerable the broader system of public governance.

Keywords: Resilience, Public Administration, Governance, Panarchy, Complex Adaptive Systems, Canada.

Introduction

Since the 1980s, governments in Canada and elsewhere have helped shape a powerful round of globalization processes, extending a modern trend with origins in the nineteenth century [1][2]. During this same period, human populations have grown and become more diverse and mobile. Modern information and communication technologies have connected people like never before, creating densely networked societies.[3] We now live in an interconnected world, characterized by complex interdependencies in political, economic, trade, finance and technical systems, among others [4].

Questions have been raised about how governments should respond in this complex environment [4]. Concerns have been expressed about their capacity to cope with the shocks, disruptions and surprises that seem to emerge with worrying frequency, and about their ability control events or to stop negative effects from cascading across interdependent systems and networked societies [4][5].

In this unpredictable context, the concept of resilience—that is, the capacity to proactively and reactively cope with shocks, surprises and adversity—has the potential to contribute important insights for scholars and practitioners in public administration. It offers an intuitively credible strategy for preparing for, dealing with, and adapting to disruptions and adversity [6].

While resilience is not a new topic in public administration, it has not been widely researched and its potential contribution in light of increased complexity in governance contexts has barely been broached. In what follows, we address this gap in the knowledge base of public administration.

We first present a theoretical perspective on resilience based on key concepts from Panarchy theory [7][8], an ecological model based in complex adaptive systems theory. We argue this explicit use of ideas from a complexity science provides added heuristic value for conceptualizing resilience in contemporary public administration in its contemporary context.

Then we use the concepts to examine the implications for resilience in public administration in light of the rise of the 'New Political Governance' (NPG) in Canada and other jurisdictions governed with a Westminster system of parliamentary democracy. The NPG is an 'ideal type' (in the Weberian sense), coined by Aucoin [9], to describe the predominant features of contemporary governance. Key among these are: "i) the integration of executive governance and the continuous campaign, ii) partisan-political staff as a third force in governance and

public administration, iii) a personal politicization of appointments to the senior public service, and iv) an assumption that public service loyalty to, and support for, the government means being promiscuously partisan for the government of the day'' [9 p.179]. We argue this move by ministers and their political staff to exert more influence and direction over the public administration comes as a particular kind of response to increased complexity in the broader governance context—it is an effort to control that context. Our analysis suggests that, from the point of view of complexity-based resilience theory [10], there are numerous weak spots that stem from this NPG strategy. We conclude the paper with some tentative guidance for public administrators in jurisdictions that feature NPG characteristics, along with some thoughts about future research directions.

Resilience and Public Administration – Setting the Stage

The idea of resilience has had a presence in the public administration subfields of emergency preparedness and response [11] and natural resource management [12] since the late 1980s. It was introduced into the 'mainstream' in the 1990s when Hood [13] highlighted it as an undervalued concept that conflicted with 'efficiency' as the predominant administrative interest. Resilience gained some prominence in the mid-2000s in response to the shocks and crises (e.g., the 9/11 terrorist attacks, financial crises) that affected public governance in that period [14] and the recognition that new strategies were needed to govern in an era of heightened uncertainty and complexity [10][15].

There have been two related lines of inquiry with respect to resilience. One has concentrated on understanding how governments can better anticipate, plan and prepare for adversity to prevent or mitigate harm. The other has focused on understanding how to better respond through learning, experimentation and innovation [13][16]. The emphasis of the former line of thought has been on maintaining stability and helping people, communities, organizations or systems to 'bounce back' to a prior state of 'normalcy' [6]. The focus of the latter has been on promoting ongoing adaptations to help them remain 'functional' (and thus resilient) during and after adverse events [17].

A more synthetic way of understanding the relationships between anticipation and adaptation, stability and change are needed in an era of increased complexity [4]. The Panarchy model [7][8], developed to understand resilience in complex adaptive systems, offers promise in gaining a more holistic understanding of how resilience works. Here we offer our interpretation of select components of this model, clarifying with examples in public administration settings. Throughout, our background assumption is that public administration can be thought of as a sub-system (itself composed of smaller sub-systems) that is connected to a broader set of complex adaptive systems (e.g., social, economic, ecological systems).

At the core of the Panarchy theory is the adaptive cycle. It describes four commonly occurring phases of change that occur in the sub-systems that comprise a complex adaptive system. These phases include: 1) exploitation and growth, 2) conservation, 3) release, and 4) reorganization (see Fig. 1-adapted from [8]). The transition from phases (1) to (2) consists of a relatively slow, incremental process of growth and accumulation of a particular kind of 'capital' (e.g., consolidation of political power and alignment of administrative capacities and resources with policy priorities). The transition from phases (2) to (4) usually begins with some form of internal or external 'disturbance' (e.g., political or administrative missteps, social unrest, or economic shocks), creating the need for rapid response and change.

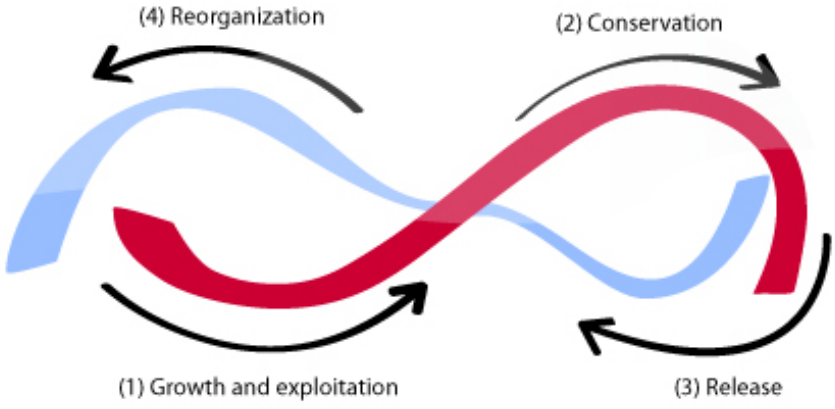

Fig. 1: The Adaptive Cycle

If anticipative capacities are in place before the needed transition from (2) to (4), it may be possible to take actions to mitigate harm or to stop negative effects from spreading. If the adaptive capacities are in place, it

may be possible for those affected to refashion and renew themselves so they, and the system of which they are a part, retain their fundamental functions and integrity (Walker et al., 2004).

If anticipative or adaptive capacities are lacking, the transition from (2) to (4) may not result in renewal. Instead, the actors and/or the system may go through a 'regime shift' the outcomes of which cannot be readily predicted. Such dramatic, qualitative changes may be adaptive, maladaptive or catastrophic [8][18]. For example, one or more of the basic structures or functions of "good government" (e.g., democratic institutions, rule of law, transparency, accountability, evidence-based public policy, etc.) may be eroded, resulting in a collapse of integrity in the governance system.

Two types of situations can make the adaptive cycle maladaptive. The first are "rigidity traps" [8 p. 400]. These develop when systems are so tightly aligned and controlled internally that they become 'brittle' and, thus, subject to failure when confronted with exogenous shocks or disruptions. Such systems may appear resilient because they have endured pressures for change, often for long periods of time; however, their capacity for responding in agile or flexible ways has been "smothered" [8 p. 400] as any self-organizing potential (e.g., discretionary decision-making, initiative) has been squeezed out of them. Autocratic regimes and classical bureaucracies are examples [7].

The second maladaptive situation consists of "poverty traps" [8 p. 400]. These appear when diversity in a system has been largely eradicated, reducing variety and, with it, the capacity to generate novel insights and options to support renewal [14]. An example would include jurisdictions in which a focus on 'austerity' or 'efficiency' has reduced investments in policy capacity and policy innovation.

Rigidity and poverty traps can affect both anticipative and adaptive processes [19], potentially reducing resilience on two fronts. For example, ideological, partisan or bureaucratic 'filtering' of information, evidence or insights can reduce the ability of elected officials and administrators to perceive and acknowledge certain risks and vulnerabilities [20]; while, centralized control structures, reinforced with standard operating procedures and a culture of compliance (or fear), can reduce the capacity for deriving novel options and exploiting them when needed [4][14].

Another key concept in the Panarchy model is its reinterpretation of hierarchy, which opens up a perspective on how anticipation, experimentation and innovation contribute to system resilience. Following this model, a complex adaptive system (CAS) consists of an array of sub-systems, arranged in interrelated hierarchies, with each sub-system going through adaptive cycles a different rates (see Fig. 2). Hierarchies in this theory are not conceived as being a top-down structure of "authoritative control" [8 p. 392]. Instead, the sub-systems in CAS are seen to have interlinked, but semi-autonomous—or loosely-coupled [13]—relationships.

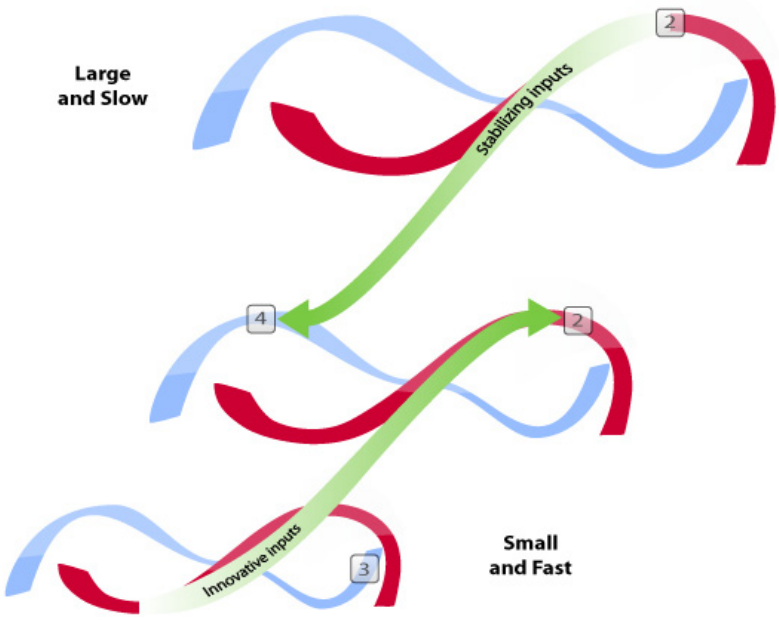

Fig. 2: Adaptive Cycles in Hierarchies

Following this view, smaller sub-systems at lower levels in the hierarchy (e.g., local governance systems) go through cycles of change at a more rapid rate than do those that are larger and at a higher level (e.g., national governance systems). As they go through their adaptive cycles, these lower level sub-systems provide anticipative and innovative inputs to higher levels (e.g., information on emerging issues or results of policy interventions), while higher levels generally serve to "stabilize" [8 p. 393] conditions for lower levels (e.g.,

supporting the implementation and further spread of policies that address local and broader system needs). As long as these exchanges are maintained, a degree of stability and continuity can be sustained in the system even as a "wide latitude for experimentation" increases the "speed of [system] evolution" [8 p. 393]. Seeing hierarchies as dynamic elements of a CAS offers a different metaphor for public administration. It suggests that i) top-down control in public organizations may not always be the appropriate focus, ii) resilient public administrations may be comprised of different sub-systems going through different phases in a learning (i.e., release and reorganization) and performance (i.e., exploitation and conservation) cycle, and iii) every sub-system may not need to be tightly connected, synchronized and aligned with the immediate priorities.

Resilience and the New Political Governance

We now turn to an analysis of the New Political Governance (NPG) in the Canadian context with a view to providing some insights about it potential strengths and challenges with respect to resilience. To do this, we apply the key concepts derived from the Panarchy theory to the four distinguishing features of the NPG.

The first of these features is that, in response to the pressures of governing in networked, information and media saturated societies, executive government engages in continuous electoral campaigning throughout their term in office. On the surface, there would appear to be potential in this behaviour for increasing resilience. If executive government authentically sought out, listened to, and learned from diverse sources at multiple levels in government and society, it might be able to tap the collective intelligence [4] and thereby improve its anticipative and adaptive capabilities.

However, three practical problems immediately arise in realizing this potential for resilience via the NPG. The first is the problem of 'short-termism.' Any term in office is relatively short, but if they become synonymous with a campaign cycle then taking a long-term perspective becomes even more difficult. This suggests the ability to anticipate risks and issues over longer time horizons and to be proactive in the face of them is reduced under the NPG.

The second problem is that elections and policy work are fought on partisan grounds, and have become more partisan over recent years [21]. If executive governing becomes synonymous with a campaign cycle, then this dogged partisanship (or dogmatism) may infect the overall approach to governing. This risks generating cognitive and other biases in both government and society, reducing anticipative capacities and limiting insights about what might 'count' as a 'good' ideas for change. For example, Aucoin [9] has observed how an increase in political pandering to core partisans in the Canadian electorate risks the creation of policies that do not reflect the interests of broader society.

The third problem is that, under the NPG, executive government's 'normal' cycle of work (based on a 4-5 year window) has accelerated to reflect the pace of a campaign cycle (of less than a year)—hence the use of 'spin' to describe what contemporary governments do [22]. This raises questions not only about substance, meaning and trust in governance, but also about the capacity of government to exercise a stabilizing influence in society.

Before the NPG reforms, the problems of short-termism, political partisanship, and balanced, evidence-based policy were seen to have been mitigated by having in place a non-partisan public administration. The Westminster system of governance that forms the basis for Canadian parliamentary democracy has long been based on the idea of having a bureaucracy of skilled, non-partisan public servants able to 'fearlessly' provide impartial policy advice to the elected government of the day and to loyally implement decisions and programs [9]. These roles, in theory, provided a source of continuity, stability, and modulated change. Three key features of the NPG appear to be having a negative impact on these traditional functions of the public administration. The features include: i) an increase in the number of political staffers in executive government, creating a new set of powerful, partisan players at the interface between ministers and the public administration; ii) a politicization of appointments to the senior ranks of the public service, and iii) an increased emphasis on generating more responsiveness within the public administration to executive government [9]. They are creating a public administration that is both more responsive to political direction and more "promiscuously partisan" [9 p. 179] than in the past. Such changes may be undermining the public administration's ability to function as a source of reliable data and information, evidence-based policy advice, and long-term thinking. Moreover, in its efforts to tightly align the internally control the public administration, the NPG may dampen the capacity for experimentation, agility and local decision-making.

At least four speculative observations can be offered about resilience and the NPG. First, there seems to be significant risk for the NPG to contribute to rigidity traps as a result of its emphasis on centralization, tight alignment and internal control. Second, the NPG appears vulnerable to creating poverty traps because of the strength and depth of the partisan political 'filtering' it engenders, which may decrease the diversity and variety of anticipative insights and in adaptive options available at any time. If combined with fiscal austerity and the propagation of a climate of compliance or fear, the risks of creating each of these adaptive 'traps' may increase. Third, the combined 'disruptions' of increased centralization, control and politicization may invoke a 'regime

change' in the public administration as a sub-system. Because the outcomes of such dramatic changes are uncertain (i.e. adaptive, maladaptive or catastrophic), such a situation could destabilize the overall governance system and create new vulnerabilities in it. Finally, if, as a result of NPG reforms, the public administration were no longer able to realize its historic functions, even in renewed form, then it is not clear where the stabilizing, anticipative and adaptive resources it once supplied would come from.

Conclusion

Overall, our analysis and speculations suggest the contribution of the NPG to resilience in both public governance (and society) is open to question, particularly over the long haul. This finding suggests NPG reforms should be pursued with some degree of caution. However, the NPG explored in this paper represents an 'ideal type'. The appearance of NPG-like governance in 'reality' will depend on, and vary with, "the [political] party in power, the prime minister, the state of competition between parties in the legislature and in the electorate, and, among other factors, the institutional and statutory constraints that provide checks against politicization" [9 p. 179]. Future research on the topic of resilience and the NPG would benefit from a comparative approach that documents actual governance practices in various Westminster systems.

It important to note that the anticipative and adaptive capacities allowing for resilience in CAS (e.g., a system of public governance) cannot be 'commissioned' when needed; they must be nurtured continually [4][14]. Their foundations reside in: the capacity for learning, creative problem-solving and innovation in families, communities, organizations, institutions, networks [16][23]; trust among actors and in public institutions, supported by trustworthy information flows [24]; and, diversity in actors, sources of knowledge and ideas [25] institutional forms and governance arrangements [26], including co-management and shared governance [15][27]. As a precautionary measure, those implementing the NPG reforms (or those studying their implementation) may wish to monitor these foundations.

Abstract

The organisation confronting economic and social challenges linked to globalisation or more concrete events is not resilient, is not resistant as such but it can create favourable conditions supporting the development of its resilience, which contribute to a better adhesion of employers and their management. Our research is focus on the link between organisation's capacity to deal with its difficulties and attachment of its employees, teachers and administrative staff to their university. Results support the existence of a link between resilient behaviour and attachment of working place. More precisely, we demonstrate that « Flexibility » and « Proactive solutions » dimensions from the inventory of resilient behaviours present significant correlations with attachment to working place.

Key words: resilience behaviour, attachment of working place, university, Romania

Cadrage théorique

Le concept de résilience est au centre de nombreux travaux actuels, dans des disciplines très diverses telles que la physique, l'informatique, l'écologie ou la psychologie [1]. Du niveau ponctuel et très concret de la mécanique, la résilience s'est enrichie en significations. Elle s'est affirmée en 2005 lors la Conférence de Hyogo comme une priorité nationale pour plusieurs pays tels que les Etats Unis, l'Australie et le Canada [2].

Dans le cadre organisationnel, Vanistendael et Lecomte (2000) la définissent comme la capacité d'une personne, d'un groupe ou d'une organisation à se projeter dans l'avenir en dépit d'événements déstabilisants, de conditions de vie difficile, de traumatismes parfois sévères. Autrement dit, qu'elle soit confrontée aux turbulences économiques et sociales liées à la mondialisation ou à des événements plus ponctuels, l'organisation n'est pas résiliente en tant que telle, mais peut créer des conditions favorables au développement de sa résilience, ce qui contribue à une meilleure adhésion des employés à sa gouvernance.

Le risque fut une de premières situations menaçantes quand la problématique de la résilience organisationnelle fut abordée, pour devenir ensuite intéressante par rapport avec la performance, dans un champ plus large du management des organisations centrées sur l'efficience économique. Hollnagel, Journé et Laroche [4] souligne que «la résilience ne se produit pas instantanément, qu'elle n'est pas de l'ordre du réflexe organisationnel ou de l'injonction managériale mais qu'elle possède une épaisseur temporelle, sans doute nécessaire à son élaboration». Les crises qui suivent une turbulence de l'environnement peuvent renforcer la résilience de l'organisation par deux processus complémentaires liés : «un apprentissage de renforcement positif au niveau de l'absorption du choc et un apprentissage double boucle incluant des changements stratégiques permettant de réduire la vulnérabilité de l'organisation» [5].

L'attachement au lieu est un concept central en psychologie environnementale qui renvoie aux liens que les personnes entretiennent avec les lieux qui leur sont chers [6]. Même si des divergences conceptuelles et méthodologiques ont traversé ce courant, la majorité des chercheurs présente l'attachement au lieu comme un lien émotionnel [7]. Plus précisément, s'appuyant à la fois sur la théorie de l'attachement de Bowlby (1980) et celle de l'attachement au lieu élaborée par Schumaker et Taylor (1983), ils le définissent comme la composante affective du lien qui unit une personne avec un lieu donné [10]. Si les liens entre résilience et attachement sont relativement bien cernés dans le cadre de la psychologie développementale, en revanche, ils sont peu explorés dans le cadre organisationnel.

Objectifs

Notre recherche porte sur le lien existant entre la capacité des membres de l'organisation à surmonter les difficultés au travail et l'attachement des employés envers leur organisation. Le premier objectif vise à valider une variante roumaine de l'inventaire des comportements résilients au travail. Le deuxième objectif se propose d'identifier les relations qui existent entre la résilience des membres de l'organisation universitaire et leur attachement au lieu de travail.

Methodology

1.1 Echantillon et procédure

Notre population est composée de 72 personnes (35 enseignants et 37 personnel administratif) d'une université roumaine, âgés de 20 à 66 ans. Le personnel administratif est exclusivement composé de femmes. Les enseignants (16 femmes et 19 hommes) sont assistants (5), lecteurs (10), maitres de conférences (3) et professeurs (17). La participation s'est faite sur la base du volontariat, pendant les heures de travail.

1.2 Matériel

Les données ont été collectées à l'aide d'un outil en trois parties : une partie signalétique permettant de repérer certaines variables sociodémographiques (âge, sexe, catégorie de personnel, degré didactique) ; l'adaptation roumaine de l'inventaire des comportements résilients au travail [11] et l'échelle d'attachement au lieu de travail - EALT [12]. Les réponses se donnent sur des échelles en cinq points allant de 1 (pas du tout d'accord) à 5 (tout à fait d'accord).

Resultats

1.1 Les analyses factorielles

1.1.1 L'échelle de résilience

Une première analyse en composantes principales a été menée en intégrant tous les items de l'inventaire des comportements résilients au travail. Elle fait apparaitre 6 facteurs dont la valeur propre est supérieure à 1. Cependant deux d'entre eux ne comprennent que deux items et ont été supprimés. Par ailleurs, l'item a été enlevé car il diminuait l'alpha de Cronbach de 0,12.

Une seconde analyse en composantes principales a alors été conduite avec les 15 items restants. Les résultats sont regroupés dans le tableau 1.

Tableau 1. Analyse en composantes principales avec les 15 items de l'échelle de résilience

	M	ET	F 1	F 2	F 3	F 4
4. J'ai essayé de trouver des solutions alternatives à un problème.	4,47	0,80	**0,77**	0,15	0,10	0,13
8. J'ai cherché des solutions à un problème avec mes collègues.	4,40	0,96	**0,74**	0,21	0,10	0,16
3. J'ai échangé avec mes collègues sur des améliorations possibles.	4,25	1,10	**0,68**	0,04	0,19	0,20
9. J'ai travaillé pour progresser dans mon travail.	4,54	0,67	**0,67**	-0,03	-0,25	0,10
2. J'ai été capable de remplacer temporairement un collègue.	3,90	1,41	**0,56**	-0,03	0,30	-0,04
13. Je suis arrivé(e) à un bon résultat en improvisant.	2,85	1,24	-0,08	**0,79**	0,22	0,20
6. J'ai pris des décisions, même si je n'étais pas sûr(e) à 100 %.	3,53	1,35	0,27	**0,73**	0,04	-0,11
7. Je me suis débrouillé(e) pour éviter certaines tâches parce que je me sentais débordé(e).	2,19	1,25	0,06	**0,62**	-0,07	-0,23
19. Je n'ai pas pu exécuter des tâches selon la procédure, parce que je n'avais pas les ressources nécessaires.	2,57	1,38	0,02	0,00	**0,77**	0,20

20. J'ai manqué d'informations pour faire face à une situation difficile.	2,96	1,11	0,24	0,07	**0,74**	-0,22
14. J'ai été sceptique face à une situation nouvelle.	2,86	1,23	0,07	0,06	**0,61**	0,15
16. J'ai adapté ma manière de travailler à la situation.	4,33	0,92	0,13	-0,07	0,14	**0,69**
11. J'ai évité tout risque.	3,38	1,20	0,22	-0,25	-0,08	**0,65**
5. J'ai considéré un problème comme un défi.	3,49	1,37		1,37	-0,15	**0,62**
18. Je me suis arrangé pour éviter une situation qui me semblait chaotique.	3,33	1,47		1,35	0,35	**0,59**
Valeur propre			2,63	1,86	1,95	1,93
% variance expliquée			0,18	0,12	0,13	0,13
Alpha de Cronbach			.75	.60	.63	.58

Une structure expliquant 56% de la variance émerge. Elle comprend quatre facteurs : F1 « Solutions proactives » (5 items), F2 « Improvisation » (3 items), F3 « Disponibilité des ressources » (3 items) et F4 « Adaptabilité/flexibilité » (4 items). Notons que l'alpha de Cronbach calculé à partir des items composant le facteur 4 parait un peu faible (0,58).

Cinq items recueillent des moyennes supérieures à 4,00, dont quatre composant le facteur « Solutions proactives ».

1.1.2 L'échelle d'attachement au lieu de travail

Le Tableau 2 présente les moyennes et les écarts-types et la structure factorielle de l'échelle d'attachement au lieu de travail.

Tableau 2 La structure de l'échelle d'attachement au lieu de travail

	M	ET	Score factoriel
1. Je suis attaché(e) à mon lieu de travail.	4,43	,80	0,82
2. Il me serait très difficile de quitter définitivement mon lieu de travail.	4,24	,90	0,62
5. Ce lieu de travail fait partie de moi-même.	4,14	1,05	0,81
6. Il y a des lieux dans l'université qui me rappellent des souvenirs.	4,08	1,09	0,81
4. Si mon université devait déménager, je regretterais mon lieu de travail actuel.	4,04	1,14	0,71
7. Après un congé, je suis content(e) de retrouver mon lieu de travail.	3,94	1,16	0,70
3. Il y a des endroits dans l'université auxquels je suis tout particulièrement attaché(e)	3,58	1,31	0,75
Attachement total	4,07	,80	
Valeur propre			3,92
% variance expliquée			56%

Nous retrouvons la structure unidimensionnelle postulée par Rioux (2006). La valeur propre est de 3,92 et le pourcentage de variance expliquée de 56%. L'alpha de Cronbach est tout à fait satisfaisant (0,88).

Les moyennes des items varient de 4,43 pour l'item *«Je suis attaché(e) à mon lieu de travail »* à 3,58 pour l'item *«Il y a des endroits dans l'université auxquels je suis tout particulièrement attaché(e) ».* Les écarts-types sont modérés (de 0,80 à 1,31).

1.2 Les liens entre la résilience au travail et les variables sociodémographiques et organisationnelles

Parmi les variables sociodémographiques cernées (genre, âge, études), seule l'âge corrèle avec la résilience au travail. Plus précisément, cette variable présente une corrélation significative à .05 avec le facteur 4 « Adaptabilité/flexibilité » (r=.32).

Les variables organisationnelles (type de personnel, ancienneté) n'ont aucun lien significatif avec les facteurs de la résilience. En revanche, des analyses de variance effectuées en prenant comme facteur le statut des enseignants (professeur, maître de conférences, lecteur, assistant) et comme variables dépendantes les scores moyens obtenus aux facteurs de la résilience, indiquent une différence significative entre le statut et le facteur «

Solutions proactives » (F_3=6,05, p<0,002). Le résultat tend à prouver que les professeurs sont capables à trouver plusieurs solutions et, peut-être plus rapidement, par rapport aux collègues ayant un statut plus faible.

1.3 Les liens entre la résilience au travail et l'attachement au lieu de travail

Les valeurs des coefficients de corrélation entre l'attachement au travail d'une part, et la résilience et les sous échelles de la résilience, d'autre part, sont présentées dans le tableau 3.

Tableau 3 Corrélations entre l'attachement au lieu de travail et la résilience (et ses facteurs)

Attachement au lieu de travail	résilience	F1	F2	F3	F4
échantillon total	-	0,23*	0,09	0,22	0,24*
personnel administratif	0,42**	0,55**	-	-	0,37*
enseignants	-	-	-	-	-

** p<.05, **p<0,02*

Lorsqu'on considère l'échantillon dans son ensemble, on constate que les dimensions « Solutions proactives » et « Adaptabilité/flexibilité » de l'échelle de résilience au travail corrèlent significativement (p<.05) avec l'échelle d'attachement au lieu de travail, respectivement r=.23 et r=.24. Ces corrélations sont plus fortes dans l'échantillon du personnel administratif et, surtout, la résilience totale est très significativement en lien avec l'attachement au lieu de travail (r=.42, p<.02).

Discussion et conclusion

Le premier objectif de cette recherché était de repérer la structure factorielle de la version roumaine de l'inventaire des comportements résilients au travail. On a retenu une structure en quatre facteurs qui regroupe 15 items et expriment 55,70% de la variance. Cependant, étant donné la faiblesse de l'alpha de Cronbach calculé sur le facteur 4 « Adaptabilité/flexibilité » (alpha=0,58) des études complémentaires de validation s'avèrent nécessaires. L'analyse a confirmé la structure unidimensionnelle de l'échelle d'attachement au lieu de travail. Il faut mentionner le score très haut obtenu par le premier item de l'échelle, qui exprime d'une manière globale l'attachement au lieu de travail.

L'unique variable sociodémographique qui corrèle significativement avec le facteur de la résilience « Adaptabilité/flexibilité » est l'âge ; on pourrait expliquer cette association positive par l'effet de l'expérience accumulée au long des années qui rend les employées plus adaptables aux sollicitations professionnelles. Ce résultat est en accord avec les travaux de Vanistendael (2005) qui affirment que la résilience est variable en fonction de l'étape de vie de la personne et des caractéristiques de la situation. Les variables organisationnelles (type de personnel, ancienneté) n'ont aucun lien significatif avec les facteurs de la résilience. Seul le statut différencie les enseignants en fonction de leur capacité à trouver des solutions proactives aux problèmes professionnels, les professeurs s'avérant les plus résilients.

Comme supposé, les résultats soutiennent l'existence d'un lien positif entre les comportements résilients et l'attachement au lieu de travail. Au niveau de l'ensemble de l'échantillon, l'attachement corrèle avec les comportements résilients exprimés par l'adaptabilité et la capacité d'utiliser des solutions proactives. Pour les employés administratifs, l'association est plus intense pour les deux facteurs déjà mentionnés. De plus, on a trouvé une forte corrélation entre le score total de la résilience et l'attachement au lieu de travail. Il faut noter que pour les enseignants, le lieu de travail est moins localisé que pour le personnel administratif qui a un lieu de travail identifiable et bien délimité dans l'espace de l'université. Pour les enseignants, on peut parler de lieux multiples: amphithéâtres, salles de séminaire, le propre bureau partagé parfois avec d'autres collègues. Au fur et à mesure qu'ils avancent dans la hiérarchie universitaire, les enseignants parviennent à avoir leur propre lieu dans le bâtiment (pour les activités non didactiques), et parfois leur propre bureau, ce qui peut consolider leur sentiment d'appartenance à l'université et par conséquent leur attachement au lieu de travail. Cela peut expliquer pourquoi les professeurs sont plus résilients que les maitres de conférences, lecteurs et assistants.

Sur le plan théorique, des recherches complémentaires sont nécessaires afin de confirmer la structure de la version roumaine de l'inventaire de comportements résilients au travail. Sur le plan appliqué, les résultats peuvent apporter des éléments de réflexion aux gestionnaires de l'université afin que les enseignants puissent bénéficier d'un véritable espace de travail, ce qui ne peut que contribuer à développer et consolider leurs comportements résilients et leur attachement au lieu de travail.

From empathy to compassion fatigue. How can health care practitioners develop resilience and keep their positive engagement?

Ruysschaert N.

European Society of Hypnosis Belgium
nicole.ruysschaert@skynet.be, yesforyou1@gmail.com

Abstract

Health care professionals are particularly at risk of burnout and compassion fatigue, As therapy/treatment involves an intense human interaction mirror neurons play an important role, quite often on an unconscious level. Some illustrations of how this affects one's personal affective state will be given.

I review some risk factors of compassion stress and fatigue, and contrast this with compassion satisfaction and resilience. Some programs to prevent compassion fatigue have been designed and tested. Readers get some idea of how to integrate self-hypnosis in this model of help. By practicing therapists can become more resilient and engaged the positive antidotes of burnout and compassion fatigue. Only by consciously taking care of one self can health care professionals and their clients benefit from a long-lasting and satisfying career.

Keywords: empathy, compassion fatigue, compassion satisfaction, mirror neurons, self- hypnosis, resilience

Introduction

Health care professionals in their daily work are continuously exposed to pain, suffering, anxiety, stress and tension of their patients. How does it affect their own life, their own wellbeing? How to be in a good rapport, show empathy, be tuned in to clients and protect against too much impact of these demanding interactions? Insight in mechanisms of empathy and interaction and practicing ways for better self-care are essential ingredients to benefit health and wellbeing in these professions.

Empathy And Mirroring

Empathy [1] can be considered as an affective response that stems from the apprehension or comprehension of another's emotional state or condition, and is similar to what the other person is feeling or would be expected to feel. By empathy one can understand, and be aware of or sensitive to feelings, thoughts and experience of another without having the feelings, thoughts and experience fully communicated in an objectively explicit manner. In helping professions there is an intense interaction. Facial expressions, posture, feelings can be shared, perceived and felt in both, patient and therapist involved in the interaction. Being with someone who is in a particular state of mood can be contagious. Emotional states can be transferred directly from one individual to another by mimicry and 'emotional contagion' [2].This can be done by the copying of emotionally relevant bodily actions, particularly facial expressions, seen in others. [3] Seeing someone suffering pain, and observing this person's facial expressions activates pain circuitry in the other. Seeing someone you love and care about in pain activates one's own pain circuitry even more! Despite the risks of caring, empathy is an important tool in therapy. Empathy is the connective tissue of good therapy.[4] On the other hand there is some cost of caring, particularly if it's too much for too long.

Compassion stress and compassion fatigue

Working as a health care worker one is at risk of some work-related stress, as compassion stress/fatigue, vicarious traumatization and burnout. Compassion stress is stress connected with exposure to a sufferer. Risks increase by long lasting exposure and some increased sensitivity. Compassion fatigue (CF) [5][6] is the convergence of primary or traumatic stress, secondary traumatic stress [7][8][9][10] and cumulative

stress/burnout [11]in the lives of helping professionals and other care providers. Primary traumatic stress is related to personal traumatizing events, experienced by the person himself. Secondary Trauma occurs when one is exposed to or witnesses extreme events directly experienced by another.

According to Figley [12] Compassion Fatigue is a state of tension and preoccupation with traumatized patients, characterized by re-experiencing traumatic events, avoidance/numbing of reminders and persistent arousal (e.g., anxiety) associated with the patient. The symptoms of Compassion Fatigue can mimic, to a lesser degree, those of the traumatized people health care workers are working with [13]

Those most vulnerable to developing Compassion Fatigue are highly dedicated individuals and those with high demand for personal competence. [14][15][16] Some helpers will continue to demand the highest level of attainment even if they are already depleted [17]. Having a personal trauma/loss history in their own life, results in increased vulnerability to symptoms [18][19]. Working in an unsupportive workplace increases risks for Compassion Fatigue, while social workers scored higher on job satisfaction and lower on burnout when they felt valued in their professional roles, suggesting that support in the workplace is a protective factor. [20][21] Workers with poorly established or unavailable social network or personal support (Killian, 2008; Mathieu, 2012a), are at higher risk, while social workers demonstrated lower levels of secondary traumatic stress symptoms in environments with greater support from coworkers, supervisors and work teams [22][23][24]

Compassion satisfaction and job-engagement

Promoting satisfaction, rather than avoiding compassion fatigue can protect from the negative consequences of the working in these settings. Some suggest to consider compassion stress as potentially positive energy culminating in compassion satisfaction. [25]. Utilization of compassion stress, experiencing some challenge to help clients find ways out and empowering them, sharing successes are only some of the health promoting approaches. Cognitive skills and flexibility to reframe problems into issues, or challenges, and seeing things in perspective can turn the negativity into positivity. One also can re-distribute attention and maximize positivity to maximize compassion satisfaction. Frederickson & Losada suggest the important role of the ratio of positive to negative affect. [26]. The positivity ratio, then, is the ratio of pleasant feelings and sentiments (or positive affect) to unpleasant ones (or negative affect) over a given period of time. Studies in various contexts confirm at least a 3 to 1 ratio theory of flourishing. [27] The outcome of a study of Killian could demonstrate that social support was rated the most significant factor associated with higher scores on compassion satisfaction.[15]. Job-engagement, another positive concept, in contrast to burnout has been defined by Bakker and Schaufeli as a positive, fulfilling, work-related state of mind that is characterized by vigour, dedication and absorption. [28]

Prevention of compassion fatigue and promoting resiliency

By reflecting on a paradigm of the Center for Disease Control and Prevention stating that: Disease is the absence of effective antibodies, not the presence of a toxic environment, Gentry and Baranowsky came up with a perceptual shift, to see mental diseases and compassion fatigue from that perspective. [29]. They started wondering how a psychological/spiritual antibody would look like … and how to help inoculate individuals with this capacity for health? They identified five professional resiliency skills or "antibodies", namely (1) self-regulation; (2) intentionality; (3) self-validation; (4) connection; and (5) self-care.

1.1 Self-Regulation

Self-regulation has been found as being the most important resiliency skill. It's being able to control the activity of the autonomous nervous system and being able to shift to a para-sympathetic nervous system dominance. Hypnosis affects heart rate variability, shifting the balance toward an enhanced parasympathetic activity, concomitant with a reduction of sympathetic tone. [31]. This means an overall health promoting impact with lower heart rate and blood pressure, and lowering of the level of stress or strain. Clients and therapist's working with self-hypnosis find it relaxing and experience some energy recovery after their practice. Research data give evidence about the beneficial effects of self-hypnosis on immune control, enhanced mood and well-being. [30] Some specific applications of hypnotic metaphors, suggestions and imagery will facilitate the usefulness of working with hypnosis in preventing compassion fatigue or in promoting compassion satisfaction. [32]

1.2 Intentionality

Intentionality encompasses deliberateness and integrity, moving away from reactivity and impulsiveness as seen in stressed individuals. One can develop an intentional attitude with full awareness of his

intention and commit to a personal mission statement. Reviewing some past satisfactory working experiences (diary, revisiting these experiences or reliving them in hypnosis), strengthens inner commitment. Some practices to become aware of real values, one can commit to, increases motivation and generates positive energy. [32] One behaves guided by this inner compass and motivation, better prepared to deal with adversity and less dependent on external circumstances.

1.3 Perceptual Maturation

Common knowledge within cognitive behavioral therapy learns that not the events provoke stress, but the way one perceives them. Several perceptual changes enhance resiliency. Hypnosis can help in catalyzing cognitive shifts and promote cognitive restructuring, enhancing flexibility [33]. In (self)hypnosis one learns to see things from a different perspective, observing, reviewing situations making the mind more open to cognitive changes. One can learn from models, finding outcomes, relying on earlier learning experiences and resources to overcome current issues and 'problems'. Reviewing, reliving some of these in self-hypnosis, and/or preparing oneself on an imaginary level equipped with these new tools and attitudes one wishes to adopt are very helpful in this maturation process.

1.4 Connection and Support

As professionals perceiving they are supported by their colleagues, friends and community exhibit less work related symptoms [24][21][20], this aspect deserves special attention. Even in the temporarily absence of these important resources, reliving some of the support in trance, remembering some appreciation, supporting attitudes and positive feedback feed this inner need. One also can connect to spiritual resources or the universe in a state of trance, and getting some resilience out of these practices to be better prepared for challenging encounters and work demands.

1.5 Self-Care & Revitalization

Some components of good self-care that work well have been found. [29] They can be considered as essential components: a good sleep hygiene, healthy diet, exercise, creative activity or hobbies, social activities, spiritual practices and professional enrichment. Some specific skills for mirroring and un-mirroring, and having control on one's own level of empathy, closeness or distance, help to better control the level of compassion.[32] Regular practice of self-hypnosis can be a first important step in self-care and promotes self-awareness, temporarily distancing one from the outside world, and entering the inner world of one's own experiences. Right from the beginning of the hypnotic induction attention is turned inwards caring for one's inner world and promoting self-care. Some more specifics methods help to letting go of intrusions and thoughts, to process emotions, to free one self and debrief, to deal with losses and failures. Some imaginary protective layers or filters – more or less permeable, depending on the situation - are prepared in self-hypnosis and anchored, and can be released in sessions, to modulate emotional impact of the work. Practicing mirroring and un-mirroring methods help to modulate impact of the work as well. Committing oneself to a particular life-style, attitudes in hypnosis precedes and promotes real-life changes.

Conclusions

Health care workers, psychotherapists, particularly those working with traumatized people are at risk of compassion stress and fatigue. Emphasis on prevention and on finding ways to get more compassion satisfaction is necessary. Some research has been done on the risks and some programs for support are under development and research. Awareness of the problem and learning skills to prevent compassion fatigue deserve special attention. It would be nice to see them spread around the world. (Self) Hypnosis is helpful to increase the impact of the different elements in the program and can be learned in individual or group sessions.

Personal growth in the context of exposure to trauma life events

Turliuc M.N., Măirean C.

Alexandru Ioan Cuza University, Iaşi, Romania
turliuc@uaic.ro, amariei.cornelia@yahoo.com

Abstract

Exposure to adverse life events typically predicts subsequent negative effects on mental health and well-being. Recently the importance of posttraumatic growth (PTG), a phenomenon of positive psychological growth beyond baseline values, has been discovered in the field of vicarious trauma. This study examined both positive and negative trauma outcome predictors within a sample of Romanian physicians. A total of 138 medical staff participated in the study. Participants completed scales for measuring posttraumatic stress, posttraumatic growth, and quality of life. PTG has been measured in five main domains: appreciation of life, relating to others, increased personal strength, sense of new possibilities and positive spiritual change. The regression analysis showed that posttraumatic stress symptoms are significant positive predictors for interpersonal relationships, new possibilities and personal strength. Furthermore, the dimensions of posttraumatic growth are positively associated with compassion satisfaction and negatively associated with compassion fatigue. These results are an important step to understanding the association between stress, growth and quality of life in context of exposure to human pain.

Keywords: stress, growth, compassion satisfaction, compassion fatigue

Introduction

It is well known that exposure to traumatic experiences may have negative psychological consequences. Although research has often focussed on effects of direct experience of trauma, indirect exposure to traumatic experiences is not without consequences and it can result in vicarious traumatization [1, 2]. In the last years, researchers have moved away from an exclusive attention on the negative outcomes toward a more comprehensive understanding of posttrauma reactions that includes both positive and negative consequences [3, 4]. The positive outcomes have been termed posttraumatic growth (PTG) [5]. A singular focus on the perception of negative outcomes without the recognition of the benefits has been criticised as presenting an unrealistic view of human experience in the aftermath of trauma. Consequently, this study investigates whether positive changes can occur in peoples life while they are constantly confronted with others trauma. We also examined the moderator role of PTG in the relationship between traumatic stress and profesional quality of life.

1.1 Direct and vicarious posttraumatic growth

Building on hardiness and resilience, Tedeschi and Calhoun (2004 [5]) proposed the model of posttraumatic growth, a new concept for the exploration of healing. Posttraumatic growth is defined as the subjective experience of positive psychological change reported by an individual as result of the struggle with trauma. Examples of positive psychological change are an increased appreciation of life, setting of new life priorities, a sense of increased personal strength, identification of new possibilities, improved closeness of intimate relationships, or positive spiritual change. Posttraumatic growth describes the experience of individuals who do not only recover from trauma, but use it as an opportunity for further individual development. Vicarious posttraumatic growth (VPG) as a construct was first used by Arnold et al. (2005[3]), who conducted an in depth exploration of the positive consequences of work with trauma survivors. They found that clinicians working with survivor clients' traumatic material report positive changes in the areas of self-perception, interpersonal relationships, philosophy of life, gains in self-confidence, an enhanced appreciation for what is important in life, and spiritual growth. However, there is a paucity of research investigating these findings. In fact, most studies have examined posttraumatic growth in persons directly exposed to different trauma [6]. To fill this gap, in our study we aimed to investigate the vicarious posttraumatic growth and the variables associated in a sample of Romanian medical personnel.

1.2 The relationship between traumatic stress, growth, and quality of life

To the understanding of posttraumatic growth it is important to note that the presence of posttraumatic growth does not involve the absence of distress [5]. In fact, the continuing distress may provide the fuel for continued posttraumatic growth. Therefore, distress is a necessary condition for posttraumatic growth to emerge. Growth in the aftermath of exposure to traumatic life event and the emotional distress triggered by these events are fundamentally linked, and it is widely accepted that both co-exist within the individual in the context of coping with trauma [7]. However, research examining the relationship between growth and distress report mixed results [8]. Some research has shown that increased distress makes growth more likely [4, 9, 10] while other studies suggest that they are two separate outcomes [11]. Tedeschi and Calhoun (2004) maintain that the lack of consistent relationship between growth and distress is not a limitation of the concept. Rather, they stated that posttraumatic growth and subjective pain may coexist for some people [5]. Accordingly, we predict that reports of negative changes are not simply the oposite of positive changes, but rather may be an integral part of the growth process.

Although some studies have showed the impact of traumatic stress on posttraumatic growth [10], there are very few studies examining the relationships between these factors and different outcomes, like quality of life [12]. Moreover, studies have reported the relationships between stress and wellbeing, on the one hand, or posttraumatic growth and well-being, on the other, but we know only one study that has looked at both posttraumatic growth and traumatic stress and their relationships to these kinds of variables [12]. Therefore, another purpose of the present study was to examine if posttraumatic growth and traumatic stress would have different patterns of correlations with other relevant variables, such as quality of life. Compassion fatigue, compasion satisfaction and burnout are indicators of quality of life studied in context of trauma exposure. The existing research on the relationship of growth to such factors as adjustment and well-being is somewhat inconsistent [13], and there are no reports of the relationships between growth and other variables, like the indicators of professional quality of life.

Method

1.1 Participants

The participants in this study are 138 medical workers from several section of the hospitals: Intensive Care, emergency, ambulance, neurosurgery, and oncology units. Our final sample consisted of 64.5% nurses, and 35.2% physicians. Our research sample was largely comprised of women (79%). Ages ranged from 25 to 66, with a mean age of 39.11 years, SD = 9.48. Participants had considerable experience in health care in general (*M* = 10.50 years, SD = 9.68).

1.2 Instruments

The Posttraumatic Growth Inventory (PTGI; 14) is a 21-item sccale that was used to measure personal growth in the following domains: relationships with others, realization of new possibilities, increased personal strength, spirituality, and appreciation of life. Participants rated items on a six-point Likert scale, ranging from 0 to 5 with higher scores indicating a greater degree of change as a result of the crisis. In our sample, Cronbach alphas for these subscales ranged between 0.67, respectiv 0.87.

Secondary Traumatic Stress Scale (STSS; 15) is a 17-item scale designed to measure secondary trauma. On a five-point Likert scale, respondents indicate their agreement with items that reflect specific responses to their work with trauma victims. A higher total score indicates higher secondary trauma. In our sample, Cronbach alpha for the total score is .87.

Professional Quality of Life Scale (ProQOL; 16) is the most commonly used measure of the positive and negative effects of working with people who have experienced extremely stressful events. The instrument is a 30 item scale divided into three equal sections: Compassion Satisfaction, Compassion Fatigue, and Burnout. In our sample, Cronbach alphas ranged between 0.78 and 0.85.

1.3 Procedure

Informed consent was obtained from all the participants. The research was presented as an exploration study of the employers' view regarding the confrontation with different traumatic situations. Participants were informed that their participation was voluntary. In addition, they were told that participation was not a requirement and that the information would be kept confidential and would not become part of their evaluation. Because the workload at the workplace is very high, the participants completed the questionnaires at home.

Results

Table 1 presents descriptive statistics and correlations of all variables from the present study. Preliminary analyses (using Pearson correlation) showed that traumatic stress is positively linked with interpersonal relationships ($r_{(138)}$=0.14; p=0.023), new possibilities ($r_{(138)}$=0.21; p=0.003), and appreciation of life ($r_{(138)}$=0.24; p<0.001). Analyzing the relationship between posttraumatic growth and profesional quality of life, the results showed that compasion satisfaction is positively linked with interpersonal relationships ($r_{(138)}$=0.26; p<0.001), new possibilities ($r_{(138)}$=0.23; p<0.001), personal strength ($r_{(138)}$=0.22; p<0.001), spiritual changes ($r_{(138)}$=0.19; p=0.004) and appreciation of life ($r_{(138)}$=0.178; p=0.037). Moreover, the results showed a negative correlation between spiritual changes and burnout ($r_{(138)}$=0,17; p=0.044).

*Table 1: Correlations, means and SDs of analysed variables; Note: **p<.01, *p<.05*

To test the role of traumatic stress as a predictor for posttraumatic growth dimensions, we used linear regression. The results highlights the fact that traumatic stress is a significant positive predictor of relating to others, new possibilities and appreciation of life dimensions.

		Relating others	New possibilities	Personal strength	Spiritual changes	Appreciation of life
Traumatic	ß	.14*	.20*	.11	.09	.24*
stress	F	2.71*	6.08*	1.95	1.05	8.36*
(predictor)	ΔR^2	.08*	.11*	.01	.01	.15*

*Table 2: Regression models predicting dimensions of posttraumatic growth based on traumatic stress; Note: **p<.01, *p<.05;*

A hierarchical multiple regression analysis was used to test the role of posttraumatic growth as a moderator in the relationship between traumatic stress and compasion satisfaction [17]. The results indicated that traumatic stress negatively predicted compasion satisfaction, while posttraumatic growth positively predicted compasion satisfaction. The STS x PTG interaction was significant (Table3). The nature of this interaction is illustrated in Figure 1.

Discussion

The aim of our study was to explore the presence of posttraumatic growth in context of traumatic stress. The results of our study suggest that traumatic stress could be a source of posttraumatic growth. These results supported the hypotheses posed and also replicated and extended findings from previous research [3, 9, 10]. Research on vicarious posttraumatic growth is relatively new and there are no specific explanatory models. Several models, however, do explain posttraumatic growth following direct trauma exposure [5] and have been applied to situations where professionals are indirectly exposed to trauma. According to Tedeschi and Calhoun theory's (2004) claim that traumatic stress can lead to different positive changes in peoples life, our results showed that between traumatic stress and several dimensions of posttraumatic growth there is a positive association. It seems that personal benefits and positive changes can arise through vicarious exposure to trauma. It is possible that observing and encouraging others' recovery to lead to positive consequence. In addition, our results revealed the fact that posttraumatic growth interacted with traumatic stress in predicting compassion satisfaction. Specifically, participants with a low level of traumatic stress had higher scores on compassion satisfaction scale especially when they reported a high level of posttraumatic growth. Therefore, our results confirm that both posttraumatic growth and traumatic stress are related to reports of the quality of one's life. This pattern of findings mean that both growth and stress may need to be considered to fully understand their impact on quality of life.

Our study is one of the few studies that examined positive changes as a result of vicarious exposure to trauma using quantitative measures. Although these findings are limited by the cross-sectional methodology used, they do offer some important information that should be considered in research on traumatic stress. People do report both growth and stress following exposure to stressful event, and the well-being a person experiences in this context can best be understood by understanding both the growth and the stress the person has experienced.

Abstract

The authors of this study examined the relationship between psychological capital (PsyCap) and psychological detachment from work during off-job time (i.e., mentally switching off) with work engagement and burnout, as well-being forms. They hypothesized that high psychological capital and high levels of psychological detachment predict work engagement and burnout. They proposed that psychological detachment buffers the positive impact of high psychological capital on work engagement. Also, other propose of this study was psychological detachment moderated the impact of high psychological capital on burnout. Data were collected from 121 blue-collar employees (48.8% women) who work in a multinational company from Romania. The age of the respondents ranged from 21 to 58 years (M = 35.88, SD = 9.58). Hypotheses were tested using two hierarchical regression analyses with dedication and cynicism, as dependent variables. The results show that the high level of psychological capital predicted dedication and cynicism. Psychological detachment from work during off-job time predicted dedication but didn't buffer the relation between PsyCap and dedication. Also, psychological detachment predicted cynicism and buffered the relationship between PsyCap and cynicism. Implications for theory and practice are discussed.

Keywords: psychological capital, psychological detachment, work engagement, burnout

Introduction

Nowadays, every organization is doing more efforts to enhance their own employee's well-being, but sometimes these organizational efforts are not enough for this. Recent researches revealed the importance of personal resources on employee well-being, together with organizational factors. Personal resources are related to individual characteristics of the employee and could be modeled by direct intervention. But, not only what happen in the organization make sense for employee's well-being. An important role in employee's well-being has what happen with employee after work, in especially psychological detachment from work during off-job time. Thus, the extension aria of researches beyond organizational boundaries it's a must for future researches because just in this way we can understand all factors who contribute on employee's well-being. Therefore, the present study has a major aim to examine the role of psychological capital, as personal resource, on employee well-being. More specifically, the study examined the relationship between psychological capital (such as self-efficacy, hope, optimism and resilience) and employee's well-being, and also the moderating effect of psychological detachment.

1.1 Psychological Capital

Psychological capital (PsyCap) has been conceptually defined by Luthans and colleagues ([1]; [2];[3]) as consisting of the four positive psychological resources of hope, optimism, efficacy, and resilience. Luthans et al. [3] describe psychological capital as "an individual's positive psychological state of development characterized by: (1) having confidence (efficacy) to take on and put in the necessary effort to succeed at challenging tasks; (2) making a positive attribution (optimism) about succeeding now and in the future; (3) persevering toward goals and when necessary, redirecting paths to goals (hope) in order to succeed; and (4) when beset by problems and adversity, sustaining and bouncing back and even beyond (resilience) to attain success" [3]. Each of these positive concepts makes psychological capital a scientific construct with valid measures, being open to development, and has a positive impact on attitudes, behaviors, and performance [3]. But taken as a whole, PsyCap has been demonstrated conceptually and empirically [3] to be a higher order core construct, according to Conservation of Resources Theory (COR). This means that PsyCap combine the mechanism(s) that these four personal resources have in common.

Numerous researchers have studied and have tested the relationship between PsyCap and different employee attitudes. Avey, Reichard, Luthans and Mhatre [4] have suggested PsyCap is positively related to desirable employee attitudes and negatively related to undesirable employee attitudes. A primary explanatory mechanism for the effect of PsyCap on employee attitudes is that those higher in PsyCap expect good things to happen at work (optimism), believe they create their own success (efficacy and hope), and are more resistant to setbacks (resilience) when compared with those lower in PsyCap; also they report being more satisfied with their job [5], and engaged to their organizations [6]. On the other hand, PsyCap has been negative "related to undesirable employee attitudes, such as cynicism toward change or turnover intentions" [7]. According to previous researches, we anticipate PsyCap will have a positive relationship with work engagement and a negative relationship with burnout.

1.2 Well-being: work engagement vs. burnout

Schaufeli, Salanova, Gonzalez-Roma and Bakker [8, p. 74] define work engagement as "a persistent and positive affective-motivational state of fulfilment that is characterized by vigour, dedication and absorption". Engaged employees are enthusiastic and energetic about their work and fully immersed in it [9]. Of the three characteristics of work engagement described by Schaufeli et al. [8], we have chosen the dedication, as a measure of strong implication in work, sense of significance and enthusiasm, which according to Sweetman and Luthans [10, p. 2] is related to "involvement in one's work, optimism in attributions of significance and pride, hope in dedicated waypower and pathways, and resiliency in continuing in the face of challenging obstacles and adversity".

Regarding burnout, Schaufeli [11] offered a comprehensive definition, stating that it is a persistent, negative, work-related state of mind in 'normal' individuals that are characterised primarily by exhaustion, which is accompanied by distress, a sense of reduced competence, and the development of inappropriate attitudes at work. According to Schaufeli and Bakker [12], two dimensions of work engagement are soundly linked to burnout, specifically vigour to exhaustion and dedication to cynicism.

Based on the idea that cynicism are logically related to dedication (as mentioned above), as opposite constructs, we expect cynicism to be negatively related to PsyCap. In one study, Avey, Wernsing and Luthans [13] found that there is a positive relationship between work engagement and hope, efficacy, optimism and resilience; similarly, they identified a negative relationship between PsyCap and cynicism as a burnout dimension. Also, Görgens-Ekermans and Herbert [14] have demonstrated that the presence of PsyCap lead to increased dedication and decreases a burnout.

Accordingly, we expect PsyCap and psychological detachment as personal resources to be positively related to work engagement and negatively related to burnout, as opposite forms of well-being.

1.3 Psychological detachment from work as moderator

The concept of psychological detachment from work during off-job time was originally introduced by Etzion, Eden, and Lapidot [15, p. 579] as a "sense of being away from the work situation". Experiencing psychological detachment from work (hereafter, detachment) is important for improving well-being. It implies that the one is not working at home and not thinking about job-related issues, problems, or opportunities during after work hours.

Concerning the relationship between psychological detachment and work engagement, Sonnentag, Binnewies and Mojza [16] showed that psychological detachment from work during off-job time is an important factor that helps the increasing of work engagement. Also, they found that individuals with decreased levels of psychological detachment were significantly more likely to experience burnout and impaired psychological well-being, compared to individuals who had achieved psychological detachment [16].

Although there are no studies using psychological detachment from work as a moderator of the relation between PsyCap and well being, Avey, Wernsing and Luthans [13] found that positive emotions act as a moderator between PsyCap and well being, and also between PsyCap and employees attitudes and behaviors. Therefore, we suggest that psychological detachment will moderate the relation between PsyCap and well-being.

1.4 Theoretical framework and Hypotheses

Based on the literature review, the following theoretical framework (see Fig. 1) and hypotheses were developed.

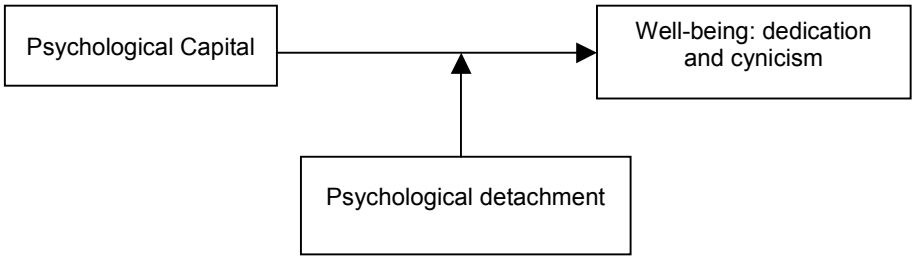

Fig. 1 Proposed Theoretical Framework

H1a: Psychological capital is positively related to dedication.
H1b: Psychological capital is negatively related to cynicism.
H2a: High levels of psychological detachment predict low dedication.
H2b: High levels of psychological detachment predict high cynicism.
H3a: Psychological detachment moderates the positive relation between psychological capital and dedication.
H3b: Psychological detachment moderates the negative relation between psychological capital and cynicism.

Methodology

1.1 Sample

The total sample (N = 121), based on a non-probabilistic convenience sampling procedure, consisted of 59 women (48.8%) and 62 men (51.2%). The age of the respondents ranged from 21 to 58 years (M = 35.88., SD = 9.58). The sample consisted mostly of employees who work in a multinational company from Romania in IT & C field, in on-line procedure. The average number of hours actually spent on their work each week ranged from 1 to 40 (M = 16.80, SD = 10.76).

1.2 Measures

Psychological capital was measured with the 24-item PsyCap Questionaire by Luthans et al. [3]. This questionnaire has 6 items for each subscale: hope, resilience, optimism, and self-efficacy. All items were scored on 5-point Likert-type scale with categories ranging from 1 = strongly disagree to 5 = strongly agree. The total PsyCap score is an average of the four subscales scores. The internal consistency of the instrument, Cronbach alpha, was equal to .86 in this research. *Psychological detachment from work* was measured with a four-item scale developed by Sonnentag and Fritz [17]. Respondents were instructed to report their general level of detachment on a 5-point Likert scale (1- strongly disagree; 5 – strongly agree). The internal consistency estimates in our sample were .91 for psychological detachment. *Cynicism* was assessed with the four-item scale from the Maslach Burnout Inventory—General Survey (MBI-GS; [18]). All items were scored on a seven-point scale ranging from 0 (‘‘never’’) to 6 (‘‘always’’), with the reliability of α = .82. *Dedication* was assessed using the three-items scale from the short version of the Utrecht Work Engagement Scale (UWES-9; [19]). Items were scored on a 7-point frequency scale, ranging from 0 (“never”) to 6 (“always”). The internal consistency estimates in our sample were .85 for the dedication.

1.3 Results

Table 1 presents the means, standard deviations, correlations and reliability estimates for the variables in the model. As predicted, a positive correlation was found between PsyCap and dedication (r = .44, p < 0.01), and respectively a negative correlation was found with cynicism (r = -.45, p < 0.01). This result supports Hypothesis 1.

Table 1. Descriptive Statistics and Intercorrelations (N = 121)

Variables	*M*	*SD*	1	2	3	4

3. Dedication	11.93	4.12	.44**	-.13	(.85)	
4. Cynicism	5.39	4.01	-.45**	.17*	.61**	(.82)

*Note: *p < .05, **p < .01; one-tailed, Note. Cronbach's alphas are listed on the diagonal.*

Table 2 presents the results of two hierarchical regression analyses. The first regression analyse tested the impact of PsyCap, psychological detachment and interaction between this, having on dedication as dependent variables, while the last analyse examined the impact of the same variables, having on cynicism as dependent variable.

As shown in Table 2, PsyCap added significant unique variance to each of the dependent variables of cynicism ($\Delta R^2 = .21$, $p < .01$) and dedication ($\Delta R^2 = .19$, $p < .01$). After the control of the PsyCap, the effect of psychological detachment on dedication and cynicism was tested in Step 2, in each regression analysis. And, this addition of the moderator variable also revealed a significant effect. Results show that psychological detachment explained 3% of the variance in dedication ($R^2 = .21$, $p < 0.05$) and 4% of the variance in cynicism ($R^2 = .24$, $p < 0.01$).

More specifically, high levels of psychological detachment were related to lower levels of dedication and with a high level of cynicism. This finding supported Hypothesis 2a and 2b.

The main hypothesis of the present study was that PsyCap would be associated with higher levels of dedication in the presence of high psychological detachment. Because we didn't found a significant interaction between PsyCap and psychological detachment in predicting dedication, as a form of work engagement, Hypothesis 3a was not supported.

Table 2. Moderated hierarchical regressions analyses for dedication and cynicism

	Dedication			Cynicism		
Predictors	Model 1	Model 2	Model 3	Model 1	Model 2	Model 3
	β	*β*	*β*	*β*	*β*	*β*
PsyCap	.44**	.45**	.33	-.45**	-.47**	-.09
Psychological detachment (PD)		-.17*	-.64		.21**	1.69*
PsyCap x PD			.49			-1.56*
R^2	.18	.21	.20	.20	.24	.26
Change in R^2	.19	.03	.00	.21	.04	.02
F for change in R^2	28.80**	4.74*	.37	31.75**	7.43**	4.01*

*Note: ** $p < .01$ *$p < .05$.*

But, for cynicism, the results showed that the two-way interactions between PsyCap and psychological detachment explained a statistically significant part of the variance for this form of burnout ($\Delta R^2 = .02$, $p < 0.05$). Simple slope analyses were conducted for only one statistically significant interaction in order to determine the nature and directionality of the interaction.

Using the procedure outlined by Aiken and West [20], we plotted the high and low levels of each variable. When confronted with high psychological detachment, employees having a high level of PsyCap reach a low level of cynicism (see Fig. 2). This result supports Hypothesis 3b.

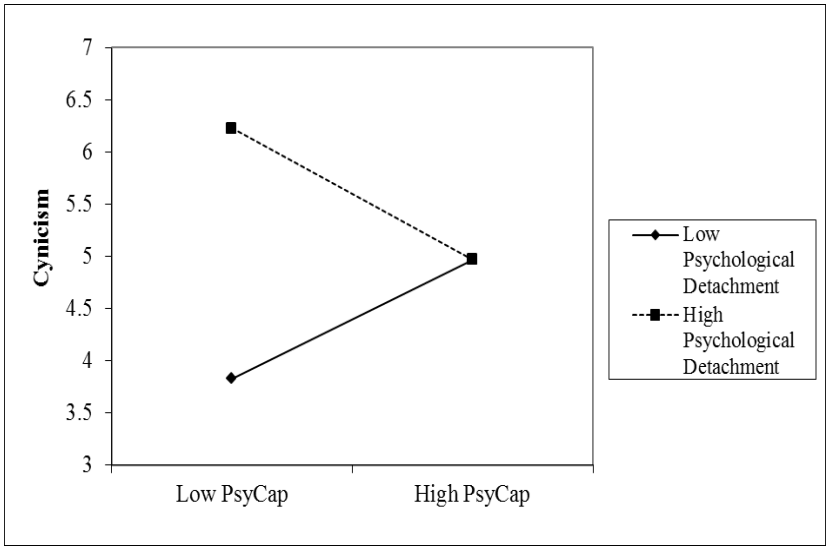

Fig. 2 Interaction effect of PsyCap and Psychological Detachment in predicting Cynicism

Conclusions

The paper investigated the relationship between PsyCap and well-being, as moderated by psychological detachment from work. The results support the proposed hypotheses, with only one exception. In this study, PsyCap, as personal resource, was associated with dedication and with cynicism which represent the cognitive part of burnout. Recent research supports our results that PsyCap is positively associated with dedication, as part of work engagement [10]. Also, in our study, PsyCap is negatively associated with cynicism and this result is similar with other study [24]. As hypothesized, we found that psychological detachment from work predicted differently two forms of well-being. Thus, psychological detachment was negatively related with dedication but positively related with cynicism.

Although there are no studies on the relationship between PsyCap and psychological detachment, it has been proven that the employees with higher PsyCap experienced a lower level of cynicism when psychological detachment was on the high level. Based on the conservation of resources model, the availability of important resources such as psychological detachment has further buffered the negative association between PsyCap on cynicism.

Our study has some limitations. First, participants were tested at a single time point. Thus, a longitudinal research design should be useful to examine temporary association between PsyCap and the outcomes. Another potential limitation concerns the self-reported nature of data. Future studies should consider including data from other sources (e.g., coworkers, partners) as external validation.

These results provide important insights on various human resources practices. Thus, practical implications of this study are link with training workshop for job incumbents. Since PsyCap is a personal resource and a "state-like", those organizations could be investing in and developing to their employees. Therefore, these types of resources protect them from cynicism, when they have a high level of PsyCap.

Over-indebtedness: consumer bankruptcy as a means of rehabilitating debtors

Bercea L.

The West University of Timisoara, Faculty of Law
lucian.bercea@drept.uvt.ro

Abstract

The paper approaches the legal treatment of consumer over-indebtedness, from the perspective of the typology of possible solutions and of the relationship between preventing and alleviating over-indebtedness. In the context of economic instability and of the imminent codification of insolvency law in Romania, the paper points out the need for a legislative reform that includes consumer bankruptcy procedure as an instrument aiming at protecting the over-indebted consumer according to European standards. The paper analyses the goals and the effects of consumer bankruptcy procedure, the role of over-indebtedness among the prerequisites for opening the consumer bankruptcy procedure and the relevance of over-indebtedness causality within the consumer bankruptcy procedure, in particular on discharging consumer debts, seen as a means of economic resilience of the consumer.

Keywords: consumer, over-indebtedness, responsible borrowing, responsible lending, responsible arrears management, consumer bankruptcy.

The legal approach to consumer over-indebtedness

1.1 The structure of the legal solutions to consumer over-indebtedness

The issue of consumer over-indebtedness was offered both legal and non-legal solutions. The latter approach the political, economic, social, educational or psychological dimensions of the over-indebtedness and transfer from those fields the arguments that are theoretically interesting and practically efficient to found and enforce the legal solutions.

To the classic legal solutions meant to treat consumer over-indebtedness, such as lesion or imprevision, added new ones from the post-modern consumer law, such as the exclusion of the unfair terms from the business to consumer contracts, the consumers' right to withdraw the business to consumer contracts, the private parties' insolvency etc. The (post)modern solutions are now about to substitute the classic ones, out of their practical efficiency.

The legal treatment of consumer over-indebtedness consists both of judicial solutions, either individual (the exclusion of the unfair terms from the contracts) or collective (the private parties' insolvency) and of extra-judicial remedies (the proceedings of the credit restructuring or those of non-judiciary resolution of the disputes between professionals and consumers – negotiation, mediation or arbitration [1]).

It is the purpose of the above-mentioned legal solutions that (re)structures them. The solutions aiming to avoid the consumer over-indebtedness (*e.g.* the consumer's right to pre- and infra-contractual information or the consumer's right of withdrawal) are thus to be distinguished from the solutions aiming to suppress the already existing over-indebtedness (*e.g.* debts' restructuring, early repayment of the credit following re-financing, consumer bankruptcy).

Despite the fact that the Romanian legislation has configured both the legal instruments of preventing over-indebtedness and those of suppressing the already existing over-indebtedness stipulated by the European directives on unfair terms of consumer credit, the Romanian consumer (and insolvency) law still lacks consumer bankruptcy, a standard at the European level out of its wide acceptance [2], whose (for the moment) non-compulsory character lacked to stimulate the adoption at national level.

Given the instability of the consumer credit market [3] and the process of reform and codification that affects national insolvency law, the Romanian legislation on consumer over-indebtedness needs to be restructured, so as to include, among others, the procedure of consumer bankruptcy.

1.2 Preventing solutions v. alleviating solutions in the legal treatment of consumer over-indebtedness

Given the tendency to abandon the *ex ante* restrictions to consumer credit perceived as impediments to the economic growth, the *ex-post* treatment of the already existing over-indebtedness acquired a prominent position among the solutions addressing consumer over-indebtedness. Such orientation is without any doubt based on the prompt legal treatment of the imminent or already existing over-indebtedness; yet, preventing over-indebtedness is always to be preferred to repressing it.

Irrespective of a potential future regulation of a procedure dealing with the consumers' insolvency, Romania needs a culture of consumer financial responsibility, designed at European level by the generic syntagm of *responsible borrowing / responsible money management*. This process implies a complex mechanism, consisting of information proceedings, education strategies and counselling instruments, to which might be added the complementary element of stimulating the economic growth as a means to efficiently manage the financial resources by the consumer. The normative instruments thus accompany the information, education and counselling strategies, allowing the consumer to take correct financial decisions even when the common law would consider it is too late. Thus, the relatively new and innovating right of withdrawal from the consumer credit agreement is a prerogative granting the consumers the possibility to re-evaluate, within a reasonable delay, their decision to indebt and to change their minds, avoiding potential (or even actual) over-indebtedness. Similarly, the early repayment of the credit allows the consumers to terminate the contract out of a minimum cost while it is being executed, by using their own financial resources or resources coming from re-financing at lower costs.

The standards of the creditors' contractual behaviour (especially as far as the financial institutions are concerned) have also undergone an evolution at European level, from the *truth in lending* original rule (requiring pre- and infra-contractual transparency of the standard comprehensible information put at the consumers' disposal) to the *responsible lending* imperative (that supposes the co-liability of the financers, obliged to assess the consumers' capacity to reimburse the credit prior to granting it to them, by reference to their resources and degree of indebtedness, such as offering an *affordable credit*).

Besides such standards, one can recall the particular supplementary instruments that apply in the relationship between the consumer and the directly and indirectly financing credit institutions: the administration of the relationship between the credit currency and the currency of the income used for the reimbursement (with the subsequent restriction of the credit established in foreign currency), the limitation of the credit costs (in particular through the repressing of the usurious lending especially as far as penalties are concerned), the regulation of credit restructuring (precedence being given to the credit adapting against the termination of the agreement), the repression of the unilateral abusive or premature termination of the contract, with the consequence of the anticipated credit settling, the insurance against the risk not to be reimbursed, the registration of consumers' banking history in the credit registrars.

The mechanisms meant to prevent consumers' over-indebtedness are not always efficient. When they fail, over-indebtedness will occur, a situation that must be approached from a curative point of view.

1.3 Rehabilitating over-indebted consumers. Does the consumer have a right to financial comfort?

The contemporary systems aiming to suppress already existing indebtedness try to reduce the negative effect of debts recovery and to rehabilitate the debtor.

First and outmost, the legal treatment of already existing indebtedness requires from creditors a *responsible arrears management* standard of behaviour, a responsible administration of the proceedings of debts recovery. The idea that one has the "right not to fulfil one's obligations" must obviously be rejected; however, the relationship between the consumer and the professional creditors initiating proceedings aiming at recovering their credits cannot place the consumer in a position that is incompatible with human dignity and a minimum living standard.

The standard of *responsible arrears management* first implies (i) flexible proceedings of debt recovery, individually enforced in accordance with the debtor's personal and financial situation, accompanied by a realistic plan of reimbursement. On the other hand, a responsible management of the debt recovery proceedings implies (ii) repressing the exploitation by the creditors of the consumers' difficult situation that forces them to ask for a credit restructuring, the abusive and inequitable solutions being avoided. Similarly, during the proceedings of debt recovery, (iii) the forced execution of the debts should remain the final remedy, residing in an efficient and well-balanced execution system, which ensures a balance between the consumers' basic needs and an efficient debt recovery by the creditors.

At the European level, the protection of the debtors' dignity and their granting of a minimum life standard irrespective of the amount of the remaining debts tend to become principles governing the legal

treatment of already existing indebtedness. Prior to asserting such principles, the national systems created normative or jurisprudential instruments of consumers' protection, such as the so called "social force majeure", a defence used by the consumers having undergone passive un-imputable over-indebtedness, when law did not grant them special forms of protection [4]. Although the principle requiring the protection of over-indebted debtors' dignity and their granting of a minimum life standard have not yet generated the acknowledgement of a formal and explicit right of the consumers' to financial comfort, elements of such approach may be identified in substance within both the sources of the European Union law and the national legal systems.

Consumer bankruptcy as a solution to alleviate over-indebtedness

1.1 Purpose and effects of consumer bankruptcy

Consumer bankruptcy is regulated for various reasons [5]: (1) it may be imposed as a reaction to their deviant economic behaviours, in the hypotheses when free access to credit turned into abusive access to credit and the consumers' faulty over-indebtedness to several creditors should be solved through a collective procedure; (ii) it may be regulated to protect the over-indebted consumers against the individual forced executions so that the minimum living standard might be granted to them; (iii) it may be promoted as a means to socially and financially reinsert them, by encouraging their involvement to the economic circuits.

The bankruptcy procedure was (and still is) considered by the legal systems that refuse to extensively regulate it as a solution fit for companies and improper as far as consumers are concerned. Besides, when regulated both for companies and consumers, the bankruptcy procedure pursues different aims: enforced to the former, it mainly aims at the payment of the creditors' debts; in respect with the latter, it emphasises the debtors' protection against the measures taken by the creditors.

The main imperative pursued at the European level by the consumer bankruptcy is the rehabilitation of the consumers (the so called *"new chance" policy* [6]), avoiding the retorsion against them out of their impossibility to pay their debts. The discharge of debts, seen as a means of economic resilience of the consumer, is generally acknowledged provided that the other measures have proved inefficient, for the purpose of granting the consumers' social and financial reinsertion through an integrative mechanism, based on utility, which stimulates the consumers' participation to the economic circuits, alleviating a financial burden otherwise impossible to be avoided within a reasonable lap of time [7].

Similarly, granting credits favours economic growth, diminishes poverty and increases citizens' well-fare. Against this background, consumer bankruptcy is seen as a special means of regulating consumers' financial status [8], encouraging the reticent consumers to use financial sources issued from credit granting and allowing the creditors in general, and the financial institutions in particular, to predict the management of the situations of consumers' over-indebtedness through an equitable distribution of the debtor's financial resources.

The reticence towards a possible regulation of consumer bankruptcy may, however, occur out of various reasons, as the side effects of acknowledging that consumer bankruptcy cannot be denied: an over-protective legislation creates a potential risk to de-responsibilize the consumers and to encourage their mentality of assisted persons (it should be noted, however, that it is unconceivable to protect consumers without the appropriate instruments of rebalancing their relationship with the professional); the recourse as such to this procedure may become a stigma that would prevent the consumers' social and financial reinsertion (despite the fact that any punitive consequence of the procedure is incompatible with the purpose of the consumers' rehabilitation, since the moral values justifying the debtors' unable to pay stigmatizing are substituted by the interest to reinsert the consumer in the economic circuits through free access to credits [9]); granted to credit consumers, the possibility to be exonerated from debts, if repeatedly and abusively addressed, may influence their legal or economic behaviour, affecting the economic circuit of payments, lowering the moral standards according to which such behaviours are evaluated and de-responsibilizing them [10].

1.2 Over-indebtedness – condition to enforce the consumer bankruptcy

The border between "mere" financial difficulties and consumer over-indebtedness is difficult to establish. Subsequently, the collective legal treatment of over-indebtedness must be enforced only in cases when the "mere" incapacity to pay the debts acquires a permanent and structural character, and, therefore, the debtor may be qualified as over-indebted [11].

A conceptual operational definition of over-indebtedness is required in order to acknowledge the existence thereof. While defining consumers' over-indebtedness at the European [12] or national level, a hesitation in choosing and organizing the definition elements can be pointed out: (i) the measurement unit of over-indebtedness is either the individual or the household, the latter characterized by the common living or common management of resources of several persons; (ii) the relationship between debts and resources generally takes into account the financial debts and expenses for living, on the one hand, and the current revenues, on the

other, without always including the exceptional sources of revenues or other elements constituting the consumers' patrimonial assets; (iii) the over-indebtedness sometimes refers only to structural and persistent payment incapacity, while in other cases it also covers the hypotheses of accidental payment incapacity.

Given this imprecision, the concept of over-indebtedness as such is reluctantly accepted and said to be a vague notion, therefore unable to be measured by a generally applicable mathematical model, impossible to be treated by generic measures as the legal ones, that should be enforced by the judge called upon to appreciate consumers' insolvency.

The precariousness of the models for measuring the (over)indebtedness of the consumer is generated by the variability of the parameters taken into account and the difficulty of fixing the proportions among them.

An attempt to systematize the models for measuring the state of over-indebtedness of the consumer [13] has identified several assumptions: (i) the administrative model, based on the official statistics regarding the formal procedures for judicial and extra-judicial treatment of over-indebtedness; (ii) the subjective model, which departs from the perception which the individual/family has/have on solvency and the capacity to honour their payment commitments; (iii) the objective (quantitative) model, based on the economic and financial situation of the individual/family, reflected in the ratio between the maturing debts and the net income, respectively between the total debts and the total incomes, including other patrimonial assets of the subject/entity in question. In addition, the *Life Cycle/Permanent Income* model is a derivative from the objective model which incorporates future incomes in the analysis of consumer behaviour, in general, and especially of the state of the consumer's debt, extending the measurement of the consumer's income, beyond their current income, to those resources which are expected to be available all throughout their life.

Viewed comparatively, these models take into account various parameters in determining the ratio between the sum of the debts and the flow of payments [14]: (i) financial liabilities, whose payment places the individual or family under the minimum subsistence level, established on the basis of the expenditure on housing, food, healthcare, etc. [15]; (ii) the difficulty of carrying the burden of the monthly payment obligations, over-indebtedness starting either in those situations in which the payment of the current obligations becomes uncomfortable, or when certain limits of percentage of the debt in relation to income are arithmetically exceeded, (iii) the existing structural arrears in at least one category of financial liabilities, parameter able to delineate the structural insolvency from the accidental one; (iv) the lack of liquid money for the payment of current debts or of any debt arising unexpectedly.

Those models are difficult to apply in practice because of the relativity of establishing several parameters: the minimum subsistence level of a person/family; the moment when the burden of the periodic payment obligations becomes too difficult to bear; the period after which arrears can be classified as structural. To these difficulties, other questions might also be added: who should be the subject of the insolvency of individuals, when debts have, in general, as a formal debtor, one of the members of the family, but their revenues are destined for the subsistence of the entire family?; how should one address the calculation of the minimum subsistence level in an economy where a significant proportion is still represented by income which is not subject to taxation?; what should be the relevance of the moment of the filing, by the consumer, of the request to open the procedure in relation to the moment of the establishment of the state of indebtedness and the evolution of the debtor's property during this period?

The option for a model and its operation represent, however, a matter of choice of the legislature. An imperfect mechanism, which can be enhanced in time, depending on the case law it generates, on the critical doctrinal analysis of this case law and the economic and social development, is preferable to the absence of any mechanism.

The content of the procedures regarding consumer insolvency is related, ever more frequently, to politics against social and financial exclusion, and insolvency mechanisms have a special importance in the economies which do not benefit from an extensive and effective system of social protection [16]. In such economic and social contexts, a systematic call for the individuals to excessively permissive insolvency procedures can represent a "political dynamite", just as the absence of such procedures or equivalent mechanisms might have the same effect.

Conclusions

Relaunching consumer credit as an instrument of economic growth requires a new architecture in the national legislation regarding the over-indebtedness of individuals, which includes in its structure the procedure regarding consumer insolvency. The imminent adoption of the Insolvency Code in Romania offers the opportunity of completing the remedies established by the consumer credit with a view to remove the causes and mitigate the effects of over-indebtedness. Will the Insolvency Code remain a (new) missed opportunity in the systematic approach of the consumer over-indebtedness?

[12] The group of experts for legal solutions to indebtedness within the European Council (CJ-S-DEBT) defined, in 2006, consumer's over-indebtedness as the incapacity to pay the obligations issued of credit agreements and the other current debts. Subsequent to this proposal, the Recommendation CM/Rec(2007)8 of the Committee of Ministers of the Council of Europe of June 20 2007 on legal solutions to debt problems took as an assumption that over-indebtedness refers to the situation where the debt burden of an individual or a family manifestly and/or on a long-term basis exceeds the repayment capacity. Lastly, in the attempt to harmonize the definition at the European level (see *Towards a Common Operational European Definition of Over-indebtedness*, a study elaborated for the European Commission by European Savings Observatory in 2008), based on an analysis of the concept in the legislation of Member States, a household is said to be over-indebted if, the costs insuring a minimum living standard being deduced, it is structurally unable to pay its financial debts.

[15] For example, the recent Commission Regulation no. 11/2013 implementing Regulation no. 1177/2003 of the European Parliament and of the Council concerning Community statistics on income and living conditions (EU-SILC) as regards the 2014 edition of the list of target secondary variables on poverty takes into account, at the household level, data on basic needs, recreation and social activities, durable goods, etc.

[16] While only 16% of the developed economies do not have consumer collective insolvency procedures, over 50% of the under-developed or emerging economies lack such mechanisms. See Ramsay, I. (2012). Consumer credit regulation after the fall: international dimensions. Zeitschrift für Europäisches Unternehmens- und Verbraucherrecht / Journal of European Consumer and Market Law 1(1), p. 34.

Legal culturalism as resilience

Bercea R.

West University of Timisoara, Faculty of Law (Romania)
raluca.bercea@drept.uvt.ro

Abstract

This paper seeks to use the concept of resilience as an assessment tool within the field of legal comparison. It particularly explains the attitude of the culturalist periphery of the discipline, determined to resist the comparativist *doxa* perceived as an agent of trauma, and to undergo a process of self-building through writing and reading to which their public is associated.

Keywords: Resilience, trauma, coping, legal comparison, culturalism, epistemology, interdisciplinarity.

Introduction

If one is to trust Andersen, at the end of any winter, long as it might be, one's reflecting mirror will no longer show "a dark, gray bird, ugly and disagreeable to look at, but a graceful and beautiful swan (...) glad at having suffered sorrow and trouble, because it enabled him to enjoy so much better all the pleasure and happiness around him" [1]. Could this be the case with the contracentric, undisciplined, peripherical comparativist fighting the *doxa* of their discipline within a process of simultaneous recovery and self-building that ultimately associates their readers? I will assess this assumption in the following paper, relying on several key concepts advanced nowadays by the studies on resilience.

Such an approach will hopefully not strike as far-fetched, since "resilience" has long overpassed the borders of general psychology [2].

Law, comparative law and resilience

1.1 Law as a trauma. The comparativist's depression

Coherent with the general positivist scientific trend of the 20th century, comparative law is shaped nowadays as a discipline conveniently emphasizing on the conceptual, systematic, logical, neutrally articulated and objectively assessable dimensions of law [3]. However, against the mainstream in the field, culturalist comparativists engage in "negative dialectics", that is "a critical mode of reflection which at crucial moments (...) negates what a discipline affirms" [4]. Such attitude of "de-position" or "dis-position" revealing precisely "distrust in positing and in positivity and in positivists and in the positivistic *Zeitgeist*" is openly qualified by the disobedient culturalist comparativists as "an *undisciplined* gesture", said to "effectuate a politics of resistance" and, ultimately, of being "transgressive" [5].

This need of transgression reveals a trauma [6].

Simply put, the culturalists' anguish is that of being a lawyer, of belonging to a field excessively vocational, insufficiently or improperly scientific [7], ultimately leading to "philosophical and epistemological bankruptcy" [8]. The feeling of disturbance only accentuates in comparative law, where, despite the very requirements of the discipline, "a geographical [but] not an epistemological deterritorialization" is currently undergone [9].

One culturalist comparativist openly confesses within this context "the acute sense of depression instilled in [him] by arid and conformist institutional agenda" [10], that he implicitly qualifies as one of the main characteristics of lawyers' psychism, otherwise "a black box of which only a few entries and exits may be analysed" [11]. Moreover, the lawyers' relationship to law exceeds the somehow neutral disciplinary belonging, being described as "the feeling of submission" to an established, self-claimed universal orthodox paradigm, a gesture however necessary if one wishes "to avoid trauma", yet at the cost of "violently reducing [the self] to silence" [12]. It ultimately becomes obvious that "one is at the mercy of the others" [13], confined to a "disciplinary ghetto" [14], where risking to be "chastised" or "abused" [15] and facing the challenge of being "weird": "here as elsewhere 'weirdness' lies in the eye of the beholder (who, in this particular instance, happens to be someone stepped in *legitima scientia juris* – a Latin phrase for 'anti-intellectualism')" [16]. All in all, what

culturalist comparatists would denounce is that while organizing reality, the dogmatic legal order institutes schemes meant to make lawyers' love both law and the submission that law itself institutes [17].

In order to address such deep trauma, a deeper deconstruction is required, "the aim [of which is] to overlay, to ruffle, to sting, to unsettle, and to trouble so that exciting and interesting things might result, so that imposed burdens can be rearranged and simplifications, those dangers to life and mind, can be set aside" [18]. Such first step response to trauma is openly and utterly de-measured: "I want to suspend the connection between comparison and measure" [19].

1.2 Writing as resilience. The building of the (resilient) self

Once the mechanisms belonging to the first defensive response to the trauma have been exhausted [20], the coping ones intervene and they should be understood as strategies allowing both for overpassing the difficult situation and for personal growth. The text produced by the culturalists while reflecting on the epistemology of legal comparison will, therefore, carry the underground sub-text of the comparativists' inner fight, allowing them to gradually take a distance from the symptom and to recover. Writing about how to compare thus fulfils protective, delivering and reparatory functions [21]. Two irritants in what appears to be the habitual pattern of academic legal writing are the very signs of the resilient function of writing: the biographical detail and an epistemology of reaction.

In quest of "a different economy of knowledge, better suited to the polyvocality and equivocality characteristic of cross-border legal scene" [22], one comparativist stumbles upon Derrida, whose concepts he turns "into a textual praxis, without embracing the French philosopher's world-view in all its ramifications" [23]. The text that explains the limits of Derrida's pertinence for the legal comparison includes the following mention, indifferent at first sight to the argument proper: "I did not beseech Derrida. Rather, he came to me through the very good fortune of a key encounter with a colleague to whom I continue to feel profoundly indebted". The biographical note deepens, as the comparativist recalls that "When I began reading *De la grammatologie*, *Marges,* and *Positions*, I had been teaching law for five years and was becoming more disappointed by the day as too many colleagues, reducing their scholarly mandate to that of compliant expositor of the law, promised more clarity, more stability, more harmony than they could ever deliver" [24].

Again, while writing *On the Unbearable Localness of the Law*, the same comparativist integrates as a *Coda* to the text a description of the debate following the conference where his argument was first presented and the story of the diner afterwards, both occasions on which he was directly confronted with the sharp disciplinary mechanisms calling him to order and that he, the marginal, described elsewhere as follows: "Wanting to preserve the capital of authority they have acquired over the years, wishing to protect the credit they have built for themselves, and desiring in effect for time to stand still, orthodox comparativists are prone to exclude dissenters, those whose work is seen by them to be wavering and, paradoxically, to be competing with theirs for the assumption of institutional dominance" [25]. The story of the trauma undergone on such occasions reveals a "therapeutic desire" assumed by the subject: "I am prepared to accept, of course, that the publication of this narrative may also wish to have a cathartic effect" [26], which thus confirms that one needs a story in order to (be able to) exist. Indeed, while narrating himself, the still fragile comparativist builds and gains a space to rest, withdrawing from trauma. Like in the genuine therapy, the written description of the autobiographical incident alleviates the symptoms that silence would have emphasized to paroxysm: "Who would be served - and what values would be honoured - if I agreed to be beaten into muted submission? What would resignation on my part – restless or otherwise - achieve?" [27]

But besides being soothing, writing participates to the very building of the resilient comparativist self, a process of growing, described in psychology as the alternation of progressive and regressive stages [28]. Thus, the same comparativist describes his decision to "overcome quietism and tell [such] story publicly" as a form of "circumspect resistance to the act of repression and suppression that was repeatedly performed at [his] expense and at the expense of the ideas that [he] was promoting", required by "integrity" and "authenticity" or urged by an "ethical call" [29]. At a later stage of the resilience process, these values will prove to be the very source of the comparativist's "conscious commitment to strategic criticality" [30]. The cultural comparativist thus becomes reactive; if, indeed, the mere resistance allows the subjects to maintain their identity, resilience always involves a form of identitarian conversion [31]: "I have, in fact, been making this case for more than fifteen years safe in the knowledge that the battle for an alternative 'comparative law' would confine me as a nomadic theorist and a theoretical nomad, to a marginal itinerancy at the periphery of the field. As was to be expected, orthodox comparativists have been content to discredit my work or to ignore it (…) To be sure, I could simply have left the field (…) rather than obstinately inscribe my protest when offered the opportunity to do so" [32].

But far from withdrawing, the peripherical comparativist decides in fact "to undermine [the orthodox] programmatic agenda by offering transgressive performances" [33], posing negativity as an epistemological principle of his approach to law: "Negativity is assertion" [34]. Against such purpose assumed by the comparativist as a germination principle for his own writing ("my own research … developed in reaction to mainstream European doctrine" [35]), one might legitimately try to address the reasons why the latter resigns at

this point, obviously refusing to take further steps in order to revolutionize the field of legal comparison and ultimately to become the centre of it or the new *doxa*. As various approaches to resilience have pointed out, within such process, the gain in the building of one's identity is generally doubled by the inconsistency of the subject's links to society [36]. In other words, along the textual self-building process, the resilient comparativist will experience an even more acute feeling of non-affiliation. Therefore, there is nothing more alien to his intellectual project than to institute a new *doxa* or to embody a new discipline.

1.3 Reading as resilience. The pitfalls of interdisciplinarity

Besides reactivity, as a second best epistemological principle the culturalist comparativists will chose interdisciplinarity. References to concepts and theories advanced by philosophers, linguists, economists or anthropologists are frequent in the culturalist comparativists' research, although performing functions of unequal complexity [37].

However, one may reasonably point out that "[w]hile the comparatist never ceases to cross the border, he never arrives on the other side" [38], in other words, while integrated in the legal comparison, interdisciplinarity only de-centers legal knowledge, without however re-disciplinizing law. Indeed, even though law may well be injected with interdisciplinary knowledge, such extraneous units seem to remain but irritants to the legal field that annexes them without genuinely re-evaluating its *a priori.*

Why would one refer, therefore, to texts outside the law as disciplined by the *doxa* if such *renvois* are *a priori* prone to failure? To whom are such references useful and within what limits?

Plausibly, references to these non-legal fields legitimate the comparativists' reaction against the established law. But there is more than that. Like writing, reading can support the resilience process, by structuring the evolution of the self and enhancing it. Within various therapies, words are used to treat disorders, to break the subject's solitude and isolation in the disease [39]. Books and references to books may indeed function as transitory items of the quest leading to the comparativists' new and resilient self.

1.4 The cultural comparativist as a therapist

The cultural comparativists are usually solitary in their approach to law that translates into solitude in their attempts to resist the disciplinary paradigm and to reinvent themselves: "The story I wish to tell is intended to show how challenging it can be for the comparatist-at-law to find an audience within the observed legal culture where the views being circulated about that legal culture *within that legal culture itself* fall fool of received and interested orthodoxies stubbornly seeking, especially against the most compelling evidence, to preserve a certain image of themselves" [40].

However, when they eventually get to their audience, a conversion occurs, the culturalist contracentric and undisciplined perspective of the legal comparison inspiring certain lawyers, equally deceived by the oppressive legal knowledge such as traditionally practiced, to similarly engage into a process of self-building. If, indeed, it is true that all patients are endowed with a potential of change that they can only put into practice when guided by a therapist, one must notice that more than a culturalist comparativist unknowingly acted like a guide for their disciples. Thus, a contribution meant to assess if two "ancillary" disciplines can join to undermine "the Discipline" (that is Law) is said to owe to the "undisciplined mentoring" of a culturalist [41], while a cultural perspective on the functions performed by judges is "a token of appreciation" of another one [42]. Furthermore, when dealing with the requirements of collective comparative research, one author expresses her gratitude towards a culturalist comparativist for the urge to settle with nothing else but a highly demanding approach [43]. In the same line, a comparativist's interdisciplinary and critical work is said to owe its very epistemological condition to the guidance of the author's culturalist director of thesis [44].

In line with the findings of the therapies focusing on resilience [45], one is forced to notice that such mentoring offers an expressive model, as opposed to the directive one proper to the established legal discipline. As the culturalist comparativists are themselves undergoing a process of identity building, their guiding model can only invite the disciples to self-reflection, any routinized injunctions being excluded. Moreover, when the disciples test themselves against the culturalist model, such evaluations will be highly formative, again as opposed to the properly disciplined and disciplinizing ones meant to preserve the purity of the legal field through an exclusive inquiry. Participants will indeed individually determine the importance of such assessment through the culturalist model for themselves. Far from being the inert object of the culturalists formative action, their disciples have to act as active subjects of the self-building process, agents of their own identitary and disciplinary rebirth.

Conclusion

As in general, resilience within law illustrates the maxim according to which becoming resilient means surviving. To be resilient is to engage in an unexpected direction, overpassing an adversarial situation. This

alternative way leads to a complex process, opening delivering perspectives. Far from being a miraculous panacea, it involves a responsible self-deconstruction, a discontinuous evolution, briefly, a new existential project [46].

The culturalist comparativists feel unease within their own field and abused by the discipline thereof. They are thus obliged to reinvent their status and build coping strategies. The programmatic de-measured overlaying of the orthodox constraints shifts into the autobiographical narrative of the initial trauma and subsequently forges an epistemology of the reaction. As the resilient self builds through writing, the inconsistency of the comparativists' links to the discipline grows, which explains why culturalism will never become the new *doxa* of comparative legal studies. In parallel, interdisciplinary references offer the comparativists and their audience a different means to elope the narrow field of law, turning reading into bibliotherapy. At the end of such journey of formation, the culturalist comparativists become the therapists of their audience equally deceived by the oppressive legal knowledge such as traditionally practiced.

The comparativists' quest thus ends with a metamorphosis, turning the initial trauma into an opportunity of growth. After all, "to be born in a duck's nest, in a farmyard, is of no consequence to a bird, if it is hatched from a swan's egg" [47].

This text was very much written with sympathy for all my law students having experienced and expressed the disciplinary disappointment and with gratitude for my resilient law professors.

À Pierre, donc.

Romanian restorative justice – does it really work?

Ciopec F.[1], Roibu M.[2]

Abstract

Restorative justice has lately preoccupied the legal criminal doctrine, as well as other areas connected to law. Legal practitioners, criminologists, sociologists and psychologists have analyzed the issues raised by the commission of offences, which prove to be extremely complex, reaching the conclusion that criminal law does not have sufficient means to deal with such intricate issues. This is in itself a great challenge and restorative justice could be an answer to it. However, the appropriate functioning of restorative justice needs to carefully adapted to the criminal justice system, known to be rigid, bureaucratic and institutionalized. Restorative justice cannot be perceived as a universal solution without considering the actual system to which it addresses. The application of restorative justice in Romania, as a form of resilience in criminal proceedings, needs to be closely examined, because the very substance of restorative justice implies that it can be truly felt in societies with a strong sense of community. Or, on a prima facie look, this is not exactly the case with our country. In what follows the study aims at analyzing the extent to which the above-mentioned aspects could bear real risks for the functioning of restorative justice in the Romanian criminal justice system.

Keywords: restorative justice, criminal justice system, communitarian paradigm, victim-offender mediation.

Perhaps the most significant development in criminal justice in the last decade is „restorative justice"[1] (in what follows RJ). This new approach has emerged in the context of the attempt to diminish the (negative) criminogenic effects of stigmatization and social exclusion, as consequences of traditional criminal justice based on the infliction of penalties (especially imprisonment). According to the labeling theory, deviance is not an intrinsic quality of the act committed by an individual, but rather the consequence of applying a label. Once labeled as a delinquent, the convicted individual becomes captive of this evaluation, permanently stigmatized and, due to that, an outsider. He is denied employment or the possibility to go back to activities of value on a social level and thus, by intermixing with other convicts, he creates "a class of outcasts". To these outsiders a criminal career appears to be the only alternative possible, supported by the development of a genuine subculture of delinquency. Given such perverse effects, it is perhaps not surprising that the rate of recidivism is of almost 45% of all inmates in Romanian penitentiaries.

Rather than stigmatizing offenders and excluding them from society, the restorative justice approach aims to bring them back into society and thus to enhance social solidarity. According to the dictionary of criminology [2] there are two types of definitions for restorative justice: one emphasizes the *process* requirement for RJ, that all parties have the opportunity to be heard about the consequences of the crime and what needs to be done to restore victims, offenders and community. The second underlines the *values* and *goals* of RJ: healing and reconciliation relationship between all parties involved, community deliberation over the problem rather than placing the criminal justice system at the center of decision-making and non-domination in order to allow all voices to be heard with respect.

RJ is an umbrella [3] term for a variety of theories and practices, but the major are:

- Victim-Offender Mediation. It brings together victims and offenders with a mediator in a tri-partite resolution.
- Family Group Conferences. A conference convener joins the parties to work towards an apology and some form of reparation.
- Restorative Cautioning. It is based on the traditional power of a legal enforcement authority (police) to caution juvenile for an offence and refers to police-run conferences involving the offender and victim.

- Sentencing Circles. There is more community input into those circles than in the case of conferences, often presided over by a judge.

Instead of a traditional trial in which the state is an adversary prosecuting defendants, RJ favors a victim-offender conference in which the state functions more as a mediator. In such a conference, which often is attended by family members and interested members of the community, the actions of the offender are condemned or shamed, and the offender is encouraged to take responsibility, express remorse and apologize to the victim.

Australian criminologist John Braithwaite [8] has furnished a significant intellectual justification for RJ. It is built on the premise of re-integrative shaming [4]. Shame refers to all processes of expressing disapproval which have the intention or effect of invoking remorse in the person being shame and /or condemnation by others who become aware of shaming. Theoretical analysis suggests that by relying on respect and relationships between the offender and those who care for him/her and for whom he/she cares, constructive use can be made of re-integrative shame to reduce crime or harmful activities [6]. Without putting it in too general terms, certain conclusions could be drawn, based on assessments made until the present, as to the positive effects of the RJ:

- Victims tend to be more satisfied with the conference, less formal process, than those who go through the court system,
- More than half of all conferences succeed in repairing the harm caused to the victim
- There is a lower level of recidivism among offenders after the conferencing process compared to those who go through court.

In Romania, the only form of RJ bearing a certain visibility in criminal matters is mediation. Although other forms of RJ seem to be very appealing, in what follows we would like to focus on the potential risks related to their actual application, estimating that the success of such procedure depends on a series of circumstances whose role should not be minimized.

In the first place, it seems that RJ is oriented towards those delinquents who committed petty offences. The efficiency of such a procedure in case of serious offences (sexual, racial or domestic violence or homicide) is still debatable. This precaution emerges as well in the Romanian legislation that provides the offences for which mediation is allowed, namely those prosecuted on a preliminary complaint of the victim (art. 67 of Act no. 192/2006). In this context, it would be appropriate to do a study on the percentage attached to petty offences in the official crime statistics, in order to be able to research the great volume of crimes that could be displaced by applying the RJ. Such a study depends on the practice of proportionate sentencing guided by the new Penal Code (in force starting on the 1st of February 2014), which brings about a new vision on the scale of penalties, which is repositioned between more reduced penalty limits.

Nonetheless, this justice seems a utopia to the victims of violent crimes, where the destructive effects can be felt during a lifetime. Money damages or the apologies of the offender will never be able to rebuild personal security that was seriously shaken. For some victims, it is very painful to notice that this system is not oriented toward the infliction of penalties. A person that was very seriously psychically injured following a criminal act initially goes through a period during which all that he/she thinks about is the punishment and suffering that he/she would like to inflict or be inflicted on the perpetrator. Such an approach could lead the victim to believe that his/her situation is not treated seriously enough [6].

In the second place, we should avoid unrealistic expectancies as to the ability of RJ to entail major changes in the character of individuals. As it is well known, the social context in which the RJ techniques are applied can be decisive. Thus, in the case of societies with a strong sense of community, such as Japan, the individuals are connected by powerful ties and interdependencies centered on the values of mutual help and trust. As might be expected, in this context shaming is re-integrative and produces low rates of crime. In the United States, communitarianism is weakened by urbanization, racial and ethnic heterogeneity, extensive residential mobility and a strong ideology of individualism [1]. As a consequence, America lacks the cultural and institutional basis that would encourage seeing offenders as part of an interdependent community and therefore America is burdened with a high rate of lawlessness.

In Romania, the situation is not much different. We lack as well a culture of solidarity and we are haunted by a sort of individualism that is fuelled yet by other resources. Essentially, Romania has not cut itself loose from the transition from the communist regime to the really democratic one. The 25 years that have passed since the events of December 1989 have not fixed the serious social cleavages performed in the name of communism. Although society was deeply fractured between the nomenclature members and the other people, solidarity within the governed class was but apparent. Solidarity would exist in deprivation and misery. On the slightest occasion it would be betrayed for mean interests, which were however able to sweeten daily life and create the illusion of privilege. This is how could be explained the efficiency of political police (secret services) which would exploit precisely the frailty of bonds among the members of society.

Many obnoxious habits were created: the idea that what is public belongs in fact to the state, and in the fight against the forms of deprivation that it imposed, there were "legitimate" the actions aiming at demolishing

the public space. Additionally, the doublespeak that the regime used to practice (the "justice-bidon" by Solzhenitsyn) created a total mystification, a remarkable difference between texts, norms or statutes and the practice that would annihilate their apparent protectiveness [7]. People would eventually react in a different or even contrary way, as opposed to what they were thinking. These circumstances led to an extreme individualism, lack of compassion derived from the loss of communication skills and to an obvious lack of solidarity. In this context, the chance to resort to the above-mentioned values, which represent the real engine of the RJ, is very feeble.

In the third place, studies have demonstrated that interventions in the name of RJ are efficient if performed in a non-coercive environment and that attempt to involve victims and community members in a collaborative and informal manner. Romania has a long formal, authoritarian tradition. The resolution of a penal dispute is almost inconceivable outside an institutionalized framework. There is a culture of written arguments in disfavor of oral ones, and of the official nature conferred by bureaucratic instruments (e.g. application of the official seal, page header, registration number, etc.) in disfavor of the gentlemen's agreement. Any approach outside these practices is underrated as private, unofficial and devoid of effects. Under these circumstances, the penal issue does not bear many chances to be solved, except on an institutional level.

In the fourth place, even if we imagined a more united society, the challenges launched by RJ are sometimes difficult to surpass. The premises of a communitarian approach to the penal conflict, with the inclusion of all interested persons in its resolution, cannot disregard the fact that delinquents are essentially different. Thus, all modern criminological theories relate social environment to the genesis of crime. Among the responsible factors for that there are: disorganized families, school abandonment, negative entourage, anomy, etc. All these factors have the ability to seriously affect an individual's character, so that it is possible to remain little room for the feeling of shame that indicates a state of morality. After all, since the very beginning of criminology, Garofalo used to identify the criminal with the moral insane, an individual with an affected moral sense. Consequently, when we try to deal with crime, we are confronted with subjects that bear a high risk of pervertibility. In this context, the idea of a regenerative debate, without the involvement of force, could be easily qualified as an illusion. Let alone delinquents who refuse to cooperate and accept the application of a RJ procedure.

Last but not least, it is important to mention certain technical concerns, such as the risk of disrespecting the due process, derived from the loss of the right to an independent and impartial forum, or the separation of judicial powers caused by the involvement of the police in solving the issues of offenders.

All these critiques await for an answer. It is possible for the RJ not to function efficiently except in isolated communities, which explains why such experiments come, in most part of the cases, from Great Britain, Canada or New Zeeland [9]. After all, the import and the transplant of an institution from one system into another is a difficult task and no one can offer guarantees against acculturation. Prudence would be highly recommendable, including as to the ability of RJ to prove a superior solution [10], as a form of resilience in criminal proceedings, a sort of universal panacea for all critical situations generated by the commission of any criminal act.

Role of self-esteem in improving the resilience of delinquent youth

Dragomir D.L.

Probation Service, Timis County Court (Romania)
diana.tomita@yahoo.com

Abstract

The specialty literature shows that low self-esteem would be the origin of many behavioral problems including substance abuse and other deviant behaviors. The paradox is the fact that a very high self-esteem but also a very low self-esteem affects negatively the psychological functioning of the individual and can lead to maladaptive behavior. This paper proposes an approach of theoretical issues, in the first place, and the research methodology clarification of the aspects mentioned above.

Subjects considered in this research are part of the juvenile delinquents in the Reeducation Centre Buzias.

The psychological tests selected for the present research are summarized in SEC (Clinical Evaluation System) and were chosen starting from the psychodiagnosis paradigma and the scientifically validated clinical evaluations: The child and adolescent scale of irrationality CASI, Questionnaire of unconditional acceptance of oneself USAQ, Scale of irrational beliefs for children CSRB, form B and C, Self esteem scale SS. Self-esteem can influence resilience in terms of increasing or decreasing risk and protective factors.

Key words: self esteem, juvenile delinquency, resilience, protection factors

Intoduction

Understanding the child/adolescent committed to a reeducation center is absolutely necessary in order to imprint a ppositive course to the forming and manifestation of interpersonal relations and to implement an efficient reeducation effort.

Due precisely to the situation he is in, the delinquent child is a specific human universe, full of contradictions, frustrations and feelings of unfulfillment. Each of them stems from this custodial universe, as a consequence of flagrant antisocial conduct, committing crimes, some of which are extremely severe. Many are socially misfit, refractory or incapable of becoming integrated to normal requests of social interaction, with a life mainly subordinate to instincts and primary necessities, with dubious morality and more than often with a painful childhood, weighing heavily on their conscience.

Often, the causes that determine criminality are found at adolescents whose resolution capabilities and social skills are insufficiently developed, in their affective immaturity and desire to be valued within the group of friends, but also in their cognitive orientation rather on achieving results in a short term and neglecting the impact of long term decisions [4].

Decisive for the child's evolution is his position in relation to the crime committed and the degree of affective and psychological security he perceives in his new living environment. Usually, in the structure of human personality, the following components are considered to be essential: affectivity, motivation, will, temper and character.Emotional manifestations are a sensitive seismograph of the emotional dynamics experienced by minors and youth in reeducation centers.

From the perspective of improving the resilience of this category of children and youth, motivation to change becomes essential, in connection to which a specific stand must be adopted with regards to significant issues, such as the future, family, relations with the centers personnel, this offering an important lever for the recovery effort [4]

It is important to promote resilience for the delinquent children because it gives them the ability to deal with life traumas and adversities, and is based on self-esteem. Resilience can help to increase and promote a child's self-esteem. If children are resilient they will be able to cope better with problems and traumas, they will be happier and more fulfilled and will be less likely to develop emotional problems like depression or anxiety.

Documentary framework

When delinquent children lack resilience, a negative event serves as a trigger for irrational beliefs. These irrational beliefs lead to excessive emotions and self-destructive behaviors. Destructive behaviors such as arguments, fights, threats, low performance are the most common among this category of children. It can also generate damaging emotions such as panic, depression, rage, apathy, resentment, passive aggression.

Self-esteem is similar to self-worth and it can vary from one day to another, but general self-esteem develops from infancy to adulthood.

Patterns of self-esteem start very early in life. The concept of success following effort and persistence starts early. It is important to develop and promote self-esteem during childhood. Parents involvement is essential to helping kids form accurate, healthy self-perceptions while they also create a self-concept based on interactions with other people. Parents can promote healthy self-esteem by showing encouragement and enjoyment in many areas.

Self-esteem fluctuates as children grow. It frequently changes because it is affected by a child's experiences and new perceptions.

Delinquent children are usualy children with low self-esteem that may not want to try new things and may speak negatively about themselves, having also a bad self image. They frequently experience a low tolerance for frustration, giving up easily any task or activity and are very critical of and easily disappointed of themselves. Often, for these children, a sense of pesimism prevails. This can make them vulnerable to stress and create difficulties in solving different kinds of tasks.

Creating a good self esteem for this children by promoting their resilience through strengthening protection factors and diminishing risk factors becomes healthy for their overall life. Thus, they interact with others, are comfortable in social settings, enjoy group and also individual activities. Children can be sensitive to parents' and others' words. Remember to praise your child not only for a job well done, so they should always be rewarded for their effort and completion of tasks, instead of outcomes.

The models of conduct provided by both parents, as well as the affective and instrumental qualities of the family home are the fundamental prerequisites for the establishment of a well-structured personality, motivated by appropriate beliefs regarding the need of respecting prosocial norms. As a result, the adolescent behavioral manifestations depend, to a large extent, on the integrity of the family function. The absence of fulfilling all the main functions of the family (subsistence, protection, affection, socialization, etc) cause the appearance of trends that are not compliant with the rules of conduct positively valued by the society [5]

Delinquent children need a positive role model and thus they might set more accurate standards and become more realistic. They shall learn to see all life situations in a positive and objective manner. Thus, juvenile anti-social manifestations must be understood by taking into consideration the combined individual, psychological, social, and cultural factors [5]

In order to improve their self esteem and, thus, better cooperation and interaction with adults and peers they need to be offered for each well fulfilled activity positive, accurate feedback. They need to feel they can be confident in the presence of certain adults, need to be encouraged to talk to them about solving problems that are too big to solve by themselves. They should become involved in constructive experiences, activities that encourage cooperation rather than competition, these being helpful in fostering self-esteem.

From the perspective of resilience, its evaluation is focused mainly on capacities, forces and family resources. Clinical interviews are essential in order to detect family problems and the way they are lived. The interview must be led in order to discover and explore the forces, interests and coping strategies specific for each family [3].

Research methodology

The aim of the present research is to analyze the level of self esteem and the irrational beliefs of delinquent children, highlighting psychological and social risk and protection factors that influence their level of resilience.

In order to study the relationship between irrational beliefs and self esteem as well as their impact on the resilience of delinquent children, we will use The child and adolescent scale of irrationality CASI, Questionnaire of unconditional acceptance of oneself USAQ, Scale of irrational beliefs for children CSRB, form B and C, Self esteem scale SS.

The questionnaires will be administered to 50 children resident in the Reeducation Centre Buzias in order to evaluate if self esteem and their irrational beliefs influence the risk and protection factors that construct their resilience. The samples will be applied individually. The sample structure is not homogeneous in age (subjects aged from 15 to 19 years old) but it is homogenous in gender.

Conclusions

This research will provide valuable information regarding the impact of irrational beliefs and self esteem on the level of resilience of delinquent children. Also, the outcomes will help us design intervention programs and activities in order to increase and promote their resilience.

Recognizing the beliefs of delinquent children will help understand better why certain adverse events cause strong feelings, long-lasting, and debilitating emotions. Beliefs give the insight into what kinds of adversity creates certain stress; and once they have been identified, they can be examined for accuracy. It is important to pay particular attention to beliefs that seem irrational or inaccurate. It is helpful to think about plausible, alternative beliefs.

Beliefs about the way things will turn out have a significant influence on the ways in which delinquent children respond to stress and adversity. Optimists view themselves as less helpless in the face of stress than pessimists do, they adjust better to negative events, and they have a lower risk of anxiety and depression.

Views about the future are very much related to views about ourselves and our ability to cope with the demands of a stressful situation. The conviction that one has the resources to deal with an adverse event predicts a better adjustment than the belief that he is incapable. Self efficacy is developed through successful experiences in similar situations, by watching others cope successfully, and by being encouraged by others who believe we can be successful.

Thus, the results of the present research will lead us to the most important protection factors that need to be focused on and strengthened in order to develop and promote the resilience of delinquent children.

Execution of non-custodial guidance and supervision orders

Fanu-Moca A., Roșu C.

Abstract

The regulation of the execution of non-custodial educational measures by Law no. 253/2013 on the enforcement of sentences, educational measures and other non-custodial measures ordered by the judicial bodies in criminal proceedings creates a legal framework that prevents minors from being traumatized by the inflicted restrictions, to the extent possible, and that also assures that minors' rehabilitation should be carried out as efficiently and quickly as possible, as a form of resilience in criminal proceedings.

The non-custodial educational measures provided for by Art. 115 para. 1 point 1 of the new Criminal Code adopted by Law no. 286/2009 are as follows: civic internship training, supervision, weekend commitment, and daily assistance. Such measures may be taken against the minor who, at the time of committing the offence, was aged 14 to 18 years.

We believe that the entire regulatory framework of the execution of non-custodial educational measures shows the legislator's intention to grant the minor an additional chance, that is aimed at preventing the minor's exclusion from his natural environment, represented by family and school, and at establishing as such the necessary conditions for his rehabilitation and accountability for the consequences of the committed offence.

Key-words: non-custodial educational measures, civic internship training, supervision, weekend commitment, daily assistance.

Introduction

Act no. 286/2009 [1] on the New Penal Code, sets out, in art. 115 the guidance and supervision orders, both custodial and non-custodial.

Principles governing the execution of penalties. Chapter I, Title I of Act no. 253/2013 [2] is entitled *Area and Purpose of Regulation*, art. 1 letter e) providing the regime and conditions under which non-custodial guidance and supervision orders, among others, are executed – counselling courses, education and vocational training programmes, confinement to dwelling-place during the weekend, and daily assistance.

The stated purpose of Act no. 253/2013 is set out in art. 3. Thus, by settling the execution of penalties, of guidance and supervision orders and other measures, the legislator seeks *to assure a fair balance* (a.n. – *A.F.M. and C.R.*) between the society's safeguard by maintaining the legal order, the deterrence from committing new offences and the *connection to community resources of the person* (a.n. – *A.F. M. and C.R.*) who committed one or more acts provided by criminal law.

Principle of legality of execution refers to the fact that the legal grounds of execution of penalties cannot be arbitrary, but must be based on a final legal decision or other disposition of judicial authorities.

Principle of respect of fundamental rights and freedoms. Penalties, guidance and supervision orders and other measures ruled by judicial authorities impose certain restrictions and limitations, but they must be applied so as to assure the respect of fundamental rights and freedoms.

Principle of respect of human dignity. Even if the person against whom the criminal courts of law previously ruled an interim order or a final conviction commits an offence, the measures to which that person is subjected must not affect his dignity.

Principle of respect of the right for private and family life. The infliction of penalties, of guidance and supervision orders and other measures ruled by judicial authorities in the course of criminal trials, even though non-custodial, still impose certain inevitable restrictions on the private life of the person. However, these measures must be enforced in such conditions as not to limit the exercise of the right for private and family life more than the inherent nature and content of the measure itself.

Principle of respect of confidentiality and data of personal nature. Natural and legal persons involved in the execution of penalties, of guidance and supervision orders and other measures are bound to respect confidentiality and the protection rules of data of personal nature, set out in the specific laws.

Principle of prohibition of discrimination. As an expression of the constitutional principle of equality of rights, art. 10 of Act no. 253/2013 has established that during the execution of penalties, of guidance and supervision orders and other measures ruled by judicial authorities in the course of criminal trials, that are of non-custodial nature, discrimination is prohibited on any ground such as race, national or ethnical origin, language, religion, gender, sexual orientation, opinion or political status, property, social origin, age, disability, non-contagious chronic disease or HIV/AIDS infection or on any similar grounds.

Principle of informing the person who does neither speak nor understand the Romanian language, nor is able to express himself. Due to the rather increased number of refugees, but also of persons with certain disabilities, the natural communication in the Romanian language is hindered. In such cases, the right to be informed of the person who is in the course of execution of penalties, guidance and supervision orders and other measures ruled by judicial authorities during criminal trials, that are of non-custodial nature, as to the content of the penalty or measure ruled against him, as well as to the main procedures carried out in the course of execution, must be expressed in a language which he understands, with the assistance of an authorized translator or interpreter, or a sign language interpreter, remunerated from the state budget, via the Ministry of Justice.

Execution of non-custodial guidance and supervision orders.

Title IV of Act no. 253/2013 sets out in detail the rules governing the execution of non-custodial guidance and supervision orders. In the first chapter – *General provisions* – the law sets out the organisation of the execution of non-custodial guidance and supervision orders, the role of the Probation Service and the right to be informed of the juvenile offender and his family.

Chapter II details the effective manner in which non-custodial measures are executed.

The first measure is set out by article 66 of Act no. 253/2013, namely the *counselling courses*.

The counselling courses to which the juvenile offender must participate, are elaborated on the basis of the framework-programme authorized by joint order issued by the minister of justice and the minister of national education, published in the Official Journal of Romania, Part I, according to the minimum standards on probation destined to the institutions in the community which are involved in the execution of non-custodial guidance and supervision orders. These establishments must respect, in the course of their activities, the minimum standards on probation for the institutions in the community, which are authorised by act of the Government.

The second measure, provided by article 67 of Act no. 253/2013, consists of *education and vocational training programmes.* This order is more complex, since it implies the participation of the juvenile offender to education or vocational training courses, as well as his deterrence from carrying out certain activities or connecting with certain persons that could affect his rehabilitation.

The third measure, stipulated by article 68 of Act no. 253/2013, is represented by the *confinement to dwelling-place during the weekend*. This is an order that involves a greater control, in order to avoid that the juvenile offender come into contact with certain persons or be present in certain places which may lead him to adopt a criminal behaviour. We must mention that any assembly or meeting place (discos, clubs and bars) may constitute favourable opportunities for the commission of offences.

The last non-custodial guidance and supervision order is *the daily assistance* and is set out in article 69 of Act no. 253/2013. The supervision of the execution of daily assistance is achieved by the probation officer or, if the case, by the person appointed by the former's decision, and is a person who belongs to an institution of the community. The daily assistance is based on a programme which contains certain activities that the juvenile offender must fulfil. The programme is agreed on by the probation officer as well as the parents, the legal guardian or other person who takes care of the juvenile offender, who is consulted in his turn.

The last chapter of the section related to the execution of non-custodial guidance and supervision orders refers to common dispositions applicable to all such orders.

When a court of law has ruled against the juvenile offender either the obligation not to attend certain places, certain sports performances, cultural activities and other public assemblies, or the obligation not to approach the victim, communicate with her and her family, with the participants to the offence and other persons determined by the court, the judge appointed for the execution of penalties issues a copy of the operative part of the judgment in order to be notified also to the persons or institutions that are entitled to supervise the fulfilment of these obligations.

In case the court rules against the juvenile offender the obligation to subject himself to measures of control, treatment or nursing care, a copy of the operative part of the judgment is notified, by the probation officer, to the institution in which the control, treatment or nursing care mentioned in the judgment are about to be carried out.

The obligations imposed by the court can be modified in the course of execution. The initiative of modifying the initial obligations may belong to several categories of persons: the probation officer; the juvenile offender; the parents; the legal guardian; other person who takes care of the juvenile offender; the injured party.

Conclusions

The manner in which the legislator has settled all non-custodial guidance and supervision orders proves his intention to offer juvenile offenders a second chance, as o form of resilience in criminal proceedings, so that they might not be estranged from their natural environment, namely the school and family, by providing the conditions to be met in the attempt to rehabilitate them and make them aware of the consequences of their acts.

Mediation – a premise of promoting assisted resilience for both victim and offender

Fiscuci I. C.

Authorised Mediator,Romania
ficarmen@yahoo.com

Abstract

Mediation between victim and offender is part of the concept of Restorative Justice, a process within which the victim and the offender meet face to face before a mediator and attempt a **restorative settlement of the conflict.** Restorative Justice implies the existence of a much deeper connection between the victim, offender and community than the one taken by the official system of criminal justice. The victim and the offender are members of the community and they need to go back to their old life within that community, surpassing the difficult situation by which they went through as result of having committed the offence In this regard, the concept of restorative justice emphasises the social interactions (including emotional, social and economic aspects), between the victim, the offender and the community. The **restorative approach relates directly to the conflict and empowers the relationships based on respect, cooperation and responsibility between those who commit offence, victims and the community members.**

Crime causes immediate negative effects in the personal and social life of those directly involved (victim and offender) but also long term consequences which have an impact up on the two main characters both at personal and social level, unless are appropriately managed. We make reference both, to the victim's physical and psychical traumas, and also to the psychical pressure, the labelling, and the stigmatisation which the offence author is submitted to, simultaneously with the latter's introduction in the criminal system and punishing him.

The article analyses mediation between victim and offender as condition of promoting assisted resilience in this particular context, relating to the general characteristics of mediation, to the objectives of the specific type of mediation and to the techniques used within it. There are also presented the results of some specialty studies which support the article idea.

Keywords: mediation, restorative justice, conflict, responsibility, assisted resilience

Mediation - alternative method of disputes settlement

Christopher Moore (2003) defines mediation as being: "The intervention in a conflict of a third accepted, unbiased and neutral party, who has no authority to decide, but who helps parties in a conflict to voluntarily reach an agreement which can be mutually beneficial''[1],

If we relate to the principles governing mediation and the practical way implementing of process, to the role of the mediator and the techniques used by him, we would like to add following comments to the previous definition:

Mediation is a volunteer process– parties decide if they accept or not their dispute being resolved by mediation, they have the right to withdraw from mediation at any time over the course of process and they are not bound to reach an agreement (settlement). Mediation promotes the parties 'self-determination – their right and ability to define their own problems, needs and solutions.

Mediation analyses the basic causes of the issue and enables the finding of creative solutions and remedies, adapted to the needs and resources of the parties having a dispute.

The mediation stimulates communication, constructive dialogue, empathy, cooperation, alternative thinking and creativity. Preconceptions, defamation, verbal aggressiveness are avoided; the trust between parties is built; perceptions are clarified; expectations, fears, emotions, dissatisfactions and frustrations there are shared, within a safety and privacy environment.

Victim -offender mediation–instrument of the restorative justice

Mark Umbreit defines the Restorative Justice as a form of reaction to crime which provides the opportunity to those who are the most affected by it – the victim, the offender, their families and the community – to be directly involved in the response towards the harm done by committing the crime" [2],

The philosophy and the principles of the Restorative Justice are based on the idea that a crime is first of all a conflict between people that harms other people, as well as their personal relationships, a harm that creates obligations and responsibilities [3], for those involved and for the community. Thus, Restorative Justice proposes a change of view as compared to the classical system of justice (which considers that crime as an act directed against the State, a law breach) by a participative approach of parties in conflict resolution and the remedy of the consequences of crime.

Victim-offender mediation follows the same consecrated procedure as in the case of other types of dispute, with the mention that it has a specific nature, determined by the parties' psychical and behavioural features –the victim and the offender – as well as by the nature of the dispute, as result of committing the offence. It is important to mention the fact that within the mediation process no guilt is established, the discussion is focused on the offender's problematic behaviour and the way in which this behaviour had affected the victim, the victim's or the offender's family

According to [4], victim –offender mediation is a process providing victims the possibility to meet the offenders in a safe and structured context, for the purpose of taking offenders' responsibility for their behaviour and awarding damages to victims for the harm done to them"

It is a non-adversarial process, of making decisions by consensus, which encourages offender's responsibility and the satisfactions of the victim's needs. Through the mediation process, people who committed crime have the chance to take responsibility for their deeds, to correct the harm done, to reflect upon their behaviour and, at the end of the process, to be able to make a behavioural change.

Victims have the possibility to express their feelings and perspective regarding to the criminal act, to get information about the crime, to find out offender's motivation for having committed the offence and to be compensated for the loss suffered (material, moral, psychical, emotional).

Each situation in which the offender made a mistake is capitalised both as learning and as behavioural change opportunity. Discontents are expressed in a non accusing manner; the conflict is redefined or "reframed" in a positive manner which can lead to a win-win solution. Stigmatisation and labelling are avoided; the offence is considered as wrongful behaviour, but is not judgemental the offender, as person. If mediation works and reaches its aim, the person having committed a criminal deed, shall refrain from committing more offence and the victim shall avoid double victimisation, shall regain trust and the feeling of control upon his own life. Thus, the life quality of the two main characters of the dispute can considerably improve.

Resilience and victim–offender mediation

Relatively newly introduced in the field of the psychosocial practice research, resilience implies the positive adaptation of an individual to difficult and adversarial circumstances appearing in the life of a person and personal development by confrontation with these circumstances. Manifesting resilience evolves during the person's lifetime, the person being able to acquire new competences and to change. Thus, "resilience appears as a dynamic concept, being rather a process than a trait"[5],

The concept of assisted resilience makes reference to the "possibilities of creating opportunities in order to develop those persons' abilities who are exposed to adversarial or risky situations, to overcome them" [6],

Researches conducted in the field revealed that self-esteem, empathy and respect for others, honesty and cooperation, internal locus of control are factors of resilience. Social skills are another important part of the development of resilience. Ability to solve a conflict, to be assertive and constructively problem solving are also skills that help a person to feel they have control over situations of his life. Taking responsibility, confidence, the feeling that one is able to establish realistic goals and getting things done, belongs also to the concept of resilience.

As seen, mediation is characterised by balance, cooperation, empowerment, potential and responsibility, empathy and competence, in other words, individuals' ability to surpass their own problems and to produce changes.

If we place the objective of mediation in the sphere of parties' progress by comparison to their situation in the past, mediation attains its aim in full when parties, as result of mediation, also experienced a progress in development their ability, development of strength of self and capacity relating with the others. All these represent the components of the empowerment in mediation (parties' empowerment): personal power and mutual recognition" [7],

Mediation, by validating the importance of one's personal competences, empowers participants, activates their ability to make decisions in adverse conditions and reactivates their sense of personal value.

Empowerment is reached when parties become more aware and more trustful with regard to their ability to face difficulties they encounter.

The recognition of the other occurs when parties manage to be more open, more attentive, more receptive to each other, being able to explore other perspectives as well. Self-preoccupation is related to defensiveness, susceptibility and the lack of acceptance towards other opinions or different perspectives. Conferring recognition means seeing things from the other party's perspective, open awareness and understanding the position and the other party's perspective, even adjusting of one's behaviour to match the other party's needs. [7]

The confidential and non judgmental feature of mediation gives a chance to parties to explain their actions, to share their experiences, their fears and, especially, helps them to consolidate their relating abilities towards other people's problems. By these, mediation contributes to mutual recognition and interest, as human beings, even between parties who started the relationship as fearful opponents. The idea that they can collaborate to repair the damages done through offence, gives the parties the feeling that they can personally control the result. All these identify with the dimension of *mutual recognition* of the mediation process.

In general, people who are in conflict feel they do not have any alternative. Strong emotions limit the abilities to creatively and openly think. Generating solutions for conflict resolution helps parties to create multiple solutions from which they can choose and they can agree upon the one that suits best their needs, and that provides them feeling of freedom, power and control.

We can state that *empowerment* in mediation means to treat both the victim and the offender in a way which respects and supports their own resources of making decisions and finding together solutions for the problems they face, solutions which might bring to satisfying their needs and interests and as last resort, solving their conflict. Both the victim and the offender are encouraged to play a active role in deciding their own future, instead of passively assisting in decisions made by others for them. It is developed the ability of self-determination and involvement in the process of conflict settlement in a free, conscious and committing way. Interaction between mediator and parties on one hand, between victim and offender, on the other hand, facilitates empowerment by the fact that participants in mediation get the feeling that they are respected, that their identity is recognised; their interests and needs are accepted.

The mediation process refers to the emotional and informational needs of both the victim and the offender, which are essential in the empowerment process and for the purpose of developing empathy. Empowerment and empathy can facilitate removal/suppression of the feeling of victimisation and its negative consequences - in the victim's case – and prevention of the future criminal behaviour, in the offender's case. Researchers have highlighted that for the victim, the possibility to express his/her feelings with regard to offence, to its impact, in the presence of the offender, most of the times, has a therapeutic value and a greater importance than reaching an agreement. [8].The fact that the victim has the chance to receive direct replies to all the questions that make him uneasy, that she can understand why he became a victim and, moreover, that she can perceive the offender as a human being and not as "something" that caused her harm, gives her the possibility to free himself of the negative feelings and experiences gathered from the moment of crime perpetration as well as to regain control of his own life.

Mediation encourages offenders to take responsibility for their behaviour and to become aware of the consequences of their decision to commit the crime, for others and for themselves. Being aware of the fact that this kind of behaviour is first of all a consequence of their decisions contributes to developing of the internal locus of control. As we have seen, resilience represents – briefly –the ability to face difficult situations. Usually, people with an internal locus of control have greater chances to surpass these situations by comparison to those with an external locus of control, they are more resilient. On the other hand, understanding the way in which his acts affected others stands for an essential factor of moral development and of resilience. The cognitive ability to understand the way in which his own decisions affect others is essential for the moral development [9].

We can draw the conclusion that the effective benefit of victim-offender mediation– beyond their dispute ending up in an amiable way – is represented by the very huge potential of transformation of participants. Due to the awarding the feeling of power to both the victim and offender and by encouraging mutual recognition of their humanity, mediation triggers a positive change and personal development by "integration of own power and of compassion for others [10], thus facilitating resilience".

To support this statement there are the results of researches with regard to the impact of mediation upon victims and offenders, results that highlighted a high level of victims' satisfaction and positive changes in offenders' attitude and behaviour[11]. Thus, it has been found that in the case of offenders, the rate of relapse was 20 % for the young people who participated in mediation by comparison to 34 % for the control group and a percentage of 81% complied with the duties to repair damages according to the agreement, by comparison to only 57% of the young people who were not involved in mediation [12].

In general, victims involved in mediation express a higher degree of satisfaction regarding the way in which they felt and how they were treated during the mediation compared to the victims of whose cases are settled within the justice system [13], and are less susceptible with regard to the risk of becoming a victim again.

Analysing the victims' feelings before and after the mediation, [14], observed that there is a lowered feeling of fear and rage and an increased sympathy towards the offender after the mediation finished.[15], conducted one of the first studies which examined the effects of mediation upon the symptoms of post-traumatic stress (PTSS),for the victims and he found out that in case of the victims who took part at the mediation, there were reduced the traumatising effects of the crime by comparison to the victims from the control group (immediately after mediation and also 6 months later).

Conclusions

In analysing the victim- offender mediation as premise of promoting resilience we have emphasised empowerment and recognition, in our opinion, these concepts being defining elements, with the most important role in building resilience

As previously mentioned studies indicate, the victims of crimes who participated in the mediation programs expressed their satisfaction to this process, as well as the decrease of the degree of fear and anxiety. It results that mediation provides victims a deeper feeling of control regarding to the circumstances which, would normally, make them feel vulnerable and helpless

People who committed crimes, proved as result of involvement in mediation, higher degree of conformity at pro-socially standards and values, of fulfilling the duties to repair damages undertaken by agreement and of being aware of the fact that own behaviour is a consequence of own decisions.

We can draw the conclusion that mediation helps participants to surpass the adversarial way of relating and to find the constructive motivations so as to solve the problems they face. Also, it represents a support for parties' behaviour and attitude change. These are helped to discover and/or to consolidate their own abilities to overcome, in the future, the unfavourable circumstances of any nature that could appear in their life.

The adjustment of the contract by rebalancing benefits – a way of overcoming the over-indebtedness the parties of an agreement

Abstract

The concept of "over-indebtedness" - which means the original assumption, voluntary or involuntary, by one of the contracting parties, of one or more excessive contractual commitments compared to the correlative one/ones of his contractual partner or which become so while fulfilling the provisions of the contract - can be found in reciprocal obligations, where the contractual balance, shown by the equivalence of reciprocal and interdependent obligations is one of the key factors contributing to the common contractual interest. The over-indebtedness of the contractual parties can have three causes. The first two of these rupture the equivalence of the contractual commitments despite the will of either contractual party, thus changing the legal effects pursued by the parties when agreeing to the contractual provisions. The circumstances to which we refer are, on one hand, those due to economical and financial changes - rebus sic non stantibus - and, on the other hand, the erroneous perception of the parties on the elements of the convention - error as defect of consent. The third cause is the very deliberate action or inaction of one of the contracting parties, resulting in the modification or alteration of the contractual purpose pursued by the other party, by disregarding the free consent of the latter, as well as the failure to comply with the contractual duties. In such cases, the legislature, in respect of the principle of favor contractus, make available to the parties, in order to rebalance mutual contractual benefits and the achievement of general and individual interest, of each of the two parties, as a form of contractual resilience, firstly, the possibility of adapting the contract, placing in the background the sanctions that result in the annihilation of the contract: the declaration of invalidity or termination of the contract.

Keywords: over-indebtedness, doctrine of frustration, adjustment of contract, reduction of benefits.

Preamble

The concept of "over-indebtedness" - a situation characterized by the fact that one of the contracting parties agrees to an excessively onerous obligation in relation to the correlative one of the other contracting party – is characteristic and generally applicable to contracts in which the obligations of the parties are reciprocal and interdependent and in which the contractual balance, founded and originated on the reciprocity and interdependence of the considerations, is essential for the contractual interest pursued by the contracting parties at the time of the agreement. Indeed, the parties in such a contract are interested to comply with the provisions of the contract to obtain their common contractual interest, just as long as, in return for their benefits, they receive a proper equivalent; this equivalence is assessed, usually, subjectively, having into consideration the contractual expectations regarding the consideration to which they are entitled in relation to the benefits to which they, themselves, are required.

Thus, guided by this objective, whenever one of the contracting parties shall notify a discrepancy between what is expected and what in fact the party receives or is about to receive, meaning that contractual benefit pursued is under the party's expectations, the party will believe that it is over-indebted.

As a corollary of the occurrence of such a situation – the over-indebtedness of the parties - is the naturally and inherently increased concern of the legislature in finding and making available to the participants suitable solutions in their contractual legal relations, designed to determine the preservation of these contractual relations in the spirit of respecting the contractual expectations of the parties.

These solutions are reflected in the drawing of lines and guiding rules that are aimed at adapting the contracting parties and the legal relations between them on how the obligations are presented at the time of their maturity.

Among the solutions proposed by the legislature in this matter are the two legal institutions, themes of our research, respectively, the doctrine of frustration and adjustment of contract, that can be seen as forms of contractual resilience.

Causes that determine the over-indebtedness and the remedies suggested by the legislature for overcoming this

Among the causes that generate the over-indebtedness of the contracting parties, the present research focuses on those that generate a contractual imbalance beyond the control of the contracting parties and those who shake contractual balance as a result of conduct committed, wilfully or not, by one of the parties to the contract.

Under the first hypothesis that determines the imbalance between the considerations of the contracting parties are taken into account, on the one hand, changes in the economic-financial field caused by the severe depreciation of the reference currency for contractual relations of the parties - conjecture that has as a natural consequence the impossibility of the parties to the contract to obtain the desirable contractual interest they express at the conclusion of the contract, namely that things remain the same, unchanged – *rebus sic standibus* - and, on the other hand, circumstances arising from the false perception of reality of the parties concerning the elements of the contract, namely error as vice of consent and determining cause of the rupture of the contractual balance expected by the parties at the time of the agreement.

The second circumstance that involves contractual imbalance, more precisely the one that concerns the reciprocal obligation of the contracting parties, is regarding the actions or the inactions of the parties that can materialize either in defects of consent caused deliberately by the parties of the contract – fraud, duress and lesion – either in the non-performance of the contractual duties as the parties have defined them at the time of the conclusion of contract.

Among the remedies proposed by the legislator to the parties confronted with these circumstances that determine their over-indebtedness, our paper focuses its attention, as we anticipated in the preamble to this study, on the legal institutions of unpredictability (doctrine of frustration) and of the adjustment of the contract.

Thus, as shown in the above, either because of the many changes and imbalances in the economical field that characterize contemporary times, or because of malicious behaviour of one of the parties of the contract, whether as a result of the failure, intentional or not, of the obligations undertaken by contractual partner, the parties of a contract may be in the situation of a contractual over-indebtedness which they had not anticipated at the time of the agreement. For this reason, the legislator, at the time of making the Civil Code, advanced the possibility of such events and put out of reach of the parties, through the rules of law, a set of rules that help effectively manage such legal situations.

Thus, for the over-indebtedness caused by external events beyond control of the parties, namely major fluctuations in economical and financial fields, the legislator decided, in a timely manner, to allocate among the provisions of the Civil Code, one regarding the doctrine of frustration and so the parties can make use of it when they are to be found in such legal situation. In this case, the solution lies in the very fact that the legislature has given this situation a specific regulation, thus creating the legal basis needed by the parties in order to request the court a renegotiation of the contract according to new economical circumstances of when the contract must be carried out, if this could not be achieved through conventional renegotiation, through good understanding of the parties.

For the over-indebtedness caused by a false perception of reality due to the expression of contractual consent vitiated by error, fraud, violence or lesion, civil law provides for the interested party new legal institution in the landscape of Romanian civil law, namely that concerning the adjustment of the contract to the expectations of the parties at the time of the agreement.

Regarding the situation in which over-indebtedness occurs as a result of the failure by a party to the contractual obligations, depending on the importance of non-performance, in order to preserve the effects of the contract and the contractual balance, the legislator's solution requires that the parties of the agreement should reduce benefits.

Therefore, it can be seen that all these solutions, drawn by the legislature and which we have chosen to discuss of in this paper, have a common denominator, namely that all converge toward keeping the essence of the contract, its effects, in the spirit of "*favor contractus*". This result is the one that really performs the part in overcoming the situation of over-indebtedness and enables the parties to obtain the contractual interest that motivated them in the first instance to conclude the agreement.

The importance and the legal basis of the legal solutions regarding the overcoming of the over-indebtedness of the parties in an agreement

Over-indebtedness arisen in the legal relations between the parties to an agreement and unmanaged properly will inevitably result in the abolition of the contract, return of benefits and in awarding of punitive damages, according to the general rules of civil obligations.

The natural consequence of this outcome will result in two negative consequences in the legal and economical fields.

Thus, on the one hand, the parties of the contract will be in a situation where they will not be able to get the expected and pursued contractual interest at the time of the agreement; moreover, the parties return to the previous situation will determine the contract termination, a major insecurity of the civil circuit, viewed in terms of its dynamic dimension.

The importance of these solutions ordered by the legislature in this matter lies precisely in the safeguarding the legal effects of the contract signed by the parties and the civil circuit dynamic security.

The legal basis of the application of these remedies lies in the rules and principles of law governing civil legal relations, in general, and the contract, in particular. Through these guidelines, the legislature indicated and requires participants the conduct must characterize the contractual relationship between them and also ensures the security of civil circuit dynamics, vital for running efficient, equitable and profitable economic relations between counterparties.

Thus, at the conclusion of any agreement of mutually binding nature, each of the parties intends to achieve, by correlating performance, personal satisfaction of a contractual interest. Because, in most of the cases, *causa remota,* which determines each party to conclude the contract is not common to the one of the counterparty and, for this to be achieved, it is imperative that the parties, while performing the duties of the contract, comply with the principles and rules imposed by the civil law of contracts in order to obtain a permanent cooperation between the parties.

The first rule of law that covers all legal relations and, equally, matters of civil contracts, is the exercise of civil rights and obligations of contractual in good faith. In this respect, it is the art. 1170 Civil Code which stipulates that the parties of the agreement must act in good faith, both at the conclusion of the contract and throughout its execution, without their ability to remove or limit this duty.

Further on, built and based on the rule of good faith imposed on any person who becomes a party to a contract, we consider the principles of binding force of the contract, conciliation, proportionality and coherence of the contract, all converging towards achieving what the law literature calls contractual solidarity [1].

Therefore, the solutions which the legislator gives to the parties of the contract faced with a contractual over-indebtedness are nothing more than legal means that apply precisely by virtue and compliance of these rules and principles and, at the same time, they are those that give an optimal efficiency of these rules and principles and, equally, a consistent exercise of contractual rights and obligations of the parties as they agreed at the conclusion of the contract.

Doctrine of frustration, adjustment of contract and reduction of benefits – remedies for overcoming contractual over-indebtedness

1.1 The doctrine of frustration

The doctrine of frustration - *rebus sic non stantibus*, in contrast with contractual interest - *rebus sic standibus* is a direct consequence of the drastic and unexpected change in economic circumstances since the time of concluding the contract to that of performing the duties of the contract [2].

At the same time, it presents itself as a genuine exception to the binding force of the contract - *pacta sunt servanda*, the parties of the contract, faced with an excessive debt due to major changes in the economical field, are not able to perform their duties as they stated them at the conclusion of the contract and they are forced, in order to obtain the contractual interest, to conduct a renegotiation of benefits.

Legal provisions for unpredictability theory are to be found in the Civil Code, article 1271. This, after a reiteration of the principle of the binding force of the contract, delineates the direct effect of occurrence of unpredictability - excessive debt the parties - the provisions under the legal rules of unpredictability can be applied – the fact that the debtor could not foresee the changes in the economical field, not assuming by the debtor the risk of unpredictable events prior to their occurrence and the procedure for the conventional renegotiation of the obligations of this contract before claiming this before the court - and the legal effects of invoking the theory of unpredictability - to adjust the contract through rebalancing benefits, primarily and termination of contract, subsidiary.

1.2 Adjustment of contract

Adjustment of contract is a legal institution, novelty for Romanian Civil Code and finds its applicability and usefulness in the field of civil legal acts concluded after expressing consent affected by one of the vices of consent: error, fraud - wilful misconduct, duress - violence and lesion.

Although the explicit legal provision for the possibility of adjusting a contract based on a flawed consent is provided by the Civil Code only in case of error (art. 1213) and lesion (art. 1222 (3)), we consider that, *aedem ratio*, this solution will also find its application in case the expressed consent of the parties is affected by fraud or duress [3].

The theory of adjusting the contract enables the parties of an invalid concluded contract, that normally would be void and would not produce any legal effect, to maintain its effects and to obtain contractual interest, if the interested party of whose consent has been affected by a defect of consent, following indication how the party understood that the legal act concluded shall be performed, shall obtain from the counterparty a consistent execution of the contract according to the provisions made at the moment of concluding the contract.

1.3 Legal rules on reducing benefits

Regarding the legal rules on reducing benefits as a means of overcoming the contractual indebtedness derived from non-performing contractual duties, they present themselves also as a solution provided by the legislature in the spirit of "*favor contractus*" [4].

In this case, if one of the parties of the contract is faced with a failure to comply the civil obligation undertaken by the counterparty, the legislator, in the provisions regarding the matter of reduction of benefits (art. 1551 Civil Code) requires the interested party, confronted with a minor breach of contract within the contracts characterized by prompt execution and also within ones with phased execution, but in the latter case, the breach of the contract should not have happened repeatability, to choose a proportional reduction of its own benefits, without having the possibility of claiming the termination of the contract. Due to the fact that in this matter the parties of the contract are not allowed to claim rescission or termination of the contract we can observe the contemporary legislator's view – preserving the legal effects of the contract and achieving the contractual interest as opposed to the dissolution of the contract, the latter representing an *ultima ratio* solution for the case when the contractual provisions are so severally damaged that the achievement of the purpose of the contract is virtually nonexistent.

Mediation - an instrument for assisted resilience in mobbing cases

Marin Ioana A.

Romania
ioana.marin@justiceforromania.ro

Abstract

The application of the term mobbing in the context of labour and organizational psychology is owed to Heinz Leymann, a German psychiatrist who shaped the most familiar definition for mobbing: "psychological terror or mobbing at the workplace involves hostile communication lacking in ethics, initiated by one or several individuals and systematically directed towards and individual, who, because of the mobbing, is in a situation of helplessness. In this view, we can speak of mobbing when there are involved harassment behaviours at least every week for 6 months [1].

Mediation offers to the victims of mobbing the possibility to settle the conflict at the workplace, thus intervening with other instruments in fighting mobbing. In this case, mediation at the workplace, victim – offender mediation and, in some cases, organizational mediation are efficient means of intervention for a consensual settlement of interpersonal and inter-organizational conflicts accompanying the mobbing phenomenon.

The paper ***Mediation - an instrument for supported resilience in mobbing cases*** begins with an analysis of mediation from the perspective of the characteristics suggested by Jean-Pierre Pourtois, Bruno Humbeeck and Huguette Desment [2] to assess useful interventions in building resilience. Thus, we are trying to show that mediation can be one of the instruments to intervene in the supported resilience process. Furthermore, the paper shows the benefits and also the challenges in the case of using mediation as an instrument to build the resilience of the victims of mobbing and for the reconciliation of the relationships at the workplace.

We end the paper by offering a practical way to integrate mediation next to other instruments for supporting mobbized persons which have the objective of fighting mobbing effects. For this end we make a short introspection in the functioning of the Colfasa Association's Bucharest Anti-Mobbing Centre and its partnership with the Professional Mediators Association in Romania.

Key words: mediation, victim-offender mediation, mobbing, resilience, assisted resilience, Anti-Mobbing Centre

The use of mediation in building resilience

1.1 Introduction

Mediation is practiced all over the world for settling interpersonal, organizational, community and international conflicts, having a long and diversified history in almost every culture of the world.

Christopher Moore [3] defines mediation as being the intervention in a negotiation or conflict of a third accepted party, with limited power or without any power at all in making decisions, who assists the parties involved to voluntarily reach a mutually convenient agreement concerning the subjects disputed upon. Besides the concrete approach of the conflicts, mediation can also establish or enhance the relationships of trust and respect between the parties or can help to terminate the relationships in a way in which emotional costs and psychological traumas can be reduced.

Mediation shapes a working frame in which the persons involved in the conflict are assisted by the mediator to create by consensus their own solutions to the issues in conflict. These solutions are based on the parties' interest and, at the same time, they are adapted to the resourced the parties have.

Can mediation support the resilience of the individual, where resilience is understood as a new way of development which the individual takes upon himself after a major existential difficulty? [2] Can mediation be a manner to assist the individual in building his resilience? These are questions we are trying to answer by analyzing the characteristics of the assistance relationship between the mediator and the parties in conflict as

well as by checking the implementation, in the case of mediation, of the criteria suggested by Jean-Pierre Pourtois, Bruno Humbeeck and Huguette Desment for assisted resilience. [2]

1.2 Characteristics of the assistance relationship between the mediator and the parties in dispute

Being an intervention in conflict, mediation concerns only those cases in which the person who suffered a traumatic or stressful event is in conflict with another person or group of persons perceived as being responsible for the situation that caused the trauma/ stress (conflicts within the family, community, work place, etc.).

Mediation is a voluntary process, based on the parties' self-determination. They freely and advisedly decide upon the solutions to their problems. In the parties' preparation stage for the mediation, the mediator must make sure that the traumatized person is able to negotiate the conflict settlement. The fact that the parties in conflict are or are not capacitated to settle the conflict by themselves has a strong influence over the mediator's intervention strategies. [3]

The mediator plays an active part during the mediation process by insuring the power balance between the parties in conflict. The traumatized person can find itself in the situation of feeling/ being the weak party. The mediator will insure the increase of the weak party's power before entering into assisted negotiation and will maintain the power balance throughout the mediation process. The mediator contributes to the recognition, organization and setting in order of the power a party in conflict has. [3]

According to the principles governing the mediation, the mediator's assistance is insured to all the parties in conflict in a neutral and impartial way. Therefore, during the intervention, the mediator keeps a position of balance regarding the parties involved in the conflict, without sympathize or support a party to the other party's disadvantage. This is the reason for which the traumatized party must be able to negotiate with the other party by itself during the mediation. The mediator's presence insures a flexible and safe working environment in which both parties interact from equal positions and their negotiation is based on collaboration.

Every intervention implies that the mediator should analyze the situation in particular and design the process to answer the parties' needs. The mediator can elaborate approach and intervention techniques suitable for each situation, meant to assist the parties to the establishment and building of relationships based on respect and trust and to settle the problems that disunite them. [3]

1.3 The application of the criteria suggested by Jean-Pierre Pourtois, Bruno Humbeeck and Huguette Desment for assisted resilience

Jean-Pierre Pourtois, Bruno Humbeeck and Huguette Desment [2] believe that, so as to assure the individual to build its identity by proving resilience, the assistance relationship must gather the following characteristics: a) to leave room for initiative; b) to allow creativity; c) to allow change; d) to always see possible the positive evolution of the individual.

These characteristics are found in what we believe it is the essence of mediation derived from the principles that govern and define it.

a) Initiative. The parties freely and advisedly decide whether they take part to the mediation. In other words, they have the initiative of the mediation process. The content of the debates and the problems to be settles are established by the parties according to their needs and interests. When conceiving the process, the mediator takes into consideration the parties' needs. By collaborating with them, the mediator insures a flexible working environment, particularly adapted to the situation.
b) Creativity. The settling of the issues in conflict is based on the parties' creativity in finding the most satisfying answers, adapted to the needs and resources they have. When the resources are limited, the mediator will stimulate the parties to work creatively so that the parties' solution be the best in the given situation.
c) Change. Moving the parties from the past to the future, reframing the perceptions of the parties in conflict, streamlining the communication, parties' reconciliation are a few of the changes that occur in mediation with the mediator' assistance.
d) Belief in the individual's positive evolution. The mediator begins from the assumption that any person is able to change, has resources of good faith and integrity, can and must have the freedom to decide over its own life, knows and understands its condition better than anyone else. The mediator believes that, by using the right instruments, it will change the adversary relationship between the parties into a relationship based on collaboration.

1.4 Conclusions

There are cases in which building resilience can be a natural process. In other cases, assisting the individual is useful and mediation can be one of the instruments for assisted resilience. Conflict resolution through mediation is an experience which can help the traumatized person increase its self-esteem, rehabilitate its image, recover certain prejudice and regain a feeling of control over its life. This is why we believe that mediation can facilitate resilience.

The mediator must asses in every case if its intervention is suitable. The help of some specialists can be necessary in certain cases so that the mediator should make sure the traumatized person is capable to negotiate the conflict settlement or that it has the necessary emotional stability to sit at a table and negotiate with the aggressor. Such cases include victim-offender mediation in mobbing cases. This is the category we will subsequently deal with.

We believe that both the mediators and other specialists try to see in the most difficult and desperate situations which are the person's resources or the beneficial resources around it in order to be able to help her.[4] Just like psychologists are the constructors of the individual's health [4], mediators are the constructors of the consensus and of the good interpersonal relationships.

We believe that mediation can be a useful tool in the "toolkit" of assisted resilience.

Mediation and Mobbing: The contribution of mediation to the building of the Mobbized Person's Resilience

1.1 Mobbing and its consequences

The German psychiatrist Harald Ege [5] compares mobbing to a war at the workplace where, with psychological, physical and/ or moral violence, one or several victims are forced to obey the will of one or several aggressors. In mobbing cases, the employee is psychologically, systematically harassed at the workplace, attacked and stigmatized by colleagues or chiefs with rumours, intimidation, professional vilification, isolation, endangering its emotional and physical state, as well as its professional abilities.

Leymann [1] claims that a faulty management of inter-organizational conflicts, as well as an inadequate organization of labour can lead to mobbing. Often, in mobbing cases, the aggressor feels that he has the implicit approval or permission from its superior chief only just because conflict management at an organizational level is inexistent or faulty.

Leymann [1] defined 5 types of actions associated to mobbing, according to the effects over the targeted individual, namely

- limiting the possibility to communicate in an adequate manner (it affects the communication with the manager, there appear verbal attacks, threats with dismissals),
- isolating the victim (social isolation, preventing communication with the colleagues or management),
- disregarding the victim in front of its colleagues (gossip, mocking over the physical aspect or personal attributes),
- professional discredit (the person receives useless tasks or does not receive any at all),
- jeopardizing the victim's health (physical attack, threats of physical attack, sexual harassment, appointing dangerous labour tasks).

In what the mobbing is concerned, resilience would correspond to the ability to adapt in a flexible and original way to stress-generating exterior factors [6] represented by the actions performed by the aggressors. Even if the victim initially has the features of a resilient person, being determined, independent, original, self-confident, in time mobbing can affect the process of natural resilience, bringing the victim to the position of seeking help.

Professionally, mobbing affects the labour power, the ability to reach performances, to develop relationships at the workplace. Mobbing shakes self-confidence and in time can lead to depression and loss of the interest to work.

Mobbing can have bad consequences over the victim's physical and psychological health. Certain studies in the field show that there are cases in which the victim can try or even commit suicide.

1.2 Victim – offender mediation in mobbing cases

Fighting the effects of the mobbing over the victim is achieved with intervention measures designed on each case. These measures include the parties' reconciliation, vocational rehabilitation, legal compensations, counselling and therapy, support groups, s.o.

There are cases in which the resilience of the mobbing victims can be build only with the specialized and focused assistance of several experienced professionals: psychologists, social workers, career counsellors, educators and mediators.

In the Anti-Mobbing Centres [7] the persons who have been/ are victims of this phenomenon can find the necessary assistance to overpass this trauma. The services are offered by specialists (social workers, clinician psychologist, counsellor psychologist, lawyer, professional counsellor) according to each and every case. Such services include: the information service, receiving requests, case assessment and forwarding to specialists, the individual and group psychological assessment and counselling service, the legal information and counselling service, mediation, the career and professional guiding counselling service.

Mobbing is a conflict at workplace, a victim – offender one, where the offender could be the chiefs, colleagues or clients. If the employee does not wish to quit its workplace, stopping the mobbing is imperative and involves the settlement of the conflict. The means of settlement used are ADR (alternative disputes resolution) methods or settlement on a legal basis, in case the law allows such an intervention.

Within the ADR methods, mediation is found next to negotiation, conciliation and arbitrage.

In case the victim of the mobbing seeks external help, the negotiation stage is usually cut out. The traumatized person does not feel capable of settling the issue directly with the offender anymore. Victim looks for an assistance that should insure a fair settlement process with the offender. If victim prefers that the neutral third party which will assist in settling the conflict should not influence his/her decision nor intervene with authority in decision making process, then mediation is the best way to solve the issue.

Understanding the situation and preparing the mediation is an important stage of the mediation. In mobbing cases, the mediator will focus on the particular aspects concerning the victim - offender relationship and the issues in conflict and will take certain specific actions. Thus, he will analyze together with the victim and, as the case may be, with other specialists involved in fighting mobbing the following elements of the case:

- if the offender/offenders are all identified or identifiable
- if the victim is able to expose its problems and feelings
- if there is a certain emotional risk (instability) that might damage the mediation process with the offender
- if the victim is able to negotiate
- if there is a lack of balance concerning the power of the parties involved in mediation and how it could be managed.

Often, in such cases, the psychologist in charge with counselling the victim is consulted on the right moment for an efficient intervention. Even if the victim of mobbing is eager and believes it is ready for mediation, the psychologist might think differently. The collaboration of the mediators with the other specialists intervening in building the resilience of the victim is important both for the adjustment of the mediation process to the parties' needs and for the correlation with the other interventions in progress.

This is why the programs in which the mobbing victim can choose from a panel of integrated services have a good result for each intervention chosen by the victim and a generally satisfying result for the victim.

The victim of mobbing chooses and appreciates mediation for the following benefits [8]:

- The mediation process is initiated by the victim only at its free will, when it believes it is ready
- The spent resources (time, money, emotions) is far reduces comparing to the conflict settlement in court or by arbitrage,
- Mediation offers a confidential working environment, providing a feeling of safety to the victim,
- Insures the satisfaction of the need for self-esteem, merit recognition and professional rehabilitation, being a settlement method based on the needs of the parties in conflict,
- Insures a flexible working environment in which the victim can have initiative,
- If the victim of mobbing wishes to keep the workplace, mediation insures an improvement of the relationships at the workplace which are vital to carry on with the work relationship in safety and health conditions.

There are cases in which the mobbing victim suffered a trauma so significant that it no longer wishes to return to the workplace. This is the case of some people who have been subject to this phenomenon for a long time, between 1 and 3 years or who suffered aggressions that jeopardized their physical integrity and psychical health. [8] In these cases, the victim does not feel able to negotiate with the aggressor and all it wants is to cut the existing relationship. In such cases, a victim - offender mediation cannot be useful. In order to satisfy the victim's needs, an employer - employee mediation can be facilitated. So, mediation could help the victim to establish the conditions for leave off work and satisfying the victim's needs of being compensated. In these cases as well, the victim often shows the need to regain self-confidence and be compensated for the suffering caused by the aggressor, which many times happens with the silent consent of the employer's management.

Another dimension the mediator will have to take into consideration in victim-offender mediation is the inter-cultural dimension, that is present in multinational companies. In these cases, the cause for discrimination

and mobbing does not reside in cultural differences but rather in the perception of these differences as implying a real or imaginary threat regarding the aggressor or a group of aggressors. [9] The inter-cultural dimension creates circumstances for specific actions in preparing and performing mediation, decided by the mediator for each and every case.

Conclusions

Mediation can be a useful tool in building the resilience of the victim of mobbing. Stopping the mobbing and settle the conflict with the aggressor in a satisfactory manner are primary objectives of the victim. In these cases, mediation can offer the victim the necessary process within victim-offender mediation or employer-employee mediation. Sometimes the mediation process can have a wider angle where the issues to be resolved include both the effect of mobbing and the lack of the politics of the employer to prevent the mobbing phenomenon. These actions can also involve other persons besides the victim, aggressor or management, such as colleagues from the same department or from another one, collaborators/ clients of the company where the victim works.

In most of the cases, the efficiency of mediation depends also on the mediator's coordination with other specialists offering assistance to the victim in building resilience. A good example of good practice in this respect is the Anti-Mobbing Centre [7] offering the victim a variety of services where the victim can choose whichever it finds the most suitable to overpass the trauma caused by mobbing and the services are correlated and sometimes even interdependent.

Mediation and the Anti-Mobbing Centres

Starting from an example we find a good practice we will inroad upon the manner in which the Anti-Mobbing Centre (CAM) is organized, functioning within the Colfasa Association of Bucharest, Romania.

The Centre for Preventing and Fighting Mobbing and Discrimination in the Labour Market, abbreviated CAM, is a structure founded within the social project "Women matter!" as an innovating instrument in approaching the phenomenon. It opened its gates on 15.06.2011.

CAM aims to prevent and fight all the cases of genre discrimination at the workplace, especially the ones involving psychological harassment of professional nature, called mobbing. The specific objectives of the CAM are:

1. Informing and offering assistance to the women making the object of professional discrimination, victimized at the workplace;
2. Psychological and legal counselling of the women who have been victims of the mobbing phenomenon;
3. Preventing and remedying some psychical, psycho-somatic, emotional and disadaptive disorders provided that they are connected to mobbing;
4. Offering support, solving guidance and catalysis of the strategies to go through personal and professional problems from an emotional point of view, to cognitive and behavioural problems and also through the inter-relational (interpersonal) ones with a disorganizing individual, family and socio-professional impact.
5. Diminishing the occurrence of destructive social phenomena such as victimizing women at their workplace;
6. Promoting the equality of opportunities between men and women in the professional environment;
7. Sensitizing public opinion with several activities of raising awareness over the existence of the mobbing phenomenon;
8. Increasing the degree of awareness among the employers (companies, private or public institutions, etc.), of the staff in NGO-s and social partners;
9. Stimulating, among the employers, organizational changes necessary to diminish the possibility of the mobbing phenomenon occurrence. [7]

The service component in order to fight mobbing includes the provision of 4 types of services:

- Information, receiving requests, case assessment and forwarding to specialists service
- Assessment and individual and group psychological counselling service
- Information and legal counselling service
- Career and professional orientation counselling service

Mediation was included in the services offered to the victim of mobbing as a consequence of the partnership between the Colfasa Association and The Professional Association of Mediators in Romania – Bucharest branch (APMR-Bucharest), starting since March 2012. The Professional Association of Mediators in Romania made available for the CAM a list with 34 mediators who have been familiarized with the mobbing phenomenon and with the manner in which the CAM is organized within the CAM seminars dedicated to the mediators. Subsequently, the mediators have also been involved in other activities of the CAM. The protocol of

the 2 organizations led to the instalment of a working environment where mediation has been correlated to the other services within the CAM. Mediation works as an externalized CAM service, the mediators being independent and organized as a liberal profession in accordance with the Romanian laws in force. The information and legal counselling within the CAM is the one that informs the victim of mobbing over the possibility of using the mediation and over the general characteristics of mediation, guiding the party to contact a mediator for information on the case regarding which only the mediator is able in this respect.

Mediation can also be integrated in the service package offered within the CAM to the victims of mobbing (internal service). The Romanian law allows the mediators to work as NGO employees. On the other hand, we believe that this must be made with caution because it might affect the other party's perception (aggressor, employer) over the mediator's impartiality and neutrality. As the activities of the CAM focus on victim support, it might appear the assumption that the CAM mediator is a supporter of the victim as well. Mediation is a process based on the parties' trust in the mediator's competence and presence of helping them settle the conflict in a favourable way. Without this trust, the parties refuse to take part in and go through the mediation process. This is the reason for which I am reserved about the pattern of integrated mediation in the CAM. I believe that the pattern chosen by the Bucharest APMR and the Colfasa Association is a more efficient one.

The statistics for the first year the CAM operated within the Colfasa Association [7] show that it processed a number of 77 requests from which 60 were from Bucharest, 14 from other areas in the country and 3 from abroad. Among these a number of 55 requests have been qualified as being cases of mobbing, the rest falling in the categories of discrimination (10), sexual harassment (1), stress at the workplace (3), pathology (3), and labour conflicts (6). There were 28 settled mobbing cases.

It is the beginning of a road we hope will continue and bring more and more significant results. For this to be possible, it is desirable that the CAM should be able to keep offering free services to the victims of mobbing. A part of them are unemployed as a consequence of having left the workplace or the employer having terminated the work contract. There is a need for the authorities' support or of other private law persons to ensure the financing of the CAM and the continuation of this type of programs.

Interdisciplinarity as resilience in legal education

Mercescu A.

Sorbonne University, Faculty of Law (France)
West University of Timisoara, Faculty of Law (Romania)
alexandra.mercescu@malix-paris1.fr

Abstract

This paper argues that the concept of resilience can be used as an illuminating explanatory tool in accounting for some of the instances of interdisciplinary work. Basically, it is possible to claim that the interdisciplinarian scholar is resilient in as much as he or she converts the dissatisfaction with the boundaries of his or her discipline into a successful intellectual enterprise.

In order to uphold this claim, I shall give specific attention to law and its interdisciplinary (*resilient*) dissidents.

Keywords: resilience, interdisciplinarity, legal scholarship, epistemology;

Introduction

Stemming from psychology, the concept of resilience has been travelling for four decades to many disciplinary turfs and has acquired a significant number of meanings along the way [1]. Although its multi-destination itinerary has made it to evolve into a rather vague notion, by not claiming any particular disciplinary identity, the concept opens itself up to the attribution of new connotations and thereby fosters innovation. In this paper I seek to connect the concept of resilience to the one of interdisciplinarity (2) and, in particular, to interdisciplinarity such as practiced by a small number of legal academics (3).

Interdisciplinarity as resilience

In its common understanding, resilience means the capability of an entity to recover from a difficult situation, be it a shock, a trauma, a radical change [2]. The Oxford Dictionary recalls us that its primary meaning is less figurative implying the idea of elasticity [3]. At first sight, it appears that "resilience" entails the idea of conservation (or resistance): "to be resilient is to withstand a large disturbance without, in the end, changing, disintegrating, or becoming permanently damaged; to return to normal quickly; and to distort less in the face of (…) stresses" [4]. This basic definition is wide enough to cover "the individuals who are resilient to emotional distress, irrigation communities that are resilient to floods, (…) an urban community that is resilient to crime, modern societies who are resilient to global economic fluctuations" [5]. The question that I want to ask here is: can there be a relation of resilience between the academic and his or her discipline?

In general, the acquisition of knowledge and together with it the implicit process of disciplinarization is perceived as a positive experience meant to cultivate the spirit and guide it through the vast arena of knowledge. No matter how strenuous the actual coming of age in a disciplinary sense might be, the historian, the jurist, the architect, etc., in a word the subject, does not envisage dissidence since its very formation (his becoming a subject who matters) depends on his or her subjection to the modes of thought prevalent in the discipline [6]. As Pierre Bourdieu famously emphasized, the process of learning presupposes a "symbolic violence" being done to the disciple for there can be no indoctrination without resorting to a rhetoric whose power resides precisely in its ability to conceal the oppressive act [7]. In fact, to gain a deep insight into a field of study through schooling is not unlike learning one's mother tongue. At every crossroad we are told what path to take until we can handle the journey all by ourselves and almost reflexively bearing in mind the exact rules that we were instilled with.

The disciplinary formation is constraining to the point in which one gives up a part of his or her own identity. From a certain point of view, this act of submission simply means being in the world. The culture we belong to inescapably moulds our identity. We might wish to resist but there are important limits to our critical thinking. Ultimately, we willingly embrace the "normal". Viewed in this light, man is by definition resilient in that he owns the capability of returning to the heart-warming fixity that renders things predictable, and therefore manageable in spite of (but also due to) the continuous violence inflicted upon him by the various disciplinary practices. In this context, how could the scholar not be resilient vis-à-vis his or her discipline?

Nevertheless, if one looks at a narrower definition of resilience the scholar shall no longer appear to be resilient unless he or she converts the initial violence into something new and fruitful. Couched in these terms, resilience would mean more than just resistance: "It is the ability of systems—households, people, communities, ecosystems, nations—to generate new ways of operating, new systemic relationships" [8]. When it comes to academic activities I claim that interdisciplinary work embodies such a new means of acting in response to the pressure exercised by the permanent confinement within the discipline's boundaries. In what follows and before turning to the concrete example of legal studies I shall expand on the affirmation stated above.

My concern here is with interdisciplinarity arisen out of pure dissatisfaction with one's discipline. Few authors acknowledge such a source for interdisciplinarity since the fact of gravitating from one discipline to another can be seen by one's peers as a failure to adapt and to become a fully-fledged professional. Additionally, such a gesture of indiscipline hailing from a conflicting relationship between self and the discipline's framework is deemed to be problematic in that it contradicts the established paradigm that wants the acquisition of knowledge to be a purely intellectual, value-free pursuit segregated from any kind of feelings. Or, more often than not, emotions play a significant role in shaping the way individuals relate to different domains of knowledge. The final outlook of one's encounter with a disciplinary culture and its corresponding idiom is conditioned by a series of non-rational factors. Indeed, as J. Frow argues "to assert the passional basis for the acquisition of at least certain kinds of knowledge is to say that there can be no unmediated relation to knowledge (no simple 'love of knowledge')" [9]. The reasons for disappointment may range from a difficult or uninteresting discipleship to a fundamental inadequacy between one's predispositions (i.e. *Weltanschauung*) and the values implied by the discipline itself or the pronouncements put forth by its mainstream, orthodox branch. Such a negative experience in relation to the discipline of one's choice engenders a complicated feeling of frustration that comes to test the scholar's capacity for resilience.

A possible reaction would be to cast the net of research wider so that his or her work encompasses other areas prone to provide for happier intellectual experiences. However, although at first glance it might appear as a liberating experience, turning away from one's discipline does not automatically lead to the creation of a comfort zone. To the contrary, what initially characterizes such a deterritorialization partakes of a disturbing sensation of anxiety in as much as the scholar, not unlike the émigré, must confront, on one hand the estrangement from his or her "home" and, on the other hand, the strangeness and sometimes even the hostility of the new "land". Having betrayed the discipline that bestowed him or her with an identity, the researcher can expect to be relegated to the confines of the field or even outside of it. At the same time, the specialists of the other disciplines will not be ready to grant membership to any "intruder" as long as the latter does not incorporate into his or her own thinking the intelligibility schemes traditionally established in the host discipline, which, in most of the cases is exactly what the interdisciplinarian seeks to refute: interdisciplinarity entails "rejuvenation and regeneration (…) negotiation and new meanings, not one more stage in 'normal' science" [10].

Moreover, "the majority of the people engaged in interdisciplinary work lack a common identity" [11] since there is no such thing as general interdisciplinarity that could function as an intellectual aggregator. Of course, there are a number of associations and institutions, such as the "Association for Interdisciplinary Studies" (AIS), addressing themselves to anyone who deals with interdisciplinarity, regardless of their field of origin. However, although many conferences, programs or workshops certainly alleviate the interdisciplinarians' anguish the fact remains that "they often find themselves homeless, in a state of social and intellectual marginality" [12].

And yet, in spite of this inimical climate, many interdisciplinarians prove to be resilient. Thus, they do not simply give up interdisciplinarity or run away from academia but while proceeding with their non-conventional projects they manage either to make their knowledge relevant for disciplinary purposes, which often means a return within the precincts of the home discipline or to achieve recognition from the gatekeepers of another established discipline. By engaging in interdisciplinarity the researcher will have certainly endured the ordeal of adverse disciplinarity more easily.

Now, I wish to exemplify these considerations by looking at the discipline of law. This example will additionally allow me to bring to light some of the limits of interdisciplinarity as resilience.

"Law and…" as a form of resilience

If the 19th century was marked by the ever-growing fragmentation of knowledge many high profile intellectuals of the 20th century raised their voice against disciplinary isolation calling for more flexibility in assessing the contemporary societal environment. Suffice it to remember that during the events that took place in France in May 1968 interdisciplinarity was one of the protestors' key demands [13]. By mid-century, interdisciplinary thinking was being promoted through several means in the United States of America as well, with the universities of Harvard, Columbia and Chicago leading the way [14].Today "almost all academic journals, in their mission statements (…) claim to be 'interdisciplinary'; so do many academic departments (…) and even entire universities" [15].

Unsurprisingly, law has remained immune to these epistemological and educational changes (from this point of view, law was said to be "amazingly resilient" [16]). According to J. Brundage, law is taught in many faculties in Europe in not so dissimilar a fashion to what use to happen during the Middle Ages [17]. The paradigm of doctrinal or black-letter rule analysis invites students to view law "in purely technical terms, as an autonomous system, with discernible boundaries (…) between law and other academic disciplines" [18]. Critics have identified a number of reasons for law's lack of permeability [19]. On the other hand, some authors, admittedly a very small number, have expressed dissatisfaction in respect of the orthodox mode of thought. While disillusionment can stem from a wide range of specific sources it usually stretches on the whole experience of being a law student, and thereafter a legal academic.

I shall further argue that the disappointment in relation to law has its origins in at least three main features of legal scholarship all of which incite the scholar to turn to interdisciplinarity.

1.1 Law is excessively vocational

One of the fiercest critiques levelled against legal education resides in its too great a concern with practice. All too often, universities train students to become judges, lawyers, public notaries and legal consultants allowing for no reflection on the relationship between law and society. Correlatively, the vocational character of legal studies infuses the discipline with a large dose of "anti-intellectualism" [20]. Having investigated the way academics feel about the activities of their colleagues from other fields, T. Becher concludes as following: "the predominant notion of academic lawyers is that they are not really academic – one critical respondent described them as 'arcane, distant and alien; an appendage to the university world'. (…) Their scholarly activities are thought to be unexciting and uncreative" [21]. More recently, in her study on legal academics, F. Cownie investigated what it means to be a legal academic and found out that "almost all the respondents were clear that being an intellectual is not a necessary quality to be a successful academic lawyer" [22].

Therefore, those lamenting the poverty of legal scholarship have manifested their resilience by embracing a pluralistic, socio-legal (or "law in context") approach.

1.2 Law is insufficiently scientific

In the civil-law world, legal scholars have no doubt that their activities can be subsumed under the label of *scientia iuris*. However, the same jurists occasionally feel troubled by law's imperfection in respect of its scientificity. Consequently, they prefer to abandon the traditional vessel, and thereby to undergo the hardship of exile, in order to embark on a perilous trip towards interdisciplinarity, which is seen as the remedy for law's sickness. Hence, legal academics will migrate to areas reputed to be "hard" sciences or in any case owning more scientific credentials than law.

It is the case of "Law and Economics" researchers who make use of econometrics and economic models or those scholars who resort to quantitative analyses of a sociological sort, amongst which statistics occupies a prime position. Ultimately, these projects do comfort their own proponents, whose resilience is thus asserted.

1.3 Law is improperly scientific

Paradoxically enough, interdisciplinarity also springs out of claims directed against law's scientism. For a number of legal scholars, the discipline of law unduly proclaims to be scientific. These authors warn against the fallacy of seeing law in scientific terms just because, on the wake of the scientific revolution, it did try to emulate the methods prevalent in the natural sciences. Accordingly, law is culturally constructed, always situated in a particular time and place, inextricably entangled with the values, beliefs and predispositions of a given society [23]. As such, it cannot be cut off from politics, linguistics, philosophy, anthropology or history. Law's textual life denies the possibility of submitting legal knowledge to a much worshiped *mathesis universalis* and reclaims, in turn, the intervention of hermeneutics.

Thus, interdisciplinary movements like "Critical Legal Studies", "Law and Literature" or "Comparative Legal Studies" [24] call into question the law's dogmatism and aim to scrutinize, beyond the sole surface of legal rules, the deep layers of legal thought and the manner in which the latter relates to issues such as politics, literary narratives or culture.

1.4 The limits of resilience

The interdisciplinary projects referred to above undoubtedly fulfil a comforting role in relation to their tenants whom they help overcome discontent with legal knowledge. As for their actual success it is difficult to pronounce a definitive judgment. Who can legitimately assess interdisciplinary work? [25]. Some inquires might be cases of "botched interdisciplinarity" [26], while others might not even be interdisciplinary at all from the

very start if one takes interdisciplinarity to mean integration of knowledge and not mere juxtaposition or unilateral borrowing of information. Moreover, these projects' contribution to how legal research is being conducted in general is of no major significance: "law resists colonization by other disciplines", and according to some authors this has to be that way: "there is no need to complicate things unnecessarily" [27]. By and large, interdisciplinarity continues to remain marginal and the conventional foundations of legal epistemology unscathed.

However, I think this case provides an excellent example for understanding that "measuring" resilience is not necessarily a question of looking at the community's consensus but rather of taking into account the manner in which each individual contends with adversity. Thus, if against all disciplinary constraints, the scholar manages to shift from an activity he or she dislikes (the discipline) to another that he or she likes (the marginal indiscipline) and still survive in academia, it is largely sufficient, to my mind, to call him or her resilient, irrespective of whether he or she will continue to be seen as that curious, elitist intellectual who, for reasons unknown to the community, has decided to tilt the windmills.

Conclusion

In this paper I argued that in some cases interdisciplinarity emerges from dissatisfaction with one own discipline. In those instances, the term "resilience" renders very well the capability of the scholar not only to resist "disciplinarization" but also to convert and integrate disciplinary knowledge into a critical analysis, thus producing new modes of operating at an epistemological level. Interdisciplinarity triggered by disappointment with law's framework is a case in point all the more so that the legal education, due to its traditional methods of knowledge transmission, epitomizes the "violent" process of disciplinarization.

The rescinding of european institutions related to human rights issue

Micu G.

National School of Political and Administrative Studies, Romania
gmicu2004@yahoo.com

Abstract

The humanity's efforts towards establishing a legislative and institutional framework to ensure the preservation of Human Rights and Fundamental Freedoms, often disregarded during the history, have had a crucial moments on December, 10th, 1948 with the Universal Declaration of Human Rights, signed by the ONU member states. The regulations of this document were taken over and developed in a number of regional conventions, as well as the case of the European Convention of Human Rights, having compulsory juridical effect. For implementing in the real life the principles stipulated in the above mentioned document, within the Council of Europe there is the European Court of Human Rights (ECHR), which has the fundamental objective to adjust deviant conduct of the political powers of the European states concerning the respecting of the human dignity, the Human Rights and Fundamental Freedoms, obtained with a many efforts during the centuries. The rescinding of the European Institution on this matter has had positive evolution, keeping up the Human Rights issue in the modern paradigm of the actual international law, as well as in the European architecture, without turning the physical person, as a subject of domestic law, into a subject of the international law. This study is trying to analyze the nature of the juridical relation might turned up between a citizen belonging to an European state and their political power in running, when the state authorities violate one of the fundamentals rights of that citizen.

Key words: European institutions' resinding, human rights, international responsibility, domestic law, international law.

Human Rights – a domestic or international issue.

The international community tends more and more to regulate in the frame of the international cooperation between states, a numerous number of issues, bilateral, regional or global, in various areas, in order to establish their conduct in certain domains, so enlarge the states commitments in the international law. In principle, states can bring under regulation any issues, including those belonging national competence, assuming each other to follow a certain conduct, engaging the international responsibility for the state which violate it. If the states decide to bring under regulation an issue belonging to national competence doesn't mean that issue should be taken out from the domestic competence [7]. In the measure in which the states assumes a certain conduct between them related to that issue which belongs to state competence, this will have a certain international character, without ceasing to belong to the domestic competence.

Such situation can be found out at the international treaties related to Human Rights' theme, following to set up a certain way of international cooperation regarding to that issue, keeping up their sovereignty, being at the same time an expression of their will to develop the cooperation in that area of their reciprocal relations. There are not any regulations affecting the state sovereignty of those states, or the separation between the international law and the domestic law, or the exclusive control of the domestic law from each these countries [8].

Guaranty, use and respect the Human Rights' issue, is a matter belonging to the national law regulating the ways of organizing the political and state life. This feature of the international cooperation it is stipulated both in the Pact for the Civil and Political Rights and the Pact for Economic, Cultural and Social Rights. These regulations emphasizing that the basis for the cooperation related to the Human Rights' issues are in the domestic regulation have taken by each state on the national legislative framework, according to their own national competences, at the legislative and administrative level.

It is obvious that social relationships are created by persons among and in conection with them, with the respect of interests and rights of the person, the protection of assets, and criminal protection of them is not just necessary, but sufficient [11].

The states takes their own commitments, at the international level, to adopt the necessary measures, individual or through international cooperation procedures, including concrete programs, in the domestic legislation and administration, in order to put in practice international norms adopted by international treaties. For example, the Pact for Economic, Social and Cultural Rights stipulate the commitments of each signatory stat to act, through own means, for assuring progressively, by legislative and institutional domestic measure, the exerting of these rights, without any discrimination. There are explicit showed the measure prepared to be taken by each signatory country, in order to ensure the complete exert of the right to work, social security, a satisfactory standard of life, the right to culture, education, etc. Commitments has been taken by the states also in the Pact for Civil and Political Rights, in order to ensure the complete exert of certain freedoms and liberties, the guaranty for the respect the right to defend, the forbidden of any sort of discrimination.

The monitoring procedure ensure a real and correct fulfill of the states commitments, through periodical reports, regarding to the measure have been taken for implementing the international regulations of these Pacts. The reports are examined by a committee of experts consisting from the state representatives, being in fact a dialog with each member state representative. Recently, the existing situation from each ONU member state is examined by the Council for Human Rights, using a procedure through which the states are periodically examined, as an expression of assuming the commitments regarding to cooperation on the Human Rights theme.

This procedure reflect also the fact that, related to human rights issues, there are not any incompatibilities between international cooperation in this domain and national competence of the state to solve itself the problems has been turned up. In the same context has been created mechanisms to examine other states and also individuals, regarding the Human Rights violation. These procedures, even for the country which agreed them, are also part of the mechanisms in the frame of international cooperation, aiming to ensure the fulfilling of the commitments taken by the states regarding to the Human Rights aspects, within the domestic legislative, juridical and administrative framework,.

The existing procedure in Europe, Latin America and recently in Africa, in last instance, ask to the national juridical order to put in practice a decision has been taken at the international level, because the Conventions throw which were set up these procedure had to take into consideration the international establishment of international life, where the state are the main representative. [9]

The Human Rights' issue has been developed both in the international law and domestic law doesn't take place a transfer from internal towards international law. Certain aspects concerning promoting and protection of Human Rights are subject of domestic law, and following a constant practice developed by states, based on these regulation, have been set up at the international level similar regulations (custom or treaties), in such manner becoming part of the international law.

Other aspects concerning Human Rights had been developed first at the international levels, and further on passed into the domestic legal order of the state, procedure well known in other domains of international law too. Winding up can be affirmed that Human Rights institution has an ambivalent feature [10]. Otherwise, domestic law and international one don't exclude each other. Each of it have been taken over norms from the other, settled them down to its specific nature, without giving up their identity and without ceasing to be part of regulation for one of them.

It is also necessary to be noticed that many countries requests a domestic procedure to accommodate the international conventions with their domestic law, in order to have national legislative means to implement international commitments at the national level, the national provision setting up as such being applicable in front of the national courts. There are also states which accept the primate of the international law in comparison with domestic law. Is the case of Romania, which stipulated in their Constitution from 1991, art.20, with the modification have brought in 2003, that the constitutional provisions concerning Human Rights and citizens freedoms, will be understood and implemented in according to the Universal Declaration of Human Rights, and other pacts and treaties signed by Romania. If there are differences between international and domestic regulations concerning Human Rights, international regulations will have priority, excepting the case in which the Romanian fundamental law or domestic regulation don't contain more favorable stipulations. This provision doesn't mean that Human Rights' issue ceases to be an issue for Romanian state, there are at the same time a domestic and international issue, these two domains remaining independents, without a clear demarcation between them.[1]

On this item can be winded up with a clear idea, international regulation reflect the idea that Human Rights remain an issue belonging to national competence of each state, being more and more subject for international cooperation, so an international law issue.

Human bean – subject of domestic or international law

There are different opinions concerning the real place of the human bean in connection with international law. Some theories affirmed the idea that the international society is a society of persons, and therefore only to the persons are addressed the international law regulation, being subjects for these. Other

theories consider human bean as an international subject, near the states. Finally, there are theories which don't recognize for physical persons the quality to be the international low subject.

In order to clarify this problem should be checked if the physical persons are direct beneficiaries of the rights and obligations created by the international law regulations, if these persons can act at the international level, to claim these rights, and can be responsible at the international level for violating their commitments.

It is obvious that the physical persons, as establishment of the society, are the final destinations either the international regulations, some of these provisions setting up rights and obligations for individuals, even for their relations with the state to whom belonging to. These principle and norms are adopted by the states by international treaties or customs procedure. So, the rights and obligations for individuals descend from the state willing and not direct from international law. Many of these regulations create a certain conduct not only by the states but also for the individuals being on their territory. [6] In some cases, the international regulations should be adopted through the national law, in order to become effective and the individuals to be the beneficiaries of the rights stipulated by treaties. In other cases there are enough that the treaty is ratified by the law.

The main aim of the international regulation is to set up a uniform standard for the signatories states regarding to the Human Rights' issue, to define Human Rights, to stipulate the states conduct in order to act for guarantying their exert. The state is in the position to implement the international provision into their legislation and their measure at the domestic level only after the treaties ratification. Each person has the right to demand from their authorities the rights and freedoms stipulated in the treaties, based on either international provision, or the national provisions which include the international stipulation after the ratification procedure or a special law with the same regulations.

It is obvious that, if the man is the indirect beneficiary of the international regulations don't mean that it is, because of this, subject of international law. The international conventions set up special conduct between the states; even these oblige each other to guaranty rights and freedoms to their own citizens. The individuals' benefits of these rights and freedoms descend from the international regulation, because these documents were accepted by the state, including rights and freedoms for their citizens and the national authorities' conduct in a national law, either by express regulations, or by the ratification or adherence law to those international regulations.

It is important to be noticed that for those states which didn't signed the international conventions related to the Human Rights can't be obliges to respect those regulations, even the costumes ones. There is a single way to do that, through the procedures existed in the framework of the Council for Human Rights, within ONU institutional structure, where can be adopted recommendations addressed to the states, not descended from their international juridical commitments.

A special interest has been showed to that stipulation from the international treaties regarding Human Rights, in which has been stipulated the rights for individuals to submit complains to international organizations and even international Courts, against to the state to whom belonging to, when considered their rights, stipulated by these international convention, violated by the state authorities. It has to be noticed that, in the international organizations case, these rights has only a procedural nature, because the individuals don't participate on their carry on, and the committees has only the possibility to give recommendations to the state for a certain conduct not to take compulsory measures. Here the procedure is over. These recommendations can be surveyed only by specific procedure, totally other from the juridical procedure.

Totally other situation can be the case in which individuals submit their claims to the regional Courts, as it is the example of European Court for Human Rights (ECHR), which can judge and deliver a sentence, compulsory for the member state who didn't respect their commitments, and their national authorities violated a fundamental rights of one of their citizens. In this case, the persons can attend to all the phases of the procedure. It is important to notice that even this situation descending from the state will, because the state is part of the international convention which set up ECHR, and assume in this way to respect the Human Rights and to be punished if violate them. Europe is not the only case in which these kinds of procedure can be used. Both in Latin America and Africa there are regional conventions according to whom the regional Courts can deliver compulsory decisions for the member states.

According to this arguments seems to be evident that various disputes between states and their citizens can be solved in a peacefully way by the ECHR, avoiding conflict situation. In the same way, there are regional means which strengthen the capacity of European Institutions to manage potentially conflicts, to increase the resigning capacity of those.

Other arguments regarding to the international capacity of physical persons is related to the fact that individuals are responsible, from the international point of view, for committing international crimes stipulated in the international conventions, as for example genocide, producing or illegal trafficking of the drugs and psychotropic substances, crime against peace and humanity, war crimes, according to the regulations stipulated in the constitution of Rwanda or Yugoslavia Courts adopted by the ONU Security Council, and recently in the treaty of International Penal Court.

For majority cases should be noticed that for each of these facts, there are regulations in the international conventions, which stipulate for the states the obligation to adopt national law to condemn its. Also, the states are requested to punish these facts through domestic legislation and national juridical organs. So, even in this situation, the obligations of the respective persons are established in domestic law, and these are responsible in their capacity of domestic law subject.

In many cases, the crime against humanity and war crimes are consequence of the international responsibility of the state, when these persons acted as organs of the state. Even if the sanction is applying individual to the implied persons, this fact doesn't change the situation of the state organs, because the crimes against humanity and war crimes create for the state the obligation to punish the guilty persons and to repair the prejudice, giving at the same time possibility to sanctions individuals. The state can punish also the persons belonging to the enemy troops if they violate the regulations related to the war law.

The protection of social relationships that are threatened or affected by committing an act with social danger, as a legal object of the offense, is an own conception of socialist law [11].

In conclusion, the right of the persons to use international procedure both juridical organs and organs of experts created by the states, in order to submit claims concerning their rights, descend from the commitments assumed by the state in international conventions, to have a certain conduct towards their own citizens and other persons being under their jurisdiction, being in a very close connection with these obligations, in fact the most important sanction for their violation. International organization and international jurisdictional effectiveness influences the quality and the strength of its resigning, their capacity to deal with conflict situations, to avoid or to managed them in a peacefully way.

The educational measures in the new penal code, model of social resilience in the juvenile criminal policy

Paşca I.–C.

Faculty of Law, West University of Timişoara, Romania
pasca.ioana@drept.uvt.ro

Abstract

The distinctive character of criminal responsibility in case of juveniles is reflected by the actual legislation in the provision of the exclusive sanction of educational measures and the removal of punishments. The institution of this innovative sanctioning regime in the Romanian legislation is but a consequence of the effort to put the basis of a criminal system that is different from that of the adult system, able to meet the specific needs of the juvenile age. Repression proved in time to be counter-productive in case of juveniles, who, during the period of development of their personality, that is full of contradictions, will rather follow the general rules of survival in a group, at the detention place where they are consigned, than try to understand the illicit committed action and choose the perspective of social reinsertion.

Keywords: juvenile, resilience, sanctioning treatment, educational measure.

Introduction

The delinquent behaviour of juveniles and the level of their emotional intelligence, after submission to the legally prescribed punishments, especially those restrictive of personal liberty, have lately formed a constant preoccupation of the legal scholars.

Initially, the draft of the new Penal Code proposed the reduction of the age of criminal responsibility from 14 to 13, by founding this decision on the significant increase, in the last years, of juvenile delinquency and, at the same time, on the statistic data that confirm, in a percentage of over 90%, the existence of discernment at minors with ages between 14 and 16 years [1].

The sociological and psychological studies have lately emphasized, however, the fact that imprisonment in case of minors represents an active factor in continuing a delinquent activity that negatively contributes to the development of their personality. Events preceding the delinquent activity, as well as certain behavioural models met in the places of detention, do have a negative influence on the future of the under aged, during the formation period of their conscience. The lawmaker has consequently given up the reduction of the age of criminal responsibility of the minor and imposed the rule of the enforcement of educational measures that are non-restrictive of personal liberty, in case of minors that commit delinquencies.

The restriction of personal liberty, as sanction, may only occur in exceptional cases, strictly prescribed by law, respectively in cases of serious delinquencies or those of reiteration of the delinquent behaviour of the under aged.

Legal literature shows that the juvenile delinquency is caused by a plurality of internal and external factors, respectively the personality factors of the juvenile delinquents and the factors concerning the social environment [2]. Thus, juvenile delinquency being a problem of social behaviour and the minor's personality being in course of development, it is necessary to correct it by methods that do not alter the minor's personality and that contribute to his positive development. The non-custodial educational measures, prescribed by the new Penal Code first aim at improving the resilience of the under aged. The resilient person will be able to face further adversities in life and, at the same time, his development will not be altered by the event occurred when he was under aged.

In case of juveniles punished for the first time, the actual legislation considers the personal development and implicitly, the cessation of the criminal behaviour by way of innovative educational measures that offer them the possibility to become aware of the antisocial attitude they have proven, but at the same time develop their resilience. The development of the emotional intelligence during the execution of educational measures,

respectively the personal and social development of the under aged shall surely contribute to their adaptation to the culture of the group where they belong and, therefore, stop the criminal behaviour.

Treatment of the juvenile delinquent according to previous penal codes

Minority is regulated by the Penal Code of 1864 in title VI, among the causes that exonerate from punishment or diminish punishment. According to Art. 62 of the same code, the criminal responsibility of the minor might be engaged starting from the age of 8, in those cases in which he acted consciously. Minors of ages between 8 and 15 years who committed crimes or delinquencies were not held criminally responsible, if they had no discernment. In case of those who did not act consciously, the sanction was to entrust them to their parents for better care or their lodging at a monastery for "correction".

In case of under aged with discernment or of those with ages between 15 and 20 years, the prescribed punishments were servitude or imprisonment. The sentence of imprisonment was executed in a special establishment or in a separate part of the correctional imprisonment house.

The Penal Code of 1936 regulates minority in Title VII, Chapter II and includes it among the cases that relieve of criminal responsibility or that diminish it.

According to Art.138 of the Penal Code Carol the second, the minor is deemed to be the person who hasn't reached the age of 19. The same article defines the teenager as the juvenile with the age between 14 to 19 years, and the child as the minor that has not reached the age of 14. The distinction is also reflected in the sanctioning regime, such as, according to Art. 139, the child is not responsible for his actions, while the teenager shall only be held criminally responsible if there is proof of his discernment.

In what concerns the sanctions, the Penal Code Carol the second prescribes corrective and educational measures for children and teenagers without discernment.

In the case of the teenager with discernment, the court could either impose a safety measure or a punishment, according to the circumstances, respectively the supervised freedom or the corrective education or, in those case in which such safety measures were not sufficient in the opinion of the court, there could be imposed one of following punishments, according to the circumstances: reprimand, correctional imprisonment or simple imprisonment.

Art. 144 explicitly prescribed that no punishment restrictive of rights might be imposed on the teenager. At the same time, the execution of punishments took place in a corrective educational institute, exclusively established for the under aged.

Thus, we can notice the attention paid by the drafters of the Penal Code of 1936 to the correction of the under aged, by the consequent regulation of alternative measures, mainly non-restrictive of personal liberty. The restriction of personal liberty, in cases of infliction of such punishments as the correctional imprisonment or simple detention, took place in a corrective educational institute, where he had the possibility to continue education.

The Penal Code of 1968 includes minority among the cases that remove the criminal character of an act, but, at the same time, distinctly regulates this institution in Title V. In what concerns the age limit of the criminal responsibility, it remains 14. In the case of minors under 14 years, the presumption of irresponsibility is absolute and in case of minors with ages between 14-16 years, the presumption is relative. In their case the court may order, according to Art. 101, one of the following educational measures: reprimand, supervised freedom, confinement in a re-education centre, confinement in a medical – educational institute. In cases of infliction of a punishment, respectively imprisonment or fine, limits are reduced to the half.

As a conclusion, the punishments inflicted over time in the case of minors were established according to their level of mental and physical development. They were mainly educational measures, not measures restrictive of personal liberty. Thus, in case of the under aged, retributive justice, the natural consequence of infringing the law, mainly concerns the application of specific sanctions, with the role of correcting the delinquent behaviour, less serious from an afflictive perspective.

The role of educational measures was that of preventing recidivism, of making minors responsible and helping their reintegration into the community, policy named in 1977 by the American psychologist Albert Eglesh, restorative justice.

The main role in the behavioural correction, according to the former codes, is reserved to the social group to which the minor belongs, respectively to the family or, in certain cases, to the specialized institutions where the under aged might be provided with educational and psychological conciliation.

Educational measures prescribed by the new Penal Code

The lawmaker regulates in Art. 113 of the Penal Code the limits of criminal responsibility, as well as the sanctions applicable to the under aged, according to the same criteria, respectively the age and the discernment. In what concerns the minimum age of responsibility, it remains that of 14 and not 13, as it was

initially envisaged in the draft of the new Penal Code. Thus, minors under 14 years do not have criminal capacity, while minors between 14 and 16 years are deemed to relatively lack discernment, there being a presumption in their favour, the proof of the existence of discernment being left to the judicial bodies.

In the new Penal Code, the minority is no more a cause that removes the criminal character of an act, but a cause that relieves of blame, The causes that relieve of blame have effects *in personam*, because "blame is rather a specific feature of the individual than of the offence" [3].

Regarding the sanctions concerning the under aged, as it was mentioned in the explanatory notes, the lawmaker wished a major change in the sense of giving up the punishments that are restrictive of personal liberty, applicable to the under aged, in the favour of educational measures. Thus, based on the age and discernment criteria, the minor may only be subject to an educational measure that is non-restrictive of personal liberty and, exceptionally, to an educational measure restrictive of personal liberty.

According to Art. 114 of the Penal Code, the restriction of personal liberty is subject to the condition of the commission by the under aged of a crime after the one for which he was inflicted upon the educational measure, whose execution started or was consumed, or in case of the under aged who committed a crime for the first time, if the punishment prescribed for the committed crime is of at least 7 years or lifetime detention.

The educational measures that are non-restrictive of personal liberty: the stage of civic training, the supervisions, the confinement at the end of the week, the assistance on a daily basis. The application of one of these measures is done, obviously, by considering the age of the minor and the criteria of individualization of the punishment. They were named in the specialty literature, community measures [4], because they observe the demands of the Recommendations R 16/1992 of the European Commission in this field. Thus, according to the same authors [4], pursuant to the mentioned Recommendations, these measures are executed in the community under judicial control and under the surveillance of the probation service.

The educational measures, restrictive of personal liberty, are the confinement in an educational centre and the confinement in a detention centre.

The non-custodial educational measures are enunciated by the lawmaker not in aleatory order, but according to their punitive valence.

Thus, the first, respectively the *civic training*, consists in the minor's duty to participate, during a period of time that can´t exceed more than 4 months, in a course of civic formation for the improvement of behaviour by non-coercive methods that sanction mainly the improvement of the resilience of the under aged. The participation in this stage of civic formation is supervised by the probation service and does not affect the school and professional program of the under aged.

The second measure prescribed in case of under aged is the *supervision*. It consists in the control and guidance of the under aged in the frame of his daily program for a period of time between 2 and 6 months. The control is achieved by the probation service and has in view the social reinsertion of the under aged, by the participation in teaching or professional formation courses.

The probation service also has, according to Art. 118 of the Penal Code, the obligation to prevent some actions or to control the interaction with certain people that might affect the correction process of the under aged.

Another educational measure is that of the *confinement at the end of the week*. This measure restricts the right of the under aged to leave the house at the end of the week, except the situations that impose the fulfilment of the obligations established by the court, for a period of time between 4 and 12 weeks.

Thus, in this situation also, the family defined in the Convention for the children's rights [5], the natural environment destined to the education and welfare of its members, has an important role for the minor to become aware of the consequences of his offence by the supervisions of the observance by him of the educational measure.

The last non-custodial measure is the *assistance on a daily basis.* This measure restricts the freedom of the under aged in regards of the performance of daily activities by imposing a program that includes the timetable and the conditions of performing the activities, as well as a program regarding the observance of the obligations imposed on the minor by the court in accordance with the provisions of Art. 121 of the Penal Code.

The attitude of the under aged during the performance of the supervision activity of the probation service might determine, according to Art. 122 of the Penal Code, the modification or the cessation of his obligations. At the same time, the non-observance of the obligations imposed by the probation service, as well as the commission of a new offence, might determine the extension of the non-custodial educational measures initially imposed or their replacement by a more serious non-custodial educational measure, and in case this is not possible anymore, by a custodial educational measure, respectively the confinement into a detention centre.

In what concerns the custodial educational measures, the new Code surprises us by the very denomination of the measures, respectively *confinement in an educational centre and confinement in a detention centre*, that are in perfect accordance with their content and that have in view, besides the punitive aspect, the re-education and reintegration of the minor.

The criterion according to which one may order one of the two custodial educational measures is the concrete social danger degree of the offence.

In the absence of a punishment limit, of a concrete reference point, we consider that the measure of confinement in an educational centre might be ordered when the court finds that a non-custodial educational measure would not suffice to correct the minor's conduct.

The confinement in an educational centre consists in the minor's confinement in an institution specialized in the rehabilitation of minors, where he will have to complete an educational and professional training programme.

The new regulation also distinguishes itself due to the measures aimed at stimulating the process of re-education, by the provision of the possibility of replacement of this measure by a less severe one, respectively the assistance on a daily basis, or the liberation from the educational centre at the age of 18. These two hypothesis are possible in the situation the under aged succeeds to acknowledge the school and professional knowledge received and to make proof of his resilience.

At the same time, just as it is natural, the absence of responsibility of the minor and the reiteration of the antisocial behaviour will either determine the extension of the initially disposed measure, to the special maximum, or its replacement by the confinement in a detention centre, as the case may be.

The confinement in a detention centre thus consists, as shown in Art. 125 of the Penal Code, in the minor's confinement in an institution specialized in the rehabilitation of minors, under a security and supervision regime, where he will complete intensive social reintegration programmes, as well as educational and professional training programmes complying with his abilities. The difference between this custodial measure and the one previously described consists in the fact that the process of re-education is an intense one and takes place under a security and supervision regime.

Just like in the case of the other custodial educational measure, the correction of the minor might bring about the replacement of the confinement by the measure of assistance on a daily basis or the liberation from the detention centre at the age of 18. At the same time, in case of commission of a new offence during the confinement, the measure of confinement is extended and in case of commission of a new offence after the minor benefitted from replacement of the punishment, the measure will be revoked and the remaining punishment will have to be performed or the confinement will be prolonged.

In case of a more serious offence, punished with a sentence of 20 years or more or in case of life detention, the confinement in a detention centre extends during a period between 5 and 15 years. The restriction of personal liberty for a period of 15 years cannot be regarded as lacking a punitive character, as it was intended by the renunciation to the repressive policy in the case of minors, in favour of a restorative policy [7].

Conclusions

Juvenile delinquency was defined in legal literature as being "a historical product resulted from the interaction of some social processes with one's own psychological-moral processes" [6]. Awareness and formation of the minor's personality, after the incident occurred in his life, form a necessary premise for his reintegration in the social environment. His turning back to the social environment obviously supposes the confrontation with new temptations, new variables and the absence of the resilience during the performance of the compulsory social-educational programs during the execution of the educational measures, will bring about in the most cases the reiteration of the criminal acts.

The sociological and psychological studies in the field have shown that the social reintegration of the minor has more chances of success in case of alternative means, and that the restriction of personal liberty and the interaction with other delinquents might constitute, in this period of social self-affirmation, a negative factor in the development of the minor's personality.

The new Penal Code meets as such to the imperatives of the Convention on the children's rights imposing "the treatment of the under aged with the respect adequate to human dignity and in a manner that considers his needs" [5, art.37] and gives up the infliction of punishments in favour of the application of educational measure. At the same time, the new Penal Code recognizes the subsidiary of custodial educational measures.

Thus, in case of minors, the new legislation renounces to a repressive justice in the favour of community programs, with educational-instructive role, carried out under the supervision of the probation service. At the same time, in case of the custodial educational measures, the correction of the behaviour is rewarded by way of replacing the measure by a non-custodial one or with the liberation of the minor at the age of 18.

Reflections upon the resilience of women inmate

Poledna S.

Babeş-Bolyai University (Romania)
polednas@yahoo.com

Abstract

If resilience is defined as individual's capacity of recovering and coming back to the initial state after experiencing an adversarial event, then this definition could hardly apply to women who are serving a custodial sentence. The experience of detention is the result of a criminal behavior. The criminal behavior is the result of concurrent intra-, inter-individual and ecological risk factors which have all facilitated the engaging in the criminal interaction. Therefore, returning to the state previous to the detention is not desirable in most of the cases. Also, we consider that resilience should be studied in the light of either a stressor system that occurs unexpectedly or an ongoing one, in our case, imprisonment and its consequences. From such a perspective we can assess if there are and which are those forces, resources and capacities that can promote resilient adaptation and rehabilitation. Considering this, our analysis introduces the concept of "inoculated resilience" [1], for this concept presents the vulnerability as a resource, even as a protective mechanism and the resilience is seen as the ability to withstand the worst effects of the adversarial experience. Therefore, when it comes to women inmate, resilience is rather focused on the dimension of the sustainability, implying the continuation of the recovery/rehabilitation achieved in prison (psychological, social, educational, spiritual assistance programs) through a post detention development and improvement of individual's functioning, highlighting as resilient solutions, new and pro-social narrative identities.

Keywords: resilience, detention, rehabilitation, narrative identities

Women Inmate Resilience, An Oxymoron?

The resilience paradigm considers the healthy reactions to the risk factors as the norm. Usually there is dynamic process of successful adaptation of the individual to stressful events; therefore, given this logic, the failure of adaptation would be unusual. From this perspective, resilience as an answer to an adversarial event, highlights at least one of two dimensions: one focused on recovery, seen as the capacity of quickly regaining balance and return to the initial state, and the second dimension, the sustainability which includes the continuation of recovering and even developing and improving the functioning, as a result of the healthy reaction to a stressful experience [2]. Does this stand when it comes to women who are serving a custodial sentence? If so, then which of the two dimensions allows us to give meaning to the resilience within the correctional system?

Hart and Billow [3], quoting Master [4], do an overview of the most consistent definitions of resilience and indicate three basic trends in describing its content: 1) "Popular resilience" (which describes anyone who got over difficult periods and experiences). 2) "Real resilience" is a comparing concept that helps us determine what is behind individual differences and life trajectories; it appears when persons with little resources and major vulnerabilities succeed unexpectedly in their circumstances. Real resilience has also the advantage of allowing the revealing of the protective mechanisms which contributed to the success.3)"Inoculated resilience" sees vulnerabilities as resources or, paradoxically, as protective mechanisms. Therefore, the concept of resilience refers to the ability to transform the adversity into a success, or, at least, the ability to withstand the worst effects thereof.

For women, relationships are imperative in identity's construction. The relational-cultural theory considers that resilience is not defined by individual attributes, but by the capacity to connect. Thus, the establishment of relationships based on mutuality, empathy, empowerment and courage are the basis of resilience as presented [5]. Such ties are crucial for women because they can "generate a sense of connection to self and to others, of valuing and comprehension [6], cited in [7]. Mutuality makes the change possible because every participant to the relationship and also relating to others facilitates the development due to mutual influence and responses. Mutual, empathic relations offers force to women, it has the effect of empowerment, it makes her equal to others and offers occasions and resources to mature and develop, unblocking her from under the position of subordination.

To these conceptualizations, we add the one called assisted resilience, suggested by Ionescu [8], which focuses on the idea of "liberating neo-development", a process that involves both the personal effort of identitary reconstructing and the supportive intervention of the assisted resilience institution, which suggests the resilient path when they manifest, encouraging the subjective autonomy, the development of identitary conscience, asserting of the person as an actor and as "author of its own existence, given the fact that he is in a position of social and personal reflexivity" [9].

Are these conceptual circumscribing of resilience relevant even if we refer to imprisoned women? Next we will try to provide some possible answers, based on some of the results of a personal research regarding the issues of female criminality.

We have started our analysis with the concepts "inoculated resilience" and "assisted resilience" because we believe them to be complementary productive, with two amendments. First, it is necessary to take into account each time the specificity of the crime, the perverse effects of the imprisonment and the traumatizing experience of the detention itself, the fact that these women are involuntary or at least non-voluntary clients of the social work, psychological and/or educational services during the period of serving the time, and last but not least, to establish objective limits to the therapeutically intervention and penitentiary assistance, at least through self-determination and confidentiality, and even through the philosophy currently directing the rehabilitative efforts. Second, we believe that the effort of those who seek the resistance path and then maybe even the resilience and the pro-social identity reconstruction path, should receive the support of an assisted resilience institution. Is there any chance that the prison becomes anytime soon such an institution? We risk an affirmative answer, because we foresee such openings in our country. As you know, assisted resilience and the institution of assisted resilience both have as theoretical premises the idea of focusing on strengths; we find that within the correctional system, including in our country, a series of assistance programs based on this perspective are being prepared, we refer to the Good Life Model (GLM), as a model for rehabilitation of the persons serving a custodial sentence applied in the program training them for the release "Reducing the relapse risk after prison" [10], [11], [12]. Also, the last several years there is a clearer accent on the strategies and programmes of psychosocial assistance within prisons, including those based on GLM, on aspects specific to narrative theory and therapies, by emphasizing the importance of identity reconstruction. These tendencies are consonant with the idea that "by giving sense to one's life trajectory and by defining a project of a new personal development (reinforced by an institution), the subject takes the reins of its history and is part o a process of identity reconstruction."[9].

1.1 Female criminality

The specialty literature speaks about a "gender gap" when it aims to highlight the fact that women are a minority in the statistics related to crime. (In 2012 in Romania, out of the total number of convicted, 94.3% were males, while only 5.7% females. [13].)This explains why the overwhelming majority of theories related to crimes referring to behaviors and causes of the criminal behavior having males as authors. However, traditional theories of the sociology of deviance and criminology (anomie theory, differential association theory, social control or the labeling theory) are sustained by evidences indicating an overlap of female and male criminal causes and of the general predictive factors.

The anomie and conflict theories show us that structural factors such as poverty and social inequality, particularly in societies where valuing success and wealth is insisted upon, may explain some of the crimes. According to these explanatory approaches, both female and male offenders come from particularly poor and socially disadvantaged categories, and the fact that men commit more crimes that women might be explained by the fact that goals such as success or profit target fewer women than men. Another classical theory is the theory of differential association, which in explanatory terms emphasizes on learning the criminal behavior, motives and techniques. In this respect, the gender gap is considered as a result of lower exposure of women to "definitions favorable to violation of law" and/or an effect of greater consistency between masculine stereotypes and negative labels. [14], [15].

Social control theories claim that criminality is due to the weakening of social bonds expressed by the attachment to parents and school, by engaging in conventional activities or internalization of pro-social beliefs. According to this perspective, offenders, male or female, come from particularly dysfunctional families, they have a low educational level and they are less involved prosocialy. Difference of gender regarding criminality is explained by the fact that women are socialized more than male to value the conventional behaviors that maintain the social ties.

Traditional theories on crime, some of which we referred to, although they help circumscribing the traits and general causes of criminality shows its limits when we try to explain exactly the persistent differences between the patters of female offenders and those of male offenders. Studies in the last decades, especially those of feminist criminology both not only those, highlight a series of traits specific for female offenders. Thus, compared to men, women are less probably to commit serious crimes against the person, or the property; when they commit crimes in groups, women are more likely accomplices of men who organize and conduct the

criminal action; when they engage in crimes, women more than men seem to be driven by relationship interest, that is why the threat of losing an important relationship, plays a bigger role in the criminal decision than in the case of male offenders. Research shows that women are not less oriented toward risk than men, but taking the risk in their case is more about emotional considerations and concerns regarding the valued relationships [15]. Finally, the data reveals that it is more likely that women offenders were victims of abuse in childhood or adulthood. Covington [7], states that many of the women serving a custodial sentence present the profile and the characteristics of "survivors of trauma" because they have gone through experiences of mentally, physically or sexually abuse and they have lived in violent families or had violent partners. Explanatory trials regarding the pattern of female offender highlights a series of aspects considered in the specialty literature relevant both for their inhibitor potential and for the facilitator of crime. These dimensions help understanding how differences appear, manifest and perpetuate; of these we mention: moral development particularities, targeting the socialization toward empathy, "ethic of care", valuing the relationships, fear of separation from loved ones, social control through careful supervision within the families for the girls compared to boys, to which we add the feminity stereotypes and less access to criminal opportunities explained by the roles the women have within the society [16].

Methodology

1.1 Contextualization

In the Romanian National System of Penitentiaries Administration (ANP) there is only one penitentiary for women and seven special sections within other detention units; within this establishment, on the 31st of December 2013 there were in custody a total of 1559 women serving a custodial sentence.(According to the oficial statistics from ANP)

Of the mandatory sentences (1355), 1039 i.e. 66, 65 % were serving sentences between 2-5 years and 5-10 years. Most of the women belong to the following age groups: 31-40 (451), 41-50 years (351) and 21-30 years (304). Their level of education shows: 33, 65% illiterate (281), or have completed primary school (243); a percent of 31, 5 % those who finished secondary education (491). According to the nature of the crimes we have the following classification: most of them committed theft (308), followed by robbery (164), cheating (163) and murder (131). There is a group of absolute figures around the economic crimes and those against the person, committed with violence. It draws attention to the number of crimes against the Law on preventing and combating the trafficking of persons (119) and the Law on combating drug trafficking and use (161). Of all imprisoned women, the statistics show that a number of 465 are re-offenders, i.e. 29, 8 %.

The subjects to which we refer within the present text match to the socio-demographic profile described in the female prison population. They belong to the age group of 31-40 and 21-30 years old, the majority committed theft, robbery and they serve custodial sentences between 2-7 years in prison. The women interviewed by us are re-offenders or with criminal record. Level of education is for majority unfinished secondary or primary, with only two exceptions; subjects have no professional qualification and no jobs when they commited the crime. The majority of them had or has at the moment cohabitating relationships, half of them having as partners also a person serving a custodial sentence or ex-offenders. With only two exceptions, all interviewed women are mothers of minors, for some of them an ongoing protection procedure is going on (placement in foster care or in maternal center).

Even if they might seem arid, these data allow us to approximate the reality, without which it is impossible to analyze the resilience issue for women inmates. Behind these data, with each interview we reveal the subjective universe and their life trajectory, marked by deprivations, traumas reflected in separations, emotional, physical and sexual abuses, limited access to education and personal development, and in many cases the experience of detention. So we can talk in the above mentioned cases that for these women serving a custodial sentence on the existential paths the dominant grade was "iresistance" and "resistance" to adversities represented a proof for sporadic and limited tryouts to find "escapes" between stages and life events which have only erode their identity capital.

Reflections on the resilience of women serving custodial sentences are based as we have already mentioned on an explorative-descriptive research, having as subjects women imprisoned in a special sections of a penitentiary unit In the NW of the country. (The results presented in the present article are part of a larger study base don GLM as model used for offenders rehabilitation; to see Poledna, S. [12].)The methodology assumes the postmodern idea according to which we need to admit a plurality of truths and perspectives, i.e. of narratives. Convinced that the investigated problem dictates the used method [17], we have chosen the life story interview as method of research. A life story role is first to bring together all essential elements, events and beliefs in a person's life, to integrate them in a whole, and to give them significance" [18]. We considered that this type of interview helps to obtain a better understanding from a perspective of resilience, of traumatic experiences, of feelings regarding these events and their significance for the women. We conducted a total of 23

interviews, of which, with the consent of the subjects, we have used the information in 9 interviews for the present analysis. The instrument of gathering the data was a semi-structured interview guide having the following thematic units: childhood, adolescence and family life, traumatic events and experiences, couple relationships, maternal role, values, social including/excluding, criminal history (risk and protective factors), family life projects.

For the present analysis we insisted on those parts referring to the traumatic events and experiences, couple relationships, maternal role, criminal behavior and life projects.

Presentation of results and discussions

We followed for the presentation of the results the ideatic and interpretative suggestions specific for GLM and for relational and trauma theory, trying to capture based on the data from the interviews, aspects relevant for the resilience issue. According to GLM the crime reflects certain types of experiences, particularly the achievement of certain goals or acquiring assets. Personal efforts of the offenders express the given meaning for what they are and for what they want to become. Thus, the narrative identity, for offenders as well as for other people, is made up of searching ant achieving personal objectives and captures both what is important for a person and the way in which the interests, the beliefs as response to personal circumstances and influence of the interactions he participates to [12]. Where there is trauma, she is part of the identity construction and the resilience could be the complex process of deconstruction of "surviving narrative identities" and rebuilding a new one through a new process that involves both personal identity reconstruction and supportive intervention from an assisted resilience institution [8].

1.1 Traumatic experiences and events

Most of the interviewed women grew up in families characterized by conflicts between spouses, inconsistent parenting relationships, lacking support, empathic feelings, often marked by neglect, physical abuse and the absence of supervision: *My parents had jobs but they used to drink, that's why too often we ran out of money, so they sent us, especially my brothers, to beg. When I was 17 they split up. By that time I was already serving my first sentence. My father was an alcoholic, my mother was a person I felt pity for, because she was intervened whenever our father tried to beat us. Still, she used to drink too. They sold the flat and bought a one-room house where they lived with my brothers. Sometimes my father came to my grandmother and threatened to take me from her if she won't give him money. He also sent me out to beg but I didn't do it. I preferred stealing. (MC, 33 years old).*

The naratives confirm the fact that traumatic experiences act as a filter for all future experiences [19]. „*I grew up in the orphanage, where I received an ID... when I came out I started to steal. Afterwards I went to the center of School number 4. It was a correctional center. I came out of there when I was 18. I have been living on streets ever since. I came back to CM and I entered a gang of drunkards... I have even slept on ice, under balconies and the ice melted under me.*" (M.M 41). As this case shows, the life events narrated in the interviews confirm the fact that trauma always appears in a social context which often contributes to long term consequences of unsettled traumatic experiences.

The childhood experience of abuse gets through these stories and consequences of the trauma are still present: *My uncles, my mother's brothers beat me up. Once I almost died from a knock in the head. Especially one of my uncles, now dead, used to beat me up to get him money to drink. In our colony (a mining city) they are all poor and men are usually alcoholics. And he used to beat me up. He hit me once with the heel of a shoe in the head. I could not hit him back, so I got so angry that I began to cut myself with a blade. In that situation I cut myself in the window's glass to escape. It was then when my brothers beat him up. (VN,35).*

Several interviewees still remember the early separation of their mothers and frequently, speaking about their mothers, they describe the absence of their ability to get attached to their own child, which in specialized literature is known as „maternal sensitivity". One of the interviewees had been placed in a placement center when she was merely a few months old and met her mother only as a teen. „*When she came for me, I didn't know my mother. I told her to leave because I don't know her. She convinced me to go with her with a doll (VN, 35)."* The loss and separation increased the feeling of vulnerability, uncertainty and anger all the more as due to the unfavorable life context, these feelings could not be expressed and were not acknowledged [20].

Other interviewees indicated the loss of one parent as the event that changed their lives:

„My mother died when I was 15. After that I began to do all sorts of silliness, I left home, I lived at my friends or my relatives (...). I had left school even before, I've been in school for six years. Then I began to steal. After he died (the father), he was only 37, I had no more support, our lives changed. If he hadn't died, this wouldn't have happened (enter the prison) (CM, 42).

The stories of women inmates confirm the fact that „traumatic experiences produce attachment disorders, which, in turn, increase the probability of reiterate the traumatic experiences or even the likelihood of

causing them to others." Thus, these interviews reveal a vicious circle in which the attachment disorders and the trauma experienced by these women combine themselves and keep them captive in life projects marked by separations from their own children, instability and violence in couple relationships, criminal behavior and detention.

1.2 Maternal role

„*Our parents take care of our girl because we've been in prison ever since she was born."* What had been normal for their early relationships became a part of their selves [20]. *C. was also stealing; he had been in school for three years. We've been together for almost 5 years; we lived with my parents-in-law. Then I went to jail. Meanwhile he went to jail too, then came out, and then went to jail again for pickpocket, just like myself. I was nearly 17 when I got married. We had a boy who is now 16. With my second partner I have three little children. He takes care of them* (MC, 33). Traumatic experiences act as a filter for all future experiences [19], that's why, in the case of women who have been interviewed, especially those with attachment disorders and relating to parents' problems, the maternal role, its understanding and performing are strongly disturbed: *When I was 14 I gave birth to my first child from my first partner. With my second partner I have three children. From my actual lover I have no children. My children live with my father but I know they are not doing well, because my father is still drinking and somebody told me he's got nothing to give them (food, clothes). I know they are not doing well. I asked to place them in a placement center; their older brother is already there (*PA, 32).

Some of the interviewed women gave birth to more children to delay the implementation of the mandate of execution of the imprisonment sentence. *I gave birth to 10 children to avoid imprisonment. I waited for a decree. When I did it I had four children. They've arrested me for theft. When the doctor saw me, he told me I was pregnant. They've released me; I gave birth and stayed with my girl until she was one year old. Because I knew I had a warrant, I kept getting pregnant... Meanwhile, I stole from time to time (TC.45)*. In these cases the maternal role is misunderstood, separation from children is included in the costs-benefits calculation, so that assuming the maternal role is delayed on purpose. These situations confirm, in reverse order, the attachment theory idea, which states that a proof of the resilient development of the parent exposed in childhood to adversities while relating to significant adults is the ability to become a secure parent for their own children [21]. Nevertheless the stories reveal the fact that the biggest worry of imprisoned women is related to their children. They often prefer not to be visited, if by this means they can be of any help: *I refused to be paid a visit for their own good; I told them to use the money they would have paid for the road and for a package to buy something for my nephews and my girl. I told them not to look for me ever since I've been arrested. (C M, 22)*

1.3 Couple relationship

Relationships prove important for the women we interviewed, as well, just that the relationships they are describing are lacking those fundamentals necessary for a resilient identity: they are non-mutual, non-empathic, marked by separations and breaks, inconsistent and often abusive. *To get away from my parents and the scandals I got married to C. I thought my life would be better, that I'll have someone to love me, that my parents-in-law would replace my parents... That's what I thought. But it wasn't like that; I had to steal for them.* (MC,33). There are relationships that do not allow women to value themselves, to know they are understood and strong. *I'm sorry I allowed him to bring me down like that, to support the children and him also, to beat me... I wasn't strong enough to take the decision in time. If only I left him 15 years ago… (E.I, 54).* In other cases, the couple relationships are passing, inconsistent, despite the fact that they result in children: *I've had another relationship and we had a child, but I didn't want to stay with him. Then he demanded the child and he raised him. Afterwards I met my actual partner. (CA, 26)* There are also many cases when women commit the crime along with their partners: „ *My husband is also imprisoned, we've been robbing together, we've been together for 13 years now, he used to beat me and live with my sister in law. We had two children together. (MR.37).* There are situations when relationships are built and legalized while executing the punishment: *I got married in prison. My husband is older than me; he respects me, and teaches me to do well. He gets out (of the penitentiary) after me. I hope I'll start all over again (SC, 26).*

1.4 Criminal behavior and the experience of detention

Criminal behavior is the result of individual and social vulnerability and also the result of the risk factors our interviewees have faced. In this context we can note that most of them have uncompleted studies, no professional qualification, and they are either single mothers or have as partner unemployed men which have criminal history themselves. The factors which contributed to their criminal behavior differ and illustrate the explanations related to female criminal behavior previously mentioned. *When I was 14 I was imprisoned for the first time for one month. The second time I went to jail for 6 months again for robbery. I got out in 2005. Until 2012 I was still free...* Some of them said they committed the crime for money. *We all had jobs. I preferred*

stealing instead of other things (prostitution). (*AE, 29years*). Others saw crime as a way to adapt and face poverty, the lack of access to resources or a way to help the family: „ *I have four brothers, now they are all imprisoned, but when they were little they were sent out to beg. To avoid seeing them beaten because they didn't bring money, I used to steal for them. That's how I began. (MC,33 years old).*

The experience of detention is in itself an experience of breaking in someone's biography; the interviewed women suffer and face the traumatic consequences of freedom's deprivation. *I learned in prison to cut myself and swallow spoon handles. The diseases I have already had grew worse, although I received treatment. Now I'm in a new cell with quieter women, they don't quarrel that much. (SC, 26).* Coping strategies are different and the stories of repeat offenders show this: *Until now in the other punishments) I have never said I wouldn't return. I don't know if I'll have to steal again, but now I said I won't steal anymore. I have diabetes since I'm here. I can't stand imprisonment anymore. Since I'm here one of my children died. I went to SM and A. I walked around. I had businesses going on to forget I'm imprisoned and I came back, to get closer to family. (DN,35)*

1.5 Life projects

The stories of women inmates show future plans related to family and first of all, related to their children: (...) *to have my children around me and go home. What matters most for me are my children, my parents and only then myself. For me I want a better life than the one I had, I want to be free, not poor and have a good husband.* (CC.32). They tell us what is important for them, to go back to the places they came from and give back what they received from the closed friends, support, help, sympathy, acceptance: *The only important thing in life is health. And also the chance to live decently. I had chances but I ignored them. My family and my friends offered me these chances. I liked having money, yet it was not the money that was important, but the freedom they gave me to do silly things on big money, not big stupid things on little money (*ZM.51). Their future plans reveal projects related to family, jobs and if valued, those projects could turn into a beginning of identity reconstruction: *I don't want to steal anymore. I will work anywhere; I'll work by day for peasants. I don't want to go to prison anymore. If my mother dies, the state will take my children away.* (VN.35). The relationships with the families they come from and their own families remain the main „keys of resilience", there can be seen intentions to „develop responsibility and autonomy" necessary for assuming roles and duties until then interrupted or even abandoned. To those is added, in some cases, the acknowledgement of new values or a new understanding of those which have been misunderstood: *What matters most in life is to do no harm to others, as I did too many people, since I was a child. I harmed old people, sick people... I regret it now* (TC, 45).

Conclusions

Through the narrative interviews we wanted to have the voices of the women inmates heard, to let them express the way they see themselves, to let them tell the experiences and events marking their lives, including the experience of detention and the meaning of what they are and what they want to become. Reflecting on this we strongly believe that the issue of female offender resilience is not an oxymoron; it may make sense and it must be brought into discussion their situation. The presented results showed that for these women, the adversities and the risk factors have determined vulnerabilities that they didn't manage, didn't try or didn't know how to face them. General human needs, some primordial such as the need of survival (food, housing, attachment, affiliation) have become, in these women' cases, criminogenic needs. Protective mechanisms, both the limited internal ones (lack of some facilitating abilities and attitudes of cognitive, emotional and behavioral nature, poor education and illiteracy, lack of a professional qualification and of a job), and the fragmented and inefficient external ones (access to the community's resources, employment opportunities, social support) add to the vulnerabilities and to the risk factors that lead to criminal resolutions. Some of the interviewees are familiar with custodial educational measures early in their teen years, falling in the criminality is a cumulative effect of the dysfunctions within the original families and in some cases of the criminal models and practices within the family. Finally, relationships with abusive partners, most of the times with a criminal record, have facilitated the options and the behaviors of women offenders included in our study.

Given all this, at the end of these reflections we suggest several possible answers to the interrogations raised within the study.

In our opinion, when we talk about resilience we need to specify on whose resilience we talk about. The situation of imprisoned women is, as we presented, somehow special than the one of others. The detention experience is the result of a criminal behavior. This behavior is the result of a cumulus of events and difficult, even traumatic, experiences. This is why, in the case of the imprisoned women, talking about resilience as the ability to come back to the initial state before facing the adversity, is not, in our opinion, a productive conceptualization.

How do we conceptualize resilience is a theme still under debate among academics and practitioners: do we consider it as a personality trait, a process or as a result? As for us, we think that the imprisoned women, given their existential trajectory, it would be more appropriate to consider resilience as a "dynamic process" [2]. As "iresilience" manifested as a process through the daily events of their biography, the resilience could settle in gradually, progressively as a result of the *resilience investments* both for the involved person and all of those forming the support system; in other words, through an identity reconstruction as through a supportive intervention from the assisted resilience institution[8], in our case the penitentiary, probation system, and/or institutions and services in the health system, social protection etc.

Thus, in order to make sense for the imprisoned women, the content of the resilience process could be configured around the concepts:"inoculated resilience" and the "assisted resilience". From the interviews, some protective factors are being outlined; some abilities that if converted in a prosocial direction would help women face some adversial situations after release. As seen, resistance is a dimension underlining the role of contextual factors in resilience [5]; they play a crucial role because the post prison resettlement, the reintegration within the community requests the involvement and the support of several services to make the transition easier, to sustain the recovery trajectory and "resilience therapy" during detention and after release.("Resilience therapy" represents a set of interventions targeting five separate domains but interdependent: forming attachement and belonging relationships, education and learning, improving the coping strategy and self development. [3].) Ways in which the resilience could be promoted [2], both during detention and after release, consist of intervention strategy meant to reduce the risk factors, to mobilize and to increase the resources, and finally to activate strong protective systems such as family, school, non-governmental organizations, community social work service; so, the resilience process would allow the prosocial identity reconstruction for the women that have experienced crime and detention. Paraphrasing Ionescu [8], we could say that they can define themselves by what they have become, rather than by what they have lived or done before walking the new path of their own development.

Resilience in children subject to parents' divorce trauma. Searching for references in jurisprudence

Abstract

The new Romanian Civil Code represents a change of paradigm regarding the programs of personal connections of the minor with the parent they do not permanently live with (so-called non-resident parent), and such aspect is reflected already in the legal practice in Romania. We believe that the establishment of joint parental authority represents a substantial remedy in the resilience of a minor child affected by the trauma of divorce, helping to maintain a positive image of both parents, diminishing in this way some of the negative consequences of divorce.

Keywords: child, parent, parental authority, divorce.

Introduction

Attachment connections are established as early as the first moments after the child is born and are vital for the further development of the child.

The mother and father are essential attachment figures with a decisive role in a child's emotional and social development, taking into account that the quality of the child's social relations as an adult is determined by the quality of their earlier interactions. Childhood represents the cornerstone of each person, a moment in time defined by magic, fascination and joy, which remains a fundamental milestone in becoming an adult.

However, childhood unfortunately is not always a happy and careless period. For many children it is marked by poor living conditions, a chronic illness or disability, by violence and various other forms of abuse, by alcoholism or drug addiction of one parent, or even both, by their divorce or death of a close one. Exposure to these traumas triggers different reactions: some children adapt overcoming adversities and painful experiences, some others do not.

Among traumatic experiences that a child may be faced with, the present paper aims to analyze the consequences of parents' divorce over the child's socio - psycho - emotional life, respectively the key factors provided by the Romanian legal system to ensure minors psychological resilience.

Psychologists identified divorce as a major crisis inside the family system, crisis that starts prior to the decision to separate and interruption of personal relationships between spouses [1]. It represents a process of readjusting and reorganizing of their lives for both partners, regardless which one of them initiated the divorce.

The separation of spouses in divorce proceedings is frequently associated with conflicting frames of mind which influence the risk of negative effects, both physical and mental, for children as well as for adults during divorce and subsequently.

Due to recent legislative changes in this area [2], this paper aims to underline some references in jurisprudence designed to outline the standards related to disputes over the custody of minors based on the best interests of the child prevailing, in order to identify the extent to which the legal system can help with the child's resilience once he's been through his parents' divorce.

Presentation

Practically, resilience can be defined as the ability to overcome the hardships of life, minimizing the negative effects of the encountered issues.

Each child is born with a certain potential to cope with adversities, therefore a certain degree of resilience, potential that, subject to a number of factors, can be developed or on the contrary, blocked. Essentially, resilience is influenced by factors related to the child's personality (self-esteem, courage, tolerance to frustration, empathy, emotional stability) as well as external factors (family, social support groups, religion, etc.).

The manner in which the divorce will take place, and particularly the background of the relationships between the child and his parents, will later on influence decisively the resilience of children who go through such difficult circumstances: "The pain of losing family relationships was frequently associated in children with the loss of sense of self-identity, autonomy, privacy and loss of sense of affiliation, loss expressed at different levels of functioning: cognitive, emotional and behavioral through behavioral disorders as well as food, somatic, anxiety, depression related disorders". [3]

The legal framework regulating the minor's custody, meaning the way the parents exercise their authority following their divorce, must comply with the areas of assessment regarding the child's best interest, as this principle is regulated by Law 272/2004, namely:

- the quality of the relationship between the parent and the child;
- the quality of the relationship between the child's parents;
- each parent's ability to raise and educate the child, parenting style and disciplinary methods, ways of resolving conflicts;
- mental health of each parent, the possible effect of domestic violence;
- the type of attachment of the child, the child's preferences, his special needs and mental health, including age related peculiarities;
- parents' income;
- social security systems, cultural, ethical and religious aspects.

A vital role in regulating the terms regarding child's custody is represented by the former spouses' capacity to make "joint" decisions, the opposite parties' positions should be amiable, both being based on the common interest they have in the future of their children. Parents should be aware that their relationship does not disappear after divorce, and that the quality of life of their children depends primarily on the way they negotiate such relationship, in terms of raising and educating their children: discipline, social and moral education, celebrating special events in children's lives, vacations, extracurricular activities, establishing a daily routine including stabile and consistent discipline.

When exposed to the trauma of divorced families, the best interest of children, in general, is related to the actual possibility of each of them to develop balanced and harmonious relationship with both parents, even though they are no longer husband and wife. Even though they are no longer married, the parents of a child should continue to function as a parenting couple. Parenting partnership, based on a shared commitment of the divorced parents to plan for the child and establish a shared parenting plan represents, the cornerstone of reconfiguring their stabile, predictable and functional structure of future family lives.

According to the preamble of the UN Convention regarding the Child's Rights, the child must "*grow up in a family environment, in an atmosphere of happiness, love and agreement* " in order to harmoniously develop his personality. Romanian legislation on family law has undergone substantial changes in the same direction as many other European countries and in line with the vision of the UN Convention regarding the Child's Rights. According to it, the exercise of parental authority by both parents is in the best interest of the child and we notice here a change of paradigm in relation to the provisions of the Family Code (repealed when the New Civil Code entered into force on October 1st, 2011), which previously stipulated that custody for raising and educating the children should be granted to one of the spouses. Even if the other spouse was granted the right to have personal ties with the child, solely the spouse to whom the court gave the custody exercised parental authority.

The provisions of art. 263 of the Romanian Civil Code from 2011, establishing the *principle of the child's best interest***,** stipulate as follows:

"(1) Any action relating to the child, regardless of its author must be taken observing the child's best interests.
(2) While deciding upon petitions referring to children, the competent authorities' duties are to give all necessary directions in order for the parties to use amiable methods for resolving their conflicts.
(3) The procedures regarding the relations between parents and children need to ensure that the wishes and interests of parents regarding their children can be brought to the attention of the authorities and are taken into account in their final decisions.
(4) The procedures relating to children should be conducted in a reasonable timeframe so that the interests of the child and family relationships are not affected."

Defined as a set of rights and duties related to both the person and the child's property, parental authority belongs to both parents, according to the New Civil Code ("NCC"), both parents having to exercise it in the best interests of the child (Title IV of NCC - Parental Authority). Nevertheless, the provisions of art. 398 NCC stipulate parental authority being exercised by a single parent, "if there are well-grounded reasons taking into account the best interests of the child" (art. 398 NCC - Exercise of parental authority by a single parent).

Therefore, by corroborating art. 397 and art. 398 of the NCC with art. 506 of the NCC, the guardianship court could decide that parental authority can be exercised by a single parent solely on the basis of consent given by parents in this regard, but only taking into account the provisions of art. 264 NCC. This is possible, first

because art. 506 of the NCC states that parents can agree upon the exercise of parental authority if best interests of the child are followed and, where appropriate, with the child's hearing in front of the court and second, art. 398 NCC provides an exception to the rule, that works for well-grounded reasons (or, the parties agreement, in view of the above corroborating articles, could be considered as circumstantial well-grounded reasons in the best interests of the child) [4]. In a correlative manner, the other parent has the right to watch over the child's development and education, as well as the right to consent to his adoption. By way of exception, and subject to the same requirements regarding the best interests of the child, the court may decide to place the child in the care of a relative or another family, person or institution.

We should bare in mind that, similar to the old regulations, the new one provides that the guardianship court's prerogative is to change measures on parental rights and obligations regarding the minor children, if circumstances taken into consideration in the initial decision are changed.

The concept of "parental authority" is new in the Romanian law, being inspired by French law and law from the province of Quebec, although it appears in other legal systems, including the Belgian one, Swiss one, German one, etc.

Regarding the content of this notion, we should bare in mind that the joint exercise of parental authority when parents are married involves the exercise of all parental rights and obligations jointly and equally by both parents on a daily basis. Thus, if the parents live together, they will exercise together and jointly all parental rights and duties, the presumption of tacit mutual mandate being applicable between them as provided by art. 503 par. (2) of the NCC. If they do not live together on the other hand, joint exercise of parental authority is reflected in them consulting one-another when making decisions about raising and educating their children (for instance choosing the school, family doctor, extracurricular activities), daily activities regarding the development and education of the children being carried out by the parent they live with permanently. This is because when parents are separated, whether divorced or just natural parents not living together, the exercise of parental authority according to the law belongs to both parents jointly, but in reality the way its exercised differs from when the parents live together, because the child will only live with one parent and they cannot be together in order to handle to handle the development and education on a daily basis and coordinate daily activities.

The connection between the concept of "parental authority" and that of "exercise of parental authority" could be compared with the connection between the legal capacity to hold parental rights and obligations and to exercise parental rights and obligations.

Conclusions

To draw a conclusion, the new Civil Code entering into force in October 2011 represents a change of paradigm regarding the programs of personal connections of the minor with the parent they do not permanently live with (so-called non-resident parent), and such aspect is reflected already in the legal practice in Romania. We believe that the establishment of joint parental authority represents a substantial remedy in the resilience of a minor child affected by the trauma of divorce, helping to maintain a positive image of both parents, diminishing in this way some of the negative consequences of divorce.

References

[1] As previously stated, "divorced adults and their family members represent a" special group of people with special needs "(Lebow, 2008), meaning that the problems the family are faced with, are special. Johnston & Campbell (1988) suggest that these problems are caused by a number of factors that contribute to the family crisis as: changes in the nature of the marital relationship between spouses, changes in the structure and dynamics of the family, social and economic status, increased vulnerability of each of the parents and specific reactions occurring as a result of loss of important attachment links (Brooke & Monin, 2008) after separation and divorce". See C. A. Borlean, *Mediation in juvenile custody litigations*, www.juridice.ro, October 25, 2012.

[2] New Civil Code attaches special importance to the regulation of this matter, establishing the principle of equal rights for children (art. 260) and the principle of the prevailing interest of the child (art. 263), and in a separate section, the effects of divorce on the relationship between parents and their children (art. 396-404). Law no. 272/2004 regarding the protection and promotion of children's rights ("Law no. 272/2004") however, is the specific law, which sets the principle of the child's best interests prevailing in all actions and decisions concerning children, whether undertaken by public authorities and authorized private institutions or in cases solved by the courts (Article 2 of Law no. 272/2004). This normative act has been amended by *Law no. 257/2013 amending and completing Law no. 272/2004 regarding the protection and*

promotion of children's rights, published in the Official Gazette of Romania, Part I, no. 607, dated September 30, 2013.

Cross-border insolvency in the new insolvency code of Romania

Popovici S.

West University of Timisoara
sergiu.popovici@drept.uvt.ro

Abstract

An important element of economic activity globalization is the extension of equity companies' influence over the territories of several states. Statutory provisions on cross-border insolvency, as a form of economic resilience of a company, are and have been the object of interest on a national as well as on a European level. The purpose of this paper is to present an analysis of the new rules of the Insolvency Code on jurisdiction of Romanian authorities in insolvency procedures with a foreign element, as well as the law applicable in these procedures, in the context of European and international law.

Keywords: cross-border insolvency, conflicts of laws, winding-up, insurance undertakings, credit institutions.

Introduction

An important element of economic activity globalization is the extension of equity companies' influence over the territories of several states. The economic recession, with various intensity in different states, has led to financial difficulties for many of these companies, irrespective of the fact that it has affected the mother company alone or one or more of its branches.

Whenever these financial difficulties result in insolvency proceedings of a mother company, all branches (internal or international) are affected, even if in certain states some segments are functioning properly. The larger the main company, the more people are affected by its insolvency. The disappearance of an important economic agent leads to a disruption in the supply chain, indirectly affecting many aspects of economic and social life, therefore becoming relevant not only to community and societal, but also to individual resilience.

Council Regulation No. 1346/2000 of 29 May 2000 on insolvency proceedings recognizes that the the activities of undertakings have more and more cross-border effects, which is why a proper functioning of the internal market requires that cross-border insolvency proceedings should operate efficiently and effectively [1].

The project of the new Insolvency Code of Romania – Government Emergency Ordinance (G.E.O.) No. 91/2013 dedicates an entire title to cross-border insolvency, which has been left unaffected by the decision of the Romanian Constitutional Court which initially repealed the entire act. The advantages and disadvantages of the rules contained in the third title of the Insolvency Code are the object of analysis in the present paper.

Innovations of the new normative act concerning cross-border insolvency

The only important difference between the old rules on cross-border insolvency and the project of the new Insolvency Code is one of structure. In substance, the new normative act maintains all the provisions contained in Law No. 637/2002 on private international law relations in the field of insolvency, in Government Ordinance (G.O.) No. 10/2004 on the winding-up of credit institutions, and in Law No. 503/2004 on revival, winding-up, dissolution and voluntary liquidation in the field of insurance.

The only element of novelty consists in the regulation of measures to be taken in the event of cross-border insolvency of group members (articles 305-311 of the project). However general these new rules, they may be regarded as an element of innovation.

Another positive aspect is the fact that most rules on cross-border insolvency (general, as well as concerning credit institutions or insurance) are gathered in the same statutory act, rather than spread among several laws and government regulatory acts.

However, as will be mentioned in the following sections, the Romanian legislator failed to remedy many of the gaps and shortcomings of the existent provisions, despite the fact that adopting a new Insolvency Code would have been the optimal opportunity to do so.

Shortcomings of the Insolvency Code in regard to cross-border aspects

As mentioned above, all the problems of the current legislation concerning cross-border insolvency have been carried over into the new project. Additionally, some of the structural changes are also criticisable.

For instance, all general provisions on cross-border insolvency, formerly in Law no. 637/2002, are contained in Chapter II of the third Title, without any subdivisions. While the solution has probably been imposed by the necessity to avoid over-fragmentation of the relatively large Insolvency Code, Law no 637/2002, with its 3 sections and several subsections, is easier to follow.

Moreover, it is difficult to understand why in the matter of insurance, only the rules concerning winding-up of insurance undertakings (cross-border aspects included) have been placed in the project. All other provisions of Law No. 503/2004 concerning remedies, dissolution and voluntary liquidation, with their cross-border rules, will be left unaffected when the project comes into force. The fact that in the matter of insurance, winding-up is regulated in a different instrument from other aspects of insolvency, affects the coherence of cross-border rules. For instance, article 324 indent 1 of the project stipulates that articles 9 and 10 of Law No. 503/2004 shall apply, and then later article 325 indent 2 mentions that articles 9 to 11 of Law No. 503/2004 shall apply. The overlap is evident and difficult to explain.

Another structural problem, inherited from G.O. No 10/2004 concerning credit institutions, is the fact that a significant part of the fourth chapter consists of definitions (article 320 indents 3 and 4, article 321 indents 5 and 6), despite the fact that the section dedicated to definitions in the project is the second section (article 5).

One of the few differences between Law no. 637/2002 and the project is found in article 285 indent 4. The current indent 4 of article 13, Law no. 637/2002, deals with unwarranted debts not due at the date of lodging, while indent 4, article 285 of the project deals with preferential debts not due at the date of lodging. In both situations, indent 3 expressly mentions debts not due in general, so it is difficult to understand why unwarranted or preferential debts, when not due, should be given a special provision.

Concerning the substantive aspects, it is noticeable from a general overview of the legislation on cross-border insolvency (current and new) that the Romanian legislator oversteps the boundaries of a general principle of private international law: Romanian authorities (legislative, administrative or judicial) cannot establish statutory provisions which are binding for authorities of foreign states. While on a European level, the legislative technique requires general references to Member States, the Romanian legislator is bound by its territorial limits, and cannot establish rules and obligations generally referring to Member States, except when Romanian authorities are the only indebted party.

For instance, article 316 indents 1 and 2 of the project (currently article 51 of G.O. No. 10/2004) state that the liquidator named within a procedure opened according to Romanian legislation is entitled to exercise within the territory of all the Member States all the powers which they are entitled to exercise in Romania. This provision, mentioned in the case of credit institutions, is reiterated in the matter of insurance, by article 327 indents 1 and 2 of the project (currently article 75 of Law No. 503/2004). Moreover, article 324 indent 2 of the project (currently article 66 of Law No. 503/2004) stipulates that decisions of Romanian courts concerning the opening of winding-up proceedings of a Romanian insurance undertaking, including its branches in other Member States, shall be recognised without further formality within the territory of all other Member States and shall be effective there as soon as the decision is effective in Romania.

Despite the fact that there is no direct reference to any European directive in the body of G.O. No. 10/2004 or Law No. 503/2004, it has been stated [2] that their purpose is to implement Directives No. 2001/24/EC and 2001/17/EC of the European Parliament and Council, on the reorganisation and winding up of credit institutions and of insurance undertakings, respectively. Both directives uphold the same principles as stated above. In implementing these rules, however, the Romanian legislator can only stipulate that liquidators named in procedures opened in other Member States may exercise all of their rights in Romania without further formalities, and to acknowledge recognition of decisions taken by courts of other Member States in Romania without any formalities. By stating that Romanian liquidators may act in other Member States without restrictions, and that decisions taken by Romanian courts are recognized in other Member States without formalities, the legislator of the new Insolvency Code oversteps the boundaries of its influence. Such rules are only applicable by effect of the instruments which implement the directives in the other Member States, or by effect of the directives themselves, certainly not by effect of Romanian legislation.

The same can be said of project articles 320 and 321 (currently articles 55 and 56 of G.O. No. 10/2004), as well as article 331 (currently article 73 of Law No. 503/2004) which stipulate that authorities in the Member States of origin are the only ones entitled to decide when it comes to Romanian branches of an undertaking or institution situated in that Member State. While the principle is in accordance with the directives, the Romanian legislator, implementing them, may at most stipulate that Romanian courts are not competent when it comes to Romanian branches of undertakings or institutions situated in another Member State. Competence of the foreign courts will be attributed to them by their own *lex fori*, as well as the applicable law in those proceedings. The error of the Romanian legislator is not random or isolated. The conceptual problem is confirmed by the fact that according to the final part of project article 331, the law of the Member State of origin is applicable on grounds

of articles 9-11 of Law No. 503/2004 and of article 328, when it is undeniable that in foreign procedures, the applicable law is determined by conflictual rules of the state of origin, not determined according to Romanian statutory provisions.

In addition to the clear breach of territorial limitations, there are a few other punctual shortcomings of cross-border legislation in the matter of insolvency. For instance, article 293 (currently article 22 of Law No. 637/2002) stipulates that individual requests or executory measures against the debtor may be suspended by the court, upon request, if not suspended according to article 292, while article 292 (currently article 21 of Law No. 637/2002) mentions that upon recognition of a foreign procedure, all individual requests or executory measures against the debtor are by law suspended.

In general, we believe that the possibility itself of simultaneous on-going foreign and Romanian procedures concerning the same debtor is relatively outdated, and the new Insolvency Code would have been a good opportunity for the overall modernization of cross-border rules.

Gaps in the new legislation on cross-border insolvency

There are several aspects of cross-border insolvency that are not at all regulated or that are just mentioned on a very general level in the current legislation. None of the gaps have been filled by the new project.

One of the best examples towards this conclusion is the fact that Romanian legislation has no rules on the law applicable in cross-border insolvency proceedings. General conflictual rules found in the New Civil Code (N.C.C.) are insufficient when it comes to insolvency. It has been suggested [3] that in this situation, the only other set of general rules – those of Regulation No. 1346/2000 – should apply, despite the foreign element's lack of connection to other Member States. Such a proposal, despite its clear practical value, is relatively difficult to support in the context of civil procedure, a matter governed by strict interpretation, where extensions by analogy are not permitted. As mentioned above, the project of the new Insolvency Code does not remove the problem.

Furthermore, when it comes to credit institutions and insurance undertakings, the only specific rules in the project deal with foreign elements from other Member States. There is no set of rules when it comes to cross-border insolvency of credit institutions or insurance undertakings outside the European Union. Even formally, at this moment the general rules of Law No. 637/2002 are excluded when it comes to these two specific matters. Despite the fact the formal exclusion has been attenuated by article 274 indent 2 of the project, which mentions that general rules are inapplicable only if special legislation exists, these outdated general rules are insufficient to solve specific matters of cross-border insolvency when it comes to credit institutions and insurance undertakings. In face of this legislative gap, it has been suggested [4] that the normative provisions applicable to procedures in connection with other Member States should be extended to all procedures with a foreign element, if compatible. Despite being pragmatic, this interpretation is susceptible to the same criticism as before.

It is also difficult to understand why article 279 of the project only mentions the New Civil Code (N.C.C.) when it states which general statutory provisions complete the title dedicated to cross-border insolvency. Why has the New Civil Procedure Code (N.C.P.C.) been omitted? The only explanation may be that both aspects of private international law (substantive and procedural) were found in the old Law No. 105/1992 – which art. 8 of Law no. 637/2002 sends to. At the moment, however, cross-border substantive aspects are regulated by the N.C.C., while the procedural ones by the N.C.P.C., and it is not implausible that the legislator of the project failed to properly adapt the new text.

As mentioned in the previous section, despite no direct indication of Directives No. 2001/24/EC and 2001/17/EC, it has been suggested that the Romanian rules on cross-border insolvency concerning credit institutions and insurance undertakings are meant to implement these directives. Most aspects of the European normative acts, however, are not found in Romanian national legislation, which simply takes a few of the principles and obligations set up by the directives, without adapting them in any way. Concerning many aspects, it is our opinion that Directives No. 2001/24/EC and 2001/17/EC have not been properly implemented in Romanian national legislation, and the project of the New Insolvency Code does not in any way remedy the situation.

A few other gaps in the legislation may be pointed out. For instance, in order to prove that there is an on-going procedure in a foreign states, whenever a copy of the decision to open that procedure or a certification from a competent authority is not obtainable, article 287 indent 2 letter c (currently article 16 indent 2 letter c of Law No. 637/2002) mentions that any proof admissible according to the Hague Convention of October 5th 1961 abolishing the requirement of legalisation for foreign public documents or any other foreign treaties shall be accepted. The status of countries not part of this convention, with which Romania has no treaty, is, however, unclear. Article 1092 of the N.C.P.C. establishes a general framework for foreign public documents, but as mentioned above, is not expressly mentioned as completing the title on cross-border insolvency. By systematic

interpretation we can reach the conclusion that art. 1092 N.C.P.C. is indeed applicable, but the adoption of new legislation should have removed the problem of article 16 indent 2 letter c, Law No. 637/2002.

Conclusions

It is apparent that in our opinion, the limitations of the new Insolvency Code when it comes to cross-border aspects outweigh its benefits. The general rules contained in Law No 637/2002 are outdated, but have in no way been modernized by the project, despite the fact that on a European level, concrete measures for updating Regulation No. 1346/2000 are already under discussion.

There are many legislative gaps that the new act should have filled, but all the shortcomings of the current legislation are perpetuated by the lack of any significant change or improvement in this particular field of economic resilience of a company. The New Insolvency Code in general is, however, a step in the right direction, as it will be more effective to work with one legislative instrument, when modernization of cross-border rules does eventually occur, rather than amend several laws or administrative acts.

Resilience-victimology-criminal justice

Predescu O.[1], Tomiță M.[2]

[1]*The Uninon of Jurists of Romania, Romania*
[2]*West University of Timisoara, Romania*
ceptim2005@yahoo.com

Abstract

The scientific demarche of the authors is based on the fact that when it comes to concepts like resilience or victimology, which cannot be understood or applied without a multidisciplinary, interdisciplinary or transdisciplinary approach (see the conclusion reached by the authors about the possibility of apparition of a new discipline, namely legal resilience), legal sciences specialist's skills in general and of those in the field of criminal law, in particular, along with those of experts in psychology, psychiatry etc. are particularly important. The authors place the above mentioned concepts at the law-psychology-psychiatry interface and analyze them in terms of criminal justice and of the relationship of persons involved, respectively, victims of offences (juvenile and adults alike) with society and with the aggressor, both before committing the criminal act and thereafter. In addition, with respect to resilience and victimology, after it is underlined that they have no unique, generally accepted definitions, the essential points on which there is agreement from those involved in researching these fields, as well as the exchange of information and procedures performed on the border between resilience and victimology are revealed. At the same time, criminal justice is treated not so much under the retributive aspect, but more from the point of view of reparatory, restorative justice, of the means by which it contributes to the mental health of the victims, of the populations who live in traumatized societies, to repairing social trauma, to establishing the causes and to preventing victimization etc.

Using strong arguments, the authors show the role that resilience and victimology have in the work of justice in general and of the criminal one in particular, concluding that this work should, after all, have as a recipient the person who suffered the consequences of the illegal act or of the traumatized family or social background.

Keywords: resilience, legal resilience; victimology; victimization; criminal justice; reparatory justice (restorative).

The role of criminal justice in preventing and combating offences and the protection of their victims.

One of the important activities of the state, which lies in resolving law disputes through specialized bodies of law, is *justice*. This is done by courts and the judges that compose them are independent and subject only to the law [1]. Administration of justice seeks termination of the conflict report, its result having consequences, primarily individual, concrete, but more or less, general, abstract, targeting all members of society. Thus, the immediate beneficiary of the act of justice must be the victim of an unlawful act. Violence can be moral or physical. Thus, the law criminalizes violences coming from other persons than the perpetrator, and not selfaggressions [2].

As in the case of justice in general, the recipient of the administration of criminal justice is or should be the person who suffered the consequences of the illegal act, namely the consequences of an offence. Guilt has the form of direct or indirect intention [2]. More than any form of justice, the criminal one "implies, on the one hand, granting increased attention to the person injured by the act constituting the offense, and, on the other hand, involves at the same time the prominent participation of government bodies" [3]. It is imperative to emphasize that compared to other forms of justice – extracriminal justice, criminal justice leans more on protecting both individual and general interest. Even if individual interest is protected in relation to the specifics of the injured party, the victim's interest is included within the larger public, general interest sphere, since the work of protection of victims of offences is one that exceeds the borders of particular needs and interests, even though it implies, as shown above, their consideration.

Specialty literature [3] has correctly shown that criminal law is necessary as long as serious antisocial acts will be committed in society, this remaining "probably the only acceptable solution that provides means for preventing and combating criminality". Thus, due to the commission of offences, injured people in need of

juridical protection will exist. Their protection, although it can be achieved through extrajudicial means, however the main way remains the law, because if they become victims of offences, this means that extrajudicial prevention means failed in their fight to prevent criminality, the intervention of law as backup to prevent and combat activities of illicit nature being imposed. Finally, in this context, the last backup solution is criminal law, which "has as integrated element of its general purpose (preventing offenses), the **protection of victims and prevention of offences** [3]".

Therapeutic and restorative justice. Their importance in repairing the prejudice suffered by victims of offences and in their recovery after the trauma suffered.

At the interface law-psychology-psychiatry, the first and most popular element met there is *therapeutic jurisprudence [4]*, defined as "the study of the effects of legislation and of the legal system on the behavior, emotions and mental health of individuals: in particular a multidisciplinary examination of how law and mental health interact [4]". We believe that the best example on highlighting and deepening the relationship between justice and the sciences that study human psyche is *restorative justice*, justice that seeks not only the criminal prosecution of those responsible of offences, but also to repair the injustices committed, the prejudice suffered by victims. In this sense, specialty literature [4] contains presented and analyzed the results of research carried out in countries such as Argentina, Chile, South Africa and Rwanda, which have suffered because of "bloody dictatorships or serious events such as apartheid, civil war or genocide". In these cases, besides the problem of holding criminally liable those responsible for starting and conducting these events, the *post factum* issue was also raised, namely that of national reconciliation, of reparation of the national social trauma.

Victimization – causes, prophylaxis and the legal protection of victims of illicit acts.

The multidisciplinary science called *victimology* and related to it, the victim-offence relation, cannot be absent from the legal- mental activity consecrated sciences equation. As is for resilience, no generally accepted definition on the concept of victimology exists. Mainly, the conceptions related to victimology are divided into two categories: the first considers that victimology is a stream of criminology [1], and the second that it is a distinct science, either multidisciplinary, ancillary to criminal sciences, or a *sui generis* science, having concerns centered on the study of victims of illegal acts or of such extra-human events [2].

For our study however, important is the link made by Mendelshon between victimology and "clinical" or "practical" victimology [see Mendelshon, *Victimologia generală* [3], considering that not only victims of offences, but also victims of natural disasters, genocide, ethnic conflict and war victims should be part of the scope of victimology. In his turn, in *The Show of Violence*, Wertham shows that it is "impossible to understand the psychology of the murderer, without understanding the sociology of the victim" [3].

Of the many definitions of the concept of victimology, we understand to remember, especially for the time we find ourselves in, the following: "victimology is a multidisciplinary science that studies the **causes of victimization, the legal protection of victims and the prophylaxis of victimization** through effective measures" [3]. Among the essential ideas for analyzing the concepts of vulnerability to and victimization, formulated in the more recent specialty literature, we believe that the following bear significance for our research: vulnerability to victimization as a predisposition, increased capacity of the individual to become a victim of criminality; it is generated by all the personal traits that interact with external factors in a given situation; not only persons vulnerable to victimization exist, but also those that are not vulnerable; vulnerability to victimization is not of fatal character.

Therefore, victimology has an etiological side, a prophylactic and a protective one.

For example, a person can become the victim of an offence for different reasons, such as: failure to take preventive measures, provocative behavior of the victim (for example, the challenge may consist of violence, serious prejudice to human dignity etc.), certain particularities of the victim's personality, social factors, economic factors etc.

As concerns the prophylactic aspect, it consists of the adoption of new measures to prevent the victimization of individuals and to study the existing ones.

The transdisciplinary approach of resilience.

The notion of resilience and the main aspects that underlie its relation with the legal factor (examples). Legal resilience – new concept, features and specific measure. Taking into account those highlighted above, we consider that both the legal component (especially that of law and criminal justice, including victimology) and that of the sciences whose object of activity is the human psyche, are two distinct

reality levels that do not exclude one another and that share the person or group of persons, victims of criminality. At the interface between them, in the process of building a new emancipatory development of the passive subjects of the criminal phenomenon, a new level of reality may appear - independent from, but closely linked to the two - namely *legal resilience*. Obviously, for this new reality to take shape, it is necessary that both law and the sciences related to the human psyche start a real, permanent and substantial dialogue on the topic in question, in a complementary and integrative vision, avoiding "exclusivist" and "technicist" cantonment. It is the establishment of normality in the researched field, as well as really connecting to the new demands of our society.

To better understand what we wish to show in connection with this new concept and to be able to define it, it is necessary to return to the idea or the concept of resilience, for later to use examples to point out the main issues underlying the relation between resilience and the juridical factor.

Throughout life, man undergoes a series of shocks, including those where he finds himself to be the victim of an offence, which may influence either his development or his destruction. We consider that the category of offenses causing serious damage to those who become their passive subjects are: offences against bodily integrity or health (for example, hitting or other violence, injury, ill-treatment of minors); offences against personal freedom (for example, illegal confinement); trafficking and exploitation of vulnerable persons (for example, slavery, human trafficking, trafficking in minors); offences against sexual freedom and integrity (rape, sexual assault, sexual intercourse with a minor); genocide, offences against humanity and war offences (genocide, crimes against humanity, such as subduing a population or part thereof in order to destroy it, in whole or in part, to conditions designed to determine its physical, total or partial destruction, torture, inhumane conduct during war etc.), terrorism etc.

Essential for our analysis is to emphasize that resilience, as a positive form of neo-development, does not take place in an easy process, but rather involves a complex process, a resilient course being the "result of a nonlinear process, often composed of nonresistance and nonresilience periods, as it contains resistance strategies" [5].

Both in the resilient process of identity reconstruction (especially in the case of assisted resilience) as well as in the prevention and combating of victimization, the scientific organization of specific activities within an institutional framework plays an important role.

It is well known that traditionally, institutions have committed to help individuals in traumatic situations likely to stop their development and threaten their existence, through assistance that relied and still relies on certain regulations, mandatory for the assisted persons.

In this context, assisted resilience proposes new institutional practices that shift from the traditional model.

Having in view the considerations on the relation between resilience and specialty institutional environment, in the following we will briefly refer to the bodies involved in preventing and combating victimization in Romania, especially those which deal with the resilience field, for finally to attempt to introduce and define the legal resilience institution.

It is eloquent to emphasize the significant concern existing at international, regional and national level for the protection of victims of criminality, through the adoption of normative acts on the protection of victims of offenses or relating to the prevention and combating of certain types of offences, including the rights and protective measures awarded to the victims of these offences.

In this context, however, the institution of resilience in general and of assisted resilience in particular, does not find a well-defined, custom place, in the sense that no specific legal framework exists that delineates its particularities, importance and role among the rights and psychological measures enjoyed by the victims of offences in the complex process of counseling, rehabilitation, social reintegration, retention or reinventing of their identity.

Also, the absence of a regulatory framework on resilience as a positive form of neo-development of the victim of an offence also negatively influences the activity of the judicial bodies lacking the possibility to inform the victims of offenses that they may enjoy resilient counseling and education from experts in the field, in an institutional framework, under the conditions of the law. Obviously, the victim would be the one that would ultimately opt for this form of counseling and education.

Discussions and conclusions

To fill this gap, a new concept, namely *legal resilience*, makes its way in the interface law-psychology-psychiatry. We feel that in those presented above, we brought enough arguments in its favor, but a definition of legal resilience cannot be easily formulated. However, assuming the risk of any scientific research, especially when it comes to lesser addressed and therefore lesser known concepts and institutions, we will attempt to define this notion.

Thus, *legal resilience can be defined as the discipline that brings together the efforts of specialists in the field of sciences dealing with the human psyche and of those in the field of law (theorists, but also practitioners), including that of victimology, in view of the multidisciplinary study of how restorative legislation and justice, on the one hand, and resilience (especially assisted resilience) on the other hand, may interact in order to provide the necessary framework to support victims of offences in breaking free from the victim status and in fully manifesting their desire to develop again, to soundly recreate themselves, using their own way of perfecting themselves*.

We feel that in order to attain this goal, the specialists mentioned above, using specific means and methods of their fields of knowledge, should analyze and propose a series of measures, as follows : a) greater exchange of information and procedures taking place at the border between resilience - victimology - law; identifying the means by which criminal justice, especially the restorative one, contributes to the mental health of the victims, an important role in this respect being that of judicial bodies having information on the relationship of victims of offences with society, both before and after the commission of the criminal act; amendment of the legislative framework in the sense of compelling the judicial bodies to inform the victim of an offense that he can opt for the assisted resilience component within the psychological counseling services. For this to take place, the legal framework should be complemented with provisions on the establishment, organization and functioning of assisted resilience departments within psychological assistance services. They would have as main activity objective supporting the victim in the work to rebuild, by means of assisted resilience, their own identity after suffering the trauma, meaning to leave room for personal initiative, to foster creativity, to enable change, to always appreciate as possible the positive development of the individual and so on; central and local authorities should include the resilience problematic in the development strategies and programs and grant logistics, information and material support to the departments specialized in this field; a review of the criminal legislation in relation to the position of the victim in the criminal law and criminal procedure system, in the sense of strengthening the protection of victims of offences, including by repairing the psychological damage suffered by them through the methods and means of resilient counseling and education. In addition, we feel that, in this way, resilience would also have a significant role on a legal plane, namely in terms of delinquency prevention, but also the protection and recovery of victims of offences etc.

The over-indebtedness of the states, companies and population

Sandor F.

National Bank of Romania
florin.sandor@bnro.ro

Abstract

This paper focuses on treating the *out of court* solutions of the over-indebtedness of states, legal entities and individuals, seen through the need of the existence of a economic-financial stability which should allow for the continuous development of the Romanian state and its citizens. It is necessary to approach the topic of over-indebtedness as a whole, as there is a tight relation between the excessive indebtedness of the states and companies and the over-indebtedness of the population, as individual economic resilience is strongly related to the general status of the economy.

Keywords: over-indebtedness, state, company, individuals.

Introduction

The term of over-indebtedness is currently very used, that is why we welcome the choice of this topic that needed a qualitative debate in order to be deeply understood and in order to clarify a series of legal controversies related to this phenomenon.

Along this paper, we shall mainly focus on treating the *out of court* solutions of the over-indebtedness of states, legal entities and individuals, seen through the need of the existence of a economic-financial stability which should allow for the continuous development of the Romanian state and its citizens.

We considered it necessary to approach the topic of over-indebtedness as a whole, as there is a tight relation between the excessive indebtedness of the states and companies and the over-indebtedness of the population, as individual economic resilience is strongly related to the general status of the economy.

Over-indebtedness of the states

1.1 Overview on the excessive indebtedness of the states

According to the dispositions of the *Government's Emergency Ordinance no. 64/2007 on the public debt*, the public debts represents the entirety of the liabilities of the type of local and governmental public debt, that may be expresses in national or foreign currency.

The public debt represents the entirety of the state debts towards its external and internal creditors at a given moment. The internal public debt is represented by loans to which the creditors on its own market subscribe. The external debt is made up of loans contracted by the state from banks located abroad and from regional and banking – financial institutions, from the governments of other states as well as from the international capital market, situation when the debentures in foreign currency are placed on the stock exchange situated in other countries.

The medium and long term external debt for Romania was of 76,951 billion EUR on the 31st December 2013 (79, 7% of the total external debt), in decrease with 0,5% as compared to the 31st December 2012. On the same date the short term external debt was of 19,491 billion EUR (20,3 % of the total external debt). [1]

The banks borrowed almost 23 billion EUR from abroad, namely a quarter of the total external debt of Romania. The amount is higher than the debt of the Romania state towards the external creditors, 18 billion, or the one of the National Bank towards the IMF, 9 million. By far, the highest external debt is in the private sector, of almost 40 billion EUR, generally debts of the foreign companies' subsidiaries towards the parent company.

Despite all these, although there are still voices that do not see the risk of this deficit, I appreciate the opinion showing that "*Our concern is not to have a zero budgetary deficit, but a deficit which can be managed. With a zero deficit one cannot develop, especially as the case is for Romania*". [2]

Although the debts of the administrative – territorial units (county councils, local councils, city halls) represent a distinct category as compared to the governmental public debts, they also fall under the name of public debt.

The local public debt is made up of the direct local public debt and the guaranteed local public debt. The direct local public debt represents the entirety of the liabilities of the administrative – territorial units at a certain time, coming from the refundable financing directly engaged by them, on a contractual basis, according to the Emergency Ordinance no. 64/2007 and of the Law no. 273/2006.

One can notice a sort of autonomy for managing the resources by the administrative – territorial units. This autonomy has still some control limits as the contracting and guarantee of the refundable financing, for performing the public investments of local interest, as well as for refinancing the local public debt is done by the administrative – territorial units only following the previous approval of the Authorization Commission for local loans within the Ministry of Economy and Finance.

The international markets become more "nervous" when the public debt in many countries, including Romania, exceeds 40% of the GDP, although the European limit is at 60% [3]. In order to avoid the situations of payment default, Romania, as other countries, adopted a series of preventive measures.

1.2 Preventive measures

In the past years it was proposed to introduce into the Constitution some provisions regarding the budgetary deficit. Thus, the proposal provided that the budgetary deficit could not exceed the limit of 30% of the GDP, while the public debt could not exceed 60% of the GDP We do not know the reasons that prevented the introduction of these limits into the Constitutions although it would have been virtually an alignment to the criteria imposed by the Treaty of Maastricht.

The economic imbalances occur because some countries – like Germany – have large commercial excess, while other – like Greece and Portugal – have large commercial deficits. Under this circumstance, the countries with deficit borrow from the countries in excess in order to finance, for example, a real-estate bubble (as it happened in Spain and Ireland). When the bubble blows, EU must intervene with emergency loans.

Four of the six legislative proposals treat the deficit and the debt, consolidating the Stability and Growth Pact. The other two introduce the surveillance of the macro-economic imbalances. Up to now, the accent was on the observance of the 3% limit for deficit. From now on, the public debt will be in the spotlight, while keeping the limit of 60% of the gross domestic product [4].

Moreover, there is the desire to automatically sanction the states that do not observe the legal commitments related to debt and deficit. Once proposed, the sanctions – of 0,2 – 0,5% of the gross domestic product – shall be rejected only by majority of votes.

The administrative-territorial units are forbidden to access loans or to guarantee any type of loan, if the total amount of the annual debts, exceeds the limit of 30% of the arithmetic mean of their own revenues.

1.3 Solution

Restructuring – *Greek solution* - On 2 May 2010, the Eurozone countries and the International Monetary Fund (IMF) agreed on a €110 billion bailout loan for Greece, conditional on compliance with the following three key points: (i) Implementation of austerity measures, to restore the fiscal balance. (ii) Privatisation of government assets worth €50bn by the end of 2015, to keep the debt pile sustainable. (iii) Implementation of outlined structural reforms, to improve competitiveness and growth prospects.

Debt default - *Argentina solution* - During the last week of 2001, the Rodriguez Saá government defaulted on the larger part of the public debt, totalling US$132 billion. By the end of November 2001, people began withdrawing large sums of dollars from their bank accounts, turning pesos into dollars and sending them abroad, causing a bank run. On 2 December 2001 the government enacted measures, informally known as the *corralito* [5], that effectively froze all bank accounts for twelve months [6], allowing for only minor sums of cash to be withdrawn, initially $250.

Excessive indebtedness of the companies

During the crisis stage of the economic activity, crisis that may include several branches and sectors or the national economy as a whole, the business environment gradually degrades as certain imbalances occur. The macro-economic indicators register abnormal values and the investments, production, request to consume, employment, salaries, profits, sales, exports or securities exchange rate tend to decrease, which confined and marks up the credit.

1.1 Calculating the Debt Ratio

The debts of a company are usually measured up by means of some *economic indicators:*

The general debt ratio: It is a general indicator of indebtedness and it calculates the proportion in which the total assets are financed from other sources than its own, such as credits, suppliers, state debts. Under normal conditions of activity, the indebtedness degree has to be around 50%. A limit under 30% indicates a reserve in resorting to credits and loans while over 80% a credit dependency, an alarming situation.

The financial indebtedness degree	
Under 30%	Low financial risk
Between 30-60%	Average financial risk
Over 60%	High financial risk

As for individuals, the main cause of over-indebtedness are the over-dimensioned loans, which together with other factors such as the failure to adjust the business model to the major fluctuations in the external environment, the lack of budgeting and rigorous budgetary operations which should signal the possible risks in time, the failure to cash the debts in due time, the dramatic decrease of sales leading to the change of the business model, may cause situations of going into payment default or insolvency.

The financial stability: a more refined version of the analysis of the indebtedness degree involves the reporting of the long term debts to the value of the invested capital (permanent). The indicator is one of the calculation elements the companies consider when classifying the security margin of indebtedness.

There are other indicators used in calculating the degree of indebtedness: *the global financial autonomy, the financial leverage, the financial lever, the interest coverage ration – RAD, the global solvability (SG), the patrimonial solvability (SP).*

1.2 The analysis of the situations of excessive indebtedness

The still modest dynamics of the economic activity, associated to the tendency to restrain the credit activity caused the worsening of the financial indicators of the companies, affecting their activity as well as the quality of the credit portfolios held by the banks.

The still fragile macro-economic context brought about the continuation of the growth in volume of the non-performing credits reported by the credit institutions, but we find a deceleration of their rhythm to accumulate (this being at 17,0% in August 2013 and at 22,0 % in December 2012, as compared to 28,9% in 2011 and 59,8 % in 2010; annual rhythm, nominal terms). The range of evolution of the indicator was also caused by the basic effect, taking into account the restraint of the volume of credits. [7]

The Romanian companies continually increased their indebtedness degree from the beginning of the crisis, and certain sectors of activity accumulated an important level of debts (as related to their own capital). Moreover, there is a tendency for some companies to manage their debts by initiating measure against the creditors (either constrained by the current unfavourable circumstances, or deliberately).

The volume of non-performing credits in foreign currency in the case of companies registered an increase of 73,7% in the period December 2011 – August 2013 (as compared to 53% for the RON credits, in the same period). The gap between the ratio of non-performing credits in RON and foreign currency was cancelled in August 2013 (23.4% for RON respectively 23.5% for foreign currency) as compared to 4.3 point in December 2011.

The payment discipline of the companies deteriorated at the level of the commercial relations with the business partners and those with the state.

1.3 Preventive measures

In view of preventing the over-indebtedness, the National Bank of Romania implemented additional measures of prudence by issuing the Regulation no. 17 on the 12th December 2012 – *Regulation regarding some credit conditions*, so that the credit standards became more restrictive.

The novelty of the mentioned regulation as compared to the previous regulation in this field is the extension, in certain parts, of the addressability sphere by including some new categories of creditors, as well as the establishment of the assumptions for the prudent ongoing of the credit activity in foreign currency of the non-financial entities, not protected at currency risk.

The new regulation also sets the means in which the warning of the debtors exposed to currency risk takes place, by imposing the creditors the obligation to show, upon each request of foreign currency credit

granting, the level of the payment liabilities for the requested financing under the terms existing on the date of request, and, as a comparison, the adjusted level following a possible severe depreciation of the related national currency, if the situation requests it with a possible increase of the interest rate.

1.4 Solutions

As we have previously shown, the over-indebtedness situations, if not solved by *out-of-court* solutions, may create payment default conditions, insolvencies and financial crises, which may be solved only by juridical solutions or mixed ones, and the results shall be more diminished for the creditor as well as for the debtor. It is a generally accepted principle at international level that the restructuring performed outside the judicial procedure bring a lot of benefits to those involved, being much more flexible and efficient than the judicial ones.

Restructuring the commercial liabilities. In order to support the companies and credit institutions, the National Bank of Romania, together with the Ministry of Finance has drafted The Guidelines for the Out-Of-Court Restructuring of the Companies' Liabilities. The provisions of this guide, although they have the nature of a recommendation, are very useful because they provide for all the necessary principles and guidelines in order to restructure the liabilities out-of –court.

Broadly speaking, restructuring means both restructuring of loans or debts through change of maturity date [8], rescheduling or [9] refinancing and restructuring of companies.

The restructuring of companies means to totally or partially re-orient/resize/redesign the company's activity in order to maintain or consolidate a competitive advantage on the market and provide viability of the business.

The causes that determine restructuring and major interventions in the company's activity are those that affect its survival: rapid decrease of the company's sales and market share; accentuated decrease of profitability as a result of continued growth of cost; major difficulties concerning financing the business on a short and long term; general degradation of the performance indicators.

Other causes that may trigger a restructuring process of the company are those that adversely affect performance and potential business development: inefficiency of the existing management system of the company; failure to adapt the company's objectives and strategies to the general context of the business environment.

Over-indebtedness of the population

There is no doubt that through credits citizens have improved the quality of their lives and access to essential goods and services, which would have otherwise been inaccessible or would have become affordable only after a considerable while, such as housing or means of transport. However, if the conditions under which credits are granted do not have a durable character – if serious problems concerning the job appear, if the monthly burden of indebtedness exceeds a reasonable percent of the monthly income available, if too many loans have been made or there have not been made enough savings to help out people in times of financial problems.

The causes of over-indebtedness are multiple and, paradoxically, even if its main cause is considered to be only credit, the facts contradict this statement and bring out the existence of a multitude of causes which generate over-indebtedness, such as unemployment and worsening of work conditions, divorce, death of one of the spouses, illness or accident, failure in self-employed activities, advertising and marketing campaigns which incite the population to intensify consumption, high interest rates, poor management of the household budget, loss of contracts or markets, increase in the price of utilities or fuel, raising taxes, rising inflation, the exchange rate etc.

1.1 Analysis on the indebtedness of the population and the credit risk

Indebtedness is relatively broad in the Romanian population, and debt is generally contracted on a long time horizon [10]:

- the number of people indebted to banks and IFN (non-banking financial institutions) is 4,31 million (in June 2013);
- it represents 43 % of the active population;
- the average duration of the credit is 21 years for the exposures secured by mortgages, respectively 6 years for consumer credits which have not been secured by mortgages;
- the amount of indebtedness from domestic banks and IFN(non-banking financial institutions),(including externalized credits) is significant (115,3 billion lei in June 2013, dropping from 116,5 billion lei in December 2011).

In terms of the number of households affected, *the over-indebtedness level* of the Romanian population is more serious compared to the average recorded in the EU. According to a survey of the European Commission [11], over 30% of the households in Romania were over-indebted [12] (in the year 2011), placing our country in the far extremity of the distribution.

In making regional comparisons regarding the indebtedness of the population, along the level indicators one must take into account the structural characteristics manifested in Romania, as follows:

(i) Romanian debtors with low income have a relatively important weighting in the banks' portfolios. (ii) Debtors with a net income below the minimum wage [13] present the highest level of indebtedness (62%, as opposed to 37% on the total economy, median values in June 2013, Graph 3) and the highest asymmetry of the level of indebtedness, while the tendency is of sharp deterioration compared to the other categories of income. Generally speaking, people with low income are the most susceptible of having problems with the timely repayment of their financial obligations

1.2 Preventing over-indebtedness of the population

The National Bank of Romania has consistently undertaken and updated, in its field of competence and within the boundaries of its attributions concerning providing financial stability, *approaches in order to avoid excessive indebtedness of the population*, by imposing a minimum set of conditions which must be observed by the borrowers in their relation with the clients- individuals, so as to ensure that the principles of responsible crediting have been implemented.

Such measures are the ones stipulated in the following legal acts: Norm no. 15 from 18/12/2003 concerning limitation of credit risk for consumer credit; Norm no. 10 from 27/07/2005 concerning limitation of credit risk in credits for individuals; Regulation no. 3 from 12/03/2007 concerning limitation of credit risk in credits for individuals; Regulation no. 24 from 28/10/2011 concerning credits for individuals.

1.3 Legal treatment of the debtors and the recovery of debts

In this respect, the National Bank of Romania has played an active role and has drawn up with the Ministry of Finance an important and very useful document meant to support the creditors but especially the debtors Guide for the *out of court* restructuring of loans secured by mortgage.

The guide establishes the principles which define negotiations and it recommends that before starting the enforcement on the mortgage, the contracting parties shall take into consideration and bring up for discussion any possible solution to restructure the loan, as a form of economic resilience. The following solutions may be taken into consideration:

a) The lender agrees with the borrower on the modification of the maturity date/ or the amount to be paid of one/more interest rates in balance without exceeding the initial duration of granting the loan.
b) The lender agrees with the borrower on the interest capitalisation or outstanding amounts. This option usually implies a prolongation of the maturity date of the loan.
c) Another modification of the contractual conditions can be the modification of the interest rate type or of the interest rate amount in the sense of reducing the monthly instalment for a limited period of time or throughout the crediting period.
d) The lender agrees with the borrower with regard to the refinancing of the loan which records amounts overdue with another loan. The initial loan agreement shall be reimbursed based on a renewed loan agreement. This option allows the borrower for example to replace a loan expressed in euro with a loan expressed in lei or over an extended period of time if the crediting policy of the lender allows it.

The risk of default and credit insurance

Sferdian I.

West University of Timisoara (Romania)
sferdian_irina@yahoo.com

Abstract

The risk insured within credit insurance qualifies as a risk in evolution, which requires constant supervision from both the insurer and the insured. To this end, the insured is bound to notify the insurer of any late payment or extension of the date of payment.

The risk of default can originate in the insolvency, insolvability or even bad faith of the debtor, which does not honour his obligation to pay at the due date or within a certain term of maturity.

The failure to pay a debt when due does not constitute a loss in itself and is considered as merely incidental to the obligation since it does not change the amount of the claim by itself. Nevertheless, the amount of the claim non-paid when due no longer corresponds to its face value because it suffers a depreciation, a loss of value, which depends upon the conduct of the recovery procedure and the erosion of the payment currency during this period, seen as factors that influence the economic resilience of the parties.

The damage incurred by the creditor is the result of a financial imbalance because, even if he can appeal for the integral recovery of the claim, with default interest, he is forced to use his own funds, which generates a liquidity crisis and a damage which, in this case, becomes permanent.

The downstream insurance is the only form of credit insurance which removes, for the creditor, the credit risk. Upon expiry of the payment term, the downstream insurer intervenes immediately so that all debt recovery costs and disadvantages of the late payment are borne by the insurer, who subrogates himself to the rights of the paid creditor.

Key words: risk of default, credit, insurance, credit risk, insolvency

Introduction

Credit risks seriously affect the commercial activity, so lending companies are forced to protect themselves financially through the conclusion of insurance contracts which cover the credits they grant. As the main object of credit insurance is credit debt, estimated to be a monetary debt and, at the same time, a primary claim, we will make, first of all, some brief remarks regarding the notion of credit and credit claim, after which we will present the main features of the credit insurance contract and the forms, traditional or rather new, of this type of insurance.

The risk of default can be controlled and insured in a particular country only if it is predictable and can be quantified, i.e. in the conditions of legislative, economic, financial and commercial stability, and not when it occurs amid an economic crisis and insecurity caused by a frequently changing legislation [1]. Therefore, although the Civil Code currently regulates this form of insurance, it hardly finds its place within the overall insurance activity.

The notion of credit

Credit is defined as the chronological gap which separates a service from its consideration. The consideration consists in the payment of a sum of money and has a primary nature since it represents the very object of the insurance contract [2].

Thus, there is no credit if one of the contractual parties benefits from a term, and the service must be rendered in nature. One service, for instance, which is not covered by credit insurance, is the risk of non-delivery of the merchandise. Also, the credit insurance does not cover the reimbursement of the paid price due to the occurrence of a cause of ineffectiveness of the contract.

Where the seller agrees to their co-contracting party a term for the payment of the price, even if there is a clause which provides for the payment in instalments of the respective price, the risk of default of the price at maturity may form the object of the credit insurance contract. The situation is similar in the case of a lease of

goods contract, when the payment of rents shall be made at a due term or of a works contract, when the contractor can insure their claim against the work's beneficiary.

Also frequently encountered is the insurance for financial credits, practiced domestically and especially internationally, such as the repayment of credits granted to a foreign country by a consortium of national banks or of the credits granted for a central bank in difficulty [1], [2].

Quality of insured party

Usually, the person entering a credit insurance contract is the insured creditor, who is also the beneficiary of the insurance. The quality of insured party can also be held by the debtor, who can insure their insolvability according to their obligations towards the creditor. Often, the insured parties are lending banking institutions, non-banking financial institutions, lending leasing companies, and not merely professionals or even natural persons, interested in insuring the risk of their debtor by means of a payment with instalments or at a term subsequent to the delivery of the merchandise.

In case the debtor has both the quality of insured and that of contracting party of the insurance, they may stipulate that the insurance indemnity be paid by the insurer promissory directly to their creditor, as a third party beneficiary.

Definition and legal characteristics of the standard credit insurance contract.

The doctrine has defined the credit insurance contract as the contract by which the insurer is committed, in exchange for a premium, to compensate the insured party for the damage they might suffer in case of occurrence of the risk which consists in the insolvability of their debtor [2].

The credit insurance contract has all the characteristics of a contract for damage insurance, marked by its unpredictable, pecuniary and *intuitu personae* nature.

Since we believe that it is not necessary to resume the analysis of these characteristics, we will only show that the justification for the *intuitu personae* nature is based on a personalized survey of the risk, on the confidence which the insurer has in the insured party and on the discretion and confidentiality of information.

We will highlight the particularities of the essential elements of the credit insurance contract, focusing on the insured risk and the insurable interest. Moreover, we will make some remarks regarding the influence which the object of the insurance – the credit claim - has upon each of the specific elements of this form of insurance.

Risk in the credit insurance contract

Credit insurance covers the normal risks of the professional, assessed according to the global turnover of the insured. Public law debtors are excluded since "public buyers" cannot be recognized as insolvent [2].

Also not covered will be any risks arising from natural or nuclear disasters.

The legislator uses, as apparently synonymous expressions, the following notions: insolvability risk, credit risk, commercial risk or financial risk. In fact, all risks which subscribe by these forms of insurance are financial risks, as they relate to financial imbalances which may consist either in the lack of liquidities (insolvency) or in the increase in value of liabilities in the detriment of the value of the assets (insolvability). Although both the insolvability risk (*del-credere*) and the credit risk are risks against financial losses, one cannot place them on equal grounds because if the credit risk presupposes the non-payment of the debt upon maturity, and therefore a "partial" damage, the insolvability risk presupposes the definitive non-payment of the debt due to the default generated by the value of the debtor's liabilities, which surpasses their assets [3].

The insurance relates either to the overall activity of the insured, or to a fraction thereof. In order to give a most accurate assessment of the value of the insurer's credits, the latter must provide to the insurer a "declaration on open policy". In this way, the insurer can globally estimate the insured party's activity, without being driven by the selection that the latter might do in order to ensure only those claims with the highest risk [2].

The declaration of open policy has as main functions the fact that it provides the basis for calculating the premium and represents, at the same time, a means of control and sanction of a possible anti-selection.

There are two main policies: "The whole turnover" and "The specific account". The first policy covers the total turnover of the insured, whilst the second comprises one or two nominated clients [4].

The credit insurer will cover *ex officio*, without the consent of the insured, a certain limit of the claims. We are referring to the debtors for whom the value of the required coverage is slightly high, the so-called "unnamed clients". For this purpose, it is necessary, however, for the insured to perform some preliminary checks: regarding the existence of the client, the absence of the client's insolvability, notorious or declared, the absence of the financial insolvency index [1], [2].

In the case of the "first delivery" clause, the insured benefits from a coverage within a ceiling for a premium and a single operation of a new client, without having obtained a prior consent, but upon condition of obtaining a subsequent agreement within a certain term, which relates to future operations. If the amount of the granted credit exceeds the "unnamed" limit, it is necessary to obtain the insurer's consent.

The risk insured within credit insurance is considered a risk in evolution. This characteristic requires a constant supervision of the risk, both from the insurer and the insured party, as a means of assuring the economic resilience of the parties. In this respect, the insured is bound to inform the insurer of any late payment or extension of the payment's due date.

Non-definitive nature of the damage by failure to pay upon maturity

The question has arisen if the failure to pay the claim upon maturity is likely to cause a definitive damage. The problem is linked both to the insured risk or, more precisely, the moment of its occurrence, and to the existence of the insurable interest. In other words, what is of interest is whether the damage must be definitive in order to entail the warranty and, if the answer is yes, in what does this damage actually consist.

In the doctrine of credits insurance, it has been shown that "a claim which is not paid is not, by this simple fact, a lost claim; the failure to pay upon maturity is not, in itself, a loss". Also, it has been considered that the failure to pay upon maturity some claims represents a mere incident of the obligation and it does not change, by itself, the value of the claim [2].

Impairment of the claim by failure to pay upon maturity

In the various forms of credit insurance, the damage occurs at different moments in time, situated during the lifetime of a claim. Thus, the damage may consist in a declared insolvability resulting from a judgment of judicial liquidation or bankruptcy or may be represented by the failure to pay the claim upon expiry of the payment's due date, at which time the insolvability, undeclared, is presumed.

If one analyses the situation of the claim unpaid upon maturity, one notices that, although its value remains unchanged, nevertheless, the creditor suffers damages since the delay in the payment of the claim disrupts their financial balance. We are not referring to the moratory damages to which the creditor is entitled anyway, but to the fact that, in order to honour their own obligations, the creditor must use their own funds, thus causing imbalances in their financial activity and, possibly, even a liquidity crisis. The damage which occurs in this case is, always, a definitive one [2].

The value of the claim unpaid upon its due date no longer corresponds to its face value since it suffers impairment, a loss in value, which depends upon the manner of conducting the recovery procedure. To this, one might also add the erosion of the currency during this time. Even though the failure to pay upon maturity entitles the creditor to appeal to recover the full amount of the claim, it is estimated that, from an economic point of view, some impairment occurs [2].

The insurable interest within the credit insurance and the theory of the definitive damage

Downstream insurance and insolvability insurance. In credit insurance, the insurable interest is a notion having a rather economic significance, which translates into the patrimonial relation between a creditor and its claim. Even if the economic relation is often doubled by a legal one, in order to ensure the validity of the insurance, it is necessary that the economic relation be submitted to risk.

In credit insurance, the insurer does not wait for the non-payment of the claim to be a definitive one. This means that the insured will be compensated, for example, in the downstream insurance, precisely upon the moment of maturity if the debtor fails to fulfil the payment obligation. Since the unpaid claim is not definitively lost, it was questioned whether the credit insurance observes the condition of the insurable interest. In the absence of the insurable interest, the indemnity does not compensate, but enrich. It is true that, in the downstream insurance, the insurer will bear all the expenses necessary for the recovery of the claim, once it is paid, upon maturity, to the insured. The insurer will not recover these expenses since they are not the object of the insurance.

In the doctrine it has been stated that, in the downstream insurance, when the insurer pays to the insured the value of the claim, the former does not compensate the latter for the damage suffered as a result of the non-payment of the claim upon maturity since this damage is not necessarily equivalent to the value of the claim; the insurance serves not for the compensation of the insured for this type of damage, but for the latter's protection against this type of damage [2].

The downstream insurance is the only form of credit insurance which removes all the inconveniences presented to the creditor by the credit risk. This happens because, upon expiry of the payment term, the downstream insurer intervenes immediately so that all debt recovery costs and disadvantages of the late payment are borne by the insurer, who subrogates himself to the rights of the paid creditor.

Unlike the downstream insurance, in the insolvability insurance, the one who bears the effects of the late payment, including the start of the claim recovery proceedings, is the creditor, who is forced to begin the necessary steps for the recovery of the claim and to continue them until the moment of the insurer's intervention.

In the insolvability insurance, the most common form of credit insurance, the creditor's compensation will be made under the terms stipulated in the policy, either upon the date of the pronouncement of the judgment declaring insolvency or at the closure of the insolvency proceedings.

Moreover, in the credit insurance with respite term, the claim is not permanently lost upon the expiry of the respite, date upon which the insurer shall pay the insurance indemnity.

In both the insolvability and the respite insurances are met the essential conditions of a genuine insurance, namely there is a patrimonial allocation of the insured interest. If the insured interest is injured in all cases where the claim is not paid upon maturity, as in the case of the downstream insurance, the former will be even more affected if the impairment of the claim occurs through its non-payment within a certain period of time after the due date, when the respite term expires or insolvability gets declared [2].

In these forms of insurance also, the amount of damage is variable in time and difficult to specify. In all cases, the insurer compensates all the damage suffered at the time of the harm, even if its value is not definitive and, afterwards, subrogates in the rights of the paid creditor, thus avoiding the enrichment of the insured creditor.

From the foregoing, it results that in any form of credit insurance, the payment of the compensation is not subject to the absolute proof of the definitive insolvability of the debtor.

The definitive nature of the damage is related to the terms of the contract. The damage is definitive in case of a breach of the insured interest under the terms of the policy.

Resilience and criminality

Stan George L.

Romania
george.stan@b.politiaromana.ro

Abstract

The evolution of the Romanian society, from the last decades, has been marked by huge transformations, from the political, social, economical and cultural point of view.

The difficult and long lasting transition, from communism to a capitalist society, as well as the regaining the right of free circulation have led, among other things, to an evolution of the recorded offences in Romania.

Characterized by discomfort, social danger and material and moral prejudices which it causes, criminality represents a complex phenomenon, materialized by the illicit actions of the individuals or of the offending groups.

Having as a main topic the individual, the connection between resilience and criminality can be seen by the two points of view, as it follows:

From the active subject of the offence point of view (the felon, the accomplice or the inciter) can be analyzed both his resistance before committing the offence (ante factum) and the given effort (post factum) for his change, the social integration and moreover, the avoiding of committing other offences in the future.

Concerning the passive subject of the offence (the victim), we can analyze the force which he opposes to the crime, as well as during the whole criminal process and his ability to recover both psychically and physically in order to come to his normal and individual state and to allow him to reintegrate in the social background.

The most eloquent example of the low resilience at the offence is that of juvenile crime.

The insufficient psycho-biological development, together with a series of social factors (the precarious family education, the school abandonment, the lack of supervision, the attendance to some doubtful places, the disorganized families, etc.) lead, to a great extent, to a deviated behavior of the children and teenagers.

Keywords: resilience, criminality, offence, juvenile crime.

Resilience and basic delinquency

The recorded criminality at present is, mostly, atypical and unpredictable. The free circulation outside the national borders, the access to all kinds of information, as well as, the using of the latest technology led to a variety of the offences and to the unusual ways of committing them. Also, the organized action of the offending groups and their specialization, simultaneously with the reduction of the execution period of time, led to serious problems concerning the investigation of the offences and the identification of the authors.

Definitely, ten – fifteen years ago, the Romanian law enforcement agencies were not informed about some kinds of offences such as: murder or robbery using fire guns; informatics offences or committed by technology or using the internet; fraud by declaiming of a false quality, the so – called methods “the prize”, “the car accident”.

In order to distinguish the process by which an ordinary person becomes the author of a planned offence, will be analyzed some significant aspects, which contribute to the diminution of the resilience to offence.

1.1 The family background

It is known the fact that, the personality of the individual is strongly influenced by the family background, the model, education and attention offered by their parents. The dysfunctions of this system constitute the main cause of delinquency, no matter if this is shown during childhood, adolescence or maturity. The lack of existence of a calm climate or of the understanding in a family, affective lacks, the low professional level or the cultural one of the parents, the frequent changes in the family background, the poor education offered by the family initially, promiscuity are elements which led to the diminution of the resistance of the child

to criminality. Usually, the individual originated from such a difficult background, will not accede to superior forms of education or culture and will be liable to committing offences, generally of judicial nature.

In adult's case, the tensions within the family between husbands and wives or parents and children, the dissatisfaction from the close people, the minimizing of their efforts or merits can also diminish the resilience to criminality. In the Romanian legislation, "the prevention and the fighting against violence in family are parts of the integrated politics of protection and support of the family and it represents an important problem of the public health." [1]

1.2 The educational background

The education received in the family constitutes the basis on which the knowledge and the abilities are gathered during the process of school enlightenment. Failure, absenteeism or school abandonment, in many cases consequences of the indifference towards school, the family opposition or the poor material conditions represent risks in the later individual development, including the resistance of offence. On contrary, a cultivated person shows an increased resistance, because he will be accustomed to analyze and to reason, he will carefully choose his friends and he will avoid the harmful relationships. Nevertheless, there are not just a few cases in which this people commit offences, being predisposed to the breaking of some legal economical standards (the so called "white collars") or the informatics ones, being given the high level of specialized knowledge they own.

1.3 Psychiatric disorders diseases, somatic sickness and disabilities

The mental, organic disabilities or delays in the intellectual development, obesity or anorexia, the appearance of some disabilities, etc. lead, most often, to an antisocial behavior, a deviated or a criminal one, arising from the frustration and the feeling of inferiority that they felt in. The resilience of these individuals is even lower when they live, learn or develop their activity in a hostile environment, which disclaims and pushes them away. In such a collectivity, the person feels abandoned, ugly and unaccepted; automatically he will develop a feeling of hatred against the others, which leads to aggressiveness. The specialists in judicial psychology consider that these offenders are among the most dangerous, being predisposed to committing some extremely violent offences.

1.4 Socio – professionals reasons

The low professional level, the poor adaptation, the absenteeism, the difficult communication or the conflicted relationships with workmates, the conflicts with the leading factors may affect the level of resilience. From the socio-professional point of view, the individual resilience has a special and important role, especially during the time of professional transition or accumulation of stress – "a syndrome constituted from the exacerbation, beyond the level of some simple homeostatic fittings, of some psychical reactions and their somatic equivalents (affects almost all body compartments) in connection, more often evident, with a configuration of unleashed factors which act intensely, surprisingly, persistent and/or suddenly and, sometimes, having a symbolic character of «threatening» (perceived or anticipated by the subject". [2]

Although devoid of interaction with professional stress, unemployed people are pushed to crime, often, by the entourage. The unsuitable places and environments are frequently combined with excessive consumption of alcohol, hallucinogenic or psychotropic substances and gambling. On its own initiative to cover daily expenses, being instigated by others or recruited by organized crime groups, they will slide inevitably to illegal actions.

1.5 Economical reasons

The diminution, the depreciation or even the lack of the means of living, the loss of the job are some of the factors which lead to delinquency, mainly together with the impossibility of finding another immediate job and a source of a legal income. Especially when these things appear independently from the subject will (inflation, the increasing of the money exchange rate or the devaluation of the money, unemployment, reorganization, mass layoffs) involving job loss, all these events impose, above all, the quick identification of solutions to ensure the livelihood of the family.

1.6 Conclusions

In most of the cases, there is a main defining issue that could explain the behavior of the basic offender. Be it physical or psychological trauma, the low level of training, lack of material needs or external influences, all this erode resilience to crime, especially during childhood or adolescence stage.

The resilience of victimisation

In judicial practice, the victim represents the passive subject of judicial offences against the person.

Identifying the victim's risk factors is determined, primarily, by the social background of the victims and its structure, by the values' typology which is considered to be harmed, by the socio-economic conditions in which the victims live, by the rules of conduct used and accepted by the victims. The risk factors also reveals the obvious way of responsibility, discernment and response of the victims to the aggressive act.

The favoring conditions of producing the victim's effect should be analyzed on various aspects: demographic, social, psychological and physiological. Knowing the conditions favoring victimization does not resume to the analyzing of causes (factors) but should also be established the conscious individual intentions of the victim to its manifestation. The favoring conditions come up as a product of a complex system of occurrences which diminish the resistance to victimization. These conditions can be contextual, punctual or typological; they increase the tensions, the conflicts and the differences between the victim and the offender, without triggering the act of aggression, attribute which always belongs to the generating causes.

1.1 Context factors

"To be in the wrong place at the wrong moment", best characterizes the contextual factors. For example, the initiation of some spontaneous conflicts with unknown people, traversing some unpopulated places are factors leading to the victimization, but not necessarily generated.

1.2 Typological factors

From the point of view of the age, the most exposed victims are children, teenagers or old people. Concerning gender, the female part is most exposed. Talking about the background, the people living in the rural areas are most exposed to the victimizing factors.[3]

The sentencing system of criminally responsible juveniles. Between resilience and resistance

Stănilă L. M.

Senior Lecturer, Faculty of Law, West University Timișoara, Romania
laura.stanila@drept.uvt.ro

Abstract

Currently, the concept of *resilience* is associated with different domains, such as scientific, social, economic, political, etc., outlining the new meanings of the concept. Thus, we can talk about psychological resilience, biological resilience, organizational resilience, urban resilience, institutional resilience, economic and financial resilience, social resilience, business resilience, etc .Resilience should be seen both as a characteristic of an element, object or entity and as a process that aims at the creation of this feature.

Given this brief preliminary explanation, the concept of resilience is particularly important in law, especially criminal law, due to the effects of applying a coercive rule on the individual who has adopted an anti-social behaviour, both in the short and average term - during the execution of the penalty imposed - and in long term - on social behaviour adopted post conviction. In this context the highly sensitive issue of criminal liability and punishment of juveniles who are criminally responsible is both a difficult and complex one, through the myriad issues that must be considered: age of the offenders, their personality, education, the possibility of social reintegration after a criminal conviction.

With regard to juvenile offenders, the State - holder of coercive power - is forced, in the penal policy delivery mechanisms, to find the most effective means to achieve the dual purpose of punishment: prevention and remuneration. But this task is an extremely difficult one, legislative developments in the field of criminal liability of minors with criminal capacity is illustrative in terms of difficulties in this process.

Keywords: juvenile offender, resilience, social reintegration, conviction, guidance and supervision orders, punishment, adaptability, educational process.

Methodology

In this study, in order to successfully achieve our scientific purpose, we are using a range of methods, such positivist method, based on the examination of the legal texts governing the criminal liability of minors. Then, using the historical method, we present the image of the Romanian sanctioning system of juvenile offenders from an evolving point of view. Comparative approach in international and European law has an important role, which is to highlight the fact that the reconfiguration of Romanian sanctioning system regarding juvenile criminals is the effect of pressure of the international criminal law.

Introduction to the concept of resilience

In this section we try to explain the concept of resilience and its connotations in criminal law. We shall explain the relation between resilience, social reintegration after conviction, personal adaptability, and psychic recover after conviction shock. We shall also try to focus on the role of probation services in managing the feedback between activity of institutions and personal behaviour of convicts.

The concept of *resilience* was first used in 1674 and was introduced in the technical circuit 100 years later.

Resilience has been defined in a multitude of ways, in terms of social life in which this phenomenon was observed. In the first place we cannot ignore the physical and technical connotation of the term, namely the ability of materials to withstand shocks without being affected in their material substance. Secondly, from the sociological perspective, the concept of resilience captures the connotation of adaptability – that means it highlights the capacity of an entity to recover and easily adapt after a relational shock or a major change in everyday life.

Resilience, although it cannot be confused with the social reintegration of juvenile convicts after serving the penalty imposed by the court, could not be analyzed without explaining the concept of social reintegration.

This shows that the effectiveness of social reintegration depends on the adaptability of resilient juvenile offender, depends on how he/she appropriates the values and aims of the educational process and skill development during the execution of guidance and supervision orders applied by the court.

Romanian criminal law sets as minimum age limit for criminal liability and criminal capacity, the age of 14, criminal liability may arise gradually depending on the degree of development of discernment and the presumptions provided by the legislation. There are three legal presumptions set by the Romanian legislator (known in the doctrine as different degrees of intensity of the presumption of lack of judgment in relation to minor's age): an absolute presumption and two relative presumptions as follows:

a) The absolute presumption - juris et de jure - of lack of discernment, according to, the minor under 14 years is not criminally responsible. Since this is an absolute presumption, it cannot be refuted by any evidence of the presence of discernment, operating by the force of law, juris et de jure. From the historical point of view, setting the minimum age under which criminal liability can not intervene no matter the circumstance is the result of conceptions related to the development of mental, intellectual and moral human being and as a result of ratification by Romania of international documents that we show in this study. If the absolute presumption of lack of discernment operates, the perpetrator cannot be criminally responsible, having no criminal capacity, according to Romanian legislation. However, in case of a minor under 14 years participating in a criminal offense with others (adults) who are criminally responsible, this form of participation to a criminal deed is called improper participation, and the adults perpetrators will be punished for a knowingly form of guilt.
b) The rebuttable presumption, juris tantum, of lack of discernment. A minor aged over 14 years to 16 years (unfulfilled) will be criminally responsible if it turns out that he committed the act with discernment. This is an exceptional criminal liability, as noted in the doctrine, because criminal liability is conditioned by the age limit and the existence of discernment.
c) The third presumption is a relative one, of the presence of discernment. A minor who is 16 years old is criminal responsible, having full criminal capacity. It is considered by the Romanian legislator that, at the age of 16, a person has reached the minimum standard of mental, intellectual and moral development, and imposing the criminal law it is possible. But still in this case there is a relative presumption, which means that if it turns out that, at the moment of committing the criminal deed the 16 years old minor had no judgment, he/she will not be found criminally responsible. Causes of lack of discernment are mainly due to mental disorders affecting the intellectual-cognitive and volitional capacities, but could be due to severe educational deficiencies.

The evolution of the Romanian legislation on the sanctioning regime of minors - 150 years of modern criminal law

In this section we attempt an overview of criminal regulatory provisions that have been adopted since 1864 to the present, highlighting the common elements and the elements of differentiation taken into modernism and the continuous development of modern criminal law. We have in mind a comparison between Romanian Criminal Code from 1864 – "Cuza" Criminal Code, the Romanian Criminal Code from 1937 – "Carol the Second" Criminal Code, Criminal Code from 1967 and the New Criminal Code – Law nr. 286/2009.

The new Romanian Criminal Code - Law no. 286/2009 and the new sanctioning system of juveniles who are criminally responsible

In this section we realize an insight into the legal provisions governing the sanctioning system of minors, the guidance and supervision orders, which are the innovations introduced by the new legislation.

The New Romanian Criminal Code – Law nr. 286/2009 in force since 1.02.2014 has attempted to correct the shortcomings of former regulations that regulate the sanctioning regime of juveniles who are criminally responsible, setting out in respect of them, a sanction regime distinct of adults, focused exclusively on guidance and supervision orders, privative and non privative of liberty. In the nearly 150 years since the first Criminal Code of Romania had been adopted, the conception of the Romanian legislator remains constant: it is recognized that juvenile offenders are a special category of offenders who require special legal treatment tailored to their age and their personality characteristics, yet education and training. Causes of an antisocial criminal behaviour of a juvenile may be various: lack in education, inadequate living conditions or simply influences of social environment, social groups and subgroups. But anti-social behaviour of juvenile delinquents should be punished, paying attention at the same time to educational process and shaping their personality for that the chances of reiterating a criminal behaviour in the future to decrease.

The New Romanian Criminal Code established a changed design in the Romanian criminal law instituting a sanctioning regime of the criminally responsible minors based exclusively on guidance and

supervision orders. The Romanian legislator indicates in the New Criminal Code that non - custodial guidance and supervision orders are prevailing. Custodial guidance and supervision orders characterized by privation of freedom may be taken only in special cases:

a) in case of the minor has committed another crime for which he was on an educational measure that has been executed or the execution of which began before committing the new offense for which he is now judged;
b) in case of the punishment provided for the offense committed is imprisonment more than seven years or life imprisonment.

Guidance and supervision orders applicable to criminally responsible minors under the New Criminal Code are non-custodial or custodial. Non custodial guidance and supervision orders are: civic training probation, supervision, weekends consignment, daily assistance. Custodial guidance and supervision orders are: internment in an educational centre and internment in a detention centre.

International instruments that changed the design of the Romanian legislature in the matter of sanctioning regime of criminally responsible minors

During this section we realize a review of international documents that have contributed in changing the Romanian criminal law in matters of sanctioning regime of criminally responsible minors as follows:

1.1 Declaration of the Rights of the Child 1959 [1]

The U.N. Declaration of the Rights of the Child (DRC) builds upon rights that had been set forth in a League of Nations Declaration of 1924.

1.2 Minimum Age Convention 1973 [2]

The aim of the Minimum Age Convention (MAC) is to establish a general instrument on the subject of the minimum age of employment with a view to achieving the total abolition of child labor (Preamble). Thus, each State Party is to "pursue a national policy designed to ensure the effective abolition of child labor and to raise progressively the minimum age for admission to employment to a level consistent with the fullest physical and mental development of young persons" (article 1).

1.3 U.N. Convention on the Rights of the Child 1989

The Convention on the Rights of the Child (CRC) is the most comprehensive document on the rights of children.[3] For the purposes of the CRC, a child is defined as "every human being below the age of eighteen years unless under the law applicable to the child, majority is attained earlier" (article 1).

1.4 European Convention on the Exercise of Children's Rights 1996

The European Convention on the Exercise of Children's Rights (ECECR) stresses in the Preamble the aim of promoting the rights and "best interests" of children.[4] To that end, it states that children should have the opportunity to exercise their rights, particularly in family proceedings affecting them; they should be provided with relevant information (defined as information appropriate to the child's age and understanding, given to enable the child to exercise his or her rights fully, unless contrary to the welfare of the child) and their views should be given "due weight"; and, "where necessary," States as well as parents, should engage in the protection and promotion of those rights and best interests (Preamble). The ECECR applies to children who have not reached the age of eighteen (article 1(1)).

Conclusions

In the last section, the fifth, we are trying to point out the role of the development of the Romanian legislation regarding the resilience of juvenile offenders and benefits of new regulation provided by the New Criminal Code regarding the resilience issue and social reintegration.

As related to the bio-psychical state of a juvenile, the imprisonment, provided by the previous Criminal Code for minor delinquents, even if its limits were reduced to half, appears to be less suitable for achieving the purpose of the criminal law in relation to juvenile offenders. The imprisonment was meant to be a way of coercion aimed to the rehabilitation of the major offender, based on a re educational process while for juvenile offenders would be required an initial education with appropriate means, in order to configure the minor's future behaviour.

Moreover, executing the sentence in a juvenile prison affects his/hers fragile mind because of harsh detention regime and the negative influence of other convicts. Under these conditions, we welcome the radical change of optics of Romanian legislator in the New Criminal Code. By creating a sanctioning system different from adults', with specific sanctions adapted to the physical, mental or moral development of juvenile offenders, the Romanian legislator has created effective ways to achieve the purpose of criminal law and the resilience of this special category of offenders. A resilient juvenile offender will succeed in avoiding future antisocial behaviours and will become a good citizen.

Wouldn't it be a shame to waste a good crisis? The role CSR could play

Stârc-Meclejan F.[1]

West University of Timișoara, The Faculty of Law, Romania
flaminia.starc@e-uvt.ro, flaminia.starc@drept.uvt.ro

Abstract

According to many economists' view, the global financial crisis is, paradoxically, the opportunity to do the important things one would otherwise avoid. Indeed, the European Commission showed in its renewed EU strategy 2011-14 for Corporate Social Responsibility (CSR) that the economic crisis and its social consequences have damaged consumer confidence and trust in business. But, by promoting CSR now, one may create conditions favourable to sustainable growth, responsible business behaviour and the generation of durable employment in medium and long term.

In line with this, the Commission defines CSR as "the responsibility of enterprises for their impacts on society". As the 2011 Communication of the Commission further underlines, CSR refers to companies voluntarily going beyond what the law requires, to achieve social and environmental objectives during the course of their daily business activities.

It is the essentially voluntary character of CSR that may conjure problems, risen by the faking of this responsibility, by companies only interested in building themselves a "good image", thus transforming it into a mere gadget marketing strategy. This is also one of the reasons underlying the European initiative aimed at creating a legal framework to assure the effectiveness of the CSR, as a means of promoting the economic resilience of a corporation, that we shall comment in this study, after having first thoroughly analysed the CSR concept from the perspective of the law.

Keywords: global economic crisis, CSR, soft law, business ethics, resilience

Defining the problem

The complex nature of the concept of CSR and the potential implications of the issues surrounding it explain the excess of papers written on the subject. Still, should anyone be tempted to think that everything that needed to be said about it was said, the 2008 crisis has proved him wrong, opening the gate for new reflection on the theme.

To be clear about what we mean from the beginning, let us refer, for example, to the topical issue that concerns the groups of companies. Nobody can deny the fact that they are playing the leading part today in global economy, international commercial transactions being mostly carried out among companies (*business to business*) and not among states (*state to state*)[1] and yet there is a generalized refusal to recognize their legal personality.

Legitimate instruments of gathering capital, the groups of companies give as such rise to many problems, as the "pretended" independence of the member companies also allows, usually the parent companies, to escape their different responsibilities and, eventually, their liability – be it social, civil, criminal or environmental [2].

Limited liability of individual companies enshrined by the law could become a source of unlimited evasion from responsibility for parent companies which sacrifice at will the interests of the parties involved, just as the commentary of Lord Macnaghten in the leading *Salomon v A Salomon & Co Ltd* case allows us to believe: "*The company is at law a different person altogether from the subscribers to the memorandum; and, though it may be that after incorporation the business is precisely the same as it was before, and the same persons are managers, and the same hands receive the profits, the company is not in law the agent of the subscribers or trustee for them. Nor are the subscribers as members liable, in any shape or form, except to the extent and in the manner provided by the Act*".[3]

Nonetheless, it is now widely accepted that the 2008 financial crisis had ethical dimensions, and that market development needs to go through the stage of securing the interests of all the involved parties. The European Commission [4] itself not long ago pointed out that "[t]he economic crisis and its social consequences have to some extent damaged consumer confidence and levels of trust in business. They have focused public attention on the social and ethical performance of enterprises […]".

The question we shall thus try to answer in this paper is what the role of the corporate social responsibility can be in this effort, which first supposes a reflection on the concept's background and external limits, and afterwards a thorough discussion on its legal consequences and effectiveness.

Contextualising CSR

Despite the traditional separation between what is moral and the realm of law [5], we are witnessing a return in force at the forefront of public concerns of morality, even though this time, in the newly accepted, modern form, of ethics, as the great French professor Bruno Oppetit remarked [6]. If, at first glance, this ethical awareness seemed to have been determined by Enron and World.com like spectacular corporate scandals [7]that burst very little before the 2008 financial crisis, as the above example of groups of companies points out, ethics is actually the answer to a more fundamental and persistent need, of finding sound reliable guiding lines, that increasingly grew in the business environment. So understood, Corporate Social Responsibility could be the long-awaited answer to the expectations of "modern times".

In 1932 already, Adolf Berle and Gardiner Means were publishing *The Modern Corporation and Private Property* and they were highlighting that "[t]he economic power in the hands of the few persons who control a giant corporation is a *tremendous force which can harm or benefit a multitude of individuals, affect whole districts, shift the currents of trade, bring ruin to one community and prosperity to another* (a.n.). The organizations which they control have passed far beyond the realm of private enterprise - *they have become more nearly social institutions* (a.n.)" [8].

And, as they further observed, "[t]he rise of the modern corporation has brought a concentration of economic power which can compete on equal terms with the modern state - economic power versus political power, each strong in its own field. The state seeks in some aspects to regulate the corporation, while the corporation, steadily becoming more powerful, makes every effort to avoid such regulation […]".[9]

Was then the prophecy confirmed? A short extract from a 2010 Internet article gives a very suggestive answer to that question: "When the Enron scandal broke, commentator Paul Krugman called it a bigger deal than 9/11—a comment that, while fatuous, helps illustrate the shock and awe generated by Enron's fall. The scandal shook people's trust in the economy and fed a popular cynicism toward business that permeates many aspects of our politics and culture".[10]

We need to emphasize here is that, though business law has always been largely impregnated by ethical concerns, at the beginning of the 20th century already serious doubts arose as to the value of the law, increasingly accused of ineffectiveness, and made up of principles that have seldom happened acted as prejudices and turned against its beneficiaries. The lack of confidence on the part of professionals and of the public at large in an economic system in which unlawful acts are somehow being encouraged *rather* than *repressed* thus caused a serious legitimacy deficit. [11]

Economy lives from its credibility, so that aware of the need to restore the fading legitimacy of the market economy, professionals of the different fields of economics, finance and company law commonly agreed that it would be wiser to set limits to their actions on their own. "This critical turning point, when decline in an actor's or institution's legitimacy forces adaptation (through re-legitimation or material inducement)" [12] is what explains the trend of independent development of business ethics.

This new emerging interest for business ethics on the part of professionals assuredly goes hand in hand with a "diminution" of the role played by the state. Such "disengagement" [13] on the part of the law-making bodies is so substantial in certain fields, like business law for instance, that it could be regarded as the recognition of a true complementary-power to the legal power.

What is new now is the fervour shown by the economic and industrial environments in giving a new impetus to the ethical concern and in systematising ethical principles.[14]

Presently, the body of rules that aim at promoting an autonomous ethics is considerable, mostly consisting of codes of best practices or of professional deontology, and rules and principles forged by international regulating bodies or organisations. CSR is a part of this larger ethical movement, professing a necessary substantial change in the perception of the role played by the corporation as a solution to the existing crisis of legitimacy. [15]

Relating CSR and the neighbour concepts

Defined by the European Commission as "the responsibility of enterprises for their impacts on society", CSR needs a few clarifications before the analysis of the nature and force of its rules, with the ultimate purpose of answering the question of its effectiveness, that we pursued in this paper.

As we have already shown, it is around the mid-20th century, at the heart of the debate on the role of business in society [16], that the idea that companies should develop rules founded on ethical values occurred, in order to counterbalance all kind of potential arbitrary acts from the part of directors or of the shareholders. [17]

Initially understood as a profit-oriented *shareholder model*, guided by the principle that the company's managers have to create as much wealth as possible to the shareholders' sole advantage, the corporate governance concept was soon extended to a more integrative *stakeholder approach*, professing that the company owes responsibilities to the society as a whole, be it its employees, its creditors and the consumers as a whole. In other words, what that new understanding tried to achieve was an integration of ethical concerns into the common legal approach to companies [18]. According to the new Guidelines for Multinational Enterprises Recommendations for responsible business conduct in a global context (revised in 2011), "enterprises should contribute to economic, environmental and social progress with a view to achieving sustainable development and respect the internationally recognised human rights of those affected by their activities.[19]

Indeed, at the time the model of "corporate citizenship" was being developed by jurists and economists, another idea, of sustainable development, emerged at international level, essentially aiming at achieving an identical purpose of integrating economic, social and environmental concerns. According to the European Commission, "sustainable development stands for meeting the needs of present generations without jeopardizing the ability of futures generations to meet their own needs […]. It offers a vision of progress that integrates immediate and longer-term objectives, local and global action, and regards social, economic and environmental issues as inseparable and interdependent components of human progress". [20]

It is in relation with these concepts, all embodying the need for flexibility, complexity, and for a new form of legitimacy, that corporate social responsibility emerged, to materialize the companies' contribution to the effort of achieving sustainable development. According to the European Commission, CSR represents "the responsibility of enterprises for their impacts on society". To that respect "[r]espect for applicable legislation, and for collective agreements between social partners, is a prerequisite for meeting that responsibility". But, "[t]o fully meet their corporate social responsibility, enterprises should have in place a process to integrate social, environmental, ethical, human rights and consumer concerns into their business operations and core strategy in close collaboration with their stakeholders, with the aim of: maximising the creation of shared value for their owners/shareholders and for their other stakeholders and society at large; and identifying, preventing and mitigating their possible adverse impacts".[21]

This is the general "state of mind" that favoured the emergence of corporate social responsibility, strengthening the idea of "corporate citizenship", by proposing that an undertaking's business, beyond legal constraints, can and should incorporate an ethical dimension, with respect to social and environmental concerns.

Interpreting the sources of CSR

Viewed from a "technical" perspective, CRS is the means by which the goal of assuring a responsible conduct in business is to be integrated into the strategy of companies [22]. It resides as such in a mixture of international texts and principles, European initiatives or internal texts [23]: corporate social responsibility has been the subject of a Green Paper and of a communication from the European Commission [24]; it is the subject of the UN launched "global compact" program in July 2000, of the 2011 OECD revised guidelines for the multinational enterprises[25], or of the ILO tripartite Declaration of Principles concerning multinational Enterprises and social practices[26], to name just the most important of its international and European sources. But CSR may also be found in the internal legislation which was adopted in order to implement these regulations. In Romania, for example, there has been made extensive progress especially in the field of environmental protection law further to the EU accession date, which resulted in a propagation of mandatory legal rules, which are all part of the CSR [27]. These examples show that CSR has at the same time international and national formal sources, with both soft and hard law versions, that all have in common the vocation of integrating values and ethical principles into the law[28].

It is also worth pointing out that, if most of CSR rules are now based on a non-binding voluntary approach, there is a present tendency of making them part of the binding enactments[29]. Besides, if the European Commission has first defined Corporate Social Responsibility as an essentially voluntary concept, "a concept whereby companies integrate social and environmental concerns in their business operations and in their interaction with their stakeholders on a voluntary basis" (July 2001), it now proposes as a new definition of CSR "the responsibility of enterprises for their impacts on society", specifying that "[r]espect for applicable legislation, and for collective agreements between social partners, is a prerequisite for meeting that responsibility". The Commission further shows that "[t]o fully meet their corporate social responsibility, enterprises should have in place a process to integrate social, environmental, ethical, human rights and consumer concerns into their business operations and core strategy in close collaboration with their stakeholders" (October 2011)[30]. We shall, however, discuss these issues into more detail a little bit later in this paper, after first elucidating a few necessary preliminary facts.

For the time being, what we should keep in mind is that CSR is a true "composite" of texts of different legal intensity. The role that it plays, then, is the same irrespective of the power of these sources, or of the international or national framework where they have been forged?

Let us take a look at them by turn. At the national level, first, as the European Commission laid down "*Respect for applicable legislation, and for collective agreements between social partners, is a prerequisite for meeting that responsibility* (a.n.)", which means that CSR supposes first the observance of the applicable legislation. The EC further provides that "[t]o fully meet their corporate social responsibility, *enterprises should have in place a process to integrate social, environmental, ethical, human rights and consumer concerns into their business operations and core strategy* (a.n.) in close collaboration with their stakeholders". This would mean, practically speaking, in Romania for instance, that CSR supposes compliance with the legislation concerning the protection of human rights or of the environment (not the imposition of such observance, as both human and environmental rights are already benefiting from the highest legal protection the law can recognize), on the one hand. On the other hand, CSR, as a complementary means, supports the implementation of these legally imposed requirements, so that statements and actions on the part of companies (as the adoption of different codes of best practices, for instance) will allow for a better enforcement of the legal protection of human or environmental rights, by way of an ethical responsibility commonly formulated by the parties involved and, thus, more likely to be respected.[31]

Is the role CSR plays in the international environment the same? In summary, the main applicable texts reside in the UN Global Compact, a strategic policy initiative for businesses that are committed to aligning their operations and strategies with ten universally accepted principles in the areas of human rights, labour, environment and anti-corruption.

The UN underlined the increasing ability and influence corporations have on the economic, political, and social dynamics of society. As such, Global Compact assumedly "exists to assist the private sector in the management of increasingly complex risks and opportunities in the environmental, social and governance realms, seeking to embed markets and societies with universal principles and values for the benefit of all" [32]. CSR's role becomes completely different when the code of conduct is enacted by a company deploying its activities on the territory of states that either do not have a level of protection of fundamental rights in accordance with international standards, or do not have the means necessary to ensure control of it. By adhering to UN Global Compact principles, multinational corporations undertake to fill these deficiencies from the part of certain states, and to harmonize the level of granted protection around uniform standards. [33]

Actually, as Professor John Ruggie's UN "Protect, Respect and Remedy" Framework, most progressive CSR project at the moment provides "(11) Business enterprises should respect human rights. This means that they should avoid infringing on the human rights of others and should address adverse human rights impacts with which they are involved". The commentary to this principle more clearly specifies that "The responsibility to respect human rights is a global standard of expected conduct for all business enterprises *wherever they operate* (a.n.). It exists independently of States' abilities and/or willingness to fulfil their own human rights obligations, and does not diminish those obligations. And it exists over and above compliance with national laws and regulations protecting human rights".[34]

Those distinctions being made, as we have promised, we shall now return to the analysis of the issue of the "hardening" phenomenon that is affecting CSR sources, which will necessarily bring into discussion the ultimate question we undertook to answer in this paper, that of the effectiveness of the CSR.

Mostly made up of soft law, CSR rules may anytime become legally binding, and be as such subjected to the hard law's regime, as we could see [35]. We need to specify that, if the hard law approach proceeds based on the enactment of an absolute rule that bears a penalty, and whose subsequent violation will be sanctioned by the judge, the soft law approach supposes, on the contrary, an incentive to do something that the public interest would wish to see accomplished, with no direct punishment by the judge, in case of non-compliance. [36]

Does not then this "hardening" of soft law bear a strange paradox in itself? Soft law adopted by the CSR was born out of the inability of traditional law to prove effectiveness in certain cases, and wanted to proceed on an alternative approach, one based on the adhesion and participation of its addresses, for better enforcement, and yet it has been ever since constantly criticized for not presenting the characteristics and the guarantees of the traditional law.[37] Would it not be better to try to solve this "paradox" by an included-middle reasoning, helping "transgress" the rather artificial cleavage between hard and soft law?

In our opinion, we could so interpret John Ruggie's key proposal made in the UN "Protect, Respect and Remedy" Framework concerning human rights due diligences, a more appropriate pragmatic risk management approach, also incorporating the additional obligation that companies resort to dialogue with the affected communities.[38]

Practically speaking, this proposal consists in establishing the company's responsibility to carry out human rights due diligences: "In order to identify, prevent, mitigate and account for how they address their adverse human rights impacts, business enterprises should carry out human rights due diligence. The process should include assessing actual and potential human rights impacts, integrating and acting upon the findings, tracking responses, and communicating how impacts are addressed. Human rights due diligence: (a) Should cover adverse human rights impacts that the business enterprise may cause or contribute to through its own activities, or which may be directly linked to its operations, products or services by its business relationships; (b)

Will vary in complexity with the size of the business enterprise, the risk of severe human rights impacts, and the nature and context of its operations; (c) Should be ongoing, recognizing that the human rights risks may change over time as the business enterprise's operations and operating context evolve (17)". [39]

Human rights due diligence is a process undertaken by a business to prevent or mitigate actions that infringe the rights of others. The Special Representative has outlined human rights due diligence with four elements: a) statement of policy articulating the company's commitment to respect human rights; b) assessment of actual and potential human rights impacts of company activities and relationships; c) integrating these commitments and assessments into internal control and oversight systems; and d) tracking and reporting performance." [40]

The issues tackled in the work of the SRSG and in the UN Guiding Principles have been included in the 2011 Revision of the OECD Guidelines for Multinational Enterprises. These are enterprise responsibilities to respect human rights, responsibilities relating to the operation of transnational supply chains and the adoption of due diligence as a mechanism for ensuring observance of the human rights and other responsibility standards in the Guidelines. The due diligence issue has gone even further than the UN Framework in that it has been adopted as a general principle of action for furthering the observance of standards in the Guidelines beyond human rights.

According to section II General Policies, point 10 of the OECD Guidelines for Multinational Enterprises, enterprises should "carry out risk-based due diligence, for example by incorporating it into their enterprise risk management systems, to identify, prevent and mitigate actual and potential adverse impacts […], and account for how these impacts are addressed. The nature and extent of due diligence depend on the circumstances of a particular situation". For the purposes of the abovementioned Guidelines, due diligence is understood as, "the process through which enterprises can identify, prevent, mitigate and account for how they address their actual and potential adverse impacts as an integral part of business decision-making and risk management systems." [41]

Summarising the key findings

There are doubtlessly multiple ways to look at the CSR, among which we had to choose those that we deemed necessary to approach the subject of this paper, i.e. contextualising CSR, delimiting its relationship with the neighbour concepts, and commenting upon the relation between its soft law and hard law sources, in order to eventually establish the level of its effectiveness.

Reflex of a change of paradigm that shifted from a constraining authority to one that feels the need to legitimate its acts, CSR attests the vocation of values and ethical principles to become part of the law, as a means of promoting the economic resilience of a corporation.

The core of our paper may however be resumed by saying that CSR is "paying" its toll to the soft law. First, it is questioned as to demonstrate its effectiveness, given the "pluralism" of its sources and the freedom left to the beneficiaries of choosing among them, all inherited through its genes. Then, even though CSR's potential for effectiveness has been proved, another congenital issue is opened for debate, namely its credibility.

John Ruggie's proposal for an independent expertise may save its reputation, showing that the non-binding character of CSR cannot finally remain an "optional" obligation. The CSR functions differently, for a distinct purpose, complementary to the ways of the law. Establishing rules of an evolving nature, inviting to adopt a certain conduct, rather than by imposing it; insisting to search the spirit of the law, and not sticking to the letter, the CSR is alive.

Resilience and relapse into crime

Sumănaru L.

livia.sumanaru@drept.uvt.ro

Abstract

If the purpose of the penalty is the prevention of other offences, and one of the functions of the penalty is the re-education of the convict, then the relapse represents a valid indicator of the efficacy of the punitive penal system. Undoubtedly, the efficacy of the punitive penal system is defied, the crisis of the punitive penal system being obvious. Over the years, specialists from different fields have tried to answer the same question: how can the relapse phenomenon be prevented, fought against, or at least diminished? Up to now, this question has remained unanswered. Specialists have reached the conclusion that this phenomenon could at most be reduced, but not eliminated. According to Émile Durkheim, "*criminality is part of the society as much as birth and death, and a society without crime would be pathologically over-controlled*". Criminality, being so closely connected to society, existed and will continue to exist, therefore it is considered that "*it is utopia to think that we could wipe out criminality completely; the only thing we can do is to reduce and tame it"*. Such a discourse seems to be up-to-date especially in the case of relapse, as "*the relapse in criminality proves persistence in the evil*", and implicitly, the offender's lack of resilience to re-offending. In this paper we would like to argue the alterations that the legislator brings to the regulation of relapse into crime in the new Romanian Criminal Code and their connotations in the context of individual and social resilience.

Keywords: Resilience, relapse into crime, New Criminal Code of Romania, rehabilitation, penal treatment.

Introduction

If the purpose of the penalty is the prevention of other offences, and one of the functions of the penalty is the re-education of the convict, then the relapse represents a valid indicator of the efficacy of the punitive penal system.

Undoubtedly, the efficacy of the punitive penal system is defied, the crisis of the punitive penal system being obvious.

Over the years, specialists from different fields have tried to answer the same question: how can the relapse phenomenon be prevented, fought against, or at least diminished?

Up to now, this question has remained unanswered. Specialists have reached the conclusion that this phenomenon could at most be reduced, but not eliminated.

Criminality, being so closely connected to society, existed and will continue to exist, therefore it is considered that "*it is utopia to think that we could wipe out criminality completely; the only thing we can do is to reduce and tame it"* [1].

Such a discourse seems to be up-to-date especially in the case of relapse, as "*the relapse in criminality proves persistence in the evil*" [2], and implicitly, the offender's lack of resilience to re-offending.

The legislator of the new Romanian Criminal Code brought important alterations to the regulation of the relapse into crime, especially to its penal treatment, that, theoretically, should significantly enhance resilience to re-offending.

In this paper we would like to argue the solution adopted in the new Romanian Criminal Code regarding the sanctionary system of the relapse into crime and the extent to which this new regulation is likely to respond to the need of reducing recidivism by enhancing resilience to re-offending.

The Theory of Resilience

The concept of resilience is relatively a new concept in the field of psychology, being criticized and considered ambiguous, especially if we are to decide what exposure to significant risk involves and what we can define as positive adaptation [3].

A relevant definition of the concept of resilience was given by the National Centre for Victims of Crimes (Washington, DC, U.S.A.), that described resilience as "*the power an individual has to cope with adversity and how successful the individual adapts to challenges or changes*" [4].

Moreover, resilience is considered to have three waves of inquiry [5]. The first wave consisted in identifying the resilient qualities as "*developmental assets and protective factors*" [5]. The second wave presented resilience as a disruptive and re-integrative process for the purpose of accessing resilient qualities [4]. The third wave reflects the postmodern and multidisciplinary view of resilience, seen as the force that drives a person to grow through adversity and disruptions [5].

As well as this, resilience was annalyzed from multiple perspectives, being approached as individual, family and community resilience [6].

According to VanBreda (2001) very few domains in a person's life have not been influenced by resilience [6] and, at the same time, the ability to be resilient is characteristic to all individuals, in general [3].

Individual resilience was defined as the capacity to successfully adapt, despite significant stress, challenging or threatening circumstances, being a combination of ability and personal characteristics, which allow individuals to cope, recover and function well at or above the norm regardless adversity [3].

Family resilience was related to those characteristics of families that help them to be resistant to disruption when confronted to change and adaptive in situations of crisis (McCubbin and McCubbin, 1988) [6].

Community resilience as stated by Paton (2000) refers to community capacity to bounce back and to use physical and economic resources in an efficient manner in order to aid revitalization soon after being exposed to harsh conditions [6]. According to Norris, Stevens, Pfefferbaum, Wyche and Pffeferbaum (2007) community resilience is the ability to adapt and function successfully in the aftermath of disasters [6].

All these definitions and perspectives on resilience help us understand the connection between resilience and recidivism, which, in the field of criminal law, show the lack of resilience to re-offending in the person of former convicts.

The Theory of Recidivism

Recidivism is a complex social phenomenon, involving multiple dimensions, such as juridical, criminological, statistical, sociological, psychological, prospective, economical, cultural, all being strongly related.

The concept of recidivism is specific to the field of criminology, including all types of reiteration of criminal conduct, regardless of the characteristics and the time of its development [7].

Criminological studies focus on recidivism from more perspectives, trying to discover the causes of this phenomenon, the characteristics of the personality of the recidivist and the solutions to prevent this phenomenon [8].

The etiology of recidivism is strongly connected to the etiology of criminality.

A large number of theories were elaborated along time concerning the causes or the generating factors of deviant behaviour. According to one criterion, these theories can be classified in two main categories, represented by the biological theories, on one side and by the social theories, on the other side.

In the first category of theories, the roots of criminality reside in the individual himself, being due to criminal heredity or to some characteristics of human personality.

One of the most important representatives of the theory of criminal heredity is known to be Cesare Lombroso (1835 – 1909), who elaborated the theory of inborn criminal, according to which many offences have a biological or hereditary nature, being caused by some physiological abnormalities, that are not present in a non-criminal personality [9].

The other sub-category of biological theories link criminality to some characteristics of human personality, such as: weak intellectual capacity, temperament, psychopatological disturbances.

The social theories work on the premise that human personality is a result of the continuous interaction between individual and the world around, as both criminal and non-criminal personalities develop in the same generic areas of social life.

The criminologist Etienne de Greef emphasized the types of environment that are likely to influence human personality, distinguishing between ineluctable, occasional, chosen and imposed environment [10].

Sociological studies highlighted some generating factors of recidivism, among which we can mention poverty, unemployment, illiteracy, political instability, illegal work, economical crisis, urbanization.

As well as this, criminality seemed to be encouraged not only by the lack, but also by the excess of goods. The high development of modern technology, in the recent decades, generates new temptations for offenders. It is well-known that economical criminality is on a constant rise, being present, under inventive forms, in more and more fields like informatics, financial, banking, business sectors.

The american criminologist Edwin H. Sutherland (1949), in his famous work, White Collar Crime, revealed a new face of criminality, combating statistical data of his time, that presented an image of the offender

belonging to the low and poor social classes. Sutherland put the light on the offences committed by the members of high social classes, regarding their business or professional activity. In connection with this, he elaborated the theory of differential association, according to which the meaning of deviant acts is connected to the positive or negative meaning that the close persons of the offender give to such acts. Social life is not disorganized but patterned through learned behavior. In consequence, association with criminal models create the premise of a future criminal conduct [11].

There are two theories that we would like to mention, in addition, and these are: the theory of social control of Hirschi Travis (1969), that states that the stronger the offender's link with society is, the more likely he will be to observe the social rules and the structuralist sociological theory of Émile Durkheim, who considered criminality a inner part of a healthy society. In his opinion, "*criminality is part of the society as much as birth and death, and a society without crime would be pathologically over-controlled*" [12]. The behaviours are qualified as undesirable and punishable by the dominant group in a society and in a society in which people are allowed to be different one from another, it is inevitable that some acts are antisocial.

Despite the large number of theories (of which we have mentioned only few in this paper), none of them seem to offer the explanation for the whole sphere of criminal conduct.

If the structure XY is responsible for committing a crime, how can you explain the fact that many criminals do not have this chromosome anomaly and, on the other hand, not all with this structure commit anti-social acts? If the socio-educational and socio-economic environment are responsible for the appearance of deviant behavior, how can it be explained that those coming from poor backgrounds commit such acts and, on the other hand, how can we explain the fact that among the offenders there are individuals who do not come from a poor background? For the moment, these are just some of the questions which seem to have no answers.

The attempt to explain the criminal conduct and put it in a theoretical frame fails in front of reality, that is too dynamic and diversified.

The phenomenon of criminality and, implicitly, recidivism is extremely complex and refuses to completely submit to one theory or other, as each of them can be accused by some intolerable generalizations.

The Regulation of Relapse into Crime in the Romanian Criminal Code

The relapse into crime, the most serious form of plurality of offences regulated in the Romanian criminal legislation, is a technical term, used in the field of criminal law, a form of recidivism (the broader criminological concept, comprising relapse into crime), referring only to some reiterations of criminal conduct under certain conditions, described in the Criminal Code.

The Romanian Criminal Code into force was adopted through Law no. 286/2009 published in the Official Journal no. 510/24.07.2009 and entered into force on February the 1st, 2014, replacing the former Criminal Code of 1969.

The new Criminal Code regulates the relapse into crime in art. 41-43 (in case of the natural person) and art. 146-147 (in case of the legal person), bringing new alterations to the definition, the terms of relapse and its penal treatment conferring the relapse into crime the character of a personal ground of mandatory aggravation of the penalty.

From the point of view of the legislator of the former Criminal Code, the state of relapse represented a personal ground of optional aggravation of the penalty inflicted on the offender for the offence committed in that state, as a result of their persistence in the offensive behaviour.

The distinction between the two regulations (the present one and the former one) are waited to rise important consequences for the prevention of relapse into crime and the enhancement of resilient qualities.

The relapse may appear in many forms, from which the Romanian Criminal Code mentions the following: the post-conviction relapse and the post-enforcement relapse, the territorial and the international relapse, the general relapse, the relative relapse, the temporary relapse, the relapse with a unique effect.

The relapse into crime, as an institution of the Romanian criminal law, implies a specific structure, which consists of two elements called terms of relapse.

In the case of the natural person, the first term of the post-conviction relapse consists of the decision of the final sentence to more than 1 year imprisonment or life imprisonment and not imprisonment for more than 6 months (the former Criminal Code) for an offence or a sequence of intentional or praeterintentional offences, sentence which was not fully enforced.

The second term is represented by committing a new offence, with intention or praeterintention, for which the law provides imprisonment for more than 1 year or life imprisonment, and which is committed before or during the enforcement of the sentence related to the first term of relapse or in the state of escaping from it (as stipulated in the former regulation).

In the case of the post-enforcement relapse, the difference consists in the fact that the conviction regarding the first term was fully enforced or considered fully enforced (through full pardon or pardon of the remaining penalty, or by expiration of the prescription of the execution of such an offence), and the offence

specific to the second term is committed after the enforcement or considered enforcement of the first term of the relapse.

In case of the legal person, the post-conviction relapse implies the legal person committing a new intentional crime after the final decision of a conviction, although the fine penalty of the prior conviction has not been enforced or considered enforced.

The post-enforcement relapse implies the person committing a new intentional crime after the final decision of a conviction, whereas the fine for the prior crime has been enforced or considered enforced.

As to the penal treatment, the new Criminal Code stipulates a stricter sanctioning system (art. 43 Criminal Code) than the one of the former Code, although practice has proved that harshening the penal treatment has not lead to the decrease of the relapse rate.

Thus, in the case of the post-conviction relapse, the penal treatment will imply the arithmetic addition of the penalties, and in the case of the post-enforcement relapse it supposes the legal increase with one half of the special limits of the penalties, both in case of the natural and the legal person.

In the former regulation, in the case of the post-conviction relapse of the natural person, the Criminal Code adopted the system of juridical addition with optional increase (up to 7 years). Thus, in case the penalty related to the first term had not been enforced or had only been partially enforced, that penalty or what was left to be enforced from it, and the penalty established for the crime committed after that, amounted to the most serious penalty, which could have been increased up to its legal limit (the special maximum). If this limit was not sufficient, another increase up to 7 years could be added to it. According to art. 39, paragraph (4) of the former Criminal Code, the sanctioning of the post-enforcement relapse was done through establishing a penalty up to its special maximum and if this was considered not to be sufficient, there was the possibility of increasing the penalty up to 10 years (in case of imprisonment) and at most 2 thirds of the special maximum (in case of a fine). If the established penalty for the new crime was imprisonment for life, the increase could not be applied.

In the former Criminal Code, in the case of the legal person, the sanctioning of the post-conviction relapse was done according to the juridical increase and that of the post-enforcement relapse was done through the possibility of establishing a penalty up to its special maximum and, if that maximum was not sufficient, another increase of up to 2 thirds from the maximum could be added

A new provision in the field is the one from the art. 43 paragraph (3) of the Criminal Code into force, through which, as an exception, in some cases, the possibility of being sentenced to life imprisonment was regulated, even if the established penalties were those of imprisonment.

As we may observe, the legislator of the Criminal Code into force adopted a more severe solution in order to sanction and prevent, at the same time, relapse into crime.

The questions that rise are: Is this new legal solution more likely to reach its goal and reduce recidivism? Is this new legal solution able to enhance resilient qualities in offenders?

In our opinion, the solution does not reside in harshening the sanctioning system of the relapse into crime, especially when, in practice, under the provisions of the former Criminal Code, did not appear the need to adopt a more severe regulation in the matter. The focus should not be put on changing the regulations, but on a more efficient and conscious application of them.

As several studies and researches have proven, there is a strong need to enhance resilient qualities in offenders, if we want to prevent them from re-offending. So far, the prison system has many flaws, that, instead of helping a person to reintegrate in society, after a conviction, actually, enables that person to re-offend. In such circumstances, how can we, as society, help an offender to develop resilience, when we choose to implement a law that may keep him behind bars for as long as possible? What treatment should that person receive in a such a long term jail, in order to develop resilience? Resilience is not important in the case of a recidivist person, being a "lost case"? If it is important, is the state, through all its institutions and authorities involved in the process of execution of criminal sentences, ready to assume such an important role?

In our opinion, the changes of the penal treatment of the relapse into crime brought by the new Criminal Code do not seem to enhance resilience in offenders, as they are focused on punishing the recidivist as severe as possible, apparently forgetting about the need of reeducating, if possible, and reintegrating these people in society, after accomplishing their penalty. This regulation is more surprising in the context in which alternative solutions to imprisonment are sought more and more in the juridical systems of other countries all over the world. Multiple scientific researches have shown that the key-solution may reside in improving the methods of communication and support between communities and their offenders and not in isolating them in a medium, that, many times, has proven to be a "school of crime".

To sum up, I would say that the issue of reducing the phenomenon of recidivism imposes multiple field investigations, approaching the criminal tendencies in time and space, their causes, the limitations of the prison system, developing efficient prevention programs, and above all, the necessity of approaching the matter from an interdisciplinary perspective, focused on the development of offenders' resilient qualities.

Philosophy of mediation

Sustac Z. D.

Mediation Council Romania
office@sustac.ro

Abstract

When we speak about the philosophy of mediation we inherently have to relate to the philosophy of law and the philosophy of conflict. The philosophy of mediation is a present-day subject and of interest among the specialists in the Alternative Dispute Resolution field.

Keywords: philosophy of mediation, conflict, Alternative Dispute Resolution, mediation

The philosophy of mediation is a present-day subject and of interest among the specialists in the Alternative Dispute Resolution field. The first paper at world level dedicated to this subject and representing the topic of a doctoral dissertation was published in 2013 in Bucharest. The work entitled "Philosophy of mediation", whose author is Zeno Sustac, proposes a new approach of the ADR phenomenon from the perspective of the origins on the basis of which they were created as well as from the perspective of the objectives that we would like to see accomplished. When we speak about the philosophy of mediation we inherently have to relate to the philosophy of law and the philosophy of conflict.

The philosophy of law, acknowledged at speciality literature level and taught in law faculties, proposes a philosophical approach on law, answering mainly in a theme, that establishes the relation between law and moral, to the question "what is law? ". The philosophy of mediation proposes the same approach, the only difference being that the question that answers must be given to is "what is mediation? ". The philosophy of mediation is not at all inferior to the philosophy of law, having a more noble nature that puts in the centre the act of encouraging the maintenance of a harmonious relation between the social players. The philosophy of mediation is not conflicting, but treats the subject of conflict philosophy which presents a low interest for the philosophy of law. Having different objectives, the efficient support of a "legal war" in the case of the philosophy of law, namely the harmonization of interpersonal relations disturbed by the occurrence of certain disputes, the two philosophical approaches slightly overlap. Although certain themes might present a common interest, the approaches are different.

The conflicts resolution models are various, these being influenced by the endogenous conflicting environments (where conflicts control and resolution mechanisms exist) or exogenous where they appear. According to the opinion presented by R. Wandberg in the paper "Conflict Resolution: Communication, Cooperation, Compromise", Capstone Press, Minnesota, 2001, the conflict resolution is "a process of reducing or calming the conflict in order to prevent violence, (...) it is a way of building or rebuilding trust within a relation".

The philosophy of law is not centred on the relation and does not focus predominantly on the conflict constructive aspect. Yevgenii M. Babasov brought his contribution in 1997 to outlining conflictology as a science in itself through the paper "The Conflictology", Pravo i Ekonomika, Minsk, approaching conflict both from a sociological perspective and a philosophical perspective and analysing both its constructive and destructive aspects.

More often than not the conflict is present as a form of relation to others. This opinion is supported by contemporary researchers such as S. Carfantan [1] who builds this point of view starting from the opinions expressed by Hegel and Sartre. According to them, the conflict is perceived through the existence of two plans, a superior and an inferior one, being situated at their meeting point. In this framework, Hegel stages the present forces which are contrary to one another and which, more often than not, are not on the same level. Hegel presents the idea according to which the conflict is "part of a healthy relationship" between individuals, being, at the same time an integral component of reconciliation. "Human beings need different institutional spheres where to find their intimacy, to update their individuality and to enjoy political communion", and "the conflict is the price of this differentiation".[2] For analyzing Hegel's ideas related to conflict and to the fact it represents a source of change and development, Charles Taylor uses the phrase "ontological conflict".[3]

Joseph S. Catalano shows that for Sartre the conflict brings into discussion the human vulnerability. For Sartre, the relation between the dominant and the dominated is established by means of a look that can lead to a creation of mutual hostility.[4] S. Carfantan shows that if we look at the conflict as a "human relationship model", then its consequences are those presented by Sartre in the phrase "Hell is other people", namely that humans' freedom is absorbed by others, despite the fact that freedom is inalienable. In this context, the author believes that humans are transformed into objects within the power relation established between them, and Sartre's expression "I think, therefore I am" becomes "I am being watched, therefore I am". In the latter case, the ego is supported by the looks of others. Failing this look, the "inexistence" feeling appears. In other words, in order to exist, humans need to be watched, to be taken into consideration, to be recognized by others. From this presentation it results that the base of human relations is not represented by communication, but by conflict or humans` hostility. According to Carfantan, we are dealing with a paradoxical situation in which, although the conflict is seen as a relation, this is not in fact a relation, but the failure of the relation, it is the "putting into stage of certain individualities that came out of the isolation state".[5]

Another aspect that must be taken into consideration when analyzing the conflict is represented by values pluralism – a problem that was widely deliberated by Isaiah Berlin. This is because, as from 1950, I. Berlin published numerous works related to the pluralism's conflict nature and the conflict of values. It must be mentioned that, those that approached values pluralism used the phrase "moral universe" to refer to "the world of values, rules, and ethics that surround human beings". Despite the fact that the ontological status of the moral universe is not clearly distinguished in the work of I. Berlin, as Connie Aarsbergen-Ligtvoet indicates, the fundamental idea of Berlin on the "moral universe" is that there exists a values and purposes diversity which generates tensions and conflicts. In this context, it was concluded that the work of I. Berlin represents, from this point of view, an indispensable point of reference.[6]

While some authors as Boulding define conflict as being a "a competition situation in which the parties are aware of the future potential incompatibilities, where each party wishes to occupy a position which is incompatible with the others wishes" [7], others see it as being "a social condition which appears when two or more actors pursue purposes that exclude each other or which are incompatible". Many definitions given to conflict relate as well to international life where "the conflict behavior can be understood as war or threat starting a war" [8]. In the book "Contemporary Conflict Resolution", Oliver Ramsbotham, Tom Woodhouse and Hugh Miall use the term conflict to indicate "a vast set of circumstances in the framework of which the parties in conflict become aware that they pursue incompatible purposes".[9]

The Romanian literature includes many books which have as debating theme the conflict and its resolution means. Thus, in the paper "Managementul conflictelor" (Conflicts management), Nicolae Tritoiu defines conflict as being "a social phenomenon which appears when two or more players in an interacting or interdependency relation pursue incompatible purposes or although they have common purposes they mutually contest their means of actions and the rules of the game". The author indicates as well that the term "conflict" is "used to describe a series of emotional states of individuals such as restlessness, hostility, resistance, as well as all types of antagonistic opposition between individuals or human groups"[10]. Other Romanian authors define conflict similarly as being "the interaction of groups (individuals) who perceive purposes, intentions, values and interests as being incompatible when their actions interfere for achieving the proposed objectives" [11].

Considering all the definitions reminded in the first chapter, but also my practical experience as mediator, we have proposed and we support the following definition for conflict: "The conflict is a contextual social phenomenon determined by the clash between the interests, the concepts and the needs of certain persons or groups when they enter into contact and have different or apparently different objectives".[12]

Conflicts that are easily to mediate (or those that can be solved through other ADR methods) many times come to be solved by means of litigant means, contusive due certain external factors (others than the parties) that have a direct impact on the maintenance and the amplification of the disputes in question.

A useful instrument in determining the intensity of conflicts and choosing an adequate resolution method is the Conflict Scale – SIG SCALE. The conflict scale, proposed to the specialty literature in 2011 in the paper "Ghid de negociere" (Guide to negotiation) published in Bucharest, Editura Universitara, by the authors Zeno Sustac and Claudiu Ignat, proposes an objective radiography of conflict by analysing the following relevant aspects:

1. Parties awareness with regard to conflict existence
2.Number of parties in conflict
3.Number of parties affected by the conflict
4.Duration of conflict
5. Previous conflicts between the parties
6. Previous resolution attempts
7. The wish of the parties to maintain the conflict
8.Resources involved in maintaining the conflict
9. Stress exposure

10.Gravity in case of non resolution

For each of these variants, a score composed of 1 and 3 points is awarded, depending on its relevance in determining the conflict intensity (in accordance with the scale developed by authors). The mathematical formula for the SIG index calculation proposed to the speciality literature is the following: *SIG Index =(C+P+PA+V+CA+IS+DI+R+ES+G)/*10

The SIG index is a value obtained using the formula above which determines the intensity of a certain conflict and positions it on the Conflict Scale. The values obtained are ranked on the SIG Conflict Scale as follows: between 1.0 and 1.6 on the SIG scale (value specific to the superficial conflicts), between 1.7 and 2.3 on the SIG scale (value specific to moderate conflicts) and between 2.4 and 3.0 on the SIG scale (value specific to serious conflicts). The value on the SIG scale indicates the intensity of the conflict measured. If the values are at the upper limit of the category on the SIG scale, the conflict can have influences from the next category. Thus, a 2.3 value situated at the upper limit of moderated conflicts can present as well characteristics of a serious conflict, the conflict actually being moderate to severe. The concrete utility for the ADR field specialists consists in supplying precious clues for the analysis and management of any concrete conflicting situation, helping them to identify exactly the type of conflict (superficial, moderate or severe) with which they are confronted and thus giving them the possibility to chose the right approach for the situation given.

The ADR conflicts resolution methods were born subsequent to the low efficiency and the imperfections existing within the traditional methods of conflicts resolution. The thinkers of various philosophical schools approached conflict along the time from a philosophical point of view. Themes such as isolation, loneliness, confusion, sympathy, friendship, love, justice, truth, religion, etc., which are strongly connected with the idea of conflict, were the subject of exponential specialty papers in global philosophy. Conflict always represented over time a subject of debate for theoreticians such as: Plato, Aristotel, Nicolo Machiavelli, Thomas Hobbes, E. Durkheim, Max Weber, David Lockwood, Lewis Coser, Talcott Parsons, J. R. P. French, Goldman Schlenker, Johnson Pruitt and many others. Relating to the idea of conflict when considering other aspects and the embraced philosophical thinking generated the most diverse possible approaches and definitions of conflict. From a religious point of view, the first conflict that can be identified is the one that took place between the first human beings created, Adam and Eve, and God – their creator, as it derives from the biblical texts. Whether we look at the conflict as being the war of all against all, the father of all things, or we are the adepts of the idea that the human being is the measure of all things, it is necessary to analyse the conflict from a multidisciplinary point of view and under no circumstances to carry out an analysis reported strictly to a certain field or a certain science, so much the less in relation to a certain school or philosophical thinking.

The purpose of the philosophy of mediation is, among others, to contribute to the identification of „life philosophy" of the parties actually involved in the conflict, of their systems of values and references and to contribute to the identification of needs and necessities hierarchization. Those who, from a legal point of view, have the powers to dispose, to transact, shall do this only in a certain context in negotiating with the other party and here the psychological and philosophical sides are those that can make a difference between building consensus or perpetuating conflict. The personal vision on conflict, expressed in many specialty papers is based on this premise: conflict is a contextual social phenomenon caused by the clash between the interests, the concepts, the needs, or the egos of certain persons or groups and is manifested when they enter into contact and have different objectives or apparently different objectives. It is omnipresent, characterising the entire evolution of human society and, due to this fact, it is important to manage it constructively and to transform it in a source generating opportunities and in a progress factor. Mediation, although is not a miraculous and generally valid solution, focuses considerably on returning to normality, proposing the accomplishment of a consensus architecture in daily life. But sometimes things do not work as we imagine and our reality is not identical to the reality of the other. Building the social balance and the social peace depends on the inner structure of the factors involved as well as on the consensus or dissension generating factor with which the parties interfere. The constructive dialogue proposed by mediation, its solid principles which rely on partnership, team work and cooperation, are solid bricks put at the foundation of a healthy society in which maintaining and improving the relations between fellow humans presents a high interest.

Children's rights as a mechanism to promote resilience. Socio-educational program based on the rights approach

Urrea Monclús A.

(SPAIN)
aurrea@pip.udl.cat

Abstract

The aim of this paper is to show the results of an investigation designed to identify the training needs of children of 10-18 years old in relation to their rights. The starting point of this analysis is the Convention on the Rights of the Child (CRC), adopted in 1989 by the United Nations.

The sample of the study involved 2,263 Spanish primary and secondary school children. The instrument used was a questionnaire of moral dilemmas with 4 open questions, 17 moral dilemmas and 8 dilemmas with justification of the answer, which have been analyzed qualitatively and quantitatively. This instrument is an adaptation of the moral dilemmas questionnaire developed by Casas, Saporiti et ál.

The result of this analysis has revealed that children know some of their rights but, in turn, they have training needs regarding knowledge of the CRC in the 3 dimensions of learning: cognitive, behavioural and attitudinal.

Knowing and living the CRC, and understanding it as a recognition of the rights and the responsibilities of the children is a mechanism that promotes resilience. Hence, it qualifies children to cope with adverse situations, whether with peers or adults.

These needs, and others, have been transformed into a list of contents and objectives that support a socio-educational program of Children's Rights. This program, which is under development, promotes resilience in children.

Keywords: Children's Rights, Resilience, Self-protection, Prevention, Promotion

Introduction

The starting point of this analysis is the Convention on the Rights of the Child (CRC), adopted 1989 as the first legally binding instrument to incorporate the full range of human rights: civil, cultural, economic, political and social [1]. The CRC stipulates (Article 42) that its content should be diffused among the children population: *Diffusion of the Convention, children are entitled to know the rights contained in this Convention. Governments have a duty to spread it among children, adolescents and adults.*

In addition, knowledge of the CRC is a good tool to promote resilience in childhood since it allows children and adolescents to know their rights and responsibilities. Besides, knowing their rights promotes self-protection because it allows them to recognize early situations of non-participation, abandonment, abuse or neglect and try to avoid them [2]. Furthermore, knowing their responsibilities facilitates self-regulation as it helps to improve cohabitation and their interaction with others [3]. Therefore, the Convention as a holistic model and as an engine of a child's life is very important [4].

Objective

The main aim of the research is to identify the cognitive, behavioural and attitudinal training needs of children and adolescents in relation to their rights. In addition, the purpose of this investigation is to transform these needs into the contents of a socio-educational program based on the rights approach to promote resilience.

Method

The study sample was 2,263 students between 10 and 18 years old distributed throughout the Spanish territory. In terms of gender, the sample is equivalent since 52% are boys and 48% are girls. In relation to age, data show that elementary students represent 56% of the sample and secondary students 44%.

In order to collect the knowledge, perceptions and attitudes that children and adolescents have about their rights, the adaptation of a questionnaire of moral dilemmas developed by Casas and Saporiti was made [5]. The reason why this questionnaire was chosen is due to the fact that moral dilemmas force moral reasoning about the values involved and demand a reflection on the level of importance of our values [6]. The questionnaire was divided into 4 open questions, 17 moral dilemmas and 8 moral dilemmas with justification of the answer.

The data analysis was carried out based on statistical analysis of quantitative data and content analysis of the open questions.

Results

The results of the statistical analysis show how children and adolescents are aware of their rights: they perceive them as essential. In general, it can be claimed that there is a high degree of awareness of child rights by both males and females, since in most of the dilemmas the degree of agreement is over 80%. But even if they are conscious of their rights, the content analysis shows that children and adolescents have training needs regarding these rights. The presentation of the results is organized according to the 3 dimensions of learning: cognitive, behavioural and attitudinal.

In relation to the cognitive dimension, children and adolescents know that they have rights but they don't know which they are. Some of these rights like education and religion are seen as a norm or obligation. Furthermore, they think that their parents are the ones who have to provide them and children don't realize that they can exercise them for themselves. Actually, parents only have to guide them in their development. They don't know either that they have a right to their personal space, to exercise their autonomy progressively together with their maturity and to participate in decision-making or in resolution of situations that affect them.

Concerning the behavioural dimension, the lack of strategies for exercising their rights is perceived. Punishment is seen as a response to an incorrect behaviour rather than a mediating, a motivating for change or a coping with problems strategy. In addition, a lack of abilities to accept the differences and to cooperate and collaborate with others is observed. Individuality is perceived in most of their actions. The results also suggest that the lack of strategies of participation and autonomy are in conflict with their desire for freedom and independence, their willingness to live in society and their wish to contribute to the society.

Regarding the attitudinal dimension, children and adolescents highlight the individualism as a value. They believe they must act for themselves and consequently the rest should do so. They don't have a cooperative, collaborative nor mutual aid attitude and they have trouble thinking of others and accepting them as equal in rights. This last attitude is related to the concepts of Kohlberg of Hetero-perception, in which they show acceptance if the situation is far from them, and Self-perception, when it is more difficult for them to accept the situation if it is closer [7]. However, this individualism is not reflected when they externalize that they are not competent to decide freely, to deal with situations that affect them or to participate in society.

To conclude this part, it seems important to highlight 2 of the perceived needs: the progressive autonomy and the participation. The data presented shows the importance and the transversal nature of these needs as they are reflected in the 3 dimensions analyzed.

Conclusions

It can be concluded that it is necessary to address these training needs to promote resilience and to prevent situations of neglect or abuse. As it is indicated in the introduction, the Children Rights are a good mechanism to promote resilience as they enable children and adolescents to deal with adverse situations.

The first step to address these needs is the transformation of these into contents that will underpin the socio-educational program to promote resilience through the Rights of Children. The resulting contents respond to the needs and to the common classification of children's rights: Provision, Protection and Participation [8]. These are: 1. Children's Rights; 2. Types of Rights; 3. Rights and Responsibilities; 4. Child poverty in developed countries; 5. Child poverty in developing countries; 6. Family and Children's Rights; 7. Identity, no-exclusion and acceptance of difference; 8. Privacy and intimacy; 9. Children's voice, view from adulthood; 10. Children as citizens.

The new concept of judicial emotional resilience

Vlădoiu N.

Transylvania University of Braşov, Faculty of Law(Romania)
vladoiu.nasty@gmail.com

Abstract

The changes at socio-political, economic and legislative level, the achievments of science, bio-technology, bio-medicine and of the informational society, and also the challenges related to the globalization process, influence a new paradigm and a new dimension of the resilience concept. It is obvious, that the above mentioned, forms a core study from which one can start proving and sustaining that resilience has become a sought phenomenon in the human society of the XXI century.

In this article, we intend to approach an issue related to juridical resilience, and more specifically, to the role and importance of assessing the degree of resilience of the suspect, the defendant or the convict, in relation to the prevention measures, the individualisation of the sentences and the manner to execute them, if applicable, and at the same time to define the new concept of judicial emotional resilience.

Keywords: judicial emotional resilience, prevention measures, certificates of resilience, variation of juridical resilience, psychosocial.

Introduction

The resilience concept is susceptible to be defined and analyzed from an interdisciplinary and multidimensional perspective, its implementation offering undeniable practical results in various fields. Although quite common, it is difficult to set up an exhaustive perception regarding resilience in terms of its applications. We appreciate, without fear of making a mistake, that the resilience is a concept with variable geometry, evolutionary, that metamorphoses depending on the influential factors existing in each field of application.

It is more than desirable, that at some point, in a determined society, an analysis of psychosocial impact, at national or international level, in terms of a particular individual, group, organization, institution, country, region, can not be considered fully performed without being introduced into the equation and without taking into account the concept of resilience, which thus becomes almost indispensable. What will still be quite difficult to obtain, but it will become an imperative in the near future, is to develop some generally applicable and accepted standards for each area of activity evaluated in terms of resilience.

As far as we are concerned, of interest in this scientific endeavor, is emotional resilience. This subject has been widely debated internationally from a theoretical perspective, reaching the conclusion that the individual needs a high degree of emotional resilience in order to be protected against everyday attacks of modern life.

The specialist have found it necessary to set up some training programs able to transpose and materialize the theoretical ideas into practical courses of extremely importance and real help for individuals or organizations, that should be taught to understand that "everything is OK when things are going not so well, or even bad ".

Those who follow such courses, must develop skills that enable them to become emotionally stronger, to think pro-actively and decisively in the creation of their own emotional resilience standard, adequate to respond to the attempts they face.

Expressing her opinion about people who follow such programs, the founder of "The Work Foundation", Dr. Zofia Bajorek said that "They are effective for the organization. After workshops, they have seen better productivity, improved sickness absence and higher staff morale. People are seeing the results and really latching on to the idea". (Source - The Telegraph , http://www.telegraph.co.uk/health /wellbeing/10660556/Emotional-resilience-its-the-armour-you-need-for-modern-life.html)The general problem in various fields is the emotional resilience; thereby we can find resilience's applications throughout the daily life, in many different situations the modern human confronts with. The individual must be aware that after a training program, will be able to achieve his own system of emotional resilience in the area of health-career,

intellectual, social, spiritual, financial and physical. We consider that it should be pointed however, that some individuals need more help than others.

Means and methods

Are to be mentioned, at least two methods and means by which individual emotional resilience can be build. The first would be that of the individual following certain courses or seeking an emotional resilience counselor, in order to help him be aware of how to envision and reflect about things he faces, so as to make him realize and understand the following tips as a key strategy in achieving a high degree of emotional resilience:

It would be necessary that the problems faced by individuals to be seen as challenges in life and not as ineluctable barriers.

The individual should consider that change in life is part of it and not the end of it.

The individual should be determined and must seek to have control at the highest rate in difficult situations.

The individual should learn from mistakes and be forward-looking, in case he cannot learn form other's mistakes.

The individual should think optimistic and see the bright side not the dark one in a given situation, because there is always something positive that can be achieved.

The individual should be confident and not become overwhelmed or negatively affected.

The individual should seek to remain conscious and, in this way will be able to identify what he feels and, why.

The individual should take into account his own person and give him, as much as possible, whatever needs a balanced human being.

The individual should surround himself with those friends, colleagues or family members that understand him, without having to make efforts in order to convince them about what he feels and thinks.

The individual should not judge, assume or expect too much from others, negatively burdening so his conscious.

The individual should not waste time trying to get people to love him, but be surrounded by those who already love him.

The individual should be aware that those who do not miss him, do not love his presence either.

And, the second method consists in exercising, acquiring and applying the above mentioned tips in as many situations in which the individual acts in everyday life.

Results

Emotional resilience is very important also when it is viewed from the perspective of criminal law and criminal executional law, specifically from the perspective of an individual on whom it shall be taken or have been taken preventive measures involving deprivation of liberty and from the perspective of individualized sanctions applicable to him and choice of the modality of enforcement of a custodial penalty, as set by decision of conviction.

From this point of view, we believe that emotional resilience acquires a specific and unique character, which allows us and gives us the possibility of shaping a new concept, that of judicial emotional resilience.

Judicial emotional resilience can be defined as the capability and capacity of emotional resilience, intrinsic or developed by the individual, on which have been exerted coercive measures, and his real possibilities of psychosocial reintegration, after the conviction or after serving a sentence.

We feel that the definition above enables us to categorize the judicial emotional resilience as a variation of juridical resilience.

It is a very well known and extensively discussed problem, the emotional state of the individual and his actual possibilities to reintegrate into society after serving a custodial sentence or measures.

If, in terms of protection of their physical and mental health status, their means of subsistence and security during the period of custody, things are quite clear, given the state's positive obligations in which the responsibility to ensure these incumbent on the state, the emotional balance and the psychosocial reintegration issue after conviction is not nearly resolved.

It legitimately raises the question whether it can be considered also among the state's positive obligations, the issue of judicial emotional resilience, as a measure of preventing unwonted, undesirable situations, in a stable society in terms of psycho-social.

If the answer would be positive, then we consider that the state should be the one who have the obligation and mission to ensure the means and methods by which the individual can develop and attain a degree of emotional resilience, able to make him strong and capable of social reintegration after judicial treatments.

Although these things concern both the situation of the minor that collide with the criminal law and of the adult in the same position, we focused our attention in this approach, on major people, considering that the minors should be subject to other special means and methods of protection in terms of their judicial emotional resilience. [3]

Conclusions

Given the presented considerations, we can notice that emotional resilience is necessary and its presence is being felt also in the criminal law field, displaying thus a new specific form, defined by us under the name of judicial emotional resilience.

Modern and democratic guarantees, generally based on fundamental rights and freedoms, and in particular on the idea of the respect of human dignity and the protection of privacy, offered by the New Romanian Criminal Code and also by the New Romanian Criminal Procedure Code, give us the opportunity to believe that, in the future, the assessment of the degree of judicial emotional resilience, will be materialized in the issuance of some Certificates of Judicial Resilience.

These certificates of judicial resilience, could be emitted, at the time of choosing a proper preventive measure, that has to be applied to the individual who came into conflict with the criminal law, at the time of individualization of the sentences, of applying accessory sentences, complementary sentences and safety measures, where appropriate, or at the time of choosing the modality of punishment enforcement and of the enforcement regime, where appropriate.

The certificates of judicial emotional resilience will be issued and individualized on grounds of moral and psychological profile of the person concerned, health status, level of education and training, age, criminal record, financial status, marital status and family responsibility, etc.

The analysis of the above unlimited mentioned criteria would be carried out by specialists in areas such as sociology, legal psychology, medicine, law and other, who are able to appreciate correctly, objectively and impartially on the capabiliy and capacity of the individual's emotional resilience, after going through judicial treatment and on the definite possibilities of his psychosocial reintegration.

Until the materialization of this *de lege ferenda* proposal, we estimate that it is strictly and absolutely necessary setting up some bodies and organizations, capable of integrating, developing and promoting the concept of judicial emotional resilience in our country and to provide ideas, methods and programs designed to help the individual to raise his level of judicial emotional resilience.

With the help of and relying on this kind of bodies and organizations, Romania will prove that it met the requirements of implementing the Concept of Social Responsibility, both nationally and internationally.

Therewith, we can become one of the countries that develop important research programs in a so interesting and sensitive matter as judicial emotional resilience. International Criminal Law would thereby enrich itself with another worthy considerable institution, in a world of the XXI century, full of atypical challenges in terms of diversity and ingenuity, and it would be offered a new modern guarantee for the individual on which have been applied specific judicial treatments.

Disabled person's tourism – a component of social tourism

Babaita C.

West University of Timisoara, Romania
carmen.babaita@e-uvt.ro

Abstract

There are enough reasons for the segment of people with disabilities to require special attention from both the service providers, of all types, as well as from researchers in the fields of management, marketing, tourism, law, computer science, psychology, sociology etc. What must be said is that the phenomenon exists, it is deepening and must be given special attention. The arguments underlying the support of this work can be viewed from different perspectives: legislative, social, economic, technological and not least psychosocial.

Based on these arguments, this paper attempts to address a very sensitive issue in Romanian tourism, namely tourism for disabled persons.

To identify this market segment, it is necessary to use the data classification provided by the World Health Organization, the first being the Classification of Impairments, Disabilities and Handicaps (ICIDH), established by the English rheumatologist Philippe Woods. This classification was revised in 2002, when it became the International Classification of ICIDH -2.

The World Health Organization (WHO) defines disability using three concepts: "Deficiencies, Incapacities and Disadvantages", the so called DID approach.

It is certain, however, that to this date, creating a social model for disabled persons, to be treated in the tourism literature has failed.

Our research sought to emphasize the context in which society is ready to accept a new segment of consumers, with special needs, on an already outlined tourism market.

Keywords: social tourism, disabled person, **social barriers, tourism industry**

Introduction

Tourism in its present form only emerged in the nineteenth century. At that time, it was accessible only to the high society elite, governments failed to include the possibility of access to this form of leisure activity under the form of leave for employees, who had to go to work every day, including Sundays. Therefore, the possibilities for the population to spend their free time on holidays were very limited. Actions related to social tourism began in 1936, when the **International Labor Organization (ILO)** agreed on access to tourism through paid leave [1].

Essentially this convention was also mentioned in the **Universal Declaration of Human Rights of 1948**, which states that "everyone has the right to rest and leisure, including reasonable limitation of working hours and periodic holidays with pay".

Thus we can say that social tourism occurred as a result of ethical demands of the employees' representatives, justifying the legitimacy of a specific right, namely the right to tourism, as an extension of the right to work, rest and paid leave.

However, some historians claim that social tourism appeared a few decades earlier, with the opening of camps for disadvantaged children and the opening, in the twentieth century, of youth hostels.

The **International Bureau of Social Tourism** was founded in 1963, by Arnold Haoult, and for a very long time has been ensuring the promotion and development of international social tourism.

Since 1959, W. Hunziker has tried to define social tourism since the second Congress of Social Tourism held in Vienna and Salzburg, as follows: *"Social tourism is a type of tourism practiced by low income groups, and which is rendered possible and facilitated by entirely separate and therefore easily recognizable services".*

Another definition was given by M. Andre Poplimont, namely: *"Social tourism is a type of tourism practiced by those who would not be able to meet the social cost without interventional, that is, without the assistance of an association to which the individual belongs".*

From these definitions and the reports of the three International Congresses on the topic of Social Tourism, several common elements can be observed. A first idea is that of "limited means", secondly, social tourism is subsidized by the state, local authorities, employers, trade unions, clubs, associations or other organizations and thirdly, it is the journey outside the normal place of residence, preferably in a different environment, which is typically in their own country, sometimes in a nearby country.

Social tourism, conceived in the spirit of the requirements to *ensure access to holidays to wide categories of the population and to respect the individual's right to travel* is stimulated and encouraged by the general policy of tourism development in each country, through the creation of specialized bodies in the field.

It can be seen that **the beneficiaries of this kind of tourism** are the categories of people with limited financial means, represented by those with minimum income or those whose social status prove it: *retired, unemployed, pupils and students, workers in agriculture, the elderly, persons with deficiencies, persons with disabilities etc.* Regarding travel opportunities, they are satisfied - partly or entirely - through subsidies granted by society through social welfare organizations or various other organizations: social insurance bodies, mutual support bodies for retired persons, unions, youth organizations, foundations, NGOs, and through payment facilities offered by tourism operators (discount rates, lower levels of fees) [2].

Research on tourism for disabled persons

Different approaches were outlined in **tourism development**. In a relatively recent paper (2008) on the subject, C.M. Hall establishes **five approaches** ("optimistic", an economic approach, a spatial approach, a community-oriented approach and an approach based on sustainable tourism). Even if the latest two visions of tourism development (community-oriented and sustainable tourism development approach) are steadily growing, most economic strategies follow the economic approach and target, essentially, increasing or at least, ensuring the attractiveness of a place. On the other hand, the attractiveness of a territory is one of the first conditions for economic development.

Internationally, detailed research on the tourism of disabled people are limited in this direction, and those that exist are more focused on the lack of physical access to certain services in hotel units.

Some academics specializing in tourism have flirted with the idea of this issue in the late 1980s and early 1990s [3].

The broad spectrum issue of persons with disabilities has become a field of study since the early 50s Typically, these studies and debates about persons with disabilities orbit the **social model of disability** emerged in Britain in 1976 following the activity of the Union of the Physically Unfit against segregation (1976).

It must be noted, however, that a number of researches have realized that the phenomenon exists globally but have focused very much on the definition of disability and less on finding concrete solutions to support this segment of consumers.

Many researchers have also investigated recreational constraints by means of demographic characteristics such as age and type of disability. *Sparrow and Mayne (1990*) examined patterns of recreation for people with intellectual disabilities aged 18-35 and found that the participation rate was low, regardless if the recreational activity took place at home or in the community. Participants were constrained by several factors, including limited access to facilities and transport services, financial constraints, opportunities, distance to recreation sites and attitudinal barriers. *Wilhite and Keller (1992*) studied the implications in how leisure time is spent in the case of older adults with developmental disabilities and the prevailing constraints reported in the study were related to limited access to transport, financial constraints, limited physical accessibility, concerns about their behavior and the discomfort felt in larger groups.

Ross (1993) found that young people with recent spinal cord injuries showed a variety of constraints pertaining to outdoor recreation activities. The lack of partners with which to spend leisure time, transportation problems, mobility issues, self-awareness and the attitudes of others have been identified as factors of constraint in terms of outdoor recreation activities [4].

Williams, Vogelsong, Green and Cordell (2004) analyzed the participation of people with mobility disabilities in outdoor recreational activities and concluded that they participate in few such activities and encounter great constraints in this situation. However, the differences were not consistent with all the examined activities and constraints. In addition, only structural constraints were observed, therefore, further research is needed to understand the whole range of constraints that may impact on outdoor recreation activities for persons with disabilities [5].

In addition, recent studies tend to focus on physical access issues (Canadian Tourism Commission, 1997; Burnett and Bender, 2001; Shaw and Coles, 2004), examining issues of access to the tourism internet site or to specific attractions or facilities (Israeli, 2002) [6].

Research and results

Considering that disability is a social phenomenon that is growing worldwide and before moving to the adoption of solutions that meet the needs of this segment on the tourism services market, we considered it imperative to research the Romanian society's position on this issue. This was analyzed by setting a general goal, namely: the identification of the behavior of people without disabilities towards persons with disabilities.

Our study had the following specific objectives: describing the socio-cultural trends enabling the recognition of mentalities and norms, knowledge of social, psychological, cultural prerequisites of interviewees and discovering the causes that lead to negative feelings (restraint or indifference) towards persons with disabilities [7, p. 43].

The research was conducted through a **questionnaire based analysis** . The sample size was 200 individuals without disabilities, chosen at random.

The segmentation of the sample was made according to the following criteria: age , sex, origin, marital status, income level and education level.

The sample's structure according to age was: 18 % aged under 24, 14% aged 25-30, 8% aged 31-35, 20% between 36-45 years, 40 % aged over 45.

Of these, 62 % were women and 38 % were males. Regarding the marital status of respondents, 2.5 % were not married, 46 % married, 12% divorced, 32% are widowed and 7.5 % live with a partner.

Surrounded by negative attitudes, persons with disabilities can internalize negative attitudes and beliefs (Beckwith & Matthews, 1995; Imrie, 1997). Their personal identity and social integration are affected as requests, desires for services and insurance evolve. Important from a tourism point of view, this change in attitude means that the conceptualization of disability involves both **social barriers and the respective handicap**. It is recognized that the nature and severity of disability can affect the scope of activities that one can participate in, but may also influence how the tourist experience is formed [8].

Following data analysis, we can say that persons with disabilities are accepted in society by most categories of people, in that they support the integration process. Respondents believe that this process is of great importance and that it should exist in any modern society and in addition to the fact that it should be present in any modern society, it is required that society also provide certain financial gratuities and psychosocial assistance to such persons.

Most persons are of the opinion that people with disabilities face difficulties in finding a job, qualified or unqualified. Their problems are supported and emphasized by the reluctance of employers, higher health and other insurance costs. In addition to these serious problems, these persons are strictly turned down in interviews because of their condition. Although 86% of respondents would not be bothered by working with people with disabilities, this is not reflected in the subjects getting a job.

Granting support to such a person is a widespread phenomenon in Romania, as reflected by the number of responses, which shows great solidarity between people belonging to all social categories and more than 10% of respondents have people with disabilities in their family and are faced with all the problems that such a person can encounter.

The most important perspective of these persons refers to the introduction of special programs against the discrimination of people with disabilities in schools. These programs lead to changes in behavior and attitude of normal persons towards persons with disabilities. Through these programs, communication barriers are removed, the emphasis is placed on socialization and integration, on unconditional help and not least in the social acceptance of all people.

Conclusions and discussions

Even if globally, great progress was made in terms of "raising certain barriers" related to transportation facilities, accommodation, sightseeing access for these persons, however a small number fully participate in tourism. Such participation is supported by the right of all individuals and is recognized as a complex interaction between the **body's functions/ structures, actual activity, participation and environment** [9]. The environment is conceptualized as both physical and as an attitude and both can hinder or facilitate the full participation of such persons.

The market of people with disabilities is growing in importance and taking it into account has become an important issue for tourism authorities. By understanding the importance of this market, many countries hope to gain high market share in this area. People with disabilities should not be considered incapable of actual participation in tourism activities or in establishing relationships with other people. It is absolutely necessary to accept the fact that travel is an equal right for all, including persons with disabilities.

The barriers on limiting the access of disabled persons must be considered both from the point of view of the service provider and from the point of view of persons with disabilities.

Considering that dealing with people with disabilities is an inescapable reality, and regardless of our feelings in this regard, the subject must be given all due attention and managers in the tourism industry must take responsibility for this subject.

Business resilience and the merger and acquisition activity

Barna F.-M., Nachescu M.-L.

West University of Timisoara, Faculty of Economics and Business Administration, Finance Department (ROMANIA)
flaviabarna@yahoo.com, mnachescu@gmail.com

Abstract

Business resilience has become a must in the last decades because, in order to survive the high economic competition on the global market, companies can no longer afford to lose time and money due to unexpected events. Their recovery plan must respect the specific needs of the organization and offer a quick solution for any situation.

One of the situations that must be specially included into the business resilience strategy is that concerning the restructuring of the company. M&A operations are risky operations that can generate important synergies for the organization or on the contrary to get the company out of business. Cultural aspects are regarded in this paper as one of the most important aspects to be handled through the business resilience plan.

Keywords: business resilience, mergers and acquisitions, risks, organizational culture.

Business resilience as the best defense against risks

Taking into account that lately, due to the increased competition and globalization, the economic environment is a more and more risky one, disaster recovery is no-longer an option, but a must. The concept of business resilience is not a new one. When talking about business resilience, one normally thinks about the ability to maintain continuous business operations and to quickly react, in an organized manner, to any event that could disrupt the normal activity of the company. This can and should enable growth and a better image, that of a trustworthy partner.

A strong business resilience strategy is a key factor in avoiding high costs in money, effort and time when unexpected events occur. Such a strategy needs to start with the complete understanding of the business and of its needs in order to survive. The higher risk in identifying what could go wrong is to become too defensive when the best approach is to be proactive. A proactive attitude not only helps you survive at low costs, but also comes forward in satisfying different other needs such as preparing for audits, changes in the environment, adapting to new customer's demands.

Lately, organizations are highly exposed to a large number of risks, among which downtime (disruptions) is a very important one, as the financial impact can put the business of the market. Downtime also has indirect effects such as a bad image of the company in front of its partners, regulatory non-compliance and even loosing the market share.

Business risks do not occur one at a time. Small events, if they appear on top of other events can generate real disasters. They can be divided into:

- Event driven risks (that cannot be controlled by the company) – can be reduced by identifying the business vulnerabilities and preparing a resilience strategy.
- Data driven risks come from the misuse of information and are usually connected to the informatics system of the entity (system failure, viruses, network problems etc)
- Business driven risks can appear when the organization fails to meet the industry standards or those imposed by specific standards, cannot adapt to the marketing promotions used by others, is faced with audits or product roll-outs that were not taken into account in the initial strategy applied.

Even though resilience plans are important, they are not easy to be set in place. In today's world, resources are extremely scarce and the return on investment of resilience strategies should be rationalized. The key is to find alternative resources during disruptive events that are available and can easily be accessed. Effective business resilience strategies allow you to have a backup solution when you need it.

Taking the human factor into account in the business resilience strategy is a must as in times of distress people are usually overworked and you need them to be at their top performance. Therefore, the business resilience approach can help managers plan the workloads according to the potential risks and sustain the overworked personnel in time of distress or unavailability of part of the workforce due to different reasons.

Another challenge is to make executives see resilience as a strategic enabler and not as a simple insurance. A sound plan that can prove the value of the business resilience across the organization accounting for business, workforce and technology can make this easier. Executives are the ones that have to decide which solution fits best their organization (taking into account what level of protection is really needed) and once the decision is taken to procure the necessary funding. They are going to design a strategic plan in respect to the business resilience strategy and make sure that resources are not wasted on unnecessary technologies or activities.

Resilience tiers are a good tool that actually helps managers understand the real organizational needs and plan resilience accordingly, optimizing the investment. Resilience tiers use classification systems that set the resilience levels needed in order to match the organization's needs. The resilience tires allow management to check if the resilience requirements can be met with the available technological possibilities, to align business to IT, to reduce the investments in resilience capabilities and to create real and adequate business resilience architecture. Resilience tiers help managers in charge with disaster recovery and operation managers better work together and approach the resilience requirements as enterprise-wide and integrated. The resilience tiers highly differ from one company to another and one of the important steps to be taken is to fully understand the optimum amount of resilience for each organization so that the management can choose to invest in the priority business resilience needs.

One of the situations when resilience tiers can serve as guidance is when two companies take part into a merger &acquisition (M&A) procedure and the potential chaos that can develop due to this must be managed. In such a procedure, many times, there are lots of incompatible processes, especially in the day to day operations, as the long term objectives are usually analyzed in the pre-merger stage. Resilience plans help management set a framework for selecting the best practices from each "actor" of the M&A and put them together into a new architecture that can work as a unit structure.

Merger and acquisition activity

One of the events that highly expose a business to risk is the M&A activity. Lately, such restructuring activities have become a part of the company's life as companies need to expand and through M&A they can diversify their activity or make it more specific, can gain the advantages of a bigger size or can simply gain new markets. Still, lately, investors are much more prudent and try to find ways of reducing the risks that they are facing. Business resilience plans seem to be the solution.

The big companies need to dominate their markets and therefore they need to grow at a quick pace and in a very short time, reason for which they enter often into mergers or acquisitions. Unfortunately, not all M&As succeed and statistics show that more than half of these operation do not lead to an improved performance of the participants and become big failures.

There are many researchers that have tried to find enough poof in respect to the performance or on the contrary the failure in M&A activity, in order to close this dilema once and for all ([1], [2], [3] etc). Still, there is no consense in this direction and lately, the focus of literature has highly changed, researchers becomming more interested in the reasons behind these operations and in the way risks associated can be reduced.

The reasons behind the M&A activity are very different. They go from consolidating a certain market position to incorporating new technologies and competences, from expanding to changing the activity field, from becoming a market leader to saving the company. Some authors classify the reasons behind M&A activity into:

- Commercial reasons, financial reasons, special situations
- Management reasons, efficiency reasons, fiscal reasons [4]
- Industrial reasons, financial reasons and management team's replacing [5]
- Financial or nonfinancial reasons.

Still, the most common reasons behind M&A could be considered:

- The commercial or industrial reasons: operational synergies, market power, external growth, diversification, entrance on new markets;
- The financial reasons: financial synergies through the risk diversification, increasing the endebtment capacity, fiscal advantages, financial survival;
- The management reasons: a more efficient management, introducing a new team, power, income, personal reasons;
- Special reasons: getting listed, obtaining certain patents or licenses, obtaining certain clients or suppliers.

The investor should take into account that M&As give place to a large number of things that could go wrong and therefore he/she should prepare a resilience strategy in case things do not work out the way it was planned. Even though M&A are planned events, as they take an entity from one equilibria state to another and create new behavioural models and new structures ([6], [7], [8]), the unexpected events are quite common. Therefore, a sound resilience strategy is absolutely vital for all companies going through such events.

One of the things that should always be kept in mind is that mergers and acquisitions are risky businesses that do not guarantee the occurrence of the synergic expected effects. Still, good planning of such an operation can increase the probability of a success. Acquisitions are inherently risky investment decisions as the acquirers have little knowledge about different information concerning the business they pursue. Even if there is always a certain amount of information available, certain details are deeply buried, far away from the eyes of the prospective buyer. Therefore, often acquisitions are done based on assumptions that can be far from the truth sometimes. Still, in the case of big deals, the buyer will not accept to base his decisions on the data the targeted company is offering and will ask to look deeper into things, in order to validate key assumptions and to mitigate the risk of unpleasant surprises. This closer look is known as due diligence. We consider that a well planned and executed due diligence review is the key to a merger or acquisition's success.

The most important causes that generate the failure in mergers and acquisitions are:

- Difficulties to adapt due to different corporative cultures, ways of interconnecting financial and audit systems, difficulties in setting effective working relations, problems in solving management issues of the new economic entities
- An inexact or faulty evaluation of the target company: no due diligence process can be translated in a too high price paid for the target company
- A significant pressure due to a high level of debts
- The incapacity to obtain the expected synergy due to different causes
- A too big diversity
- Problems in communication at organization level
- The focus of the managers just on the acquisitions, with the ignoring of other obligations regarding the management of the entity
- A too large entity leads to difficulties in getting a consistent management process. Formal rules and politics can get in the way of flexibility and innovation.
- Differences regarding the authority.

Even though the reasons found by different authors regarding the M&A failures are quite different, most of them are connected to one of the following aspects:

- Management failing in the strategic due diligence operations – these operations should allow the buyer to question in a critical way the aspects on which the financial and operational due diligence must insist upon. Also, this way, the managers can decide if they need to use external experts.
- The management fails to understand the relations between the clients and the employees of the target company which will lead to loosing clients when different employees decide to leave the company.
- The management fails to perform the financial and operational due diligence for the target company, leading to the incorrect prognosis for the income increases or the generated synergies.
- Failure in including the organizational culture of the purchased company in the purchasing company's culture.

In 2003, Weber and Camerer [9] have studied the impact of organization cultural differences in mergers and acquisition proving that such differences can generate important problems during the restructuring process. Still, one of the oldest studies on the influence of cultural conflicts on the success of mergers and acquisitions is that of Chatterjee, Lubatkin, Schweiger and Weber from 1992 [10]. This study analyzed the cultural typology of 52 management teams and has identified the existence of a strong negative connection between the cultural differences and the variation of the shares value on the market.

Organizational culture and its impact on the resilience strategy in M&A activity

Cultural differences between two organizations that merge can result in conflicts. Many authors have analized the cultural compatibility's effect over the new company's performance ([12], [13], the cultural conflicts and their impact on the integration process [14, [15]. A better management of the behavioural and cultural aspects could increase the M&A quality [16], [17], [18].

Literature concerning the cultural dimensions of M&As can be divided into two main groups:

- One representing a mainstream thinking and adhering to a classic concept of culture, where culture is seen as an empirical category, "a system of values and norms which can be objectively described something that

members of a group, an organization or nation have or bear collectively" [19]. Researchers consider that by systematically observing the behavior and attitudes of a community's members, the basic cultural values and beliefs can be drawn. Whenever individuals from two cultures come together, a change takes place whereby individuals adapt or react to the other culture. M&A provide fertile ground for such cultural changes and exchanges and supporters of the classic culture concept focus on cultural clashes and see problems of integration as being caused by cultural differences, which need to be bridged. A good resilience strategy would need to include details about how cultural disparities can be eliminated. Researchers expect that a cultural analysis of the companies involved, performed before a merger or acquisition has taken place, will make it possible to predict problems of integration and to timely adjust the company's integration strategy.

- One, representing an alternative to mainstream thinking and working with a constructivist concept of culture [19]. In the social constructivist concept of culture, culture is seen as "ever changing patterns of interpretation"[19] and it is based on shared or partly shared patterns of interpretation, which are produced, reproduced and continually changed by the people identifying with them. Culture is made up of relations and therefore, a culture comes into being in relation to and in contrast with another culture. In this case, mergers and acquisitions shall generate a transformation process that leads to a self-image of the organization that is being developed by interaction. Such interactions shall formulate new cultural identities [19] that cannot be predicted. Therefore, the authors that adopt this approach, consider that a resilience plan that includes the cultural aspects of the M&A is almost impossible to be designed.

In the 60s-70s, Geert Hofstede [20] carried out a large-scale questionnaire study and came up with five cultural dimensions that "describe basic problems of humanity with which every society has to cope. The variation of country scores along these dimensions shows that different societies do cope with these problems in different ways". He considers that culture is a relatively stable system of collective values, and allows managers to establish the kind of reaction a group shall have at the changes in its environment.

The organizational culture is regarded by some authors as a "unique social construction of reality" with an almost infinite number of combinations of determinants possible (Rousseau in [19]). Consequently every organization develops its own culture that is so unique as to bear little resemblance to the national culture of its members. Individuals tend to select organizations which they perceive as having values similar to their own. When a good fit happens between corporate and national values, a strong psychological bond is formed between the organization and its employees (Very et al. in [19]).

Alfonsus Trompenaars [21] identifies four broad classes of corporate cultures based on the criteria of equality/hierarchy and person-orientation versus task-orientation: family culture, Eiffel Tower culture, guided missile culture, incubator culture.

In establishing the plan for the merger and also the resilience strategy of the company resulting after the merger or acquisition one should take into account that in order to work together, one must trust and in order to trust, one must understand. The persons in charge with the merger or acquisition should fully understand the cultures of the companies involved and try to fill all the gaps that exist between them.

Conclusions

In order for the organizations to survive on a very competitive market, they are taking into consideration more and more often the possibility of using M&A. Still, the risks such procedures involve reduce the willingness of managers and shareholders to accept mergers or acquisitions as being good solutions for the wellbeing of their organizations.

The organization culture is in most cases the biggest risk that has to be overcome. Therefore, including in the business resilience strategy procedures that can reduce the disparities between the components of the new organization that comes into being after the M&A is a must that can make the difference between success and failure. Still, cultural disparities are not easy to eliminate and in order for this to become possible, during the designing of the resilience strategy, the cultural characteristics of the company must be included in different categories regarding the power distance, individualism or collectivism, uncertainty avoidance, long term or short term orientation and masculinity or feminity.

Analysis resilience to people affected by unemployment

Călăuz Adriana F.

Cluj-Napoca Technical University-North Baia Mare University Center (ROMANIA)
adrianacalauz@yahoo.com

Abstract

In 1995, Gordon has defined resilience in the following terms: "a person's ability to form and develop his skills when faced with adverse situations, obstacles imposed on the living environment." These difficult circumstances can become chronic and consistent or sporadic. To develop these skills a person must bring all its internal resources, biological and psychological and also external resources provided by the environment.

Recently, in socio-economic publications was introduced the phrase "Elastic community", making reference to the intrinsic ability of communities to find a balance or a new balance, which can ensure their operation under threat or adversity.

Unemployment can be considered a phenomenon of social and economic adversity affecting some population group. Romania, like other European Union countries, also confronted itself with socio-economic crisis which generated an increase in the unemployment rate.

The aim of this presentation is to show the way in which the informational, counseling, mediation and professional orientation activities can influence the mobilization of people on the labor market. An important aim of this exposure is to analyze the degree in which the personal abilities/personality features determine resilience. The evaluated group was formed of 250 unemployers. These come from the North-West region, Maramures County, from the rural as well as the urban area.

Keywords: resilience, economic crisis, integration, unemployment, counseling.

Introduction

The term *resilience* is widely used in various fields: legal, economic, social, cultural, such encountering expressions moral strength, physical strength, strength community, cultural resilience, ecological resilience, and others.

Resilience word comes from the Latin word "rescindere", which means to cancel or terminate an agreement, an act. This concept is presented in the Anglo-Saxon dictionary for *support moral / quality of someone who not leave strayed (back) from his path [1]*

Specialty papers mention the fact that people who manage with successfully the adversity situations have certain features that are visible since childhood and continues to manifest in adulthood. They are characterized as being actives, energetic, optimistic, determined, strong frustration able to contol your impulses and usually enjoys a positive attitude from family, acquaintances, with satisfactory living conditions. Therefore, the role of the environment in resilience equation can not be ignored, external factors are very important [2]

Recently, in socio-economic publications was introduced the phrase "Elastic community", making reference to the intrinsic ability of communities to find a balance or a new balance, which can ensure their operation under threat or adversity. At the community level, resilience can provide some protection from the effects of deprivation/unemployment and has been associated with norms of trust, tolerance, support, participation and reciprocity [3].

Unemployment can be considered a phenomenon of social and economic adversity affecting some population group [4].

Romania, like other member states of the European Union has been facing over the last years and is still facing a recession causing a rise of unemployment rate. Given the circumstances, between 2011 and 2012,in the North- West of Romania, more precisely in Maramures county, the integrated project - *Integrated project for integration in the workforce*- was carried out, whose general objective was improving employment opportunities in the workforce for deprived people by having them take part in integrated, personalized and efficient services of information, counciling , the development of professional skills, as well as other skills specific to more professions by participating in programs of professional training authorized by CNFPA. The

purpose of the project was to draw and maintain a number of 250 people from the target group into the workforce, by bringing the integrated activities for employment closer to their possibilities and needs, in an area like Cavnic , remote from the centers capable of providing such services.

1.1 The purpose of the study

The aim of this presentation is to show the way in which the informational, counseling, mediation and professional orientation activities can influence the mobilization of people on the labor market. An important aim of this exposure is to analyze the degree in which the personal abilities/personality features determine resilience to the unemployers.

1.2 The objectives of the study

Identify frequency obtained (very poor, poor, average, good, very good) to the assessment of cognitive skills (generic skills learning and decision making) by age, gender, level of education, labor market status, geographical background.

Identify frequency levels obtained (below average, average population, above average) personality tests (autonomy, extraversion, emotional stability, conscientiousness), depending on age, gender, labor market status, living environment.

1.3 Target group for research

The target group was made up of 203 individuals, 111 of whom were women, 92 men, and according to the status in the workforce: 46 individuals searching for employment, 66 inactive individuals, 46 unemployed registered, 45 unemployed unregistered. 119 of these come from urban background whereas 84 from rural background.

1.4 Research methods

The study was conducted following the results obtained from the tests administered to the individuals by the *Cognitrom Assessment System*which is legalizedand authorized for psychological assessment tests. In order to achieve the objectives that were set in the case of the present study , we have considered the following tests :

A. Belonging to the category of cognitive ability tests:

a) General learning ability test
b) Decision-making ability test

B. Personality tests:

a) The A.P. test regarding the concept of " personal autonomy"
b) The CP5F test measuring:

The statistic processing and analysis of data was achieved with the help of SPSS program, version 20, both crossed frequency analyses (for obtaining the Qhi-Square quotient) with the view to obtaining significant differences and double varied correlations (the Pearson and Spearman quotient) being measured, the latter dealing with significant connections of variables, in the present case, between cognitive abilities and personality features.

1.5 The results of the study

Following the statistic processing of data, we have obtained a set of data out of which we bring into view only those with a relevant significance (given by Asymp. Sig index- the significance threshold "p" which has to be < 0,005).

We have obtained significant differences in frequency as far as age and general learning ability are concerned (p=0,00). The general learning ability represents the capacity to acquire new information, to reorganize it and operate with it in the problem solving process. It includes attention focus, resistance to interference, ability to organize information in memory, cognitive inhibition, short term memory and an operational component involving: analytic reasoning, analogical transfer, work memory, flexibility in categorizing [5*]*.

Compared to the other age groups, the young ones (18-24 years old), have scores of general learning abilities at the "very poor" level as well, and at "very good' level they have the smallest percentages.

The highest scores for learning ability levels (11,7 %) are represented by those aged between 25-45.

Significant differences (p=0,00) between men and women as far as general learning ability is concerned can be found. A significantly greater percentage than women (11,7 %) is held by men (17,1 %) as far as "good" learning ability is concerned (the fourth level) (Table.1).

Table 1 Significant differences concerning general learning ability according to age and gender

General learning ability / Age/gender	Very poor	poor	average	good	Very good	Total	
18-24 years	1,0%	9,3%	12,7%	9,3%	1,0%	33,2%	
25-45 years	0,0%	2,9%	32,2%	11,7%	2,9%	49,8%	Chi-Sq. =41,0
45-54 years	0,0%	0,5%	5,4%	6,8%	2,4%	15,1%	P = 0,00
55-64 years	0,0%	0,0%	1,0%	1,0%	0,0%	2,0%	
Total	1,0%	12,7%	51,2%	28,8%	6,3%	100,0%	
feminine	0,0%	7,8%	32,2%	11,7%	2,9%	54,6%	
masculine	0,0%	4,9%	19,0%	17,1%	3,4%	44,4%	Chi-sq.=.213,4
Total	1,0%	12,7%	51,2%	28,8%	6,3%	100,0%	p =0,000

Huge differences are noted (p=0,01) as far as decision-making ability is concerned between the four categories of deprived individuals in the work market. The decision-making ability represents the reasoning of the decision maker, the ability to choose the most rational decision out of many alternatives available. The unemployed registered at AJOFM have a far greater decision-making ability (11,7%) compared to those unregistere (Table.2).

Table 2. Significant differences concerning decision-making according to status in the work market

Decision-making ability / Status	Very poor	poor	average	good	Very good	total	
Unemployed registered	0,5%	1,5%	3,9%	11,7%	4,9%	22,4%	
Unemployed unregistered	0,5%	4,9%	2,4%	5,9%	8,8%	22,4%	Chi-sq.=25,6
Individual searching for employment	1,0%	5,9%	7,3%	5,4%	3,4%	22,9%	p. =0,01
Inactive individual	0,5%	5,9%	8,8%	10,7%	6,3%	32,2%	
Total	2,4%	18,0%	22,4%	33,7%	23,4%	100,0%	

Significant differences (p=0,003) of behavioral autonomy between men and women have been recorded. Women are more independent as far as behavior is concerned (37,1%) as compared to men (24,4%). Behavioral autonomy represents an individual's ability to act according to their own decisions and to manage on their own [5*)* (Table.3).

Table 3. Significant differences in behavioral autonomy between men and women

Behavioral autonomy / Gender	Below average	Population average	Above average	total	
feminine	6,8%	37,1%	10,7%	54,6%	Chi-sq.=15,99
masculine	14,6%	24,4%	5,4%	44,4%	p=0,003
total	22,0%	61,5%	16,6%	100,0%	

The results achieved with the help of CP5F on personal autonomy, which is considered to be a synthesis of axiological, emotional, cognitive and behavioral autonomy, points out significant differences(p=0,00)between men and women. Women show higher scores at "above average" personal autonomy (21%) which means that a high percentage of women are independent as far as self-assessment and decision-making ability are concerned (Table.4).

Table 4. Significant difference between men and women in personal autonomy

Personal autonomy / Gender	sub medie	media populatiei	pestemedie	Total	
Feminine	4,4%	29,3%	21,0%	54,6%	Chi-Sq.= 13,271
Masculine	6,3%	29,8%	8,3%	44,4%	p=0,01
Total	11,2%	59,5%	29,3%	100,0%	

According to the statistics of the population in question(p=0,01) it can be concluded that the individuals from the urban background are more extrovert than those from the rural background. Since extraversion is a psychological tendency towards things outside their own person, focusing attention on physical and social atmosphere (objects and people around them), an intense desire to act, prone to taking action, ease in communication, sociability, need for experiences, it can be concluded that those living in urban areas are more inclined to action, searching a professional identity and financial independence (Table.5)

Table 5.Significant differences in extraversion according to uran/rural background

Extraversion / background	Below average	Population average	Above average	Total	
Rural	2,9%	16,1%	22,4%	41,5%	Chi-Sq.= 8,083
Urban	11,2%	24,9%	22,4%	58,5%	p=0,01
Total	14,1%	41,0%	44,9%	100,0%	

As far as emotional stability as part of personality is concerned, women show higher percentages (26,3%) than men (13,7 %) at "above average " level. On the whole, women show an increased emotional stability. Emotional stability means being able to maintain one's emotional balance in stressful situations without resorting to emotional extreme outbursts that are not adequate with a particular situation. It is also noted that those living in urban areas developed an emotional self-control ability to a greater extent compared to those living in rural areas (Table.6).

Table 6.Significant differences in emotional stability according to gender and background

Emotional stabi.lity / Gender	Below averag e	Population average	Above average	Total	
feminine	4,9%	23,4%	26,3%	54,6%	Chi-Sq.= 10,395[a]
masculine	7,8%	22,9%	13,7%	44,4%	p=0,03
Total	13,2%	46,8%	40,0%	100,0%	
Rural	4,9%	14,1%	22,4%	41,5%	Chi-Sq.= 12,464
Urban	8,3%	32,7%	17,6%	58,5%	p=0,002
Total	13,2%	46,8%	40,0%	100,0%	

As far as conscientiousness is concerned, this varies significantly (p=0,02) according to study level, being higher in high school graduates. According to background, people living in urban areas are more conscientious and responsible.

Establishing double varied correlations between cognitive skills, (learning ability, decision-making ability) and personality aspects (extraversion, emotional stability, conscientiousness, personal autonomy), we have obtained only one significant connection p=0,045), namely between decision-making ability and emotional

stability, which means that individuals who are more emotionally stable are capable of making correct and efficient decisions.

Concluzions

On the study group, it follows that The subjects in the age group of 25-45 years old achieve performance on general learning ability. Male subjects achieve a good level of general learning ability, and female subjects achieve an average level.

Unemployed people registered at CEA have increased decisional capacity and those unregistered have lower decisional capacity and lower self -assessment ability.

The unemployed with primary education, and those with higher education achieve low performance in Axiological autonomy. The unemployed high school graduates have an increased level of performance, at a psychological scale –their "consciousness".

Urban unemployed unlike those in rural areas, have autonomous / stable principles and personal values and selfassessment capacity, critically analyze and make decisions about their own person ; they have improved their capacity to express emotions easily, are more extroverted, with a manifest need to act, are responsible ,with an increased capacity for emotional control.

Women, compared to men, have a bigger capacity to act according to their own decisions, they try harder to be on their own, have increased personal autonomy and, in stress situations, they are more emotionally stable.

Unemployed who have increased decisional capacity have also emotional stability.

Analyzing the influence they have had counseling [6], information and media on unemployers, following the personality assessment on certain aspects(skills, interests, motivation, personality) the psychologist devised an individual career profile (with the most relevant aspects of psychological functioning at cognitive, motivational, behavioral level). Based on this career profile but also on a structured interview (centered on professional history/ career expectancy of an individual), certain recommendations were made for professional training courses.

Each person from the target group of the project was informed about the job market and the evolution of professions, benefited from professional guidance, which lays the basis of professional career building by increasing self-esteem with the view to making decisions about their own careers. Each person was also trained in methods and techniques of searching employment. There was a permanent searching and identifying of job opportunities, discussions with potential employers were held, activity which resulted in the employment of a significant number of people from the target group.

As a result of the project activities, the following findings were noted: 250 individuals informed, psychologically guided, mediated in the job market, trained in computer science skills and also in the following professions: trade workers, carpentry, waiters, bakers, pastry workers, textile workers , construction workers, 30 individuals employed over a 6-month period since the completion of the project.

Resilience at work

Cameron J., Hart A., Sadlo G.

University of Brighton, (UK)
j.cameron@brighton.ac.uk, a.hart@brighton.ac.uk, g.sadlo@brighton.ac.uk

Abstract

An ecological conceptualisation of resilience was one of the major orientating concepts for this doctoral research which used critical realist methodology to gain explanatory insight into the job retention challenges faced by employees recovering from mental health problems. Methods involved a literature review of qualitative job retention research, a comparative case study approach, and service user collaboration.

One case study comprised seven employed people who were using acute mental health services. The second comparative case study comprised fourteen users of a community-based job retention project.

Work mattered to people during recovery because of feelings of guilt about not working, and because some feared that work had, or could, exacerbate their mental health problems. Such fears co-existed with a strong sense that work was an important part of people's lives in terms of finance, social capital, occupational capital and personal capital. These assets were under threat, but they also had the potential to be deployed to support a resilient recovery.

Participants were on complex and uncertain return-to-work journeys, facing a combination of internal and external obstacles. Barriers arose from the direct impacts of mental health problems, external and internalised stigma, job demands and the workplace environment – particularly relationships with colleagues and, above all, managers. Findings suggest that return-to-work trajectories are likely to be more successful and sustainable when such challenges are addressed.

Broader implications were that occupational and ecological resilience perspectives can be integrated to help understand the challenges people with mental health problems encounter when seeking to retain employment.

Keywords: Resilience, employment, return to work, mental health, occupational science.

Literature review

A literature review, informed by Paterson et al's [1] meta-study approach, was conducted focusing on qualitative research into job retention experiences of employees with mental health problems. Some qualitative studies' concern with learning from the strengths displayed by workers with mental health problems [2,-6] signalled the potential relevance of resilience to the research topic.

Understanding strengths and vulnerability as separate constructs rather than bipolar opposites of a single phenomenon [7] possibly explains some of the paradox of how work can act as both a potential stressor, as well as a resource which can provide strength in recovery. Furthermore, if strength and vulnerability are not part of a shared continuum then this may explain the suggestion that strategies influenced by stress-vulnerability models of mental illness [8] may not always be helpful in vocational terms [9, 10]. By contrast, the literature review findings suggest that a degree of acceptance of mental health problems, coupled with flexible illness - or lifestyle management - strategies, can be helpful. Van Niekerk's [11] conclusion regarding a worker's ability to respond to mental health problems with flexibility, tolerance of mild symptoms and to "roll with the punches" (p463), was particularly redolent of resilience formulations.

Some mental health recovery accounts have explicitly referred to the resilience displayed by individuals [4, 12-14]. A central aim of such accounts is often to challenge negative and passive views of people with mental health problems as victims, dependent on mental health systems to rescue them. An understandable consequence of this aim is that sources of resilience more related to the individual come to be emphasised. This is potentially problematic if this emphasis is detached from the implicit critique of paternalistic service provision – and thus may explain criticism that recovery perspectives are used to justify withdrawal of support undermining the sustainability of people's recovery [15].

Yet, rather than counterpoising individual resilience to service provision, Ungar [16] has gone so far as to define resilience as "Adequate provision of health resources necessary to achieve good outcomes in spite of serious threats to adaptation or development" (p429). Rutter [17] maintains that "resilience does not constitute

an individual trait or characteristic" (p135). Roisman et al [18] argue that resilience is best understood as "an emergent property of a hierarchically organized set of protective systems that cumulatively buffer the effects of adversity and can therefore rarely, if ever, be regarded as an intrinsic property of individuals" (p1216).

There is a strong body of resilience research and theory which has followed this ecological perspective of resilience [19-25]. Here resilience is seen as a process, or outcome, residing in both individuals and their context and collectivities. It follows that resilience-building can aim to build individual and environmental assets – or challenge restrictions to both. Much of this resilience literature, however, relates to children, families and young people.

While concepts and theories of resilience are increasingly being discussed in relation to adults with mental health problems [4, 13, 14, 26, 27] there is very limited explicit application of them in relation to the topic of work and mental health. UK policy [28] has proposed that people with mental health problems may experience more success at work if they are resilient, where this was defined in predominantly individualistic terms, as having the capacity to endure adverse circumstances and maintain emotional stability and well-being. Furthermore, claims for the relevance of resilience in this document were largely reliant on research and practice interventions focused on developing resilience through childhood and adolescence.

The concept of resilience can be found in the more general world of work-related literature. However, here a more sophisticated understanding of the concept is often absent. Thus, some resilience-at-work tools, interventions and resources focus on how individuals can be made more resilient to cope with pressures of work [29-31] and display limited consideration of how these pressures could be reduced. Exceptions to this include the research report produced for the Chartered Institute of Personnel and Development, which presents the relevance of resilience to the workplace with a thorough grounding in resilience theory [32], though cites limited research directly related to the world of work. A similar environmental perspective of resilience is apparent in the blogs and guide produced by 'The Resilience Space' [33] which also criticizes elements of positive psychology for an expectation on individuals to change their thinking to cope with adversity rather than challenge the adversity.

Understanding resilience as emerging from complex processes involving interactions between individuals and their environments [17, 34, 35] has enabled researchers and practitioners to see resilience as something that can be developed and nurtured [22, 36, 37]. The literature review found evidence of this development occurring as some people with mental health problems seek to retain their work. This occurs at the individual level, as people construct and deploy their own strategies, or are helped by others to do so. It can also be seen in attempts to create more supportive environments, either at the immediate level of the workplace or at the level of policy and service developments. Consideration of resilience seems to bring with it an emphasis on the sustainability of recovery that adds to the other perspectives. The review identified that resilience was a valid orientating concept for the research study. Notably the more ecological conceptualisations of resilience may help in understanding the adversities that workers with mental health problems face, and may also call attention not just to whether they manage to return to work, but to the sustainability of the return.

Methodology and methods

This study adopted a critical realist research methodology [38, 39]. This holds that there exists an external reality but that people's perspectives of this may vary (e.g due to factors such as class, gender, ethnicity and age). Critical realism considers it is possible to gain explanatory insight into structures and mechanisms that shape reality using a range of inductive and deductive analytic procedures.

The research recruited participants from two settings: 7 users of acute mental health services and 14 users of a community-based job retention project for people with mental health problems - both in South of England. All had a range of moderate to severe mental health problems and were employees on sick leave form a broad range of jobs. Service users collaborated in the study design, implementation and analysis in both settings through user group panels.

Data were collected for both studies using semi-structured interviews, which are consistent with the critical realist combined inductive and deductive approaches and were designed to capture the depth and breadth of job-retention experiences. The analysis methods were derived from Danermark et al's [39] six stages of explanatory research, based on critical realism (p109-110).

Findings

Participants found that their working lives were severely disrupted for reasons related to their mental health problems. All were on sick leave from work, and described a similar range of challenges. These included internal challenges, such as symptoms which undermined their ability to sustain work, as well as external challenges such as the experiences of stigmatising attitudes.

I nearly crashed one of the work vans because I heard voices. I physically can't concentrate on anything when I hear the voices. […] I was like halfway in a bush and I had to pull myself out. (Ben)

I would just retreat to my bed because I couldn't cope, I felt overwhelmed and although I'm not doing the sleeping here [psychiatric inpatient unit], I think when I get home I'm just going to do the same […]. (Hilary)

I felt so dreadful, my depression was so bad, I was really in a bad place mentally and physically as well […] I couldn't go back. I had to contact them. I felt dreadfully guilty […] and didn't even feel that I could speak to my line manager because she was so unsupportive and uncommunicative as well. (Alice)

[my manager] was basically complaining about the fact that I'd gone off sick […] – oh, what was it her words were – 'Oh I don't suppose you can help your sickly friend out can you and do this visit for her.' (Rebecca)

Multiple parties were involved. All this meant that for both groups the task of navigating a return to work was considerable and complex. For the community participants this was also apparent in the broad range of interventions which they received; for the acute mental health service users it was often revealed in the degree to which they struggled to address those challenges with limited and uncoordinated support. All but one of the acute participants lacked sufficient co-ordination, collaboration and strategy to support their job-retention needs. They did, however, benefit from some more recovery-orientated interventions that appeared to support vocational as well as general recovery.

[The psychiatrists] could talk about your friends at work, […] 'Do you go out with them?', 'What do you do?' […] maybe even talk about people that you don't like at work and why […] because they're more likely to be the ones that are causing the problems […] maybe asking about the bits that you don't like about work, because they're the bits that are going to upset you. […] It's like it's a forgotten part of your life […] let's face it – most people spend more time at work than they do at home. (Ben)

I […] did structured groups like pottery, creative art, gardening, things that would distract you from maybe suicidal thoughts or self-harm. (Gavin)

we've [participant and job retention project worker] been looking at actually what is ok about me with my illness and not what's wrong with it – [it] has helped me to […] really stay above that and keep myself from getting really negative[…] I've not had to go into hospital and I've actually had a really positive outcome. (Alice)

The community job retention project provided a high degree of co-ordination of return-to-work planning, either by the project workers making contacts with people's employers, or by them enabling and encouraging the participants to do so. In the process, they displayed a high degree of collaboration with both the participants and their employers. Collaboration with health services was less apparent. In part this may be because the participants were less engaged with either their General Practitioner or community mental health services – but it may also be that such collaboration was more difficult because the project was neither organisationally nor physically integrated with either primary or secondary mental health services. This may have arisen because it was a charity-funded pilot and not a health-commissioned project. We do not know if it would have undermined the project's efficacy had more of the clients been engaged with mental health services.

In terms of strategy, the co-ordination and collaboration enabled a range of effective interventions to be deployed, focusing on the worker, their work and their environment. For some the experience of doing engaging productive or creative activity helped.

One of the very first things that [the project worker] did […] was […] to try and offer suggestions of proper adjustments […] like changing my start time slightly so that I wasn't battling rush hour traffic when I was feeling very stressed already, which would also help my childcare situation. Or the possibility of […] transferring […] perhaps of a job share and making lots of suggestions. (Alice)

[…] the soldering […], the time just flies by because you're really concentrating […]. The [feelings of anxiety and depression] drop. They drop because I'm concentrating more and [have] less time to think of what I'm actually feeling. (Gavin)

[…] we have a pampering evening [on the inpatient ward], so I'll actually do reflexology on people, I'll do aromatherapy, I'll do hand massage […] it's quite empowering, it feels like I'm doing something positive and not just being a passive sort of like recipient of health care, really . (Penny)

In providing the interventions, the project workers' interpersonal skills were valued as highly as more knowledge-based skills. The peer support group also contributed to developing and sustaining effective job-retention strategies. It did this by activating some of the more general recovery-promoting mechanisms (also experienced by some of the acute study participants), notably in terms of reducing feelings of isolation and by people sharing effective problem-solving strategies and knowledge.

Sometimes you think you're alone, you're experiencing a unique experience but then you come up and meet up, you find 'ah' you all face the same problem. It sort of makes you less bothered… (Steve).

Many voiced concerns about what their return to work would be like revealing feelings of anxiety and self-blame.

You're just anxious, since I haven't been at work they've taken on new staff and they've moved to a new part of the building and there's so many things that are new, […] and then you think, 'am I going to go and not be able to cope and make myself unwell again?' and they all just sort of in your head: go round and round. (Yvonne)

I feel like I'm letting my employers down a bit by not sort of being able to cope and be reliable so that worries me. (Mark).

Discussion

Resilience perspectives are useful given evidence of a range of poor outcomes for employees who experience mental health problems [40, 41]. The research has provided insights into the multi-factorial nature of the adversity faced when mental health problems disrupt people's working lives. This study was based on data derived from a cross-sectional interview during recovery, but it was striking how important the sustainability of a future return to work was for participants. Trajectories appeared stronger when there was confidence in future sustainability. Like more established recovery perspectives in adult mental health, resilience calls attention to learning from the people's strengths, as well as their challenges. However, whilst recovery and resilience are related they also have distinct qualities. Both show some concern with the sustainability of recovery, but this is stronger in resilience concepts. In this way resilience frameworks can make great contribution to the analysis of the durability of supports for people with mental health problems.

Where recovery is an individual's journey towards a personally defined state of well-being following crisis or adversity, resilience is a dynamic and evolving outcome of a constellation of interacting internal and external mechanisms which support and sustain that recovery. This new definition draws on Masten's [35] sense of positive outcome despite adversity, Roisman et al's [18] emphasis on the emergent nature of resilience coming out of people's interactions with their environments, and Ungar's [16] even greater emphasis on the importance of the environment to foster resilient outcomes.

The success of return-to-work trajectories should include measures (quantitative and qualitative) of how sustainable any return to work is and whether the experience of work after return fosters long-term recovery or undermines it. That appraisal needs to consider people's experience of precisely what they do at work – which is part of the occupational perspective. Here the terms 'occupational' and 'occupation' are used in a manner consistent with the broader meanings associated with the profession of occupational therapy and the discipline of occupational science [42-44], referring to the full range of consciously performed human activity.

Pemberton and Cox's [45] call "to understand time as a dimension of being, not just a measure for the content of existence" (p80) implies that the sustainability of being over time also should be of concern. For instance, are the demands placed upon individuals by their workplaces ones which call for occupation participation in a manner which enhances health and well-being over the long term? This question further underscores the value of the more ecological understandings of resilience than the individualistic ones present in some literature [46, 47]. This may be particularly important because a narrow individualised understanding of resilience could reinforce the self-blame felt by many participants and thereby increase obstacles to recovery. We found it helpful to consider how the occupational space in which people found themselves could be made more resilient, rather than simply considering how individuals could harden themselves to adversity.

Occupational and resilience perspectives speak to the issue of the humanisation of work. An occupational perspective implies that it is intrinsic to what it is to be human to engage in productive occupations, and thus it fulfils a human need [44]. To restrict that opportunity is to deny people access to what we defined to be 'occupational capital' [48], amounting to occupational deprivation [49], and therefore an occupational injustice [50]. However, if participation in work occurs in a way which is dehumanising, then rather than providing an affirming occupational experience, work can be experienced as a denial of human nature.

Supporting the case for a human need to be productive, there was still an overriding desire to be working amongst our participants – although for some of them their specific jobs were in contexts which threatened to undermine, rather than enhance, their recovery. For their immediate futures, the 'resilient move' was not to give up on the prospect and aspiration to work, but to help preserve their work identity and assist them to find alternative work in less adverse, and ideally more affirming, contexts. Nonetheless, the challenge remains to consider what might happen to the next person in line who fills the vacancy, or to former colleagues to whom potentially toxic tasks may be redistributed. This means asking how workplaces and working practices can be made more resilient so that the working lives for all can be improved, even if that means calling on moral principles of humane experience rather than economic imperatives of efficiency.

Economic resilience to disturbing forces

Ciote C.

Steliana'Spiru Haret' University Of Bucharest, Faculty Of Financial Management And Accounting Constanta, Romania
cristinaciote@yahoo.com

Abstract

Interpretation and analysis on the global recession permanently enrich literature on economic growth and development, but we notice a considerable and increasing interest in studying resilience of the free market. It seems that theoretical routes converge on the question whether monetary and fiscal policies should not put more emphasis on a stable and predictable economic environment to ensure a global economy less volatile and more resilient to disturbing forces.

Resilience should not be an isolated economic objective, but it is advisable to be considered a significant additional constraint on economic growth and employment strategies. Microeconomic changes and reaching social objectives should complement each other and the contribution of private companies and stability and growth-oriented economic policy being therefore essential and empowering themselves.

Conceptualization of resilience of adaptive systems in the economy is reduced to describe social, economic and cultural adaptability of communities and individuals in the context of a globalized world. Most relevant for understanding resilience are topics on the relationship between resilience and vulnerability, institutional analysis and robustness of socio-economic systems.

Keywords: economic resilience, vulnerability, robustness, adaptive capacity, self-organization.

Introduction

The concept of resilience has been widely debated and theoretical approaches have its origin in extremely varied fields, ranging from ecology to sociology, from economics to psychology, political science to engineering sciences. The first definition of the concept comes from the perimeter of ecosystems. Four decades ago, Crawford Stanley Holling defined resilience as 'a measure of the persistence of systems and of their ability to absorb change and disturbance and still maintain the same relationships between populations or state variables' [1] or 'the ability of a system to maintain its structure and patterns of behaviour in the face of disturbance' [2]. More concise, the concept was defined as 'the ability of a system to absorb disturbances and still retain its basic function and structure' [3] or 'the capacity to change in order to maintain the same identity' [4]. Other authors [5] think that resilience can be best described by three essential features: (a) the amount of disturbances that a system can absorb by keeping the same state or domain of attraction, (b) the degree of self-organization that the system is capable of and (c) the competence to produce and enhance the ability for learning and adaptation.

Systems resilience

1.1 Social-economic systems resilience

The analysis of social-ecological resilience of systems requires consideration of the system as a whole and the interdependence between the human and biophysical systems; therefore resilient thinking will inevitably be a systemic thinking. In this context, the resilience is integrated into systemic thinking and for understanding the essence of the phenomenon it is necessary to clarify the following three aspects [3]: (1) people inhabit and operate in social systems inextricably linked to the ecological systems of which they are part, (2) socio-ecological systems are complex adaptive systems characterized by unpredictable, nonlinear, non - incremental changes and (3) resilient thinking provides a framework for socio-ecological system' view as a system operating on multiple spatial and temporal scales. In short, the concept of resilience focuses on how changes occur in the system, especially the way it handles the noise recorded.

1.2 Related concepts

The term resilience is used in combination with other terms such as vulnerability, adaptability, adaptive capacity, transformability and robustness and they are used according to different reference scale [6]. In the literature, the concepts of vulnerability and adaptability refer generally to individuals and households, while the concepts of adaptive capacity, transformability and robustness concern selection of decision-making units, such as local communities and central government.

1.2.1 Vulnerability

Causes of vulnerability [7] can be ecological, economic and social and can be summarized in: geographical proximity to certain areas that have a certain risk factor, poorly maintained public infrastructure and high density of built environment, the health of the community, closely connected to commercial and industrial development, demographic and social characteristics, inequalities affecting access to resources and informations, the capacity to absorb the impact of hazards and disasters without government intervention and political marginalization of the poor inhabitants.

Economic vulnerability is a phenomenon well documented in the literature, both conceptually and empirically [8]. Most studies on the economic vulnerability provide empirical evidence which show that small states, particularly islands, tend to be more vulnerable [9] than other countries due to a high degree of economic openness and export concentration, which leads to exposure to exogenous shocks and increases the risk that may arise in the process of economic growth and development [10]. Studies [11] show that increased risk may adversely affect economic growth and the negative effects of shocks are proportionately higher damage than the effects caused by positive shocks. The high degree [12] of fluctuations in GDP and the export earnings recorded by many small states are considered as one of the manifestations of exposure to exogenous shocks.

The macroeconomic stability, market efficiency, good governance and social development are mechanisms [10] through which the economy reacts endogenously at the negative shocks in order to diminish their effects. These mechanisms confer resilience to the economy by absorbing or counteracting the shocks it is exposed to. The capacity of the economy to recover quickly after a shock is associated with its flexibility which allows return to the initial state and structure; this capacity is more limited in the case of a chronic tendency for large fiscal deficits and high unemployment rates. On the other hand, this capacity will be increased if the economy has discretionary policy tools that can be used to counterbalance the consequences of negative shocks, like a strong fiscal policy, which implies that policy makers can use discretionary spending or tax cuts to counter the effects of these shocks. Regarding the instruments on shock absorption, the existence of a flexible and multi-skilled workforce would operate favourably to weaker external demand which may affect a particular industry and a reallocation of resources in another sector that enjoys a higher request could be a viable solution.

Resilience should not be an isolated economic objective, but it is advisable to be considered a significant additional constraint on economic growth and employment strategies. Microeconomic changes and reaching social objectives should complement each other and the contribution of private companies and stability and growth-oriented economic policy being therefore essential and empowering themselves. European socio-economic model [13] provides a foundation for a resilient structure, because it is less prone to short-term goals and financial innovations and speculations don't carry the same role as in the U.S.A. The economic performance will increase if European countries should avoid strengthening of existing structures in the productive sector and public sector. So no change is recommended as especially proactive adaptation to the future through more open structures and the production of buffer stocks that provide added security and long-term dynamics.

1.2.2 Adaptive capacity

The key feature that distinguishes the resilience of simple systems of the complex adaptive systems' one is adaptive capacity [6]. Adaptability is the ability of systems (households, people, communities, ecosystems, nations) to generate new ways of operating, new systemic relationships and if we consider that certain parts or connections in the system fail or become unbearable, the adaptive capacity becomes a key determinant of resilience. Therefore, in the complex adaptive systems, the resilience can be better defined as the ability to resist, recover and re-organize in response to the crisis, while maintaining the functions of the system, but not its structure. Self-organization is related to novelty and innovation and it inherently generates new modes of operation previously not taken into account. Researches in urbanism and architecture [14] show that resilience grows in dense cities because of innovation: the confluence of different people, ideas and environments generates systemic behaviour with a high degree of self-organization, which continuously creates novelty.

1.2.3 Transformability

Another conceptual notion of resilience is transformability, [6] seen as the ability of complex adaptive system parts to assume a new function. The utilization of these two terms (adaptive capacity and transformability) is relative to the function assumed by the system. To illustrate this relativism, we exemplify through a state community: if the function of this system is to maintain a reciprocal relationship between state and community, then the collapse of the state necessarily indicate transformability because a necessary component of the function was lost. But if the system's function is limited to the provision of essential services to individuals, then a failure of the state does not necessarily indicate transformability, adaptation through self-organization can reproduce its operating.

1.2.4 Robustness

During the past decades, an approach to institutional economics focuses on aspects of complex systems and self-organization. Institutional analysis and development framework developed by the Bloomington School is suitable for all forms of political organization, regardless of the complexity, including self-government as a form of decentralization in the absence of hierarchical order within social systems. The first woman winner of the Nobel Prize for economics, Elinor Ostrom, embraces her neo-institutionalist approach based on a concept related to resilience - robustness, a similar notion which refers to maintain system performance despite uncertainties and exogenous and endogenous changes. A number of case studies evolved by the researchers [15] discloses different forms of adaptations to certain categories of variability and examines vulnerabilities that may develop as a consequence of the adaptive process.

The theme of robustness of socio-economic systems has been widely addressed in the literature for the past decade. After a detailed analysis of the causes [16] that lead to the deterioration of the system capacity of absorbing or counteracting to predictable and unpredictable shock:

- *Connectivity* affected robustness in proportion as the contamination effects increase in intensity in the absence of the mitigation instruments. The epidemics proliferate rapidly under conditions of ineffective control instruments and intense movement of individuals and goods;
- *Explosive development of information technologies and communication* encompass the increase of vulnerabilities of information systems;
- *Interconnectedness of financial markets, increasing of speculative actions* and *the occurrence of toxic financial products* led to increased systemic risks;
- *Poorly managed globalisation* embrittled economic systems and the dynamic comparative advantage caused a zero-sum game in the global space;
- *Exceeding economic dependence of structures that induce shocks* tends to increase vulnerability. Production systems depending on certain sectors are less resilient. The capital structure (borrowed or direct investments) influences resilience, meaning that if the source is a vulnerable sector or country will impress the same fragility to the systems that are dependent on them;
- *Geographic location*, *proximity to other systems* (robust or vulnerable), structural compatibility between neighboring systems influences their state;
- *Insufficient reserves and under-investment in basic infrastructure and education systems* adversely affect resilience;
- *Neglecting the relationship between economic growth and income distribution* leads to weakening of social cohesion;
- *Erosion of the welfare state resources* decreases the capacity of institutions for social dialogue maintaining homeostasis of the system;
- *Complexity* may increase the vulnerability of systems. In the absence of effective dissipative structures (adaptability, self-organization and learning) will appear new vulnerabilities;
- *Demographic change* may generate adverse effects; migration strongly affects the balance between generations and professions.

Conclusion

In conclusion, conceptualization of resilience of adaptive systems in the economy is reduced to describe social, economic and cultural adaptability of communities and individuals in the context of a globalized world. Most relevant for understanding resilience are topics on the relationship between resilience and vulnerability, institutional analysis and robustness of social-economic systems.

Hypostases of resilience for sustainable development

Constantinescu A.

Institute of National Economy, Romania
andreea_constantinescu07@yahoo.com

Abstract

Although both are multidisciplinary concepts, *vulnerability* was extracted by professionals from the usual vocabulary in order to be placed in the center of research in specific areas, while the concept of *resilience* raises several conceptual problems due to its multiple characteristics. But once clarified the meaning of *resilience* related to the scientifically researched context, its paradigm reveals interdisciplinary valences which permits analysis of multiple phenomena in human social area. Particularizing, by replacing separate study of vulnerability and of resilience characteristics with that of *resilient vulnerability*, we believe that sustainable development gains some value capable of exceeding the transversal nature of dedicated studies, in favor of those longitudinal characters, more appropriate for the claimed holistic perspective.

As the horizon of sustainable development includes the benefits of research and practice in the economic, social and environmental fields and, to a small extent, those of individual resorts investigation, this article aims to draw the sustainable development framework around the *resilient vulnerability* by integrating personal plan with others already mentioned here. Thus, a new multidisciplinary bridge arises towards responsible governance as well as the need to integrate adaptive cycle theories and panarchy, which studies the foundations of system transformation under the integrated sustainable development system. Thereby we overcome the vision where the environment is only a sub-component of social systems, and the society just a sub-component of ecological systems, sustainable development becoming a privileged access platform to understand the consequences of interactions between the individual and its social, economic and environmental area, under a system able to integrate alternative perspectives.

Keywords: Resilience, vulnerability, adaptive cycle, panarchy, sustainable development
JEL Classification: Q20, Q56, Q57

Conceptual framework

Despite the fact that we do not have a universally accepted definition of resilience, this concept has all the attributes of a paradigm. Being associated with various scientific and appearing in multiple phrases (from psychological, biological, social, economic and political, to the information resilience*), the concept of resilience refers to the quality of a phenomenon as well as a systemic property*. Because here we are interested in particular relation between individual and global reference to socio-ecological systems, we must discern the characteristics of resilience due to some distinctions. Thus, if on individual level, researchers found between the characteristics of *resilient people* self confidence, active social life, flexibility in the face of change and the ability to set specific objectives, for *ecosystem resilience* must be taken into consideration the ability to cope with natural or man-made catastrophic events that causes or may cause loss of life and property damage (Direction SA, 2011).

Generic resilience refers to the ability of a system to absorb disturbance and reorganize as the situation changes, so that to further keep the same essence, function, structure, identity and feedback. The most common metaphor which renders resilience is the stability of a landscape (Walker B., 2004). While psychology believes that *individual resilience* aims maximum trauma that an individual can record before reconstruction, economic science believes that *economic resilience* refers to preserving the complete system before a shock without excluding renewal system through qualitative changes structure. If in the first case we talk about a *proactive resilience* - of the individual who has the personal capacity to anticipate, learn, adapt and recover from an event, in the second case we have a *reactive resilience* - of the system, that occurs right in the time of the event, to cope with change (Provitolo D., 2009).

Because, technically, depending on the subject under discussion, resilience is defined either as the capability of materials to withstand shock without permanent deformation or rupture, either as a trend of entities to easily adjust or recover after a major harmful change, we frequently meet the distinction between *engineering*

resilience and *ecological resilience*. While the first one defines resilience based on elasticity - as capacity of a system to resist disturbances and / or the rate of reversion to pre-existing equilibrium state, the second one highlights the fact that, for example, a region has a higher ability to return to equilibrium after a shock, and could also accommodate multiple equilibria (Dawley S. et all., 2010). Moreover, it is a measure to estimate the degree of danger posed to the ecosystem, considering that the degree of ecological resilience of an ecosystem is inversely proportional to the degree of danger which is threatening him (Fridolin B., 2008).

In turn, systemic approach distinguishes between *specific resilience* and *overall resilience.* While the first one refers to the resilience "of what, what" (egg resilience of crops to drought), the second considers that disruption does not affect any aspect of a particular system. Due to this distinction, we can identify the effect manifestations threshold above which the system cannot recover (Gunderson L. & all, 2010) and also clarify the conditions transition from *individual resilience* to *systemic resilience*.

In the case of socio-economic systems, resilience is often associated with vulnerability, if not like reverse side of the coin, at least as a further test of the degree of their maturity. The concept of vulnerability is found in the institutional, organizational, community, family and personal analysis, despite the fact that - according to the different traditions and methods of research - it has been defined in various ways (Janssen M., 2006). However, most often, the conceptualization of vulnerability includes components that indicate exposure to perturbations or external pressures, sensitivity to them and ability to adapt. In general, vulnerability includes both personal or group attributes that enable them to cope with disturbance as well as ecological attributes that help systems to adapt to natural hazards (Direction SA, 2011).

Also, in socio-ecological systems, *adaptive capacity* is linked not only to their genetic and biological diversity, but also to existence of institutions and networks that can learn to keep their knowledge and experiences, in order to solve problems and preserve balance. Therefore, in these systems there is a linear relationship between *resilience* and *adaptive capacity*. From comparative study of ecosystem dynamics resulted another thinking instrument that draws attention to processes of destruction and reorganization - *adaptive cycle*. It provides a more complete picture of system dynamics that links together system organization, dynamics, resilience and vulnerability. It consists of a sequence composed of four phases of change in complex systems: exploitation, conservation, creative destruction and renewal and is classified alone or in various development policies aiming to increase adaptive capacity and resilience (Ford J., 2013).

Alongside, the concept of panarchy also involves examining similarities and differences between human systems and related natural environment in ways that can generate theories and models, like the *adaptive cycle*. As understood in the light of recent research, panarchy takes into account whole cycle of resilience, as it is found at personal, social, economic and environmental level. Panarchy theory was developed as an integrative theory, to understand the source and role of systems change, focusing on the interactions between change and persistence. Thus, *panarchy* becomes a conceptual framework that takes into account this duality represented by resilience and vulnerability in complex systems, its purpose being to develop the necessary conceptual describing *the change dynamics of torque formed by change and stability at all levels of scale* (Holling S., 2006).

Resilience Operational Coordinates

In order to become operational, resilience needs both structure and tools to be developed (Barroca B. & all, 2013). However, as a fundamental property of a system which is based on predictability, resilience can measure the magnitude of change or disruption that this system can experience without crossing into an alternative state. Classic examples of change between states include transition from coral reefs to algae covering the rocks, from grassland to shrub-dominated landscapes and clear waters from lakes in muddy waters (Gunderson L. & all, 2010).

Explanations for resilience facing an increased interest from both researchers and policy makers must be searched for, on one hand, in its ability to merge operating capacity with heuristic size, and on the other hand, *to support interconnected perspective of vulnerability and adaptation issues*. Even though the challenges of using resilience are major, practical implementation of the concept is still waiting the right answer from the association between human vulnerability and environmental hazards. Moreover, interest in the concepts of resilience, vulnerability and adaptation is increasing both for specialists in many fields of research, and also for those who design and implement sustainable development policies (Vogel C. & all, 2007). This success is accounted both to the fact that resilience has become a tool of thought and practice, as much needed, as fertile in terms of exploration (Cyrulnik B., 2012) and of that resilience allows finding relevant answers to questions that enable advancement in research (Ionescu Ș., 2013).

Although the rapid expansion of using the concept of resilience can generate a series of questions awaiting scientific answers, its success should not be searched in the etymology (from the Latin verb salio-ire, jump, leap, accompanied by the prefix re – counter, back), but in its metaphoric ability to describe any system that has the ability, subject to imbalance by confronting different disruptive factors, to resist pressures and return to original state (Pike A. & all, 2010).

By extension, resilience meaning gradually widened and penetrated in all fields of study, keeping the connotation of stability indicator. In addition, ecological resilience is even a measure of persistence by absorbing change, which is contrasted with stability that shows ability of ecosystems to return to previous state. Thus, based on its property to absorb over time changes introduced in system, resilience becomes indispensable for analysis of human-environment interactions, in particular to describe how humans affect ecosystems (Gunderson L., 2000).

From here to the practical application, it is necessary a mechanical model validation of resilience that would capitalize high-accuracy data collected from a changing system (Zell C., 2013). Therefore, naturally, resilience has expanded its application in social context because of its ability to explain possibility of groups or communities to cope with external stresses and disturbances as a result of social, political and environmental changes (Brand F., 2009). However, given that resilience key in socio-ecological systems is diversity, moving it from the sphere of ecology in the social field should describe the behavioral response of individuals, communities, social institutions or economies facing various imbalances. On the other hand, transferred to psycho-social field, resilience will illustrate the individual's ability to cope with crisis situations, including the ability to respond to predictable induced stress (Stângă I., 2011).

In the case of systemic level operationalization, resilience owes part of its success to multidisciplinary research group *Resilience Alliance* that studies *the dynamics of socio-ecological systems based on adaptive cycle*, assuming that ecological and socio-economic systems are related. However, the adaptive cycle disputes the traditional view of ecosystem succession as a linear process of transition from operation to reorganization, emphasizing the importance of growing and maturing stages, succession evolving from linear evolution to become phase of a cycle (Wilkinson C., 2011). Another part of resilience success is due to adaptation of *panarchy concept*, departing from the idea of need for renewal and reorganization of the systems. Thanks in particular, to research conducted by Lance Gunderson, panarchy believes that resilience interferes in operation and the interactions that allow the system to return to equilibrium state.

If the adaptive cycle highlights the ability of a system to go through phases that correspond to its resilience, with good application to urban systems, panarchy as multistage analysis of resilience in dynamic systems can highlight the resilience capacity of a meta-system based on memory (Gunderson L, 2000). Therefore, restoration of Dresden is considered the best example, panarchy representing the mechanism of connection between two levels of complex adaptive systems that are resilient (Provitolo D., 2009).

Resilience success as operational instrument is also manifested by a significant increase in risks science publications (cyndiniques). In this area, resilience is accompanied by theoretical research aimed at its understanding in contexts in which it is used, its heuristic, methodological and practical contributions, scientific boundaries as well as ethical and political once, thus becoming an additional component of risk analysis that complements existing approaches (Reghezza-Zitt M., 2013).

Integration of personal resilience within sustainable development

From the *sustainable development* perspective, resilience is not only a differentiating factor at regional and sectorial level but also one able to serve its purpose - to create and maintain social, economic and ecological prosperity of all systems affected by human activity (Resilience All., 2010). Also, the concept of resilience gains a growing interest among policy makers and scientific community researching sustainable development because it offers the opportunity to present some practical use, especially in the context of climate change policies. Being a purely descriptive concept which assumes that a system does not turn into another due to exogenous disturbances, resilience is in contrast to sustainable development which is a normative concept based on ideas of justice and accountability inter-and within generations.

However, through their reconciliation can be generated ecological-economic models to create natural capital reserves for human wellbeing and to derive both requirements for system dynamics and sustainability criteria (Derissen S. & all, 2009). *Resilience can also provide as means and goal of sustainable development*, providing conceptual framework for economic analysis of risk management which illustrates the capacity for action. It is in progress the study of opportunity to make *resilience the core purpose of sustainable development*, but this raises issues regarding complexity analysis of individual capacities for action and articulation of these capabilities to collective dynamics (Lallau B., 2011).

However, *individual resilience is a prerequisite for achieving sustainable development* because it guides policies irreversibly towards sustainability. One argument is that socio-ecological systems analysis based on resilience is presented by researchers as a major contribution to sustainable development issues (Lallau B., 2011). Although the idea of resilience capacity of socio-ecological systems becomes slightly ambiguous when we take into account their sustainable development, defining and assessing resilience at individual level is an attempt to overcome these limitations (Sall C. & all, 2011). This approach is based on personal adaptive capacity and tends to articulate through intersection of several areas of research interested in transforming individual

potentialities (mainly related to differences in owned capital: monetary, physical, human, social) into opportunities (marketable or not) during the entire existence (Lallau B., 2011).

As finality of sustainable development, *individual resilience* is a strategic sequence consisting of interactions between sustainability and resilience. If resilience through flexibility provides means for sustainable development, then we should accept the fact that individual resilience constitutes by itself, an indicator for sustainable development that can turn from means into purpose to ensure sustainable development (Lallau B., 2011).

A first step in achieving the conjunction of resilience and sustainable social development was done by deploying sustainable urban development. By maintaining urban functions at an acceptable functional level, capabilities of urban systems resilience contributes to achieving economic, social and environmental targets of sustainable cities. Specifically, improved resilience may be the way to restore balance between the three pillars of sustainable development when disruptions question social, economic and environmental operation of urban system called to adjust (Toubin M. & all, 2012). Similarly, by adding the personal pillar, is completed the sphere of sustainable development, which will thus be able to overcome both self centered approach (which aims to protect all living beings) and on the anthropocentric one (that targets the human right to welfare).

Without integration of individual resilience in sustainable development, it is difficult to overcome the dichotomy of economy, ecology, especially when there are social issues (Sébastien L., Brodhag C., 2004). By including personal plan into sustainable development, must be kept in mind that not all people are resilient or vulnerable in the same way, so we must be informed, in order to protect both their weak and strong points (Messier J-B., 2009). Also, for individual resilience to actually become operational and directly implemented in sustainable development studies, it takes time for confirmation of indicators sets quality which determines resilience value (Stângă I., 2011).

Resilient vulnerability role in sustainable development

Until the moment of indicators acknowledgment, must be kept in mind that both resilience and vulnerability are polysemic terms, used in exact sciences as well as in those humanistic, in analytical and synthetic definitions corresponding, on one hand to resistance and on the other hand to fragility of the system as a whole. Moving from ideas of strength and weakness to concepts of resilience and vulnerability within an integrated system covers both the ability of a system to absorb changes and to persist after a disturbance, and the one of highlighting weaknesses (Barroca B. & all, 2013).

As concepts that emerged in different fields, both resilience and vulnerability can become dominants of the paradigm of sustainable development, due to the possibility of pursuing two different possible a priori approaches for this study: environment vulnerability analysis – approach with rather negative connotations, and systems resilience – approach considered to have positive connotations. Hence, resilience is a factor for fight against vulnerability, due to its capacity of returning the system to a state of balance prior to a disturbance or the possibility of transformation, reorganization, renewal of its structures and operation (Provitolo D., 2009).

Even if resilience can be seen as a singular concept at the moment because of different points of view in various disciplines, its positive connotations have imposed formation of the couple resiliency – vulnerability as a possible model-maker of sustainable development system. Moreover, studying the vulnerability of a socio-ecological system is the same as to study its ability to cope or to recover, which connects it to resilience. This raises *a new research perspective* where *vulnerability and resilience are seen as a continuum*, by the concept of *resilient vulnerability*. This concept allows the release of a binary vision exceeding both the negative connotations of vulnerability and those positive once of resilience. Thus, vulnerability does not only describe the factors that could damage the individual or collective response and resilience no longer represents just the adequate *de facto* response. *Resilient vulnerability* does not suggest that socio-ecological system elements would not be affected or injured, but can explain how they adapt and recover after the shock. This notion has translated the idea that *vulnerability can be crossed and amended by resilience* (Provitolo D., 2009).

Considering the fact that there is no perfect symmetry between resilience and vulnerability, it is essential to establish strategies to combat vulnerability and promote resilience, mitigating risk effects of existence in general, while increasing capabilities to ensure sustainable development (Rousseau S., 2007). Thus, resilient vulnerability becomes core element of sustainable development also because direct measurement of resistance is difficult due to its necessity of taking into account all thresholds and boundaries that separate areas dealing with socio-ecological systems dynamics.

Precisely because measuring resilience differs in several ways from traditional ecological indicators, some researchers use the word „surrogates" instead of „indicators", considering that they might show important aspects of resilience that cannot be directly observed. Also resilience relationship with its substitutes may change over time, since they correspond to specific theoretical aspects, making resilience depend on context (Carpenter R. & all, 2005).

Instead, resilient vulnerability does not need such proxies to perform the evaluation of interactions between scales because it can cover both studies from individual households' perspective as well as overall socio-ecological systems, from a systemic perspective. Specifically, through *resilient vulnerability* can be overcome observation of the ability to cope with risks on personal level – perceived both *ex-antes,* as uncertainty about the future, as well as *ex-post*, when the individual faces a risk. Also, granting resilient vulnerability a central role in sustainable development system, becomes obvious that a low resilience is reflected on personal level through primacy of fatalistic and defensive strategies, aimed to save what you can, without projection into the future - resulting in the inability to cope with major existential risks (Cantoni C., Lallau B., 2010).

Functionality of sustainable development integrated system

From resilient *vulnerability perspective*, a disturbance can be considered – including on individual level – both creator of system rupture as well as promoter of resilience. Because disruption of socio-ecological systems include diseases, drought, fire or hurricanes, and, as well, recessions, innovations, technological changes and revolutions in an ecological system, human intervention itself can be considered a form of disruption (irrigation channels, over fishing and mining operations). As population and consumption levels increase, disturbance caused by humans is increasing, with consequences for overall system resilience (Gunderson L. & all, 2010).

Therefore, sustainable development integrated system (see *Fig. 1*) which makes *resilient vulnerability* its the central element – methodologically neutral - and that also integrates resilience individual level, will allow disturbance analysis both by adaptive cycle sequential method as well as by hierarchical linking panarchy model, which they integrates. This approach could be useful on multiple levels analysis of how resilience is modeled in order to ensure a development with its basic attributes: ability to absorb disturbance and reorganize, so that to preserve substantially its function, structure, identity and feedback. Also, functionality of integrated system consists of prominence of all elements to be taken into account when assessing sustainable development, by associating individual resilience with the one on social, economic and environmental levels in a whole, represented by resilient vulnerability manifested in each of these levels and in resulting interactions of their intersection.

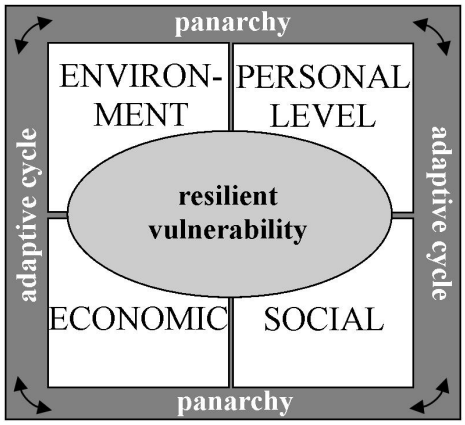

Fig. 1: ***Sustainable development*** *integrated system (personal contribution)*

Also, this integrated system framework of sustainable development may be considered a step towards functional approach to all components of resilience, by interconnection of vulnerability components, highlighted particularly on personal level. Also, linking individual resilience and sustainable development we can analyze how resilience requirements are fulfilled for each system area. In addition, for a specific ecosystem, integrated system opens up new perspectives about connection of services and components of natural capital as well as reglementation of socio-ecologic services confronted with economic pressures (Ferrari S. & all, 2012).

Attention paid to resilience may be a response to widespread modern point of view on uncertainty, insecurity and seeking a formula for adaptation and survival. In this regard, use of this trendy concept comes from both a heightened sense of risk (political, economic and environmental) as well as from perception that processes associated with globalization have made regions and cities more permeable to effects of what was once considered as external influences (Christopherson S. & all, 2010).

Furthermore, because the intersection of an economic and an environmental crisis has heightened sense of vulnerability at all levels, consequently, stimulating the search for new ways of affirming resilience, integrated approach of sustainable development centered on the concept of *resilient vulnerability* may enhance

our understanding of the forces that influence that influence both the scope of the measures and policies as well as their conceptual frameworks.

Because resilience already imposed in both academic research as well as managerial strategies, its components will feed further debate on the use and its heuristics and operational relevance. Therefore, the purpose of any article that approaches issues of resilience hypostasis is not to decide in these debates, but to show, based on a multidisciplinary approach, that there are multiple tackling possibilities (Reghezza-Zitt M. & all, 2012). From here to implementation of conclusions of this article is a road paved with hypotheses and demonstrations that could significantly expand research horizons.

Emigration – Romanians' form of resilience to the dysfunctionalities of the labour market

Horea-Şerban R.-I.

Univeristy Al. I. Cuza of Iaşi (ROMANIA)
ralusel@yahoo.com

Abstract

The change of the political regime in 1989 triggered profound mutations on the Romanian labour market, involving its structural recomposition, mainly because of the incompatibility between the mechanisms of the dirigiste economic system to those of the market economy. The present paper deals with emigration as a form of resilience of the Romanian labour force to the post December industrial recession resulting in the massive and forced dismissal of significant contingents of people, for whom the main subsistence options in the new context were either the return to the rural environment or the temporary working emigration abroad, now possible as a consequence of the flexibillization of the borders of the country. At the same time, the paper also aims at assessing the main (both positive and negative) repercussions of the Romanians' emigration, approached from the economic, demographical and social points of view.

Keywords: unemployment, resilience, emigration

Emerging unemployment – a priming factor for Romanians' emigration movement

Originating in the artificiality of the way of inserting industrial units in the communist period (according to the logic of the industrialization at any price) as well as in the difficulties of adjusting them to the functioning manner typical of a capitalist economy, unemployment first appeared in 1991, experiencing an alert dynamics during the first post communist decade under the action of a whole complex of social, economic and political factors, partly overlapping the political changes Romania underwent during that period [1] (Fig. 1).

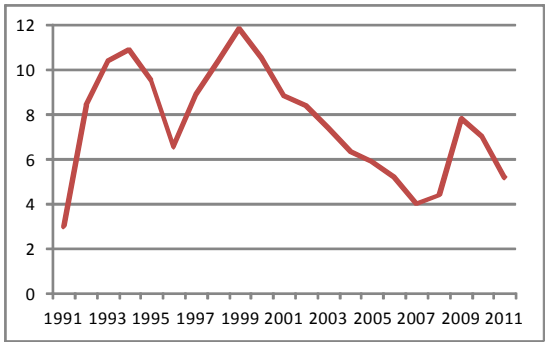

Fig. 1 – Unemployment rate dynamics in Romania (%), 1991-2011

The graphical expression of the statistical data indicates a strong increase up to 10.9% in 1994, which reveals the downfall of the Romanian economic environment and the brutality of the economic mutations triggered by the change of the political regime. During the next period, the indicator's value decreases to 6.6% (in 1996), as a consequence of the attempt of creating new jobs under the impulse of the nearing elections, as a consequence of the measures taken at the last moment by the government at that time, which in fact lost the elections. This trend cannot be kept for a long time and between 1999-2000 we deal with the maximum values of this indicator throughout the whole analyzed period (11.8%, 10.5% respectively).

After this year, the unemployment rate experiences a diminishing tendency, up to a minimum of 4% in 2007. The factors that lay behind this positive dynamics are not strictly related to the revitalization of the economic system (which we do not deny), there also existing at least two other elements that favour the decrease of the number of unemployed active population: on the one hand the significant percentage of the population employed in activities of the primary sector (which, although not remunerated, obtains material results from the work performed); on the other hand, the change of the temporary labour migration abroad into a mass phenomenon, which decongested the pressure on the job market.

As a matter of fact, the same two factors explain the unnatural differences existing between Romania and many western economically developed countries, whose statistical framework reveals apparently more serious economic "flaws" if we consider the higher unemployment rates (comprised between 8.4 and 9.5% in 2006 in the case of Germany, Spain, France

and Greece). The explanation for the seemingly "luckier" economic situation of Romania must be looked for precisely in the massive number of people working abroad, as well as in the atypical structure of the employed active population. In 1992, because of the political support previously offered to the industrial field by the socialist decision organisms, whose actions were meant to industrialize the Romanian society at any cost, by virtue of an assumed aversion towards agriculture, the secondary field represented nearly 44%, much more than it was the case in the industrialized western European countries. The shares of the other two fields were not congruent either with those in the developed world. In spite of the sustained efforts performed by the communist regime in order to industrialize as much as possible an obviously rural territory, the percentage of the population employed in primary activities was rather large (23.1%), much more than in the EU states, where that value was below 10 or even 5%. The tertiary activities (33%) were much underdeveloped, illustrating the population's low purchasing power (Fig. 2).

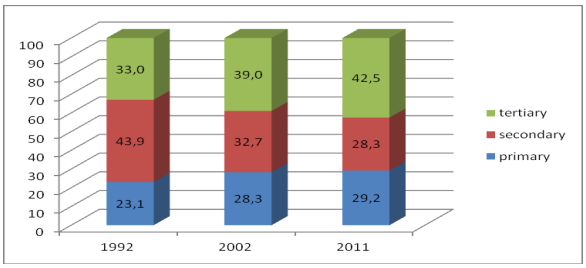

Fig. 2 – Population structure by main economic fields (%)

The percentage game of the three activity sectors as revealed by the statistics of the censuses in 2002 and 2011 certify the insertion of a new demo-economic pattern resulting from the artificiality of the communist evolution trends. The initiation of an ample process of industrial restructuring and destructuring (its share decreasing to 32.7% and 28.30 respectively) due to the rigidity of a centralized economy to the mechanisms of a competitive market resulted in the massive dismissal of the employed population, the outlet being found on the one hand in emigration, and on the other in (little productive subsistence)agricultural activities, causing the primary sector to increase at about 29.2% in 2011, such a pattern of the employed population economic structure taking Romania away from the EU states. Figure 3 emphasizes the transition from an industrial-services profile in 1992 to a mixed profile in 2002 and 2011, however with a clear tendency of moving towards a services-agricultural profile in the future.

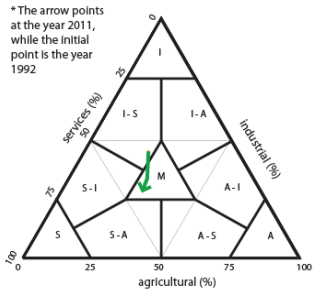

Fig. 3 – The evolution of the socio-professional structure of the Romanian population (1992-2011)

Emigration – Romanians' manner of resilience to economic dysfunctions

Most of the time perceived as an alternative of surviving in an economic system left to drift by the disappearance of the levers which had formerly provided the coherence of the economic mechanisms, emigration has become common practice during the post socialist period, rapidly spreading throughout the whole Romanian space once the repressive means of stopping extra national mobility were removed.

Although trammelled in the legislative restrictions imposed by western countries on the Romanian citizens, the emigration phenomenon has taken remarkable scale beginning with the year 1990, being however difficult to quantify from the statistical point of view due to its mainly clandestine character. In this context, there is a huge gap between official documents and unofficial estimations. The legal statistics reveal the contradictory dynamics of the emigration process, with a strongly decreasing trend after the sharp peak of 1990 (when nearly 97,000 inhabitants left Romania), the yearly average number of people emigrating from Romania between 1992 and 2011 being of about 14,986 (Fig. 4). But these data are far from illustrating the real dimension of this phenomenon it is precisely the official statistical records that clearly show it: for 1992-2002 intercensitary period there is a gap of 520,068 people in the general population balance that cannot be explained but through emigration [2].

However, the numerous surveys conveyed by different associations clearly show the real amplitude of the Romanian emigration flows. They talk about a number of 3,250,000 Romanians living abroad, out of which 2,000,000 in Italy and Spain, whose main motivation on leaving the country was the economic one.In 2002, the year when Romanians could travel freely in the Schengen space and emigration exploded, the minimum average wages (according to Eurostat) was of 1,140 Euros in Belgium, 1,127 Euros in France, 1,008 Euros in Ireland, 571 Euros in Greece, 515 Euros in Spain, with 50,33 Euros Romania ranking last, even after Bulgaria (51,38 Euros)

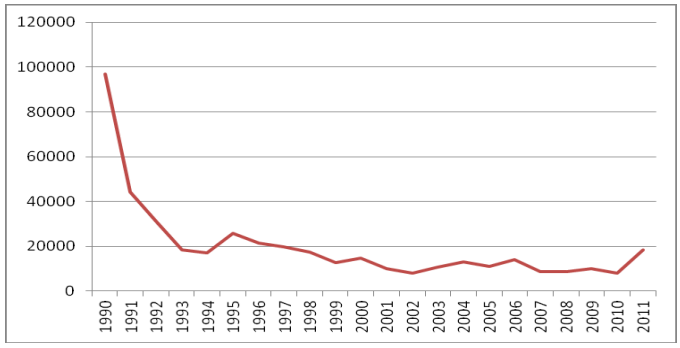

Fig. 4 – Dynamics of the number of Romanian emigrants (1990-2011)

2011 census – measure of Romanians' emigration amplitude

The map of the population dynamics between 1992 and 2011 (Fig. 5) highlights the general decline of the Romanian population during the last two decades in all counties, except for one: Ilfov, benefiting from the advantage of its proximity to Bucharest, the capital city of the country, a fact which has largely contributed to the development of its residential function. The southwestern part of the country clearly stands out due to its strong population deficit. Of course, we cannot ignore the negative role played on the general balance by a "modern" demographic behaviour (characterized by a strong tendency of efficiently controlling one's own descent, these areas being among the first of the country to rally to a western demographic mentality based on low birth rates).

At the same time, we must not forget that some of these areas (such as Alba, Hunedoara, Caras Severin) used to be industrialized to a great extent before 1989, while after this year secondary activities (especially heavy and mining industry) were very much restructured, causing serious subsistence problems to the local labour force, solved out either by returning to the origin areas they had once come from (through internal migration) or by making their way to foreign countries. The province of Moldavia also stands out as a typical area of population decline, especially when it comes to its southern part, already a traditional provider of emigrants after 1989. Of course, there are also Moldavian counties which have experienced a slighter demographic decline – Iaşi and Suceava are two counties which obstinately still preserve a certain demographic dynamism, which softens the migratory balance of the population. In some other cases, it is not the natural component of the total population balance that plays this positive role, but an economic vitality they enjoy, which makes them attractive to both investors and population (Timiş, Constanţa, Cluj).

In order to try to establish a correlation between the dysfunctionalities of the labour market and emigration, we made a hierarchical ascendant classification taking into consideration 7 parameters, summed up in Fig. 6. We identified 6 types.

Type 1 includes 7 counties: Suceava, Neamţ, Vaslui, Galaţi, Alba, Braşov and Brăila. It best resembles the average profile of the country. It is characterized by a slightly superior activity rate and a slightly inferior inactivity rate which, in the case of the Moldavian counties and of Brăila county can be explained by the very good representation of the primary sector, which explains the not very high ratio of economic dependence. However, these areas clearly show a predisposition to emigration, justified by the rather high unemployment rate deriving from the massive economic restructurings of some huge industrial units, which left hundreds of thousands of people without a job.

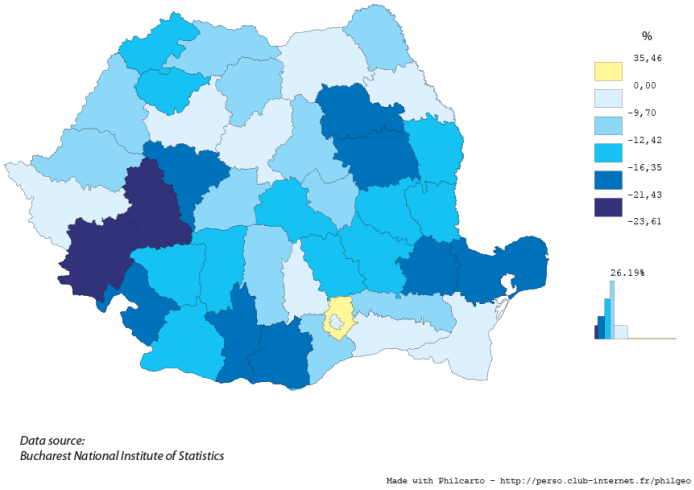

Fig. 5 – Romanian population dynamics (1992-2011)

Type 2, the most widely spread (15 counties), presents a remarkable spatial coherence, covering the most part of the southern, western and central part of the country. Their main characteristic is an emigration rate which is below the national value, either as a consequence of a certain economic dynamism induced including by significant flows of direct foreign investment (as in the case of Timiş, Bihor, Mureş, Sibiu, Ilfov counties) or as a consequence of a certain lack of

propensity for migration (as in the case of the southern counties - Giurgiu, Teleorman, Vâlcea, Gorj, which have more actively rallied to emigration during the last decade – [2]).

Type 3 includes only 2 counties in Muntenia (Ialomiţa and Buzău), their profile resembling the one of the previous type, with the distinction of a deeper discrepancy in comparison to the average national outline.

Type 4 comprises 2 counties (Bacău and Bistriţa Năsăud), whose population seems to be very keen on emigration in spite of an apparently more encouraging economic framework (with higher activity and employment rates, lower unemployment and inactivity rates and a lower ratio of economic dependence).

Type 5, including 9 counties and Bucharest, the capital city, is very much like type 4, the difference to the national average profile being however slighter. In certain cases, the smaller economic pressure on the active and employed population may be explained through a more diverse economic profile, many of these counties enjoying the presence of a big, economically powerful city (which could justify a less pregnant emigration behaviour – Iaşi, Argeş, Timiş, Dolj) or, on the contrary, through a traditional, conservatory mentality attached to a significantly rural population and economy (Vrancea, Botoşani, Satu Mare).

Type 6 circumscribes 6 counties which have a migratory behaviour that largely overlaps the national average. They are either counties which inherit former industrial structures that have raised lots of problems during the last years (Hunedoara, Prahova, Constanţa) or counties with a very little offering economic profile (Călăraşi, Covasna, Tulcea), which explains the relatively high unemployment rate.

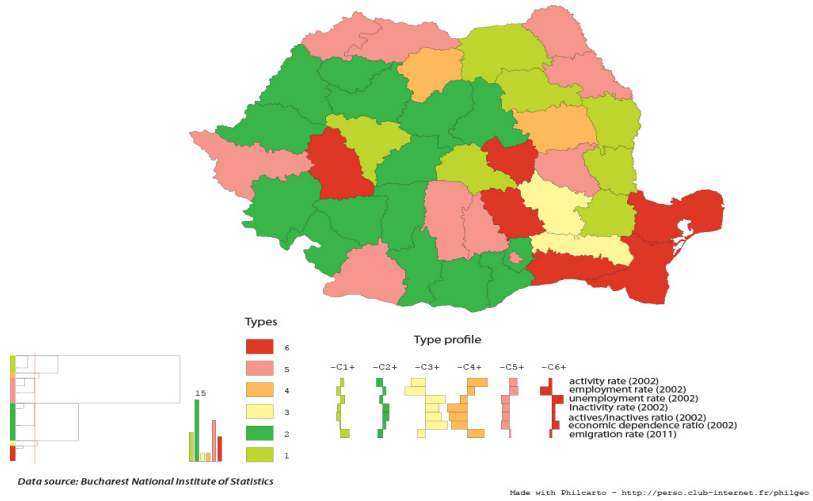

Fig. 6 – Hierarchical ascendant classification of counties by certain demographic and economic indices

Instead of conclusions...

Absent from the public discourse of the communist authorities (for which the socialist society was a perfect and not perfectible one), the leaving to work abroad became a genuine social phenomenon in this context, taking the form of an individual life strategy. The consequences are manifold, but they largely fall into two categories: positive and negative.

Among the advantages, we can mention the change for the better in respect of the emigrants' behaviour and mentality (including as regards their entrepreneurial spirit and psycho-social mutations [3]). However, the most palpable effect is undoubtedly represented by remittances [4], whose volume increase from 1.5 billion Euros in 2005 to 8.7 billion Euros in 2008 proves once again the large extent of the last decade's emigration flows.

However beneficial to the population's living standard, these positive facts are sadly rivalled by obviously negative effects, such as the most serious ageing process that more and more areas have to face, the deficit of active population, increasing incidence of divorce, dangerous psychological mutations. Of course, the most delicate issue is related to the large number of "Euro-orphans" who, beside an indisputable increase in their daily living standard, find themselves forced to experience a whole series of negative consequences that may leave deep marks on their psychic [5].

Sparks of modeling resilient socioeconomic systems

Oneaşcă I.

(Romania)
iulianoneasca@yahoo.com

Abstract

The article aims at deepening existing approaches on the study of resilient socioeconomic systems. Specifically, it goes beyond previous accounts, building upon resilience core traits and considering adaptive cycles as integrated and innovative components of the social dimension.

Societies' multiple identities are deeply rooted in society's cultural and institutional foundations. They structure and decide the balance of socio-economic systems. Institutions aim to control mechanisms that induce their stabilization, conserving growth. Cultures and institutions have a memory that intervenes in the recovery of adaptive cycles, generated by the pursuit of equilibriums, as phases of evolution. Hazards trigger involuntary reactions and deliberate counter reactions. The latter ones are meant to offset risks and limit their recurrence. They pave the way from collapse to reorganization by directing the pulsations of human interaction networks, covering a growing range of hazards.

The analysis pays a particular attention to robustness and redundancy properties that are considered for modeling purposes and illustrated in fiscal and social protection systems. The results suggest that polycentric nested structures are more resilient and likely to stand the test of time if their equilibriums are based on balanced lower levels of organization. Balancing the development opportunities of territorial structures is a necessary step towards bridging the gap between developed and less developed regions. The endeavor increases the socio-economic resilience of the systems, by toughening the weak links of the chain. At the same time, as resilience is culturally driven, objectives, expectations and actions of society lead the way towards modeling a multilevel resilient society.

Keywords: Modeling, resilience, socioeconomic system, society foundations, robustness, redundancy

Modeling identity

Societies' multiple identities (also known as multiple stable attractors), are deeply rooted in society's foundations. Specific characteristics, such as race, ethnicity, tribe, caste, clan or class, together with rules that keep individuals together - customs, traditions and beliefs, represent the historical or cultural foundations of societies [1] . They impregnate the legal systems, marked by an ideology, a religious or political view on the organization of social and economic life [2], and generate a specific institution building, constituting the modern or institutional foundations of societies [1].

Evolution of human society is guided by its inertial forces, cultural and institutional foundations [3]. Any combination of the two defines a variety of patterns of socio-economic systems, each with its specific phase space. Modern institutions are designed as ranking systems, while dominant cultures are decided by the control of social institutions. Accordingly, institutions define the structure and quality of socio-economic systems, co-evolving with cultures.

Socioeconomic systems are dynamic and characterized by self-organization [4]. Their development involves multiple, reciprocated interactions on all levels, as part of nested networks. The infrastructure facilitates nested processes, with different time cycles and increasing spatial scales [4] [5]. Self-organization is a feature often ignored, even by development specialists: beyond the recognition of change needs and the introduction of new rules in society, one should count on the fact that the action based on old principles and attitudes, deeply rooted, would persist.

Under such conditions, the right approach to direct complex systems through human will "is to support and strengthen the self-organization and self-control of the system by mechanism design" [6]. Again, the institutions play a major role in development. They have to address objectives, expectations and actions of society, all part of the ideology meaning.

Promoting equilibrium

The ordering of multi-layered and disparate components of the system is achieved, as in any open system, by moving towards a state of equilibrium [4]. Equilibration comes naturally in the market economy or society. The difficulty is to advance a favorable balance.

Institutions are meant to control mechanisms that induce stabilization of the systems, conserving growth (foreloop). Automatic stabilizers are known as elements of fiscal policy moderating fluctuations of national production without involving discretionary government action [7]. ILO analyses show that "the increased expenditure on social and economic stabilizers has helped to save as many jobs worldwide as discretionary ad hoc stimulus packages" [8].

However, institutions bear the burden of their human design and management. They are flawed and can be used as extractive instruments [9]. When institutions fail, the balance is moving downwards, at the level strong enough to withstand the change, by absorbing or eliminating the weakest ones. In such a process, social progress is affected, because it depends on complex equilibriums with multiple conditionalities, generated by specific human needs, rights and aspirations.

It is only a significant input of energy, with certain continuity, which can move things towards a desired balance. Variation of energy brings changes, generates patterns and regularities in space and phase. Such alterations underlie reforms of society. They are initiated by a variety of factors with role in development, namely political, institutional, technological, cultural and geographical ones.

Cultures and institutions have a memory of their own [10] that intervenes in the recovery of adaptive cycles [11],generated by the pursuit of equilibriums, as phases of evolution. The study of pre-modern interaction networks reveals a series of expansions and contractions over time, termed pulsation, which makes the interconnectedness specific to human systems to integrate larger territories [5].

Hazards, threatening human systems, are manifestations of infusions or losses of energy. Beyond disturbances in systems' equilibriums, they trigger involuntary reactions, as well as deliberate counter reactions. Reactions follow the initial impulse, naturally, as energy reverberations, generating a pendulum effect to re-balance the system. Deliberate counter reactions are voluntary impulses that succeed events in the form of measures that offset risks and limit their recurrence. They pave the way from collapse to reorganization (backloop). Such reactions are manifestations of hazard awareness and relate to society's responsibility and ability to promote a better future for mankind. They direct the pulsations of the human interaction networks, which tend to cover a growing range of hazards. In this regard, the societies' evolution is similar to the network expansion over larger territories. All that is of interest to mankind falls within the scope of interaction networks, which tend to expand over time.

The emergence of the European Communities can be seen as a counter reaction, a less expected result of the Second World War. Beyond its economic justification, a system to prevent future military conflicts was needed. And the system bears fruit in promoting peace and cooperation among peoples.

Other examples of manifestation of counter reactions are occasioned by financial crisis, a risk affecting nations. Recently, the extent of the current crisis has accelerated collaborative processes to reduce future risks. And projects aimed at banking, fiscal and political union in the EU emerged. Likewise, the plans of rapprochement between the EU and Canada markets and the EU and the U.S. ones are just steps towards improving global economic governance and reducing crisis-specific risks.

Increasing resilience

Socio-economic systems are composed of nested sub-systems, embedded in the complexity of society. Accordingly, authority is based on multilayered institutions. The best-performing systems possess organization and planning cores, placed at different levels, which facilitate decision making. Corresponding analysis and information facilities also contribute.

Robustness and redundancy are properties of resilient systems [12]. They are in line with basic critical systems design, aiming to maintain system's function in the event of a crisis [13].

1.1 Robustness

A historical perspective of human interaction networks leads to a conclusion of great importance for the design of inclusive societies that all systems based on hierarchy reveal a pattern of growth and decline of powerful state formations [5]. It means, on the one hand, that layered, polycentric or nested structures (e. g.: multi-state, multi-regional ones) are more durable as associations inter pares, and, on the other hand, that whatever social construction, it is more likely to stand the test of time if it is balanced at lower organizational levels (sub-state). Such conclusions are largely spread by constitutional and political checks and balances, underlying modern states. Separation and balance of powers (hierarchies) provides a necessary systemic programming for guiding the authorities to act in the general interest of the many [14].

Balancing the development opportunities of territorial structures is a necessary step towards bridging the gap between developed and less developed regions, nationally and internationally. Such an objective is, firstly, in line with human rights and constitutional mandates of international institutions committed to human development (e. g.: UNDP) and social justice (e. g.: ILO). Secondly, it ensures a better use of human resources potential in the global economic competition. Thirdly, it creates conditions for a long-term future association inter pares. Fourthly, it increases the socio-economic resilience of the systems, by toughening the weak links of the chain.

The process is of pulsation type, reflecting the historical evolution of strengthening the cohesion of human interaction networks.

1.2 Redundancy

Generally, socio-economic systems have two main vital resources: people and money. Redundant traits can be identified in their administration, in well-developed systems.

The economies with the highest growth rate in the world have vast reservoirs of human resources, either within the country (e. g.: BRIC / China, India, Brazil and the Russian Federation), or in its immediate vicinity (e. g.: Hong Kong, Singapore, Taiwan). Other countries supplement their labor force resources through migration. Still, highly efficient economies, such as UK, Sweden and Norway, relying on immigration, display a chronic disability and keep approx. 40% young unemployed (Eurostat). Wealth is providing a cushion that only social order and education, tradition based or institutionally nurtured, can confront.

The collection of revenues from companies and individuals, and the redistribution of income and wealth, are performed by all countries. In the US, the Internal Revenue Service (IRS) collects the revenues that fund the federal government. IRS has developed alternate paths to achieve results, making some operations, facilities and command centers redundant [15]. Critical services to the government and the economy must not be disrupted.

Another redundancy feature is expressed by the universality principle in the provision of social benefits. The Scandinavian countries advocate universal inclusion, 'de-familializing' welfare responsibilities by differentiating individuals within households [16]. In a society committed to up-holding human rights and ensuring equity and justice, the risk of failing to meet social needs is not worth taken. Resilience is culturally driven.

The weee management in Romania in the context of economic resilience

Popescu M.-L.

The Bucharest University of Economic Studies, Romania, maria.loredana_popescu@yahoo.com

Abstract

The use of electrical and electronic equipment has risen significantly in recent decades, especially due to the development of information technology and communications. The large amount of gadgets available on the market can be correlated with rapidly decreasing of prices, a phenomenon known as obsolescence. The volume of waste electrical and electronic equipment (WEEE) has an increasing trend and it is considered as one of the fastest waste streams growing manifested in Europe. Also, waste electrical and electronic equipment is one of the priority flows in waste management because it generates significant challenges.

The paper presents the concept of waste electrical and electronic equipment (WEEE) according to the literature and legislation. The focus of the article is the Romanian WEEE situation presented in the context of economic resilience. Waste management is presented and analyzed in amount of electrical and electronic equipment put on the market, collected and then recycled WEEE .

Keywords: waste electrical and electronic equipments (WEEE), WEEE management system, economic resilience.

Introduction

The problem of waste management of electrical and electronic equipment is becoming more acute in Romania due to increased quantity and diversity of their negative impact on the environment and health, but also because of the obligations undertaken by the legislation in force. In this aspect, reference is made to Directive 2002/96/EC, which was reformed and ended with the publication of the new Directive 2012/19/EU of the European Parliament and of the Council of 04 July 2012 on waste electrical and electronic equipment, still not been transposed into Romanian legislation. In the last two decades, the number of environmental policies and legislation underwent substantial changes on the environment and its protection. Although progress has been made in waste management, Romania has large amounts of waste still remain unmanaged.

The connection between economic resilience and weee management system

1.1 *Defining concepts as resilience and sustainable development*

The term resilience is defined in Larousse dictionary as mechanically different materials which withstand to external shocks and return to the original state. Etymologically, the word derives from the Latin verb salio, -ire, which means to jump, leap, accompanied by the prefix re- , meaning counter back.[7] Only since the 70s, this concept has been used in a metaphorical sense to describe systems that are experiencing various disturbing factors and undergoing various periods of imbalance, with the ability to withstand and return to the original state.[2]

In the socio-economic domain, the concept of resilience has been associated with sustainable development. Sustainable development is explained by the International Institute for Sustainable Development as ‘’a development that meets the needs of the present without compromising the ability of future generations to meet their own needs’’. [8]

Resilience is also defined as the ability of a system, community or society to resist at changes. This is determined by the degree to which the social system is able to self-organize and its ability to increase the capacity for learning and adaptation, including the capacity to recover from a disaster. [7]

1.2 WEEE management - Economic and legislative resilience

For Romania, the resilience proved to be a challenge to the new rules regarding the WEEE management system, especially by trying to align to the other European countries. Being one of the emerging states of EU, Romania has the profile for the developing countries. According to the World Bank and specified in 2012, the countries defined as developing have a gross national income (GNI) of US $ 11,905 and less. It is very hard for

an emerging state to keep up with other developed countries taking into account the national budget. However, Romania has managed the situation of WEEE within the budget.

The amount of electrical and electronic equipment (EEE) sold in Romania has increased progressively in recent years, growth rates being slowed after 2008 only by the economic crisis. [1]

Technical progress and increase of living standards are important causes of the high rhythm of growth of WEEE generated every year regionally, in Europe and worldwide. Managing this category of solid wastes needs a specialized collecting, transport, treatment and final disposal system. [5]

EU legislation promotes the collection and recycling of waste electrical and electronic equipment and provides for the creation of collection schemes where consumers return their used waste equipment free of charge. [6] Directive 2002/96/EC of the European Parliament and of the Council of 27 January 2003 on waste electrical and electronic equipment has been in force since February 2003. The Directive contains the categories of EEE that become wastes and they are found in table 1:

Table 1. Categories of electrical and electronic equipment (EEE)

Category 1	Large household appliances
Category 2	Small household appliances
Category 3	IT and telecommunications equipment
Category 4	Consumer equipment
Category 5	Lighting equipment
Category 6	Electrical and electronic tools
Category 7	Toys, leisure and sports equipment
Category 8	Medical devices (exception of all implanted and affected products)
Category 9	Monitoring and control instruments
Category 10	Automatic dispensers

Source: www.anpm.ro

The WEEE Directive currently sets a rate of separate collection of at least four kilograms per inhabitant and year of WEEE from private households.

The Directive 2002/96/EC will be repealed from 15 February 2014 and will be replaced by Directive 2012/19/EU on waste electrical and electronic equipment (WEEE) which introduces stepwise higher collection targets that will apply from 2016 and 2019.

Waste electrical and electronic equipment presents a risk to environment because of its hazardous components. In our country there are regulations on hazardous substances from electrical and electronic equipment, stipulated in Directive 2002/95/CE. Generally, WEEE contain over 1.000 substances, which can be both dangerous and non-dangerous in what regards the impact they have over the environment and human health. [4] The materials used can be ferrous (iron, steel) and non-ferrous metals (copper, aluminum, precious metals such as silver, gold, palladium etc), plastic, glass, wood, ceramics, silicone and others. The presence in the composition of WEEE of items such as mercury, arsenic, cadmium and selenium explain the inclusion of these solid wastes in the category of dangerous waste with special diet. [3]

The WEEE management system

1.1 The responsibility in WEEE management

According to the Implementation Plan for Directive 2002/96/EC, the responsibility for achieving collection targets go to the economic operators (manufacturers and importers), local authorities, Ministry of Environment and Waters Management and Ministry of Economy and Trade [9]. WEEE management is assured also by National Agency for Environment Protection, National Environment Guard, National Authority for

Consumer Protection and not least by consumers, which have the role to separate collection and delivery of the wastes to organized collection systems.

Statute and operating mechanisms of collective systems vary from case to case, but in most cases the collective system is supported by NGO (Non- Governmental Organizations) sector or by specialized companies and non-profit organized and specialized according to main categories of WEEE, of which management appears in the object of activity. [1]

In Romania, several organizations took responsibility for the annual objectives of separate collection, reuse, recycling and recovery of waste electrical and electronic equipment. The following organization obtained operating licence for WEEE management: ECO TIC Association, Romanian Association for Recyclig RoRec, RECOLAMP Association, ENVIRON Association, CCR LOGISTICS SYSTEMS RO S.R.L., ECOPOINT Association and ECOMOLD Association.

WEEE collection from households in Romania is organized through three collection channels: by organizing a collection day at fixed dates from the population, by giving back to the store the old equipment when purchasing a new one (free take-back system) or by giving it directly to the municipal collection centers. [1]

1.2 EEE and WEEE

1.2.1 Statistics on quantities of electrical and electronic equipment (EEE) put on the market

Regarding the amount of EEE put on the market, the analyzed period is 2005-2010. In Table 2 we can observe an uptrend, a sign that the market offers more and more products from year to year despite the economic crisis that began to emerge after 2008.

Table 2. EEE put on the market (kg per capita)

Year	EEE put on the market (kg per capita)
2005	-
2006	6,5
2007	8,7
2008	11,3
2009	15,8
2010	17,1

Source: epp.eurostat.ec.europa.eu (Eurostat), accessed on 05.02.2014

Across the 6 years taking into consideration for the analysis, the total quantity put on the market was 59.4 kg per capita.

1.2.2 Statistics on collected waste electrical and electronic equipment (WEEE)

In 2005-2010, there was collected a quantity of 4,3 kg per capita. The trend of the amount of collected WEEE registered an increasing in 2005-2009, but in 2010 there was a decrease of 0.6 kg per capita compared to 2009 as can be seen in Table 3.

Table 3. Collected quantity of WEEE (kg per capita)

Year	Collected WEEE (kg per capita)
2005	-
2006	0,1
2007	0,2
2008	1
2009	1,8
2010	1,2

Source: epp.eurostat.ec.europa.eu (Eurostat), accessed on 05.02.2014

We can assume that in 2010 the population was not provided for collection an amount so large, a sign that they kept the old equipment or the entire amount of WEEE has not been declared using informal methods for the equipment reception.

1.2.3 *Statistics on recycled and reused waste electrical and electronic equipment (WEEE)*

The collected amount of WEEE decreased in 2010 compared to 2009 which generated a small amount of only 1 kg per capita of recycled WEEE in 2010 as shown in Table 4. The total WEEE recycled amount in 2005-2010 period was 2,7 kg per capita.

Table 4. Total recycled and reused quantity of WEEE (kg per capita)

Year	Total recycled and reused quantity of WEEE (kg per capita)
2005	-
2006	-
2007	0
2008	0,3
2009	1,4
2010	1

Source: epp.eurostat.ec.europa.eu (Eurostat), accessed on 05.02.2014

Conclusions

Romania is making great efforts adapting to legislative changes, to the existing rules concerning waste electrical and electronic equipment, the evolution of the market and what it offers. So far, a small fraction of such waste put on the market was then collected and recycled. Recycling targets under Directive 2002/96/EC are not accomplished yet and most likely will be close to fulfillment when the target collection is reached at least 4 kg per capita. For now, according to statistics provided by Eurostat, it was collected only a quantity of 1, 8 kg/capita in 2009 and 1, 2 kg/capita in 2010. A solution to increase collection and recycling it may be the application of economic instruments such as fees, fines and penalties.

Professional judgment of the financial analyst in the context of normative and positive theories of accounting directed by the economic resilience

Stefan-Duicu Viorica M.[1], Stefan-Duicu A.[2]

Abstract

The professional judgment develops multiple understandings when taken into consideration the positioning of the financial analyst into an economic dimension integrated in the aggregation of extended ramifications of the society.

Throughout the content of this paper we aim to punctually highlight the modulations that appear in forming the professional judgment of the financial analyst starting from the positive expression of an explicit demarche made in the accounting field and continuing with the normative character imposed by the corpus of the activity performed.

The emergence of accentuating these aspects derives from the two faces of the presentation of accounting theories that support significant alterations through the analysis of the professional judgment framed as time and space in a sinusoidal progressive specter generated by the economic resilience.

Keywords: Financial analyst, positive and normative theory, economic environment, financial and social mutations, economic resilience.

Introduction

Through this paper we aim at exposing an overview of forming the professional judgment of the financial analyst considering an exhaustive background for the normative and positive theories of accounting directed by the economic resilience.

The financial analyst, a true user of the digits, uses the instruments that are generated by the vast area of domains and filters the information in order to create a proper decisional mechanism suited for the organization in which he activates. This decisional mechanism is distinguished by a high level of accuracy and rigor so it represents the mechanism that supports the activity.

The association of concept represents a "mutation of concept relocation" [1] and requires a short brief of their incorporation in the environments that have assimilated them.

Progressive vision over the professional judgment of the financial analyst

1.1 Defining the concept of professional judgment

The notion of "judgment" defines a set of related logical reasoning that have as goal the issuance of conclusive results for the activity it conducts. The construction "professional judgment" indicates a cognitive demarche based on factors that support the creation of a correct decisional structure.

1.2 The purpose of the financial analyst and the factors with reformation character in issuing a financial judgment

The professional reasoning of the financial analyst is identified as a way of critical, reflective and purposive reasoning [2].

Professional judgment has known several labeling from which a different approach is distinguished – that labeling by social and informational influences (at the level of individual that does not need a group) and the social normative (associated to group ideas).

Accordingly to this influences, the professional judgment can create a stronger individual argument or can push the analyzed subject in complying with the majority's opinion [3].

Taking into consideration the above mentioned influences we propose a number of factors involved in the activation, maintenance and progressive development of the professional judgment of the financial analyst:

- Psychological factors
  - Factors related on one side to the human nature (behavioral features, qualities obtained or born with, related to the financial analyst interactions with the organizational environment and the activity performed);
  - Factors related on the other side to the economic and social environment (influences of local markets, of globally transitive phenomenon);
- Deontological factors of legislative nature (Ethical Code, internal regulations based on professional judgment, job description);
  Ethics represent a mandatory element in forming a professional judgment, stating that ethical practices lead to expansion of the business environment [4].
- Historical factors (succession of economic character elements, types of governance, evolution of the state and environment);
- Economic factors (periods of crisis, recession or increase, specific indicators).

On an evolutionary scale, the purpose of the financial analyst is specialized, meaning that the financial analyst is found, as a profession, in a small area of industries, fact explained by a large number of information that he has to process [5].

1.3 General and specific responsibilities of the financial analyst

The activity of the financial analyst is divided on several types of responsibilities.

1.3.1 From the general responsibilities we name:

- respecting the internal rules manual of the company;
- respecting the quality and environment plan and procedures specific to the job and those that ethically interact in order to act properly in its activities;
- assuming and respecting the law in force in the health and security field and the measures needed for compliance and acting in a manner that does not expose to danger, accidents of professional sickness both itself and other personnel that can be affected by his actions or omissions during the course of work;
- Leading, motivating, developing and supervising the activity of subordinates in order to act efficient in fulfilling the general requirement for the direction that he coordinates.

1.3.2 Specific responsibilities are related to the following:

- the financial analyst attends and makes recommendation in the financial planning and budgeting processes in accordance with the internal rules and regulations and assures the control of agreed budget variations in order to monitor the financial performance on cost centers and projects for substantiating the measures in a proper manner;
- provides monthly or as required macro-economic analysis and financial reports regarding the board indicators;
- issues scenarios and cost-benefit analysis in order to develop and underlie recommendations for improving the company's financial performance;
- provides expertise and counseling for team members in order to assure a good course of the activity, develops team's ability and improves the performance;
- Designs and proposes for approval new procedures or improved procedures in order to increase the efficiency of the company;
- Applies and uses various ways for extraction and consolidation of the accounting information from the accounting system and internal reporting information and responds to occasional or periodically reporting for the management, external auditors or authorities.

The financial analyst issues reports monthly or whenever necessary, attends the budgeting process, tracking the realization of the budget, performs economic and financial analysis of budgets and investment plans.

The financial analyst uses accounting information and has an extended vision over the environment in which he activates, holding information regarding the market both globally and individually, trading market and future label markets (virtual – the appreciation of the new type of currency – bit coin [6], etc.).

The concept of economic Resilience

Resilience, as primary definition, followed a psychological path and was alliterated by Boris Cyrulnik, a French Doctor, as being the positive capacity of people to cope with the stress and adversity [7].

Subsequently, the concept of resilience knew a major extent of doctrinal applicability and currently is used in a multiple areas like economics, ecology, engineering, construction and other domains.

As we look at the resilience as a unitary whole consisting in more likely from ordinary processes rather than extraordinary processes [8] we can appreciate this concept as being a positive economic quadrant, completed by elements with a reforming character. These elements are presented in the ordinary economic environment, the process of reforming being nothing but a self-regulating system of existing resources (Fig. 2).

Economic resilience, in this paper, represents the capacity of the economic quadrant to adapt at shifts that intervene in this environment. These shifts imply an entire evolutionary process and affect the practical and theoretical basis of both the positive and normative theories.

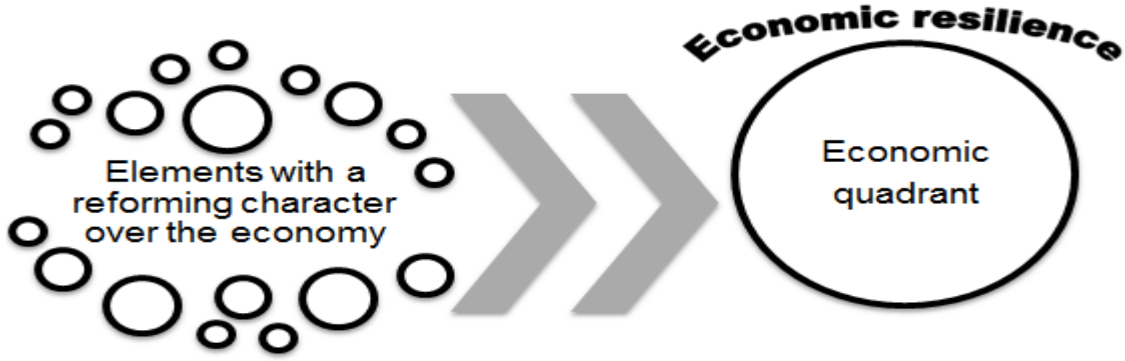

Fig. 1 The reformed space of economic resilience

1.1.1 The process of resilience in an environment with a readjusting character

We propose the following versions of environmental reactions in the moment when the resilience process is activated:

- The resistance based on the impact of the phenomenon that creates the shock over the economic environment;
- The recognition activity of the newly born phenomenon and the factors that determined it;
- Positioning the newly created phenomenon inside a negative or positive posture;
- Identification of consequences generated by the entrance in the environment of a disturbing factor;
- Looking for possibilities of elimination or containment of phenomenon's action, when it has a negative impact;
- Embedding the components that developed subsequently as result of a symbiotic process between the environment and the phenomenon in order;
- Maintaining the positive result obtained and the attempt to develop activities on an increasing trend using as basis the adaptation to the new circumstances.

Considerations regarding the professional judgment of the financial analysts in the context of positive and normative accounting theories

1.1 The positive theory acknowledgement

The positive theories relate to the exposure of phenomenon as it is, without a previous processing of content, without applying a subjective mark.

The positive theories are characterized throughout the inductive judgment and express the emerging of pure accounting explanation.

Briefly exemplifying the positive theories we name the Theory of Agency [9], the Theory of Positive Economics [10], the Transaction Cost Theory [11], etc.

The representatives of the positive current have the excessive tendency towards classification and organization considering that these attributes lead to the development of science [12].

1.2 The normative theory acknowledgement

The normative theories have as starting point certain standards and principles that delimitate, in context, the development of a guide that comprises the accounting practices and procedures. In these theories the deductive judgment is used, having as purpose obtaining some improvement of the environment described.

Briefly exemplifying the normative theories we name the Theory of Efficient Capital Markets [13], the Theory and Measurement of Business Income [14], etc.

1.3 The professional judgment of the financial analysts in the context of positive and normative accounting theories

The professional judgment of the financial analyst in the context of positive theories of accounting refers to the operational/decisional board issued at organization level throughout the positive filtering of the financial statement information.

Through the positive filtering we understand the assimilation of information taking into consideration a reality highlighted by the features of the financial statements.

The exposure of these information results from the previously established character of the financial statements through the objectives and limits stated in the legal framework.

In this process the interpretation capacity as other qualities related to the expression of professional judgment of the financial analyst does not interfere with the objective collection of data.

Moving into another register, the involvement of the financial analyst in shaping the data obtained, in interpreting the sets of indicators (job description, information in setting a strategic and operational corpus within the company) through filtering by own judgment and through subjective action over the financial statements generate a structure individualized by the normative theories of accounting.

Creating an abstracting of the concepts of "professional judgment" and "normative character" of the accounting theories we can state that there is a slight tendency of equalization of these theoretical build-ups (Fig. 1)

This equalization appears due to understanding the professional judgment as an element of professional conduct pre-established in normative acts.

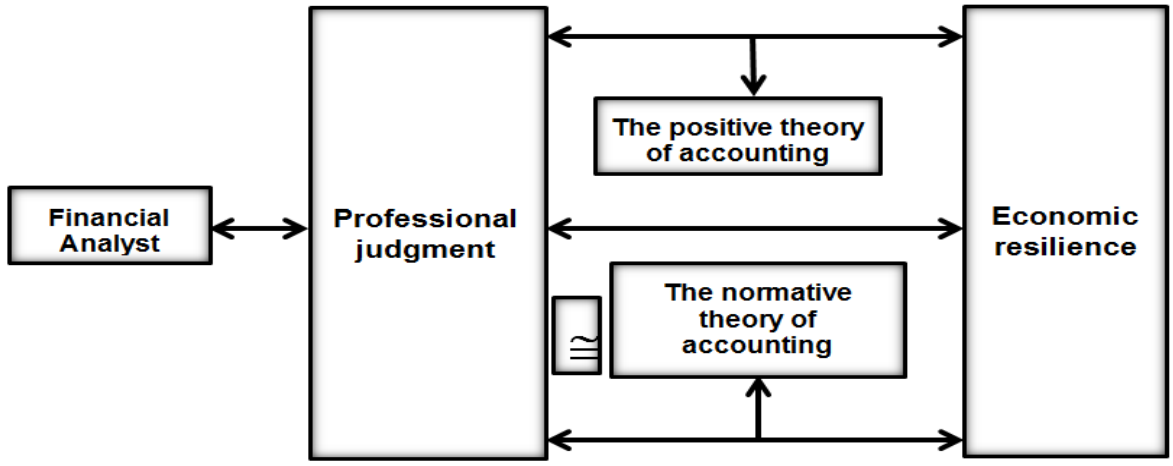

Fig. 2 The flow of judgment in economic resilience

Conclusions

The inclusion of the financial analyst in a community with high argumentative nature does nothing but to strengthen the idea that both the individual development and the group development lead to the harmonization of knowledge at the level of the company. A positive result of this aspect is the positioning on an ascending and optimistic trend.

The risks taken no longer represent a balanced load but a careful orchestration of all information at a pragmatic level on one side and a result of "rhetorical cognition productive process" on the other side [15].

In resilience given conditions, no matter the approach (through positive or normative theories), the information in use takes modifications, meaning that independently from the ways of understanding and analysis of the circumstances, the economic dimension is adapting as its action over the newly emerged phenomenon.

Although perceived as analytic and descriptive toolkit, the applied theories develop dynamism with a continuity feature leading to the enhancement of the scientific research world-wide.

Abstract

A large part of disabled people confront the situation of isolation in terms of communication. Finding a place of liberating and aggregative words is a groping process. The problem of finding such a place, a space without risks, in which we can all meat each other without risks of mix contacts or discrediting is arising. We consider that Internet can be such place.

Our view will focus on an Internet devise dedicated to people and their closed ones diagnosed with Guillain Barré syndrome: what rests after medicine interventions? What could be the role of a public testimony posted in a public web site? Can this provide a framework for assisted resilience?

Key words: digital resilience, communication, sickness, disability.

Etat de l'art

Il est certains cas où la guérison ne signifie pas la fin du mal à dire, empêchant ou du moins fragilisant le travail de reconstruction de soi.

Le handicap lui-même et ses stigmates ne sauraient se réduire à un état physiologique. Goffman [1] a parfaitement décrit certains usages sociaux de personnes aujourd'hui dites, en France du moins, en situation de handicap. Ces dernières ayant recours à d'habiles stratégies de présentation de soi afin de ne pas se retrouver discréditées, en situation d'interaction. Elles peuvent ainsi chercher à éviter certaines situation à risque, telles les contacts mixtes, « (…) *instants où normaux et stigmatisés partagent une même « situation sociale* » (…) » [1]. La norme étant celle du plus grand nombre, les personnes en situation de handicap se retrouvent donc en situation d'isolement communicationnel (nous parlons ici de véritable intercompréhension et non d'information ou d'interaction). Le lieu de la parole libératrice et agrégative se cherche à tâtons. Gardou [2] parle d'un autre état de danger, à propos du non-lieu de vie de personnes meurtries : « *Vouées au manque de place, par incompréhension, peur, abandon ou rejet, elles sont maintenues dans une position indéterminée. Dans un ailleurs. Dans un nulle part. Dans une sphère sociale indéfinie où se jouent des relations ambiguës. Dans un espace d'errance.* ». La problématique du lieu, de l'espace sans risque, se pose donc pour permettre à certains de se retrouver et de se raconter, ensemble, sans risque de contact mixte et de discrédit. Cette problématique est d'autant plus aigüe lorsqu'il s'agit de rassembler des individus « singuliers de la même singularité », épars géographiquement qui plus est.

Resterait donc à penser un lieu qui ne serait pas régi par des lois conventionnelles, une utopie réalisée, une hétérotopie [3], un « ailleurs-ici- et-maintenant ». Hert [4] semble nous indiquer que le lieu que nous cherchons est tout trouvé : Internet.

Précédemment, nous avons eu recours à l'approche microsociologique de Goffman pour avancer une première idée, relative aux modes de communication des personnes en situation de handicap.Cet auteur est bien plus connu pour son analyse des rites d'interaction [5]. Ces derniers peuvent être intégrés dans un cadre général, une théorie du lien rituel [6] : « *Les pratiques rituelles dans leur ensemble peuvent être considérées comme des instances de médiation de première importance, constituant des contextes de communication complexes et complets.* ».

Cependant, si l'Internet fournit sans conteste un cadre hétérotopique favorable à un récit de soi - condition de résilience, comment aborder cet espace ? Quels rites d'interaction s'y pratiquent-ils ? Amato et Boutin [7] apportent de consistants éléments de réponses. Mais sont-ils toujours robustes en toute situation, dans notre cadre d'étude ? Quelles sont les formes de ritualités numériques mobilisées par des individus que des tragédies personnelles ont réunis ? En quoi ces ritualités numériques portent-elles les ferments d'une résilience, au-delà d'une guérison froide et déshumanisante ?

Notre regard va se porter sur un forum de discussion dédié aux personne et proches d'individus ayant été, ou étant, atteints du syndrome de Guillain Barré : que reste-t-il après que les troubles pris en charge par la médecine ne soient repartis ? L'individu a-t-il pour autant pleinement recouvré son statut de sujet ? Quel peut-être le rôle, le cas échéant, d'un Dispositif Socio-Technique d'Information et de Communication (DISTIC) ? S'agit-il de témoigner ? [8]. En quoi peut-il fournir un cadre de résilience assistée ? Nous nous proposons d'apporter quelques éléments de réponse au travers d'une analyse nethnospective [7].

La résilience, appréhendée de façon dynamique, peut être considérée comme un processus qui permet à un individu ou à un groupe humain (familial, communautaire, organisationnel, etc.) de faire face suite à un événement traumatique ou stressant (selon l'orientation théorique du chercheur). Ce point de vue est d'importance car il se centre sur la mise en mouvement de la résilience, à appréhender de façon systémique. L'individu est en interaction avec un environnement. L'approche peut devenir situationnelle.

Récemment, le périmètre du concept de résilience a été considérablement élargi. S'il avait préalablement été restreint à des contextes exceptionnels (catastrophes naturelles, actes de violence, accidents de transport, accident écologiques majeurs…), Ionescu [9] l'utilise aussi dans des situation de « tracas du quotidien » qui provoquent des retentissements sur le bien-être psychologique, tels que les embouteillages.

Pour notre part, nous nous intéressons tout particulièrement ici à certains événements pathologiques de nature somatique. Certains d'entre eux sont vécus de façon extrêmement violente et, une fois la guérison advenue, des traces pas toujours visibles peuvent subsister. La prise en charge thérapeutique s'intéressant bien souvent au cure qu'au care, l'ancien malade devient impatient de se dire, quand seuls ses symptômes intéressent le corps médical. Aussi semble-t-il qu'une forte part d'indicible ou de non audible soit un frein à l'expression de son mal-être.

Parmi les pathologies répondant à ce type de critère, l'une d'elle a retenu toute notre attention. Il s'agit du syndrome de Guillain Barré. Dans sa forme classique, il apparaît dans un premier temps en présentant différentes caractéristiques cliniques : faiblesse musculaire qui survientsubitement, diminution des réflexes, problèmes sensitifs (picotements par exemple)… Dans un second temps, les troubles deviennent généralement extrêmement invalidants et peuvent aller jusqu'à la paralysie. Dans certains cas, les muscles permettant la respiration sont atteints. A l'hôpital, l'objectif est d'empêcher la dégradation neurologique. Il est alors question d'agir sur le corpset la dimension psychologique de l'atteinte n'apparaît pas comme systématiquement prise en compte. Pourtant, « L'évolution des paralysies et la perte progressive d'autonomie crée un état d'anxiété et d'inquiétude. L'état du malade peut se degrader très vite nécessitant des mesures de réanimation impressionnantes (intubation, monitoring du rythme cardiaque). Le découragement et le renoncement peuvent s'installer, surtout lorsque les progrès tardent à arriver, et qu'il existe des séquelles potentielles. Un soutien psychologique peut donc être nécessaire pour le malade et ses proches. » (Repéré le 4 février 2014 à https://www.orpha.net/data/patho/Pub/fr/GuillainBarre-FRfrPub834.pdf). Le plus souvent, dans un troisième temps, les victimes de ce syndrome recouvrent leurs aptitudes physiques au bout de six à douze mois. Il s'agit de la phase de récupération. Ce temps qui voit disparaître les symptômes handicapant peut se vivre en centre de rééducation. Mais au bout du compte, quand la « boucle est bouclée », l'événement laisse un souvenir violent et il semble que les anciens malades isolés dans leur corps éprouvent le besoin de se raconter, en même temps qu'ils entament ou poursuivent leur travail de reconstruction. Ni valides, ni handicapés, ils sont d'anciens handicapés, plus totalement valides, ils sont à la recherche d'un nouvel équilibre, dans un entre-deux éprouvant. Cet état n'est pas sans rappeler la notion de liminalité [2] qui, en se basant sur l'anthropologie culturelle, fait des personnes handicapées des sujets liminaux. Un équilibre est à pour eux à (re)trouver. Cet équilibre peut passer par une nouvelle reliance, par la recherche d'une agrégation avec les membres du groupe virtuel de ceux qui ont déjà subi pareille épreuve. Le processus décrit emprunte ici aux « rites de passage » décrits par Van Gennep [10] : l'individu est séparé du groupe (cf. irruption de la maladie, mort symbolique), puis isolé (cf. hospitalisation, état d'entre-deux à l'issue incertaine), et enfin réintégré (réincorporation dans le groupe, renaissance rituelle). Mais s'agissant du syndrome de Guillain Barré, c'est à dire d'une maladie rare (i.e.affectant un nombre restreint d'individus), les relations de pair à pair ne sont pas des plus aisées pour les personnes qui se retrouvent alors isolées IRL (In Real Life). Pourtant, il semble que ces relations, en même temps qu'elles facilitent la renaissance rituelle, permettent la construction d'une nouvelle identité. Cette étape de parcours de résilience apparaît comme fondamentale : « Si la résistance permet le maintien identitaire, la résilience quant à elle suppose toujours plus ou moins une forme de conversion identitaire. Le sujet au terme de son parcours revient certes à lui-même mais il se perçoit néanmoins comme différent de ce qu'il était avant le fracas. L'individu engagé dans un tel itinéraire résilient attend d'être considéré par son entourage pour ce qu'il devient. » [11]. L'expression d'un chemin de résilience, témoignage pouvant aller de la maladie jusqu'au « né au soi », peut permettre l'accompagnement de l'évolution personnelle. Aussi, le récit de soi peut devenir écriture-soin [12] et accompagner le mieux-être, dans le cadre de maladies somatiques : « On ne peut énumérer ici tous les travaux aboutissant à la même démonstration : l'écriture aiderait au soin de bon nombre de maladies somatiques. Certains malades le sentent intuitivement et affrontent la maladie grâce à l'écriture. Lagarde a rédigé son journal accompagné de photographies dès l'annonce de son cancer du sein. Elle envisage l'écriture comme un « accompagnement ». ».

Pour autant, des résistances (pudeur, mésécoute, recherche d'une véritable intercompréhension…)peuvent empêcher le discours autobiographique. Pour certains, la condition de production de celui-ci sera dans l'expression aux pairs, à ceux qui partagent un bout de vécu commun.

Comment, alors, se raconter à des pairs alors que l'on a quitté les murs de l'hôpital ? La prévalence du syndrome de Guillain Barré semble interdire les rapprochements de pair à pair, amoindrissant le caractère performatif du rite d'agrégation et, par la même, de la renaissance dont il s'agit ici. Ce rite peut, semble-t-il alors, se vivre sur un mode numérique, grâce aux Nouvelles Technologies d'Information et de Communication (NTIC). Pour Tisseron [13], la question d'un usage résilient des espaces numériques se pose effectivement : « L'environnement proche de chacun est organisé autant, si ce n'est plus, par des centres d'intérêt partagés via Internet que par un critère de proximité physique. Au désir d'intimité comme valeur motrice du XXe siècle s'est substitué le désir d'extimité [défini comme la volonté de partager ses expériences les plus personnelles avec tous ceux qui ont pu en avoir de semblables, même si aucun lien de contact physique réel ne confrontera jamais à eux.».

Divers éléments convergents nous poussent donc alors à considérer les différents modes du récit de soit sur l'Internet (l'exemple du blog étant sans doute ici emblématique [14] comme autant de modes de résilience assistée. Comme le discours centré sur soi y prend-il forme ? Permet-il la création d'une véritable « identité narrative » ? Quelle est la place de la narration, de l'inscription de la personne dans sa production discursive ? Telles sont les questions qui nous ont conduit à analyser un espace Web d'information sur le syndrome de Guillain Barré (http://sgbfrance.free.fr/), mais aussi d'échange autour de cette maladie. En page d'accueil figure un témoignage, le dernier qui a été posté dans la rubrique dédiée, présentée sous forme de liste. Figure aussi le nombre total de témoignages postés depuis la mise en ligne du site, ainsi qu'une invitation à raconter sa propre expérience ou bien celle d'un proche, victime de la maladie. Un autre espace d'expression est disponible, il prend la forme d'un forum de discussion ouvert ou chacun peut alors échanger avec tous. La place allouée au témoignage par le dispositif étudié nous a semblé supérieure à celle du forum. Aussi, la page d'accueil constitue un passage obligé, une porte d'accès au reste de l'espace post-liminaire, elle détermine un sujet unique (vs. le forum où les discussions peuvent porter sur les traitements de la maladie, ses séquelles, etc.). La dimension rituelle de ce récit nous est apparue comme concomitante à l'amorçage d'un travail de résilience assistée. Aussi, la comparaison de ces récits peut avoir du sens dans la mesure où témoigner et non de discuter autour de sujets divers préfigure une unité thématique. C'est pourquoi nous nous attardons particulièrement ici à cette forme de ritualité numérique, récit de soi particulier et porteur, potentiellement, d'un mieux-être souhaité, d'une renaissance à un autre soi-même.

Question et problématique de recherche

Une des questions qui se posent est la suivante : un Dispositif socio technique d'information communication peut-il fournir un cadre neutre permettant la libre production d'un récit de soi ? En d'autres termes, certains espaces numériques permettent-ils vraiment de se produire par les mots et d'avoir le contrôle de cette production narrative. Cet aspect là nous paraît d'importance : les individus ayant perdu la maîtrise d'un épisode de leur vie doivent pouvoir être assurés de produire le discours qu'ils veulent. Cette question, au delà des apparences, est loin d'être anecdotique. Nous avons donc cherché à amorcer une réponse en nous basant sur une étude du terrain que nous avons sommairement décrit.

Une première lecture flottante a semblé faire émerger une impression. Les témoignages paraissent présenter des traits communs en termes d'identité narrative [15] et cela peut sembler conforme aux attentes. Par contre, cette simple lecture semble révéler une forme de mimétisme stylistique : de nombreux témoignages ressembleraient, du point de vue du style, à ceux qui les précèdent. Sans qu'il nous soit permis d'être catégorique sur cet aspect, ceci nous pose problème. En effet, si pour Ricoeur [15] le sujet est une histoire, pour d'autres auteurs, il est aussi un style [16]. Aussi envisageons-nous qu'un élément venant altérer l' « identité stylistique » d'un individu en viendrait à en altérer un travail de résilience en cours. Les prémisses de cette hypothèse méritent d'être vérifiés.

Méthodologie mise en oeuvre

Nous avons téléchargé les 106 derniers témoignages sur le site http://sgbfrance.free.fr/ . Chaque témoignage a fait l'objet d'une analyse de contenu.

Nous choisissons alors de caractériser chaque témoignage en fonction de différentes variables qui dépassent la seule dimension stylistique. Ainsi prenons-nous en compte :

- Le style d'écriture : narratif, énonciatif, descriptif, argumentatif ;
- La mise en scène : dynamique, ancrée dans le réel, prise en charge par le narrateur, prise en charge à l'aide du « Je » ;

- Le type de verbes utilisés : performatifs, statifs, déclaratifs ;
- Les types d'adjectifs : objectifs, subjectifs, numériques ;
- Les types de pronoms utilisés : je, tu, il, nous, vous, ils…

Nous caractérisons aussi chaque témoignage par des variables descriptives :

- Age de la victime au moment où elle est atteinte du syndrome ;
- Age de la victime quand le témoignage est rédigé ;
- Ecart de temps entre la déclaration de la maladie et le témoignage ;
- Auteur du témoignage : la victime, la mère, la fille… ;
- Genre de la victime ;
- Genre du narrateur ;
- Nombre de mots du témoignage.

Toutes ces données sont collectées et codées dans un tableau. Nous faisons l'hypothèse que si les témoignages s'inspirent des témoignages antérieurs, cet emprunt doit se retrouver par une certaine proximité de modalités successives pour certaines variables. Nous cherchons à mettre en évidence des formes de mimétisme et à déterminer autour de quelles variables elles s'expriment.

Nous cherchons à déterminer de façon globale si un témoignage s'écrit par mimétisme avec le témoignage immédiatement antérieur. Nous avons à trouver une mesure de distance entre les témoignages pris deux à deux. Sachant que les variables ne sont pas toutes sur la même échelle de valeur, nous optons pour la distance coefficient de corrélation. Nous considérons donc toutes les variables de notre étude et nous calculons la corrélation entre les valeurs de chaque témoignage et les valeurs du témoignage antérieur. Nous obtenons ainsi pour les 106 témoignages de notre étude 105 coefficients de corrélation. La moyenne de ces coefficients est de 0,9878.

La question est de savoir si cette corrélation peut être considérée comme faible ou forte. Si la corrélation est forte, cela signifie que chaque témoignage est influencé par le témoignage précédent.

Nous comparons la corrélation moyenne entre nos observations à celle qui résulterait d'une permutation aléatoire des lignes de notre tableau de données. En procédant ainsi, on détruit le classement chronologique du tableau par témoignage successif. On observe ainsi une nouvelle corrélation entre témoignages. Comme nous disposons de 106 enregistrements, nous disposons de 106! permutations possibles de témoignages. Ne pouvant les tester toutes, nous optons pour une méthode du Bootstrap qui est une méthode de simulation qui va reconstituer de nouveaux échantillons aléatoires à partir de l'échantillon de départ. Dans notre exemple, nous réalisons 30 itérations successives en notant à chaque fois la moyenne de la corrélation. Ces trente itérations successives permettent d'estimer un intervalle de confiance et de définir si ou non on peut considérer le mimétisme entre deux témoignages comme statistiquement significatif

Résultats

Nous obtenons ainsi trente coefficients de corrélation :

0,9845-0,9848-0,9865-0,9861-0,9843-0,9829-0,9843-0,9844-0,9845-0,9841-0,9832-0,9853-0,9854-0,9847-0,9842-0,9845-0,9845-0,9862-0,9859-0,9856-0,9847-0,985-0,9838-0,983-0,9818-0,9854-0,9834-0,9838-0,9863-0,9836.

La moyenne de ces 30 valeurs est de 0,984556667, et son écart type de 0,001107555. Avec ces valeurs, il est possible de construire un intervalle de confiance. Compte tenu des trente simulations que nous avons effectuées, nous pouvons affirmer avec une marge d'erreur de 5% que la moyenne réelle des coefficients de corrélation inférée sur notre population est comprise dans l'intervalle [0,9841; 0,9849]. La corrélation observée (0,9878) étant supérieure à cette fourchette, nous concluons que cette corrélation est significativement importante ce qui signifie que le classement des témoignages n'est pas du au hasard : la corrélation entre deux témoignages est significativement plus élevée que ce qu'elle devrait être si on répartissait les témoignages aléatoirement.

Notre approche est globale. Elle permet de valider statistiquement le fait que les témoignages ressemblent aux témoignages immédiatement antérieurs. En fait, sur les 106 récits observés, certains sont plus proches du précédant que d'autres. La distribution des coefficients de corrélation permet d'identifier les discours qui ressemblent plus que les autres aux discours antérieurs. Nous avons identifié les témoignages pour lesquels le récit ou le témoin précédant a pu constituer une forme de source d'inspiration stylistique. Pour cela, nous avons considéré les 10% de coefficients de corrélation les plus forts. On obtient le tableau 1

Tableau 1 : témoignages les plus corrélés les uns aux autres

Témoignage les plus mimétiques	Coefficient de corrélation
Corrélation entre témoignage 28 et témoignage 29	0,999604238
Corrélation entre témoignage 62 et témoignage 63	0,999586447
Corrélation entre témoignage 90 et témoignage 91	0,999521934
Corrélation entre témoignage 34 et témoignage 35	0,999223463
Corrélation entre témoignage 103 et témoignage 104	0,999166336
Corrélation entre témoignage 50 et témoignage 51	0,998856254
Corrélation entre témoignage 106 et témoignage 107	0,998765132
Corrélation entre témoignage 35 et témoignage 36	0,998720131
Corrélation entre témoignage 102 et témoignage 103	0,998662904
Corrélation entre témoignage 73 et témoignage 74	0,998544996
Corrélation entre témoignage 71 et témoignage 72	0,998460898
Corrélation entre témoignage 60 et témoignage 61	0,998425765
Corrélation entre témoignage 40 et témoignage 41	0,998400081
Corrélation entre témoignage 89 et témoignage 90	0,998341613
Corrélation entre témoignage 78 et témoignage 79	0,998228723
Corrélation entre témoignage 88 et témoignage 89	0,998202871

Nous avons jusqu'à présent réalisé une étude macroscopique. Nous examinons maintenant les variables qui sont les plus déterminantes pour évaluer un phénomène de mimétisme.

Nous choisissons une nouvelle mesure de la distance plus facile à concevoir. Pour la variable retenue, nous calculons la valeur absolue de la différence entre les deux observations successives.

Pour illustrer la démarche, considérons par exemple la variable « nombre de mots » par témoignage. Nous disposons, pour chacun des 106 témoignages, du nombre de mots comme illustré dans le tableau 2 (colonne A et B)

Tableau 2 : étude de la distance entre deux témoignages successifs : le cas du nombre de mots

Colonne F	Colonne A	Colonne B	Colonne C
Nombre aléatoire	Numéro du témoignage	Nombre de mots	Ecart de nombre de mots en valeur absolue entre deux témoignages
0,52	69	542	
0,31	70	540	2
0,41	71	432	108
0,91	72	575	143
0,88	73	338	237
0,4	74	560	222
0,13	75	1213	653
0,44	76	559	654
1	77	503	56
0,84	78	1295	792
0,52	…		
0,31	177		403
0,41	MOYENNE		600.4

En colonne C, nous ajoutons la distance entre les témoignages successifs. La distance est ici l'écart du nombre de mots entre deux témoignages. Sur la dernière ligne figure la distance moyenne entre témoignages.

La question est de savoir si cette distance peut être considérée comme petite ou grande. Si la distance est considérée comme petite, cela signifie que la taille des témoignages est influencée par la taille des témoignages antérieurs.

Comparons maintenant la moyenne observée avec celle qui résulterait d'une distribution aléatoire du nombre de mots par témoignage. La colonne F comporte des nombres générés de façon aléatoire. Si le tableau est classé avec la colonne F comme clé de tri, alors les nombres de mots par témoignage sont reclassés aléatoirement. Mesurons alors la distance entre deux observations, selon le même principe que précédemment. On observe ainsi une nouvelle distance moyenne entre témoignages. Comme nous disposons de 106 enregistrements, nous disposons de 106! permutations possibles donc classements possible. Ne pouvant les tester toutes, nous optons pour la méthode du Bootstrap présentée lors de la première étape. Nous réalisons 30 itérations successives. Le tableau 3 illustre le résultat. Les valeurs obtenues sont à rapprocher du 600,4 que nous avons obtenu dans l'étape précédente.

Tableau 3 : résultat du Bootstrap

Simulation	1	2	3	4	5	6	7	8	9	10	…	30	Moyenne	Ecart type
Distance moyenne	*689*	*644*	*646*	*613*	*592*	*665*	*657*	*670*	*664*	*689*		*634,6*	659	*27,5*

A partir de ces informations, nous calculons l'intervalle de confiance. Compte tenu des 30 simulations que nous avons effectuées, nous pouvons affirmer avec une marge d'erreur de 5% que la moyenne réelle inférée sur notre population est comprise dans l'intervalle [649 ; 668]. La moyenne observée étant de 600,4, nous en concluons que cette valeur est significativement inférieure à la précédente ce qui signifie que la répartition des tailles de témoignages n'est pas due au hasard : l'écart entre deux témoignages est significativement plus faible que ce qu'il devrait être si on répartissait les témoignages au hasard.

Nous avons réalisé ce travail pour les variables étudiées. Pour certaines d'entre elles, présentées tableau 4, nous observons une influence d'une modalité sur la modalité suivante.

Tableau 4 : variables à partir desquelles le mimétisme est observé

	Moyenne des 30 tirages aléatoires	Moyenne observée	Intervalle de confiance avec marge d'erreur de 5%
Nombre de mots	659	600	[649 ;668]
Style : argumentatif	0,46	0,39	[0,45 ; 0,47]
Style : narratif	0,27	0,25	[0,27 ; 0,28]
Style : énonciatif	0,3	0,26	[0,29 ; 0,32]
Mise en scène : prise en charge par le narrateur	0,47	0,41	[0,46 ; 0,49]
Prise en charge à l'aide du « Je »	0,16	0,12	[0,15 ; 0,16]
Type de verbe (factif, statif, déclaratif)	5,18	5,06	[5,12 ;5,24]
Type d'adjectifs (objectif, subjectif,numérique)	11,72	11,34	[11,6 ;11,9]
Type de pronom (je, tu, il, elle, nous, vous, ils, elles, on)	8,17	7,46	[8,05 ;8,3]

Cette relation pourrait être affinée par le choix d'une distance intégrant, par exemple, le témoignage immédiatement antérieur mais aussi des témoignages plus éloignés. Ceci n'a pas été mis en œuvre ici.

Discussion

A ce stade, il nous semble permis de tirer certains enseignements. Notre recherche montre que certaines conditions et modalités de médiation sur le Web provoquent, sans doute sans que les individus n'en aient pleinement conscience, une influence sur leur style, la forme du récit qu'ils formulent, s'agissant de raconter une histoire mettant en scène un événement traumatique les concernant. Ce constat peut sembler paradoxal dans la mesure où l'Internet semble être le lieu de la libre expression, de la parole sans entrave. Or ici, nous montrons clairement que les sujets ne sont plus tout à fait les maîtres de leur narration, plus réellement les producteurs de leur discours. La disposition de témoignages sous forme de liste semble être une des sources de l'effet observé, comme cela a déjà été montré par ailleurs [17]. Une forme d'amorçage cognitif semble être à l'œuvre. S'agit-il vraiment d'un effet de mimétisme ? Peut-on parler d'effet de primauté (l'individu serait influencé par la tonalité du dernier message lu dans la liste) ? Pour aller plus loin dans l'interprétation de notre étude, il nous faudrait multiplier les observations mais aussi interroger les personnes concernées en premier chef, c'est à dire celles qui ont produit les témoignages sur lesquels nous nous sommes basés. Toujours est-il que la résilience assistée sur le Web se trouve questionnée. Pleine de promesses, cette dernière pose aussi question. Quel type de structuration de l'information et de la communication est à imaginer pour que la parole s'en trouve plus libre ? Nous l'avons dit, le récit de soi sur le Web peut fournir un cadre de résilience des plus pertinents, dans certaines situations. Mais la réflexion sur les dispositifs doit se prolonger pour que réellement (ré)émerge une parole singulière.

Abstract

The Internet is a complex ecosystem in which it is possible to observe some regularities, coordination dynamics in real time. This functioning of ecosystem ca be observed at the level of a micro community composed by members sharing a centre of common interest. We are focus on presenting what is going to become a part of the ecosystem while a web community is exposed to a brutal shock. Our research hypothesis is that the shock modifies the functioning of this ecosystem and introduces a polarisation of exchanges around privileged places which place the role of totem, churches, worship places, or build a history of collective memory, or share of emotions (Norris).

Within the work, we choose to realise a case study which allows us to research a community of fans after the dead of their idol: Michael Jackson. The paper proposed a retrospective observation to characterise exchanges on the artists before and after his death (privileged places of exchanges, number of people sharing, nature of exchange).

Field research will emphasise the dynamic of Wikipédia French page dedicated to Michael Jackson. This approach will allow developing a particular methodology for resilience.

Key words: numeric communication, coordination, numeric resilience, *Wikipédia*

Le travail de Norris et Stevens [1] a permis d'identifier les facteurs qui contribuent à rendre une communauté résiliente. Une communauté serait d'autant plus résiliente que :

- Il existerait des ressources économiques importantes et bien réparties ;
- Le capital social est important ;
- Il existerait des réseaux organisationnels qui peuvent être mobilisés rapidement en cas d'urgence ;
- L'information sur les dangers est précise et rapide d'accès ;
- Le groupe est capable de construire une histoire collective, de partager des émotions suite à un évènement traumatique.

C'est précisément ce dernier point qui va nous intéresser. Provenant du domaine des Sciences de l'Information et de la Communication (SIC), il nous a semblé pertinent d'étudier le rapport qu'il pouvait y avoir entre résilience et communication, notamment dans le contexte des nouveaux médias. Nous allons nous fixer sur la relation entre communication et résilience pour étudier de quelle façon une expérience narrative partagée [2], [3], [4], [5], la construction collective d'une histoire [6] permettrait d'accroitre la capacité de résilience d'un groupe.

Nous formulons alors l'hypothèse selon laquelle un choc initial serait de nature à introduire, sur l'internet, une polarisation des échanges autour de lieux privilégiés qui joueraient le rôle de totems, d'églises, de lieux de recueillement ou se construiraient une histoire et une mémoire collective, où se partageraient des émotions. Dans ce travail, nous avons choisi de réaliser une étude de cas qui nous conduira à étudier une communauté de fans suite au décès de leur idole : Michael Jackson. Nous mettrons en place, de manière rétrospective, un observatoire infométrique pour caractériser les échanges autour de la star avant et après sa mort (lieux d'échanges privilégiés, nombre de personnes échangeant, nature des échanges). Cette approche permettra de révéler une topologie particulière des échanges qui pourrait être un marqueur de résilience.

Présentation du contexte :

S'intéresser, 4 ans après la mort de la star, aux traces laissées par les internautes sur les dispositifs numériques à l'occasion de son décès n'est pas simple en raison d'une certaine asymétrie informationnelle. Les acteurs majeurs du Web reconnaissent que le décès de Michael Jackson a créé un pic de fréquentation historique. Google précise que sa disparition a engendré un des plus gros pics de recherche qu'il ait connu mais il se garde bien de préciser combien de requêtes il a reçues ce jour là. Yahoo n'est guère plus loquace en révélant que Yahoo News a battu un record avec 16.4 millions de visiteurs dont 4 millions entre 15h et 16h PDT le jour du décès. Twitter précise que ce jour là, 5000 tweets par minutes concernaient Michael Jackson. C'est le plus grand nombre de tweets depuis la dernière élection présidentielle américaine. Sous Facebook, la tendance est la même, le réseau social ayant observé le triplement des comptes modifiés le jour de l'annonce du décès. Les géants du Web donnent des offres de grandeur mais ne permettent pas d'accéder aux sources de ces données.

Ceci explique que notre travail de terrain va s'appuyer sur la plateforme Wikipédia qui donne accès à un niveau d'information brute consistant.

Revue de la littérature :

Un certain nombre de travaux antérieurs ont étudié la façon dont un ensemble de contributeurs retraçaient sous Wikipédia, en temps réel, la mémoire [7] d'une catastrophe, d'une crise [8], d'une révolution [9]. Wikipédia y apparaît comme un laboratoire d'observation de la façon dont la dynamique de coordination opère en temps réel pour rendre compte d'un événement. Inutile d'être expert pour contribuer. Les contributeurs ont des motivations diverses, un accès inégal aux ressources informationnelles. Certains parmi eux n'ont jamais travaillé ensemble. L'alchimie pourrait sembler improbable mais elle fonctionne.

Méthodologie :

Dans cet article, nous allons nous intéresser à un article de rupture qui relate un évènement d'actualité. Notre étude va porter sur la page Wikipédia francophone consacrée à Michael Jackson (https://fr.wikipedia.org/wiki/Michael_Jackson). Cette page a été modifiée 6394 fois entre le 22/12/2003, date de sa création, et Janvier 2014. Cette page est donc le fruit d'une collaboration en ligne de large échelle. Afin d'étudier la dynamique de cette page, nous allons mettre en œuvre une méthodologie plurielle combinant une approche infométrique [10] et une analyse de contenu des versions stockées. L'étude permet de reconstituer la sagesse des foules [11] par laquelle un collectif instable, sans centre, sans rôle attribué parvient à coordonner une tache complexe. Notre approche permettra de dégager le profil des contributeurs, les grandes controverses, le lien entre la dynamique de cette page et l'actualité. L'approche permet de mettre en évidence que certaines lois du Web [12] se trouvent observées : par exemple, les contributions sont surtout le fait d'un petit nombre de contributeurs très impliqués [13]

Wikipédia est un projet d'encyclopédie collective construite à partir de contributeurs volontaires. Après avoir souscrit à un compte Wikipédia, il est possible de consulter la chronologie des contributions sur une thématique donnée. Wikipédia offre aussi à ses membres la possibilité de suivre les modifications (ajouts, suppressions) introduites par les contributeurs successifs. La figure 1 présente une capture de l'utilitaire « différence entre versions » de Wikipédia.

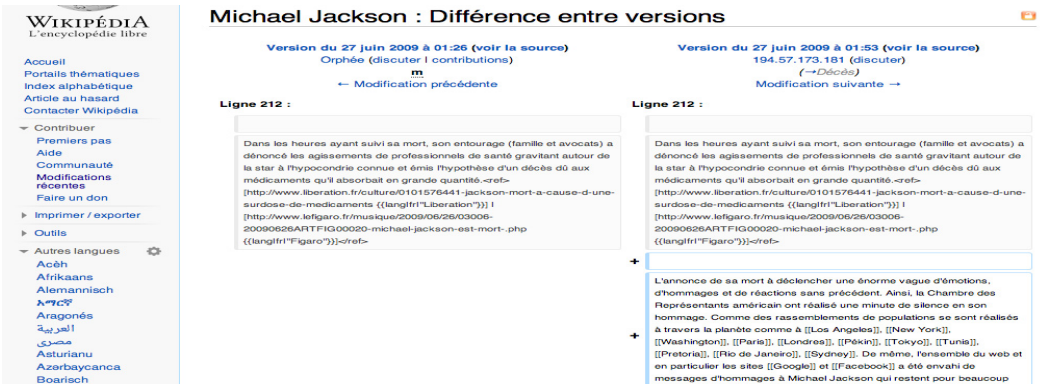

Figure 1 : la différence entre versions sous wikipédia

Il est possible, grâce à cet utilitaire, de reconstituer la dynamique par laquelle une page Wikipédia est élaborée.

Résultats de terrain :

1.1 Approche quantitative

Le moment du décès du chanteur va se traduire par un pic de contributions comme le montre la figure 2.

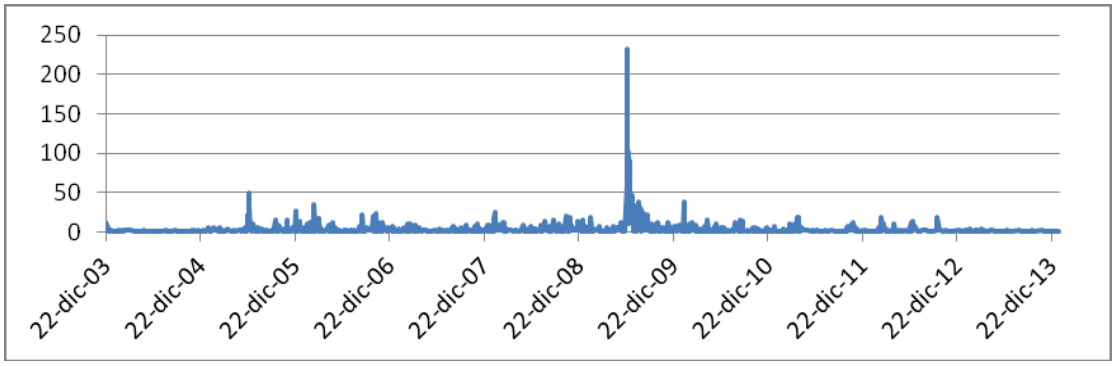

Figure 2 :Nombre de contributions par jour sur la page Wikipedia France de Michael Jackson pour la période 2003-2013

On observe sur la période antérieure à la date du décès une moyenne de 1.41 modifications par jour. Entre le 25 Juin 2009 et le 24 Aout 2009, la page consacrée à Michael Jackson est modifiée en moyenne 29.66 fois par jour.

La moyenne n'est pas forcément l'indicateur le mieux à même de rendre compte du nombre de modifications par jour. Un focus sur le nombre de modifications journalières entre le 25 Juin et le 25 Août fait apparaître figure 3 des pics à plus de 200 modifications par jour.

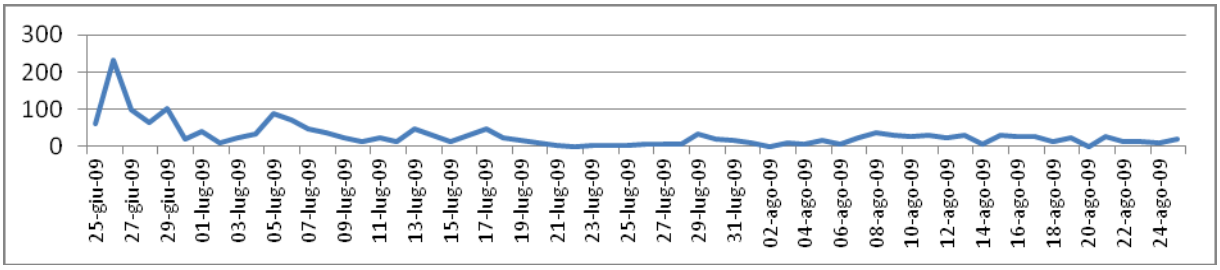

Figure 3 : Nombre de contribution par jour sur la page Wikipedia France de Michael Jackson du 25 Mai au 25 Aout 2009

L'étude exploratoire a étudié la chronologie des contributions entre le 25 Juin 2009 à 21h36 et le 27 Juin à 18H34, soit moins de 48h après l'annonce du décès. Entre ces deux dates, nous avons relevé manuellement 250 contributions significatives. La fonctionnalité « différence entre versions » proposée par Wikipédia a permis de suivre les évolutions entre les contributions prises deux à deux.

La méthode que nous avons retenue nous conduit à revivre les évolutions de cette page. On observe un fourmillement, une grande activité. On a le sentiment qu'une page d'histoire se tourne, que quelque chose se prépare, que chacun s'affaire et reprend le texte initial pour en faire un nouveau à la mémoire du chanteur. On a l'impression que chacun veut apporter sa pierre à l'édifice. Tous les contributeurs ne travaillent pas tous dans le même sens. On observe certains actes de vandalisme… mais ceux ci sont rectifiés avec dignité, sans commentaire. L'examen des auteurs de ces 250 contributions permet de voir qu'elles sont le fait de 125 « individus » différents. On observe que 77% des contributeurs n'ont fait qu'une intervention et que les 4 plus importants (en volume), présentés tableau 1, ont réalisé à eux seuls plus du tiers des contributions. Il y a donc une concentration des contributions entre les mains de quelques uns. Les pages Wikipédia sont modifiables par tout un chacun mais certains contributeurs reviennent de façon récurrentes pour proposer des modifications.

Tableau 1 : contributeurs ayant réalisé 33% des contributions

Contributeur	Nombre de contributions
Steff	47
Céréales Killer	14
Hercule	13
Bouchecl	12

Afin de clore cette vision statistique des contributions, nous avons réparti les contributions en trois catégories : contributions avant le décès, contributions dans les deux mois suivant le décès, contributions postérieures au 25 Aout 2009 (2 mois après le décès). La répartition des contributions selon ces trois catégories permet de rendre compte de profils de contributeurs différents, certains participant exclusivement avant le décès, d'autre à l'occasion du décès, d'autres se révélant après, d'autres intervenant à différents moments. Le tableau 2 montre comment se ventilent les interventions des 5 contributeurs les plus actifs sur toute la période (2003-2014).

Tableau 2 :Ventilation des interventions des 5 contributeurs les plus actifs sur la période 2003-2014

	Nombre de contributions	% de contributions avant 25 Juin 2013	% de contributions entre le 25 Juin et le 25 Aout 2009	% de contributions après le 25 Aout 2009
Orphée	215	7%	88%	4%
Steff	214	61%	39%	0%
SpeedDemon74	202	100%	0%	0%
Gandalfcobaye	129	0%	100%	0%
Céréales Killer	120	8%	38%	53%

Une approche plus microscopique permet de voir qu'après le décès, certaines dates (jour anniversaire de la date de décès, jour anniversaire de la date de naissance, 1er Novembre) sont choisies par certains contributeurs parmi les plus actifs pour revenir sur la page et la modifier. On observe une fréquentation, ces jours là, qui est toujours significativement supérieure aux jours immédiatement antérieurs. On observe aussi tableau 3 qu'en s'éloignant de la date du décès, les contributions s'appauvrissent quantitativement.

Tableau 3 : fréquentation de la page wikipédia certaines dates (anniversaire, 1 Novembre)

Nous allons maintenant nous livrer à une approche qualitative du contenu des contributions

1.2 Approche qualitative

Moins de 48h après l'annonce du décès, on observe une évolution des contributions. Deux grandes étapes peuvent être distinguées, même si ces étapes sont largement recouvrantes.

La première étape est celle de l'annonce du décès. L'évènement sera affiné, détaillé successivement. Il est probable que tout ce détail ne résistera pas à l'épreuve du temps. Toutefois, au moment du décès, les internautes veulent se situer au cœur de l'actualité et il faut leur communiquer une information fraiche et validée. Durant cette période, seule la partie du texte consacrée au décès est modifiée : la date et l'heure du décès sont affinées, les propos sont étayés par des références.

Dans la deuxième période, les contributeurs vont s'attacher à une relecture précise du texte qu'il s'agit de modifier, compte tenu du décès. C'est dans cet esprit qu'une controverse tourne autour du fait de savoir si la présentation de la biographie doit désormais se faire au présent ou à l'imparfait. Le premier à mettre la première phrase de la biographie à l'imparfait est le contributeur 44 post mortem. Même si la contribution 48 précise que dans les biographies on utilise le présent dans l'introduction, le temps du premier verbe de la biographie sera modifié 23 fois, ce qui représente plus de 11% des contributions.

Dans cette seconde phase, il s'agit pour certains d'apporter leur pierre à l'édifice en corrigeant des erreurs stylistiques, typographiques ou orthographiques. Le premier à corriger une faute d'orthographe est le 43^{ième} contributeur après l'annonce de l'évènement. 28 contributions corrigent des fautes d'orthographe ce qui représente 13,5% des contributions.

D'autres proposent une nouvelle rédaction de certains passages. Ces passages ne sont pas forcément liés au décès et peuvent concerner les procès, affaires ou situation la financière. Ces modifications sont souvent faites dans une ou plusieurs des 4 perspectives suivantes : authenticité, refus du sensationnalisme, gommage ou édulcoration de certains passages, hommage.

- Authenticité : loin des formules ampoulées ou administratives, les contributeurs sont à la recherche d'une certaine authenticité. C'est dans cette logique qu'il faut comprendre les échanges nombreux quand au fait de savoir s'il est préférable d'employer « mort » plutôt que « décès ». La question débute à partir de la contribution 118. Elle générera 17 contributions jusqu'à la contribution 250, soit 13% d'entre elles. Un commentaire d'un contributeur justifie l'usage du terme « mort » plutôt que « décédé » en disant « *non au politiquement correct* » (contribution 193). Un autre (242) précise que « *décès » n'est pas plus soutenu que « mort » ; le TLFi indique que « décès » est un terme administratif ou juridique ; aucun des deux ne correspond au contexte de Wikipedia* ». C'est sans doute en suivant cette même logique d'authenticité qu'un certain contributeur proposera une nouvelle illustration en lieu et place d'une image existante (Figure 4). Celle-ci correspond à l'original de la photographie qui a permis de construire l'image antérieure qui n'était qu'une retouche (contribution 82). Cette nouvelle image est perçue comme moins belle, prend plus de place mais dans les 168 contributions suivantes, elle ne sera modifiée qu'une seule fois avant d'être rétablie.

Figure 4 : Une photographie plus authentique

Dans la même logique, (37) supprime de la biographie le terme superstar.

- Refus du sensationnalisme : on supprime frasque dans un titre (contribution 90). La contribution 144 supprime le passage où il est question du livre Guiness qui déclare Michael Jackson homme de spectacle le plus célèbre. Dans la même logique, la contribution 112 propose de supprimer le lien vers « Pédophilie » dans la rubrique « voir également ». La dernière ligne a été modifiée dans la capture de la figure 5

Figure 5 : la rubrique voir également

- Reformulation de certains passages : Ainsi (78) remplace « sa plus grosse affaire financière a été » par « homme d'affaires avisé, MJ a réalisé un coup de maître ». L'histoire de son fils suspendu dans le vide est raccourcie (92), (180) . Certains passages où il est question de ses dettes sont supprimés ainsi qu'un autre où il question de ses conflits avec son ancien conseiller financier.
- Lui rendre hommage : La contribution 213 est la première à parler des hommages rendus au chanteur. La première intervention sur le sujet fait référence aux hommages institutionnels (chambre des représentants) qui lui sont consacrés mais aussi aux hommages anonymes. Ce paragraphe est repris successivement pour décrire de façon plus fine l'ensemble des personnalités internationales qui ont rendu hommage à Michael Jackson mais aussi pour parler de ses fans (215). Le contributeur (217) créé une rubrique « réactions » pour y mettre les hommages. Il simplifie le texte des hommages. Il souhaite rester sobre sur le sujet et éviter « l'excès et des anneries ». Une référence est rajoutée par le contributeur (220). Il ne restera in fine en (250) que le texte suivant, à propos des hommages : « À l'annonce de sa mort, de nombreuses personnes se sont rassemblées spontanément pour lui rendre hommage. Les membres de la Chambre des représentants des États-Unis ont observé une minute de silence en son hommage ». Cette phrase délivre peu d'informations mais distingue les hommages des fans des hommages officiels.

Dans ce second temps, on observe que les petits détails du décès qui ont fait le jeu de la première étape sont peu à peu gommés pour ne retenir que ce qui restera dans l'histoire. Ces deux étapes sont un peu contradictoire l'une et l'autre. La première focalise sur le décès, la seconde remet le décès à sa juste mesure dans la vie de l'artiste. Cela se traduit par une simplification de la partie relative au décès qui aura donc été éphémère (moins de 48 heures).

Ces quelques observations sont à replacer dans le cadre des recherches sur les dynamiques à l'oeuvre durant le deuil, dynamiques qui font appel à des processus de résilience. Le deuil est une douleur souvent individuelle et certains espaces numériques nous donnent à observer des deuils collectifs. Souvent, le travail de deuil passe par l'acceptation et du décès de la personne concernée, et de la biographie du défunt. Le fait d'édulcorer certains épisodes de vie, de ne « retenir que le bon », comme on le voit ici, fait complètement partie d'un travail de résilience. Après le moment de stupeur lié à la perte elle-même succède celui qui permet de dépasser l'événement tragique et de faire sans, c'est à dire avec. La notion de « loyauté familiale » semble ici pertinente à transposer pour montrer une « loyauté sociale », servant de support à la perpétuation de l'esprit qui, lui, demeure…

Abstract

When facing serious challenges in life, individuals tend to find their way out through many coping mechanisms to override the harmful effects of changing circumstances on our mental health. In the last three years, the Arab world was shaken by a wave of protests fueled by a lack of social justice and a very difficult economic situation. During the five days following the fall of the dictatorship in Tunisia, Marzouki et al. [1] analyzed a sizeable text corpus about the role played by Facebook during the revolution as perceived by Tunisian citizens. Although the results were in favor of a perception based on information sharing, media coverage and political challenges that Facebook was able to carry during the revolution, resilient processes were not explored in this seminal study. One key feature in Marzouki et al. work is the presence of a Virtual Collective Consciousness (VCC) generated by a momentum of complex interactions between individuals sharing common goals and driven by a widespread consensus. On the other hand, strengthening social ties during times of misfortune is a common feature among the resilient processes. Our hypothesis is as follows: Facebook can be also a placeholder for collective resilient processes modulated by risk factors during a crisis (i.e., revolution). After revisiting the same corpus collected by Marzouki et al., the analysis of similarities showed that the Facebook informational support is well anchored in seeking social support. Moreover, protective factors (mainly collective) seem to give rise to this informational role significantly assigned to Facebook during the uprisings. These findings show that the ability to keep working toward a goal in the face of difficulties can be enhanced by virtual interactions, which makes social networking a good outlet for resilience when positive feedbacks and common shared values are available in the cyberspace.

Keywords: boosting effect; social networking; Facebook ; Tunisia; Jasmin revolution.

The background

Over the past three years, the Arab world has been shaken by a wave of protests fueled by a lack of social justice and a very difficult economic situation. Tunisia was the flagship of these uprisings. During the five days following the fall of the dictatorship in Tunisia, Marzouki et al [1]. analyzed a large text corpus collected from 333 respondents about the role played by Facebook during the revolution as perceived by Tunisian citizens. Although the results are in favor of a perception based on the sharing of information, media coverage and political challenges that Facebook has achieved during the revolution, resilient processes have not been explored in this seminal study.

Studying resilient processes in a large-scale group begins to gain importance (e.g. Countries affected by poverty, war and other collectively experienced traumas led to the hypothesis that resilient processes can also be shared within the social network (e.g., [2]). For example, Panter-Brick and Eggerman [3] interviewed 1,011 pupils and 1,011 caregivers in their school settings in Afghanistan to identify key life stressors and possible solutions to attenuate them. The subjects' responses were analyzed using an approach based on thematic inductive analysis. For adults, the main concern is to fix their "broken economy" which is the main source of the experienced discomfort. For students, the primary focus is on how to be able to evolve in decent learning environments and thwart poverty. Thus, any tendency towards hope comes from values centered on moral and social order such as faith, family unity, morality, honor, etc.

Collectively shared high moral values such as freedom and dignity were at the heart of the drive that put forth Tunisian citizens in the worldwide scene as the leader of a new breed of revolutions. A key element to the success of this new kind of revolution, referred to as leaderless revolution, is the presence of a Virtual Collective

Consciousness (VCC) generated by the dynamics of complex interactions between individuals sharing a common goal and motivated by a broad consensus [4]. On the other hand, the strengthening of social bonds during time of crisis or trauma is a common feature to resilient processes. Our hypothesis is as follows: Facebook can also be a space where resilient collective processes caused by risk factors (e.g., [5].) during the revolution may occur following decades of dictatorship, oligarchy and lack of freedom of expression (i.e., *social suffering* - [6]**)**. We also expect to observe more pronounced collective protection factors in the corpus relative to individual factors since Tunisian citizens are akin to sharing common values via their social networking platforms.

The goal

We used the corpus collected by Marzouki et al. [1], to examine if the Facebook informational support is anchored in seeking social support, and to what extent individual and collective protective factors play the role of buffers to mitigate risk factors and to ultimately generate this informational role during the Tunisian revolution.

Method

An online questionnaire consisted of two closed questions: (a) Are you a Facebook user? and (b) How do you feel the importance of Facebook in the Tunisian revolution of January 2011 (from 0: not important at all to 10: very important)? The open-end free question was: According to your rating, please explain in one sentence your choice. All participants were anonymous Internet users completing the questionnaire. The original sample was 352, of which 333 (94.6 %) were retained in the final analysis.

Results

We have selected the participants' answers that contain the following key words typically associated with the resilient processes: *support*, *aid*, *solidarity*, *hope*, *project*, *collective*, *better life*, *love*, *potential*, *positive*, *best*, *solution*, *collectivity*, *together*, *resolution*, *support*, *help*. Two main branches are linked as shown in Figure 1: **Facebook** and **Information**. In fact, in the first branch "seeking informational support" can be considered as part of "seeking social support" that is a critical dimension to give rise to resilient processes. Hence, it is likely that this first branch would support the emergence of the second one. This begs the question: *what the part individual and collective factors play in this complex social dynamics as a function of risk factors*? That's why risk factors were extracted based on the following key words: *poverty, dictatorship, combat, suffering, aggression, despotism, violence, lie, suppression, and the protective factors were extracted based on (individual): freedom, truth and (collective): family, united, union, people, religion, mobilization*. Consequently, only 26% of the original sample was used in this study. As expected, the results revealed more prominent collective factors reflected by three big clusters: Information support, social support and virtual social support (see Figure 1).

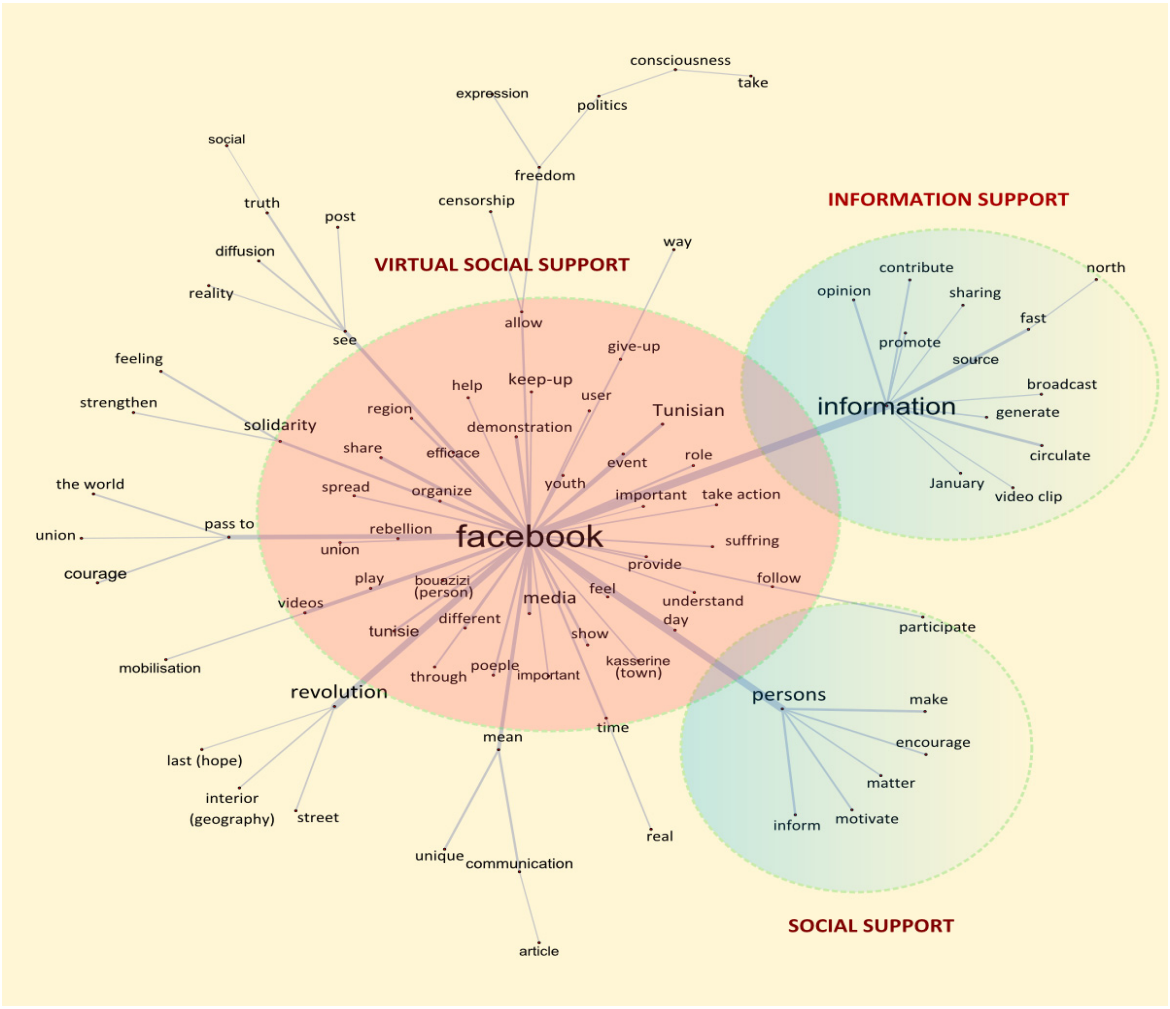

Figure 1. Maximum leaf-spanning tree solution after the lemmatization of the partial corpus that was extracted based on the presence of key words associated with: resilient processes, protection factors (individual and collective) and risk factors in participants' answers.

Conclusion

The exposure to traumatic events forces people to look for outlets via multiple coping strategies in order to circumvent the adverse effects of such negative incidents on our mental health. After revisiting the same corpus collected by Marzouki et al. [1] study, the similarity analysis showed that informational support provided by Facebook is rooted in seeking social support. In addition, collective protective factors occupy a large place relative to individual factors and are more likely to lead to this informational role during the revolution. One may ask why only 1/4 of the original sample exhibited words associated with resilient process? A possible explanation of this interesting statistic maybe attributed to the time frame where the study was launched. Indeed, few weeks after the fall of the regime, Tunisian citizens were not yet focusing on future plans for their social life but were more trying to collectively enjoy the unexpected retaliation that Facebook played in their favor. Hence, resilient processes take sometime to be settled providing a clear orientation in the future as partly showed in some studies (e.g., [7]).

The present study showed that the ability to continue to work actively to achieve goals in the face of life's difficulties could be enhanced by virtual collective interactions. Consequently, social networking can be considered as an interface where the expression of resilient processes is made possible by the presence of positive feedbacks and common values shared within the cyberspace. Future studies on the anthropology of well-being and hope can further investigate the role that social networking may play in shaping individual and collective resilience as well as virtual social identity and its dynamics (e.g., [8]).

Digital literacy and resilience: correlational and comparative study among two groups of adolescents

Vaquero Eduard T.

Postdoctoral fellowship. Department of Pedagogy and Psychology. University of Lleida (SPAIN)
eduardvt@pip.udl.cat

Abstract

Little attention has been given promoting resilience through technology. Nowadays, in a global, distributed and informational society, is important to know how young people deal with digital risks, how adolescents use Internet to cope with problems, and also how we can promote resilience online for adolescents could deal with social and digital risk situations.

Behind this approach, a study carried out with a sample of 435 adolescents between 12 and 18 years-old. The aims were exploring if resilience and digital skills are related and compare the levels of the resilience and digital literacy among two groups.

The results show some resilience factors are significant correlations with different elements of the digital competence. Concretely, family cohesion is one of the most important factors. As well as, statistical differences on the resilience and the digital skills was founded. Conclusions have important implications for future research and professional practices.

Keywords: digital skills, adolescence, resilience, technology

Background

Resilience is characterized as a dynamic process given in relation to the context where people socialize [1], [2]. It's not strictly a personal attribute, many social and cultural factors are involved in this process [3]. In developing resilient skills a force field which involved risk factors and protective (social, family, individual) determine the unique setting and in a situation of adversity is established [4].

Resilience is a capacity that occurs in interaction with the social environment. But the question arises whether in front of technologically advanced social environments, people develop resilient responses using technology as a mechanism to deal an adverse situation. For these reasons, it's important finding new ways to overcome risks and new protection mechanisms, especially for children and adolescents living under situations of vulnerability [5].

Three main aspects are related to the resilient uses of technology: 1) the level of technology adoption, 2) the type of use, i.e., how and for what purpose is used digital media, and 3) the level of digital literacy. Factors such as age or gender [6], [7], socioeconomic and educational level [8], and certain psychological or emotional characteristics may influence on the use of technology and the level of self-rated digital competition for teenagers.

On certain contexts, the use of technology can generate on childhood and adolescence feelings of rejection, stress, frustration, anxiety, dissatisfaction and develop risk behaviors involving the neglect of other obligations and responsibilities [9], [10]. However, technology can generate opportunities for social support and meeting positive relationships for adolescents [11].

Method

1.1 Aims

The aim was analyzed if there are differences between resilience and the digital skills of two groups of teenagers. Also, raised to know the relation between two variables, resilience (R) and Self-perceived Level of Digital Competence (SLDC), analyzing the influence of different factors and dimensions.

1.2 Sample

The sample was 435 adolescents between 12 and 18 years-old from the region of Lleida, Spain. It was divided in two groups: 364 from high schools and 71 from foster care centers. The first group was living at home with their birth families. The second group were in a temporal foster situation and represents 47.5% of adolescents that living in foster care centres in the region. The 49.3% were boys and 50.7% were girls. The mean age was 15.41 years-old.

1.3 Instruments and variables

Resilience was measured using the Resilience Scale for Adolescents (READ) [12]. The 28 items examines 5 factors related to resilience: F1) Personal competence, F2) Family cohesion, F3) Social resources, F4) Structured style and finally F5) Social competence.

To measure SLDC, an improved version of the Digital Skills Scale for Adolescents (DSS-A) were used [13]. The 81 items assessed 4 dimensions related to five literacies of digital competence [14]: D1) Digital Culture, D2) Digital Devices, D3) Software and apps and D4) Information, communication and web tools.

1.4 Data analysis

Spearman's Rho (ρ) was calculated to measure the relationship between resilience and digital skills in both groups. Also, T-student and was calculated to compare both variables among two groups.

Results

1.1 Correlational outcomes

Results notes a negative correlation between R and SLDC on the second group. It means that the lower the self-perception of digital competence that these adolescents have, the higher resilience is. Adolescents with a lower perception of their digital skills are nevertheless capable of reacting positively and find strategies that allow them to cope with risk situations in which the use of technology are supposed difficulty, obstacles or problems. Fig. 1 and Fig. 2 shows in more detail that this relation it mainly happen between F2 READ factor and D2 (ρ=-.409, p<.01) and D3 (ρ=-.521, p<.01) DSS-A dimensions.

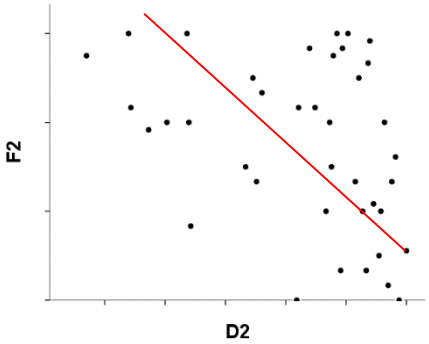

Fig. 1 F2-D2 correlation

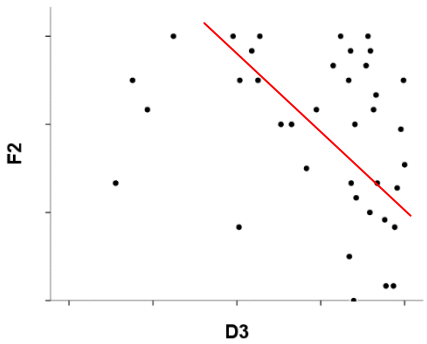

Fig. 2 F2-D3 correlation

1.2 Comparative outcomes

Comparative analysis shows there are differences on R and SLDC between two groups. There were differences on the resilience among two groups but in only one factor: CF (σ=.05, p<.01). It also there was statistical differences in the self-perception of digital competence, specifically in D3 (σ=.032, p<.01) and D4 (σ=.027, p<.01). It means that SLDC is lower when adolescents live in less stable and/or difficult personal, social and economic situations, and thus it's related to resilience and family cohesion.

Conclusions and professional implications

Family is maybe the most important core to overcome risk because of provide resources for children develop their capacities, also the acquisition of digital skills. There was a little digital divide between two groups. Both do not have the same SLDC and do not use technology in the same way, given their different characteristics and situation. Factors such as family status or level of technological appropriation may influence in this different perception.

For this reason, the professional interventions should address the challenge involved to help adolescents to cope their difficulties, also to reduce differences in youth people. Thus it's possible using technology resources as social resources. It means use technology as a mechanism to promote resilience and improve the adolescents at social risk quality of life.

This is a resilient perspective of social intervention using technology. Promoting digital literacy on foster care centres may reduce the digital differences among adolescent population, improve the social perception about technology and open new ways for the communication and participation of the birth families, children and professionals.

Acknowledgments

This study has been developed with the support of the Research Group about Social and educational Interventions in childhood and youth (GRISIJ), and financed by the University and Research Agency of the Government of Catalonia (AGAUR).

On the temperaments and personalities in the post-pc era

Voicu M.-C., Gergely T.-T., Popa A.-C.

West University of Timisoara (ROMANIA)
mirela.voicu@feaa.uvt.ro

Abstract

Recent years have been marked by unprecedented evolutions in the IT area. The cloud computing technologies and the Internet have transformed and affected our habits. In this paper we start from the famous book "Understanding Your Personality With Myers-Briggs and more" by Patricia Hedges, 1993. We continue with a study on the personality and temperament of different people at young ages, in accordance with their activities in the online environment. The activities in the online environment refer to the using of different tools (e-mail, browsers, social networks, documentation, online learning, online shopping etc.), as well as development or activities, such as website building, online marketing, etc. The Internet world comes with many opportunities (e.g., in business, in learning, entertainment, etc.). For some people, understanding and exploring the online environment, in various forms, can be a simple game. For others it may remain an unknown, a strange, or a dangerous environment, which does not come with benefits in terms of education or knowledge.

Our goal is to detect the way in which different types of personalities and temperaments react to these technologies. We have carried out this study, because for many people from around the world, online activities are increasing, becoming habits, and will certainly affect their lives, one way or another.

Keywords: personality, temperament, cloud computing, Internet.

Introduction

In the last years, the IT area has been marked by important evolutions. Cloud computing technologies are becoming dominant and these have marked the transition to the post-PC era. This transition brings many changes to our lifestyle: how we entertain ourselves, the way we learn, we work, we communicate with others, we travel, etc. For some people, these radical changes seem to come only with added value. However, not all people are excited about the changes in the online environment. On the one hand, there are people affected negatively by these developments (they may feel overwhelmed).

Currently IT developments are at a stage that most people would not have dared to dream 25 years ago. It's a mistake to meditate on how we could move away people from the things offered by the online environment. On the other hand, the IT evolutions are powerfully increasing and impossible to stop. In the context described above, we wish to emphasize that, whether we like it or not, we must accept that people's way of life in many parts of the planet is undergoing powerful, irreversible changes. The study on the way in which these changes are affecting people is a complex problem. However, different aspects can become studies on these subjects. We consider relevant and interesting to study the behavior and reaction of different types of personalities or temperaments. We start our study remembering the concepts presented in [3], which are used to find out how people perceive the world and make decisions.

Now, we recall the basic pairs of personality characteristics and their meaning: ***Extraversion (E)*** and ***Introversion (I)*** tell about an outer or inner attitude to the world. Extraverts like collaborating with others. Introverts need to have more time alone. ***Sensing (S)*** and ***iNtuition (N)*** tell how people perceive the world around them. Sensers live in the present and they are concerned on the practical things. Intuitives are creative and look often to the future. ***Thinking (T)*** and ***Feeling (F)*** reflect the way in which people make decisions. Thinkers use logic and impersonal analysis, while feelers are human need oriented. ***Judging (J)*** and ***Perceiving (P)*** characteristics tell if people prefer to judge things or just to perceive them. Judgers are organized people, while perceivers are open to new things.

Starting from the basic pairs of personality characteristics, there are sixteen personality types***: ESTJ , ESFJ , ISTJ , ESTP, ENTJ, ESFP , ENFP, INFJ, INTJ, ISFJ, ISFP, ISTP, ENTP, INFP, ISFJ, ENFJ***, and also, there are four temperament groups: ***NF*** temperament (*ENFJ, INFJ, ENFP* and *INFP*), ***NT*** temperament

(*ENTJ, INTJ, ENTP* and *INTP*), ***SJ*** temperament (*ESTJ, ISTJ, ESFJ* and *ISFJ*) and ***SP*** temperament (*ESTP, ISTP, ESFP* and *ISFP*). For more information we recommend to read [3].

On cloud computing

Cloud computing is the use of computing resources (hardware and software) that are delivered as a service over a network (typically the Internet) (for more information, see [2] and [4]). *Deployment models* define the type of access to the cloud i.e. the way in which the cloud is located. Cloud can have any of the four types of access: Public, Private, Hybrid and Community.

Service Models are the reference models on which the Cloud Computing is based. These can be categorized into three basic service models as listed below: *Infrastructure as a Service* (IaaS - provides access to fundamental resources such as physical machines, virtual machines, virtual storage etc.), *Platform as a Service* (PaaS - provides the run time environment for applications, development & deployment tools etc.), and *Software as a Service* (SaaS - model that allows the use of software applications as a service to end users).

The end users simply access the items they need (anywhere and anything), using web browsers. They can use a desktop, a laptop, a tablet or a smart phone.

When you use Gmail or Yahoo mail you are using a cloud service. All messages are stored somewhere on a server (in the cloud). Some services in cloud are free, for others you are obliged to pay. The advantage is that in cloud you pay only for what you use.

Most important providers are: Amazon, Google, Microsoft, Apple, IBM, Oracle, Netapp, Dropbox, Evernote, Rackspace, etc. See also: http://aws.amazon.com/, https://cloud.google.com/, https://developers.google.com/, http://www.rackspace.com/, http://www.windowsazure.com/en-us/, http://windows.microsoft.com/en-us/skydrive/download, https://www.dropbox.com/, https://evernote. com/, http://office.microsoft.com/en-us/, http://www.apple.com/icloud/setup/, http://www.ibm.com/ cloud-computing/us/en/, etc.

Today, on the Internet, we can book a hotel room (e.g., see www.booking.com), we can buy flight tickets (e.g., see http://www.lufthansa.com/), we can buy (and pay online) products from different countries (e.g. amazon), we can learn with people around the world (e.g., see https://www.coursera.org/about/community - with more than 21 million enrolments), we can go on a virtual visit of the earth (https://maps.google.com/), we can find all our friends, from childhood until now (www.facebook.com), we can listen to music or see movies (www.youtube.com), and we can continue with many other examples, all these existing due to cloud computing technologies.

The development of online commerce has led to the development of online marketing strategies. Social media marketing (see on Facebook, Twitter, Pinterest, Google+, Youtube, LinkedIn, Insagram, Blogging, etc.) is one of the important elements of online marketing (also, see [6]).

Recent years have also been marked by an explosion of tools used for developing websites and apps for mobile phones (especially for iPhones and Androids), including cloud computing technologies. See, for example: http://www.buzztouch.com/, http://appinventor.mit.edu/explore/, http://mobile. conduit.com/, http://developer.android.com/, http://www.wakanda.org/, http://ibuildapp.com/, etc.

All the examples presented above demonstrate remarkable scientific developments in the IT area. We should, however, point out that these evolutions are not limited to IT area. They tend to capture activities from more and more areas. Finally, we must observe that these evolutions transform and affect people's lives.

Some people feel that the changes in the online environment make them evolve faster. Others may feel nothing or feel that they cannot keep up with everything and feel left behind. Some people are affected only as consumers, while others (implied in activities of online business) may be affected as workers/developers. In this paper we present a study on different types of temperaments or personalities - their attitude towards certain changes in the online environment.

Study on temperaments and personality characteristics

In our study we consider two groups of students. The first group consists of 71 persons that are around 19 years old. They are in the first year of university studies and they study accountancy. The second group consists of 31 subjects, around 22 years old, they are in the third year of university and they study business information systems. In *Table 1* we present our results for the first group of respondents, and in the *Table 2*, for the second group.

In order to detect the respondents' personality characteristics, personality types and temperaments we use the questionnaire presented in [3]. For the first group we find 52 extroversions (73,24% of all respondents) and 19 introversions (26,76% of all respondents); 58 sensers (81,69% of all respondents) and 13 intuitives (18,31% of all respondents); 47 thinkers (66,2% of all respondents) and 24 feelers (33,8% of all respondents); 52 judgers (73,24% of all respondents) and 19 perceivers (26,76% of all respondents). According to the

temperament types, we find 6 NFs (8,45% of all respondents), 7 NTs (9,86% of all respondents), 44 SJ (61,97% of all respondents), and 14 SP (19,72% of all respondents).

Table 1 *- Personality characteristics, personality types and temperament types - on online preferences -the first group - studying in accounting - 19 years old*

According to temperament types, we find 24 ESTJs (33,80% of all respondents); 10 ESFJs (14,08% of all respondents); 8 ISTJs (11,27% of all respondents); 6 ESTPs (8,45% of all respondents); 4 ENTJs and 4 ESFPs - each 4 representing 5,63% of all respondents; 3 ENFPs (4,23% of all respondents); 2 INFJs, 2 INTJs, 2

ISFJs, 2 ISFPs, and 2 ISTPs - each 2 representing 2,82% of all respondents; one ENTP and one INFP - each one representing 1,41% of all respondents.

For the first group we consider the following 11 questions: 1 Use of the Internet most often for learning or for entertainment; 2 Use of social networks; 3 Use of the Messenger; 4 Time spent on the Internet; 5 Gaming on the Internet; 6 Having a personal blog; 7 Considering the online environment as offering opportunities for developing business activities; 8 Intention to manage business using the online environment; 9 Knowledge of the newest IT technologies; 10 Knowledge of cloud computing technologies and services and 11 As future accountants, if they think that they are going to work much in the online environment.

In *Table 1* we present the results of our questionnaire. In each value cell, the percent refers only to the people who possess the characteristic or type specified in the column header. For example, for Q1 we can observe that 57% of extraverts prefer to use the Internet for learning, and 43% of them prefer to use the Internet for entertainment.

As we have seen above, most respondents are ESTJ, ESFJ, or ISTJ. For this reason, in *Table 1*, we present the results only for these personality types. From *Table 1* and the results of Q1, we can observe that intuitives (especially NFs), followed by perceivers, are more preoccupied with entertainment on Internet, than with learning. Also, ESFJs seem to be most preoccupied with learning.

The perceivers and ESFJs seem to be most preoccupied with social networking, while introverts seem to be the least interested than others. The least interested to spend time on messenger are the intuitives (especially NFs). At Q4 we can see that the introverts like to spent time on Internet, more than the extroverts. Also NTs like the Internet life, while NFs don't like this more than the others.

The introverts, followed by the perceives are the most passionate about Internet games. Also, at Q5 we can remark that extroverts are not so keen on the virtual world. Extroverts, thinkers and perceives are the ones more likely to have a personal blog (this could be translated as interest for the personal image). This way of communication is not much familiar to feelers (it seems that the virtual world does not meet their needs so well). Although it is not surprising, one notable aspect is the response of introverts - in this group of students, they do not have personal blogs. At Q7, we can observe that most people consider that the online environment offers opportunities for develop business activities. However, the feelers, especially NFs, are not as confident as the others. Even if people notice that the Internet offers opportunities for business (Q7), at Q8, we can see that the interest to manage such a business is rather low. In this case, also the intuitives and feelers are the least enthusiastic people. The perceivers seem to be more optimistic about this kind of business. At Q9 we can notice that the newest IT technologies are more important for introverts, whereas the most disinterested are the feelers. Cloud computing technologies are the dominant technologies in the post-pc era. Introverts seem to be the most documented on this subject. In the IT environment, things are evolving quickly. Intuitive features are very useful. The intuitives' answer at this point tells us that they are not educated enough in this area. In the case of intuitives, a more special attention to IT education would be desirable. At the last question, we can see that almost all respondents understand that, as accountants, they will work in the online environment.

For the second group of students, we find 19 extraverts (61,29% of all respondents) and 12 introverts (38,71% of all respondents); 23 sensers (74,19%of all respondents) and 8 intuitives (25,81% % of all respondents); 20 thinkers (64,52% of all respondents) and 11 feelers (35,48% of all respondents); 26 judgers (83,87% of all respondents) and 5 perceivers (16,13% of all respondents). In accordance with the temperament types, we find 3 NFs (9,68% of all respondents), 5 NTs (16,13% of all respondents), 20 SJ (64,52% of all respondents), and 3 SP (9,68% of all respondents). According with the personality types, we find 9 ESTJs (29,03% of all respondents), 5 ISFJs (16,13% of all respondents); 4 ENTJs and 4 ISTJs, each 4 representing 12,90% of all respondents; 2 ENFJs and 2 ESFJs - each two representing 6,45% of all respondents; one ENTP, one ESTP, one INFP, one ISFP and one ISTP - each one representing 3,23% of all respondents.

For this group of students we consider the following 11 questions: 1 Do they enjoy online shopping; 2 Do they intend to use the Internet in business activities (as customer); 3 Use of social networks in the activities which imply business goals; 4 Intention to be a mobile application developer; 5 Intention to be a website developer; 6 Intention to work in an environment using Internet services; 7 Using cloud computing services (virtual machines or cloud web hosting); 8 Do they consider the online environment as offering opportunities for develop business activities; 9 Do they intend to manage business using online environment; 10 Do they consider the IT evolution of recent years as help in their work activities and 11 Do they consider the IT evolution of recent years as impacting them negatively in any way.

As we have seen above, most of the respondents are ESTJs. For this reason, in *Table 2*, we present the results only for this personality type.

From the *Table 2* and Q1 we can observe that perceivers are more interested than others in online shopping. The feelers seem to be least interested in this kind of shopping. At Q2 we can observe that respondents are involved in different business activities using online environment. These activities also occur in social networks (see Q3), especially for perceivers, followed by feelers. The last years have been marked by a relevant interest for mobile application, used for business activities. It is considered that they allow you to stay closer to your customers in a way that other tools cannot. At Q4 we can observe the preference of the intutives, and the disinterest of the perceivers. Introverts and feelers are more interested in web development and online business (see Q5 and Q6). A small part of respondents are users of virtual machines or cloud web hosting. The introverts seem to be more interested (see Q7). Almost all respondents believe that online environment offers opportunities for developing business activities (see Q8). At Q9 we can notice the interest for managing an online business. From Q10 we can see that respondents feel that new technologies help them evolve in their working activity. Rapid IT evolution affects only a small part of respondents negatively (see Q11).

Conclusions

The Myers-Briggs Type Indicator (MBTI) assessment is a psychometric questionnaire designed to measure psychological preferences in how people perceive the world and make decisions. Such questionnaires are often used in recruitment or employee professional activities in order to track the employee evolution (also, see [1], [5] and [7]). This is the reason why in our study, such a questionnaire was considered as a benchmark.

Patricia Hedges's book comes as a support for scientific activities, or as a pleasant lecture for anyone interested in self-education. For more information we recommend reading this book or other studies on the Myers-Briggs Type Indicator (MBTI).

From the study presented in *Section 3*, based on personality characteristics, we have seen that people feel more or less comfortable in the online environment. We saw that the IT area is known to all, but with different degrees of interest. For example, we saw that introverts like the online environment a lot. But even here, the socialization is not their strong point. If their activities are mainly professional or social, the online environment can be beneficial to them. But if they spend too much time on the Internet, basically wasting time, they will obtain a more pronounced self-isolation that can strongly affect their behavior and life. For extroverts, important are the activities related to personal image or quality of life. Perceivers seem to consider important the activities bringing money or fun. Hard work in online environments is not attractive to them.

Studying the two groups of people, where the professional education was different, we can observe something very interesting: in the first group, the intuitives and the feelers seem not to enjoy the online environment so much, but in the second group we find a totally different result. At this point, our conclusion is that the intuitives and feelers, generally, do not enjoy online environments as much as the other groups. However, with a thorough professional education, they can be involved in online working activities, and their attitude can be changed significantly.

Related to sensers, thinkers and judgers, we remark that they feel comfortable in the online environment and that, in general, do not approach the extremes.

In our study, we have seen that even the personalities' characteristics strongly influence the way in which we react in online environment. These characteristics are powerful completed by other factors, such as professional education. Sure this is not the single factor, many others can be formulated, as the following: age, nationality, gender, religion, culture, etc.

Using appreciative inquiry in social interventions and develop resilience in the context of chronic adversity

Cojocaru S.

Alexandru Ioan Cuza University, Department of Sociology and Social Work (ROMANIA)
contact@stefancojocaru.ro

Abstract

The aim of the study is to examine how the use of appreciative inquiry influence the development of resilience adults faced with chronic adversity. Based on the theory of social constructionism and appreciative approach, this intervention strategy can be successfully used in the development of resilience. Using a language based on deficit by vulnerable and disadvantaged persons in some contexts lead to a chronic style of this language, which leads to reduce the chances of developing resilience. Our study tries to demonstrate that resilience can be developed in a context in which personal experiences are appreciated, the personal interactions and definitions are guided by an appreciative approach. In general, intervention in social work is guided by the paradigm of deficiency; from our point of view, this approach highlights the gaps, threats, weaknesses and consolidates vulnerability and, if not develop, at least keep the problem. Applying Appreciative Inquiry in the intervention group (parental education, support groups, group counseling, group therapy, etc.) participate in the development of resilience and profound changes in the client's situation, the result of changing how they define situations of vulnerability. Vulnerability from the perspective of social constructionism is generated by how the individual defines by language of deficit, their situation in a certain context. Or, from the perspective of constructionism, changing the definition leads to changing realities. Appreciative intervention (individual or group) it just uses the perspective that contextualizes the particular situations in which the individual is at any given time, with special emphasis on its interactions with the outside world (peer group, family, neighbors, community, etc..). Based on qualitative research, the study highlights the importance that has specialist approach that provides services to vulnerable and disadvantaged, the ways in which language influences the language used by this client.

Keywords: appreciative approach, appreciative inquiry, social constructionism, social vulnerability, appreciative intervention.

Social Constructionism and the Social Vulnerability

1.1 Characteristics of constructionism

Constructionism is a new orientation in sociology, based mainly on Gergen's works printed in the '80s [1] and it designates diverse approaches ale of the way reality can be known and especially how realities can be constructed. There are multiple definitions of social constructionism, due to its very nature, due to the recognition of the multiple realities generated by the diverse interactions between the individuals who construct these realities. By its very nature, constructionism cannot generate a unitary definition, due to the fact that knowledge is socially constructed. This approach considers that reality cannot be known in itself and asserts the existence of *multiple realities* constructed in the interactions between individuals. "The inquiry of social constructionism is focused mainly on explaining the processes through which people describe, explain or *interpret* the world they live in (including themselves)" [1]. Social constructionism is interested in the communication and relations between people and in the process of producing meaning in social interactions. A point of departure is represented by the fact that people, in the same circumstances, are capable of producing very different social constructions of the same reality. Some of the most significant features of constructionism are: (a) Language, communication and discourse are considered means of interaction between individuals who construct multiple realities [2] [12]; (b) Social constructionism focuses on the *relations* through which social actors construct realities [1] [13]; (c) This type of approach considers that the *subject-object distinction* is not productive and generative enough, maintaining a dualism which considers that the subject and the object are independent one from another [3] [4]; (d) Knowledge and social reality are dependent on the *social relations* and on the *negotiation processes* between people [3] [14].

1.2 Social Vulnerability Based on Constructionism

Keeping the lines drawn by Boudon in his typology of social actions [5], we can consider that vulnerability is a form of social passivity generated by the individual interpretations of certain situations, and can take the following forms [6]: (a) *Utilitarianist vulnerability* – the situation in which the individual/group does not sense its own interest, or the actions it undertakes are not adapted to it; the individual definitions of certain social situations or contexts constructed by the individual ignore the individual's own interest or deny personal interest; (b) *Teleological vulnerability* – the situation generated by the fact that the means are not adequate for reaching the established purpose, or that the established purpose is inadequate for the available resources; the individual's interpretation of the situation can generate a mental map that is adapted neither to the current or future situation, nor to the potential of the person or of the environment he/she lives in; (c) *Axiological vulnerability* – the situation in which the individual/group cannot carry out an action because the normative principle is not appropriate to their own beliefs, or the system of personal values is incompatible with that of the society system; the value system according to which the mental activated map is structured is different from the system of values that are recognised by the environment as being acceptable; individual definitions are constructed depending on the individual's own system of values, without being negotiated socially or without taking into account the values of the environment in which the individual acts; (d) *Traditional vulnerability* – the case where the individual/group acts in virtue of their habit, or in which the state of social passivity is perpetuated due to the influence of the environment; habit is a stereotype, a static mental map, considered by the individual as valid, true, verified through experience and activated each time it is needed; vulnerability is enhanced precisely due to the lack of flexibility and dynamicity of personal interpretations; (e) *Cognitive vulnerability* – the situation of the individual/group is generated either by the inexistence of an effective theory or by the fact that the individual does not believe in an already verified theory; all our knowledge constructs the interpretations we give to the situations we are in; moreover, these interpretations are dependent on, and generate knowledge; this type of vulnerability is detected in the situations where individual interpretations, as an effect of knowledge, are not processed from the perspective of the new theories accepted by the collectivity.

Appreciative Inquiry – intervention for transformative changes

1.1 Appreciative Inquiry in Group Intervention

Researching the problems in an organisation results in their preservation, deepening and amplification; therefore, although in each organisation there are things that do not work well, in order to diminish their influence on development, the researcher must start from what works well in an organisation, from its successes, identified and interpreted as such by its own members. The appreciative inquiry does not deny the existence of problems in an organisation or a community; however, in order to diminish them, the positive aspects are identified, cultivated and promoted. Cooperrider and Srivatsva [7] built the appreciative approach based on Kenneth Gergen's constructionism [1], which sees reality as a social construction and as a constant reconstruction in the interactions between individuals. The description given by the authors shows [8] that, in order to broaden the domain of knowledge, we must find *'the best of what is'* in the organisation's experience and, based on these successes, to create *a collective vision with "what could be" and with "what we wish there was"*. *"What is"* does not mean only the present in the sense of a reality manifesting itself, but also current interpretations given by agents to past events. *'What is'* represents a social construction at the time of analysis, but it can be a result of interpreting past events [9]. From this perspective, the present is something people think at this moment about the organisation [10].

Cooperrider and Whitney [11] consider that the appreciative enquiry is based on five principles, which form the foundation for viewing social intervention at the level of interpretations of reality. These principles help us establish the theoretic foundations for the way the appreciative inquiry is organised, bearing in mind the social constructionism vision: (a) The constructionist principle; (b) The principle of simultaneity; (c) The poetic principle; (d) The principle of anticipation; (e) The positive principle.

1.2 How Appreciative Approach Develop the Resilience

In order to use the Appreciative Inquiry technique, Cooperrider, Sorensen and Whitney [15] developed the 4-D model (the 4 D-s represent the initials of the stages of the appreciative inquiry: Discovery, Dream, Design, Destiny), which explains the stages of the inquiry. Applying Appreciative Inquiry in support groups means going through the four stages. The *first stage* of the appreciative inquiry is the stage where "what is best" in personal experiences is to identified and consists in finding positive "histories", personal experiences considered successful. One relatively frequent form of appreciative inquiry uses as an initial method of finding positive aspects – and of documenting them – a list of questions that generate positive interpretations, which is

handed to every member of the group. Thus, the individuals have the opportunity and the time to reflect on their experiences. An analysis of research in the field of resilience [16] highlights the importance of the role of the positive aspects of the individual in his own existence and the strengths in building resilience in developing and strengthening the personal skills. In the support groups, for example, built on the basis of similarity of participants' particular situations, develop resilience occurs given that each of the participants are stimulated to identify positive aspects of past experiences and successful strategies that they used in those contexts. *The second stage* is the stage where people describe their desires and their dreams related to their life, work, motivations, relationships, the community they live in etc. Desires and dreams expressed by members of the support group participants is an important motivation to change; on the one hand, it is desirable models operating, on the other hand, it means the use of positive language. The participants are directed to use affirmative expressions, especially when talking about their desires. *The third stage* aims to build *new life architecture*, oriented towards "what could be", designing new life structures, processes and relations capable of bringing the members closer to the *imagined vision* of the previous stage. In this stage, members are supported to build provocative phrases that relate to the desired situation. According to the poetic principle, this stage represents a process of *reinventing the life*, based on *imagination*. *The fourth stage* is the stage of implementing the plans established in the previous stage and supposes *establishing roles and responsibilities, developing strategies,* building new interaction networks, using resources in order to obtain results.

Conclusion

Having as a foundation social constructionism, the Appreciative Inquiry is forms of intervention in the support groups that can produce a rapid change in the way and member define the personal life. Thus, the theory of social constructionism seems to be operational in the personal life, as it focuses on the *relations* through which social actors construct realities. The approach of social constructionism starts from the assumption that the language people use in order to understand the world is a social artefact, the historical product of exchanges between people. Appreciative inquiry used in the support groups can produce favorable contexts for increasing resilience individuals. Using positive language and affirmative rhetoric can produce positive results in the development of attitudes that can lead to change. Transforming situation where there are vulnerable people (poor, addicted to alcohol, victims of domestic violence or other abuse, etc.) is primarily a transformation of language and how people relate to themselves and to others.

Formes de recit et de resilience

Lani-Bayle M.

Université de Nantes, Professeur en Sciences de l'éducation, CREN (FRANCE)
martine.lani-bayle@dartybox.com

Abstract

The narrative of life is mediation between self and the world, for each of us invents the time and allows a form of representation of our life journey, maintaining on surface some traces that populate the memory. In doing so, it sorts, accentuates, leave aside, forgets, brings together, orders, distorts ... confusing sometimes the antecedents and causation.

Now what it updates also depends on the weather when it is produced. Therefore the narrative will ruminate or will resign; it could inhibits, skates or exacerbates the disorders and the sufferings of life. It may equally express or serve, and even bring out a perspective of" clogging" or "reconciliation" (Chaput), looking a reframing of channels that can be described as resilience. Resending the humans to the world.

Indeed, this "power" to narrate becomes more complex if we consider that not everything can be narrate; but also that the river of the story has two sides: narrative and non-narrative ("no" in the sense of Bachelard). It is thus time narrative diggers who develop the narration, as it is non-narrative marchers who rather condense it.

Potential resilience includes perhaps two sides: thus reciprocally and the vegetal model, there would be the possibility of resilience cryptophytes, as resilience éphémérophyte [10]. Which all, act with and despite adversity of extreme situations, specific such as chronic.

I propose to present some illustrations of these crossed narrative and resilience forms.

Keywords: nomadic / sedentary; recounting / antiracontage; cryptophyte resilience / resiliency éphémérophyte.

Avant-propos

Si la mise en récit de sa vie est souvent parée de toutes les vertus, si le récit peut être travaillé avec des attentes thérapeutiques ou cathartiques, peut-il être considéré *en soi* comme facteur de résilience, ou permet-il d'en révéler, après coup, l'éventualité ? Est-il vecteur d'émancipation ou enfermement de sa vie dans des mots, impasse ?

Des liens entre récit et résilience

D'abord est née l'oralité, bien plus tard l'écriture qui en a fixé les traces anciennes sur des parois. Par là, l'écriture a figuré le passé et la profondeur du temps.

1.1 Homo narrans, homo scribens

Notre époque n'a rien inventé côté narrativité : le récit de soi constitue une pratique séculaire (Victorri). Mais celle-ci s'est trouvée investie depuis le début du XX^{e} siècle d'attentes thérapeutiques, ainsi que de perspectives de recherche en sociologie (École de Chicago) ; plus récemment de perspectives de formation en sciences de l'éducation.

Dans ce dernier cadre, la mise en récit d'une expérience de vie s'effectue *via* une démarche interactive dialogique qui se démarque des démarches à objectif ouvertement thérapeutique. Sa mise en œuvre permet l'élaboration de ce que Ricœur a nommé l'« identité narrative » (1983), associant cette capacité humaine reliant temps et personnes à la constitution de chacun en particulier : le récit que je fais me construit en me rendant *auteur* de ma vie, pas simplement *acteur* agi par elle. Qu'elle s'exprime par oral et/ou par écrit, la narration occupe donc une place majeure et centrale, dans le développement du genre humain, au service tant de la fonction affective et relationnelle que cognitive et scientifique.

Cette démarche permet aux sujets de « prendre ensemble » les événements et rencontres ayant jalonné leur parcours, en les intégrant dans un contexte socio-historique qui leur permet de démêler leur part propre de celle émanant du collectif.

Le récit ainsi produit, s'il ne modifie pas ce qui s'est passé, modifie la façon de se le représenter et de le penser. D'où un besoin, parfois, de dire. Jusqu'à mêler, voire confondre, divers univers ou temporalités.

Alors, et afin de maintenir un tissu identitaire au-delà des bifurcations et ruptures de l'existence, certains vont éprouver le besoin d'aller vers le passé pour se raconter.

1.2 Une sensibilité à l'extrême

Mais l'existence tisse des situations ordinaires voire heureuses à des situations extrêmes qui parfois, vont rendre le récit impossible à conquérir en transférant les dangers de la vie vers les savoirs.

C'est une première expérience/recherche auprès d'enfants de l'Aide sociale à l'enfance qui m'a permis de mettre la lumière sur ces impasses et d'envisager des liens entre cette (in)capacité de mise en récit et ce qui ne s'appelait pas encore la résilience [4][5]. (Enfants retirés à leur milieu familial de naissance estimé dangereux ou inapte à s'en occuper, et placés en famille d'accueil ou institution.)

J'ai en effet remarqué que les enfants, alors placés en famille d'accueil, et qui s'en sortaient à peu près, étaient ceux ayant eu en mains les éléments nécessaires pour faire de leur vie un récit et ce, au-delà de la gravité de leur vécu.

Le travail sur son espace de vie se développerait ainsi autour de la capacité de mise récit, dans un environnement rendant le récit *possible*, récit au plus près de soi et en interaction, de proche en proche récit des autres et du monde. *A contrario* un ressenti de vide, d'inadéquation voire d'interdit de savoir, mettant à mal voire empêchant la mise en œuvre de cette capacité narrative, entraverait la réactivité aux conditions extrêmes de vie.

Car il est des limites à la fonction des récits

Mais le récit une fois dit ne peut pas tout et ne sécrète pas toujours ses antidotes…Parfois, il peut même renforcer les difficultés.

1.1 Et pourtant…

Car force est de constater que la mise en récit ne résout pas, par un retour obligé, les difficultés vitales, ni leur supportabilité.

Ainsi, j'ai pu montrer [7][8] que :

- Dire/raconter ne suffit pas pour « résilier » *a posteriori* de vécus extrêmes.
- Dire/raconter peut, *a contrario*, provoquer-accroître la souffrance des vécus extrêmes. Et ce que le récit met en évidence peut aussi susciter l'effroi et un rejet de l'idée-même de résilience.
- Dire/raconter peut aussi fixer la souffrance traumatique qui, « pas dite », garde la capacité de s'envoler – ce qui ne signifie pas, pour autant, qu'elle serait déniée et/ou oubliée.
- Dire/raconter peut également aveugler, détourner.
- Ne pas dire/ne pas raconter n'empêche pas la résilience, qui peut passer par d'autres voies ou voix. Dont le silence.
- Ne pas dire/ne pas raconter n'empêche pas d'être entendu, voire *peut* permettre d'entendre.

Ainsi, « taire » *peut être* aussi une ressource. Car, comme le dire, le silence est à double tranchant. Il est comme la graine qui se dessèche en apparence mais reste vivace, prête à rejaillir quand les conditions redeviendront propices.

1.2 Malgré tout…

Il n'a été ni attendu ni aimé.

Il est né avec déjà des traces de mauvais traitements, la gueule cassée. Le foie vaincu par la cirrhose de la mère. Toute son enfance, il est resté nourri de coups et d'alcool.

Malgré tout il a survécu. Malgré tout il a écrit.

On ne peut donc dire que Franck Ribault (2001) ait été élevé, dès le départ ni à aucun moment, dans un milieu sécure. Malgré tout il a utilisé l'écriture et a mis en récit son enfance désastreuse, il a construit une vie avec famille et métier, il a eu du succès avec son écriture et son livre, son histoire a été mise en scène devant lui et a fait un succès théâtral… par une sorte d'effet-Phénix [9] ou de *réserve* [9].(Sur le modèle du dromadaire qui porte ses réserves d'eau sur son dos, ce qui lui permet de résister aux conditions désertiques – ce que nous avons appelé auto ou *anti*résilience, à savoir une résilience basée sur des modalités différentes des modalités

apparaissant généralement.) Il paraît ainsi possible d'imaginer une (*anti*)résilience à l'œuvre sans tuteur, voire même *parce que* sans tuteur. ("*Anti*" au sens de différent, autre face du processus.)

Mais on peut encore chuter, une fois relevé. Par exemple, la socialisation publique du récit révélateur d'une forme de résilience peut susciter, par la suite, une *désilience* [13]. N'être vu qu'à travers la façon dont on a mis en mot son rebond peut, à la longue, ne plus laisser la possibilité de se voir autrement que par ce filtre devenu trop pesant. De quoi pouvoir retomber gravement.

Rien n'est acquis une fois pour toutes, d'autant que le terrain est fragilisé. La résilience n'est pas un état stable, elle se reconquiert jour après jour.

Cheminements croisés de vie et d'écriture

Car la vie est chemin, mouvement. Et tout ne peut ni ne veut se dire : les mots, le vécu se croisent sans que leurs liens soient obligés ni prévisibles : entre eux les correspondances restent hasardeuses.

1.1 Écriture sédentaire, ou nomade ? Temporelle, ou météorologique ?

Si donc les récits, petits ou grands, universels ou singuliers, sont utiles voire parfois nécessaires, la capacité narrative n'est pas une panacée. Beaucoup de récits sont générateurs de souffrance, certaines personnes sont mal à l'aise avec, le refusent ou n'en n'ont pas le goût. Ne pas vouloir faire le récit de sa vie ne signifie pas, pour autant, avoir des problèmes dans sa vie.

Et il ne convient pas à tous. Car il est des sédentaires-fouilleurs, mais aussi des nomades-marcheurs ; il y a *par nature* des (ra)conteurs mais aussi des taiseux (2006).

Récemment, mes travaux avec Éric Milet (2012), photographe-voyageur, m'ont induite à reconsidérer la question de l'écriture ou du récit et d'en distinguer deux formes, en apparence opposées mais que nous avons posées comme complémentaires : le récit proprement dit et ce que nous avons qualifié d'*antiracontage*[3]. J'ai alors proposé des modélisations de recours à la mise en forme (*anti*)narrative de sa vie en distinguant 4 dominances.

Fig. 1 : ***Déplacements et rencontres espace-temps dans le rapport au (non-)récit***

Espace / **Temporalité**	**NOMADE** Fluide (eau) *"Réserves" portables sur le dos*	**SEDENTAIRE** Solide (terre, racines) *"Réserves" dans le sol*
NARRATION	**1) Voyageur** Griot *Transporteur d'histoires*	**2) Cueilleur** Conteur *Biographe*
***ANTI*-RACONTAGE**	**3) Chasseur** Capteur-traducteur de traces *Poèmes, haïkus, photos*	**4) Semeur** Taiseux *"Réserviste"*

- Le voyageur et le cueilleur sont des creuseurs de temps : l'un se déplace dans l'espace ; le deuxième demeure auprès de ses "racines" dont il ne veut/peut s'éloigner.
- Le chasseur et le semeur survivent de l'air du temps, leur ressource n'est pas au fond de la terre mais en surface, dans l'eau qui coule sur le sol ou tombe du ciel. Le chasseur va et vient selon les opportunités du moment. Le semeur bouge d'une saison l'autre. Leur parole est en "réserve", quand elle survient elle est brève, présente.

Ces formes sont variables selon les périodes de la vie et les circonstances mais nous avons, chacun d'entre nous, des tendances portant plus spontanément vers tel ou tel quartier.

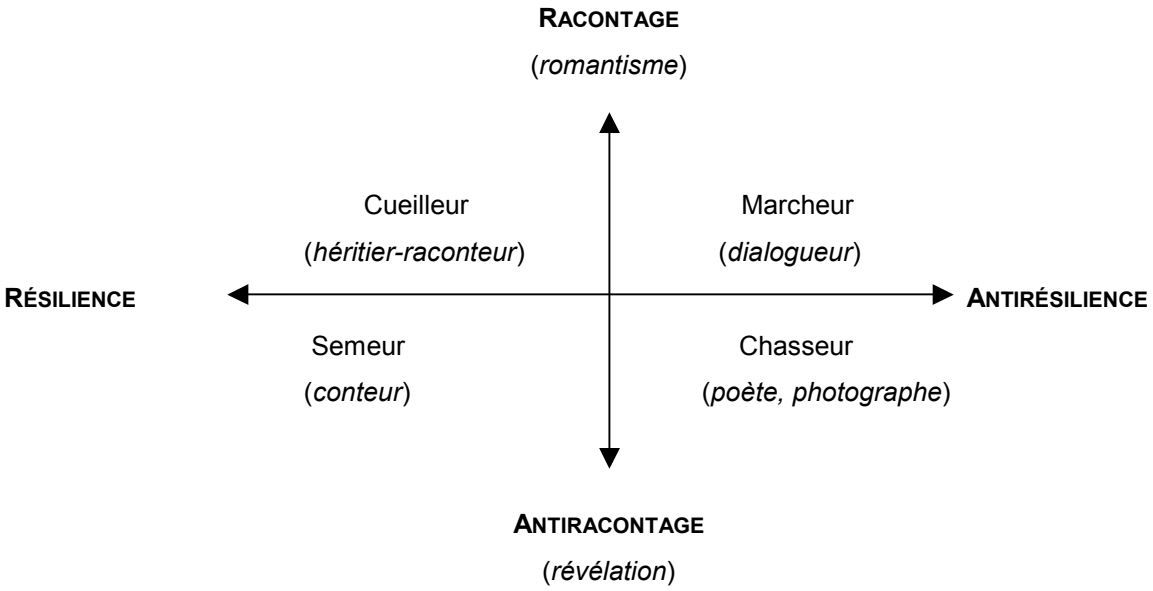
1.2 Vers deux formes de résilience, sur le modèle végétal

Face à cette fonction paradoxale voire contradictoire de l'écriture, nous pouvons esquisser deux façons d'user des ressources nécessaires à notre survie, en articulation avec les deux modalités de résilience des plantes dans le désert :

- La plus « courante » s'apparente à la résilience dite *cryptophyte* des plantes qui, à l'aide de longues racines, vont chercher leur subsistance au profond des nappes phréatiques.
- L'autre forme, dite *éphémérophyte*, sait capter l'eau du haut et celle du ruissellement ou de la fugace rosée matinale, au fil des déplacements des graines. Elle suit un rapport au temps qu'il fait.

Croiser ces modalités de résilience avec celles du récit, ou du non-récit *alias anti*racontage, permet de délimiter 4 points de rencontre modélisant leurs rapports au récit et à l'écriture :

Fig. 2 : ***Au carrefour du récit et de la résilience***



Pour survivre en cette période de changements permanents et mouvements nécessaires, peut-être faut-il connaître les ruses du couple nomade-dromadaire, traçant dans le désert leur chemin sinueux accompagnés de leurs réserves transportables, en quête de conditions favorables.

Conclusion

Le récit peut éclairer, révéler voire activer un processus de résilience, mais sans obligation et dans l'ombre, sans éblouir, afin de déployer les représentations possibles de son existence vers des horizons qui feront signe : tel est un des enjeux majeurs que la démarche d'écriture, biographique *comme de l'instant*, met à notre portée. Ce qui nous conduit vers d'autres formes d'expression possibles, qui pourront servir autrement des objectifs analogues, résilients au besoin.

Car n'est-il pas mille et une autres façons de faire de sa vie une histoire en passant par d'autres chemins, en apparence diamétralement opposés ? Un récit sans récit, jaillissement de l'instant, sans temporalisation, voire sans mots, une expression du silence, de l'image, du mouvement, une poésie…

Épilogue

« Si l'homme fait partie de ce grand tout à la fois un et multiple, pour quelles raisons n'y aurait-il de pas de Printemps Humain, de Cerisiers en Fleurs ?

Existe-t-il un déterminisme géographique de la résilience, une influence solaire, des petites météorologies du corps meurtri ?

Peut-être qu'il existe toujours un après qui recommence, c'est tout, un printemps pour sortir de l'hiver, le retour des pluies après la période sèche, un état qui succède à l'état mais dont ne nous prenons pas cas, tout absorbés que nous sommes par nos convictions, par notre désir d'infléchir le désir au lieu de se laisser guider par lui.

Peut-être que la résilience est juste un phénomène non-agi et que ce que l'on considère comme étant de la résilience n'est que la prise de conscience de ce phénomène, tout simplement. Dans ce cas le retour sur soi est nécessaire, comme un repliement, un enroulement, une vis sans fin, un mouvement perpétuel... » Éric Milet (*courriel*, juin 2012).

Study on the remigration of Romanian children: 2008-2012. Quantitative and qualitative aspects

Cătălin L., Gulei A.-S., Foca L.

Alternative Sociale Association (Romania)
cluca@alternativesociale.ro, agulei@alternativesociale.ro, lilianafoca@alternativesociale.ro

Abstract:

Over 21.000 children returned to Romania during January 2008-May 2012, as a result of a failure in the migration plans of their parents. Using the Strengths and Difficulties Questionnaire, a sociological questionnaire as well as focus groups, the research highlights reintegration difficulties for approximately 30% of the children investigated.(SDQ was developed by R. Goodman in 1997 and normed on the Romanian population in 2010.) They show a significant/major risk of developing a specific disorder from the prosocial spectrum: emotional symptoms, conduct problems, hyperactivity/ inattention and peer relationship problems. These children require additional attention from their families but also psycho-social assistance and specialized support for their school adjustment.

Keywords: *remigrant children, readjustment, emotional symptoms, conduct, hyperactivity/ inattention, peer relations.*

The remigration of the romanian children – context

The present research investigates a subject that is rarely approached in the professional literature. With the exception of Félix Neto from the University in Porto, nobody studied and published about the phenomenon of child remigration and its consequences [15]. (For the purpose of this study the term remigrant child refers to a child who returned to the home country after having moved to/with his/her migrant parents abroad to live there (as opposed to going abroad for a vacation).

Contemporary migration patterns are however largely driven by globalization and economic push-pull factors, such as the labour needs of income-rich countries and the wage levels of income-poor countries. (...) This multi-faceted phenomenon which on the one hand provides opportunity for financial betterment, cultural exchange, language and skill development, and yet on the other, is too often a process of loss, displacement, alienation and family separation [16].

Italy and Spain are the main countries from the EU where Romanian citizens have migrated for employment [31]. As result of the way they were affected by the separation from children left in Romania, many of the migrating parents have chosen as a viable solution to take the children with them in the country where they worked, thus minimizing the problems caused by separation.

As a result of the failure of migration plans of families many children returned to the country of origin (Romania). The study finds that some of the children who return experience re-adjustment difficulties that might compromise their adjustment and subsequent development if the specialized support is lacking.

From January 2008 to May 2012, 21.325 children returning from Italy and Spain applied for the recognition of their studies and re-enrolment in the Romanian educational system.(Response address No. 49367/27.07.2011 from the Ministry of Education, Research, Youth and Sports, *Department for the Equation and Recognition of Studies* completed with Response address No. 802_CNRED/18.05.2012/N.V)

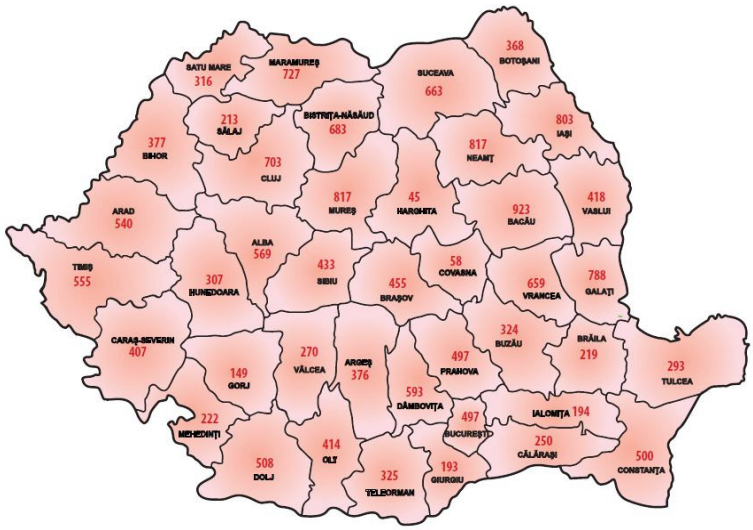

Fig.1 The distribution per county of remigrant children returning from Italy and Spain who applied for the equivalence of their studies during January 2008 - May 2012

The study examines four aspects of well-being: mental health, psychosocial needs, education and social integration.

Description of the sample

The study is largely based on the perception of children re-enrolled in the Romanian educational system with regards to remigration. The study was conducted during September 2011 – May 2012 in Romania.

1.1 Investigated population

1.1.1 a. Remigrant students

Quantitative data about migration was collected by applying a questionnaire to a total number of 245 children from 6 counties of Romania: Vrancea and Vaslui (Moldova), Buzău (Muntenia), Dolj (Oltenia), Arad (Crişana-Maramureş) and Cluj (Ardeal).

The questionnaires were applied by professionals from each of the counties, respecting the scientific principles for certifying the accuracy of data and of the ethical procedures.

In order to collect the qualitative data a focus group was organized in each of the following counties: Buzău, Vaslui and Vrancea with the participation of a total number of 23 children (boys and girls aged 12 – 17, living both in urban and rural areas).

1.1.2 b. Parents

Parents' perception on migrating children returning to Romania was investigated in 3 focus groups (one in each of the counties Buzău, Vaslui and Vrancea) with the participation of 16 parents/care givers.

1.1.3 c. Stakeholders: school counsellors and other child protection professionals

Three focus groups (in Buzău, Vaslui and Iasi) with the participation of 21 school counsellors and other child protection professionals were organized for the purpose of analysing issues regarding the readjustment of children after their return to Romania.

The instruments used in the research

a. The sociological questionnaire was drafted according to the principle of logical and psychological succession of questions. It was structured on four sections: the structure of the family and the person/persons looking after the child, information regarding the emigration, information on remigration and readjustment in Romania and factual data.

b. The Strengths and Difficulties Questionnaire (SDQ) is a simple but efficient instrument in screening children and teenagers' behaviour in order to identify four types of difficulties and the way they affect their daily life (emotional symptoms, conduct problems, hyperactivity/inattention and peer relationship problems). This questionnaire was normalized for the Romanian population in 2010.

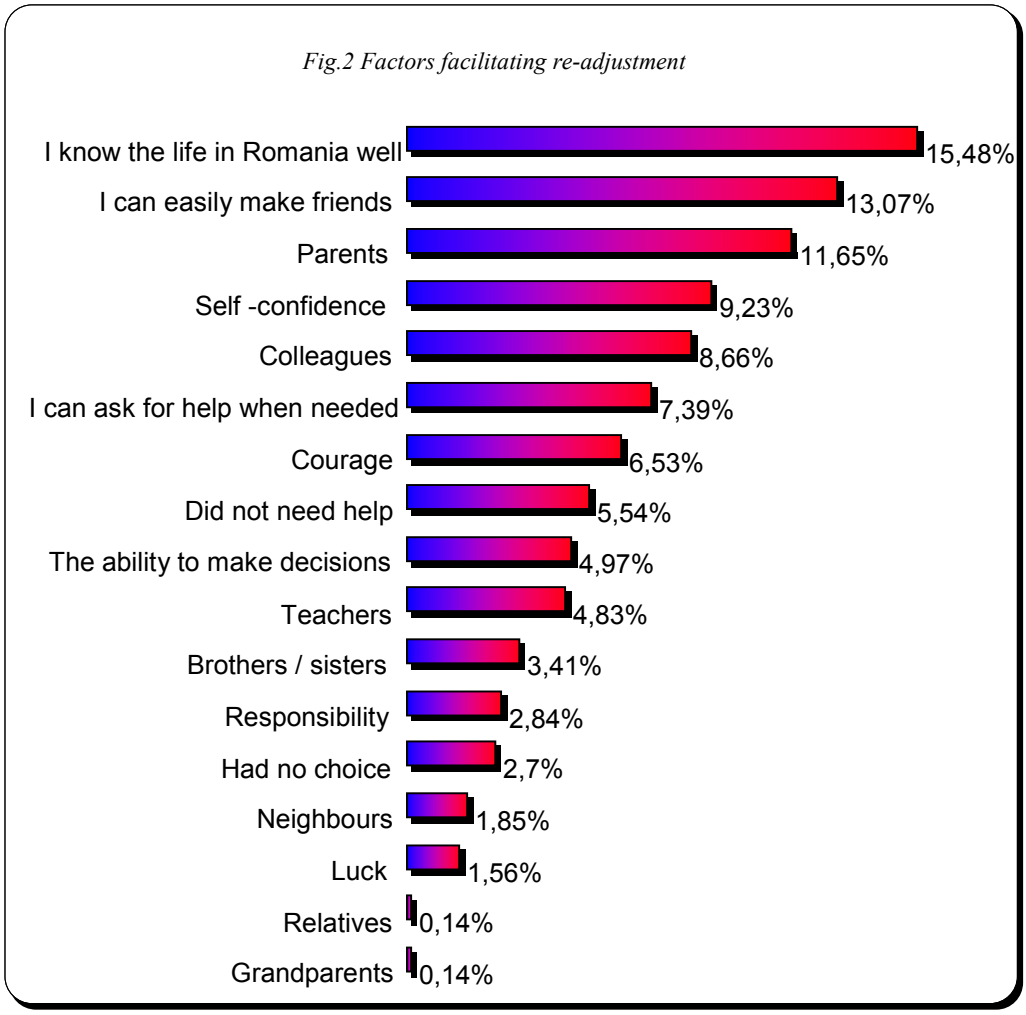
The research design and also the implementation activities that involved children have been carefully planned and organized so as to respect children's rights. The ethical aspects of this research project were supervised by Professor Doina Balahur, PhD.

Quantitative findings

1.1 Factors facilitating re-adjustment of remigrant children

The following chart (Fig. 2) shows the percentage of answers given by the remigrant children regarding the factors which, in their opinion, have facilitated their readjustment to the life in Romania:

Fig.2 Factors facilitating re-adjustment



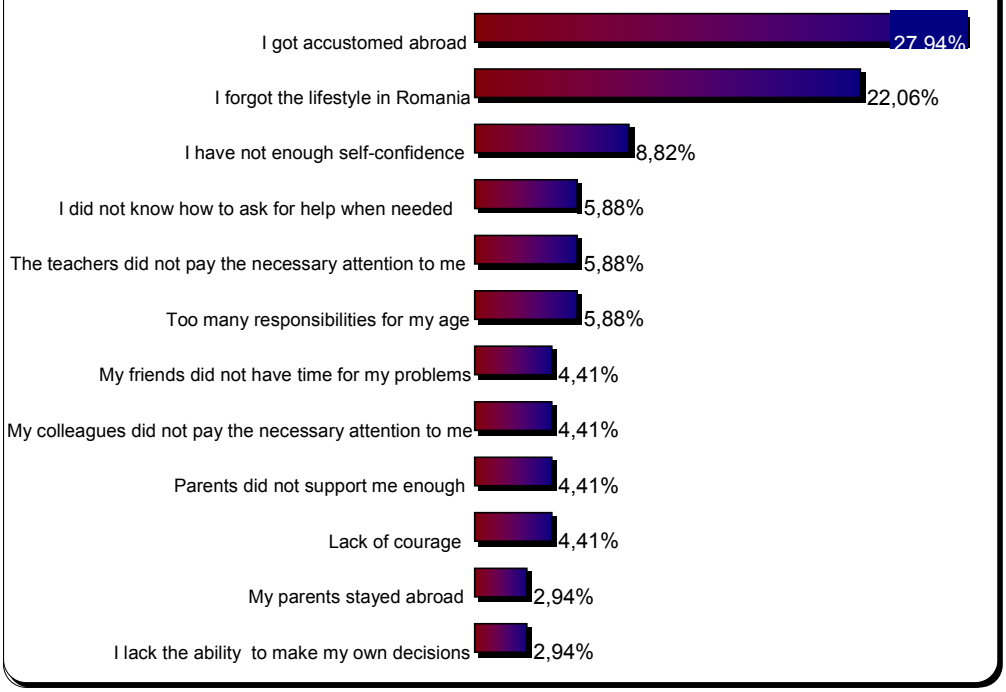
When reading the chart (Fig.2) we should take into account that the question regarding the factors facilitating the re-adjustment implied the possibility that a respondent may give more answers and therefore the presented percentages refer to the 704 valid answers from the 218 respondents considering they have readapted to the life in Romania.

From the perspective of the resilience factors (Ionescu, 2009) the child's perception is that his/her personal success with regards to readjustment is due mainly to individual factors (61.07%), followed by family (15.34%) and community (15.34%) factors.

1.2 Factors inhibiting the re-adjustment of remigrant children

The following chart (Fig.3) shows the percentage of answers provided by the remigrating children with regard to the factors which, in their opinion, inhibited their re-adjustment to the life in Romania.

Fig.3 Factors inhibiting readjustment:

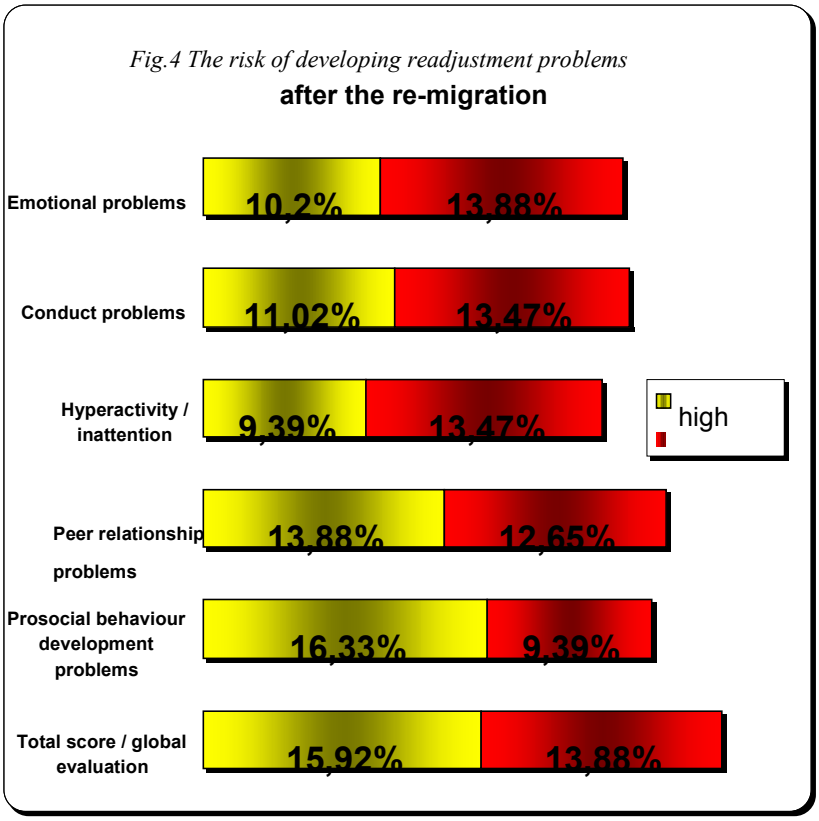


When reading the chart we have to take into account that the question related to the factors which inhibited the readjustment allowed a respondent to give more answers, but it was addresses only to those children who consider they have not readapted, therefore the percentage shown in the graphic representation refer to the 68 valid answers obtained from the 25 respondents considering they have not readapted to the life in Romania.

From the perspective of the resilience factors (Ionescu, 2009) the child's perception is that the factors which inhibited his/her re-adjustment are mainly to individual (77.95%), followed by community (14.7%) and family (7.35%) factors.

1.3 The risk of developing readjustment problems after the remigration

The following chart (Fig.4) provides data regarding the risk to develop different types of problems for children returning to Romania after a period of time spent abroad:

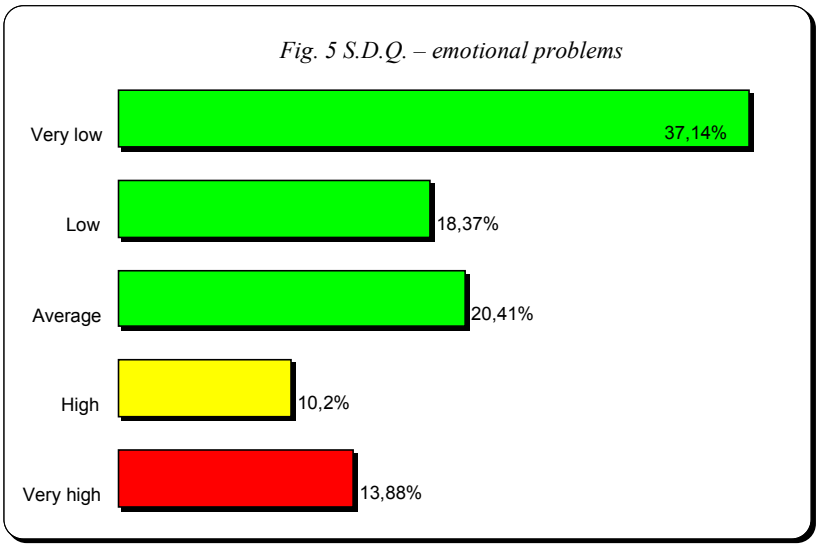


According to the statistical data shown in the chart, around 10% and 15% of children returning to Romania show a significant (high) risk of developing a specific disorder (emotional, conduct, attention, peer relationship), these children requiring a special attention from the family, the social environment and also specialized support.

At the same time, other 10%-15% of the children returning to Romania show a major (very high) risk of developing a specific disorder such as the above-described, their subsequent development as well as adjustment to social and educational requirements being compromised to a great extent if not supported by specialized intervention in order to maintain their psychosocial development within the limits of normality.

1.4 Emotional Problems

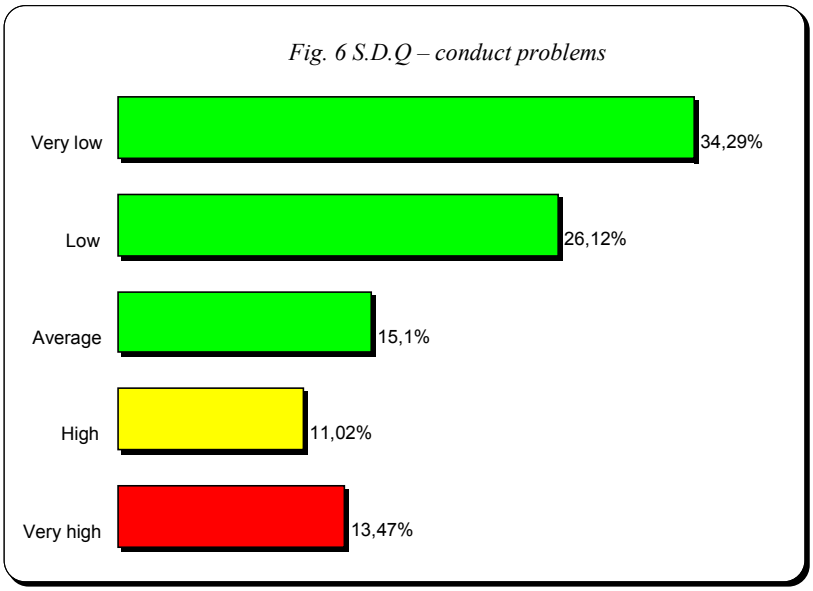
The following chart (Fig.5) shows the distribution of standard scores obtained by the children for the scale of evaluation of emotional difficulties in the S.D.Q.:



With respect to the emotional problems, the risk is minimal in approximately 76% of the cases, while approximately 10% of the remigrating children show a significant (high) risk of developing emotional disorders. For approximately 14% the risk of developing such disorders is major (very high), requiring specialized intervention.

1.5 Behavioural difficulties

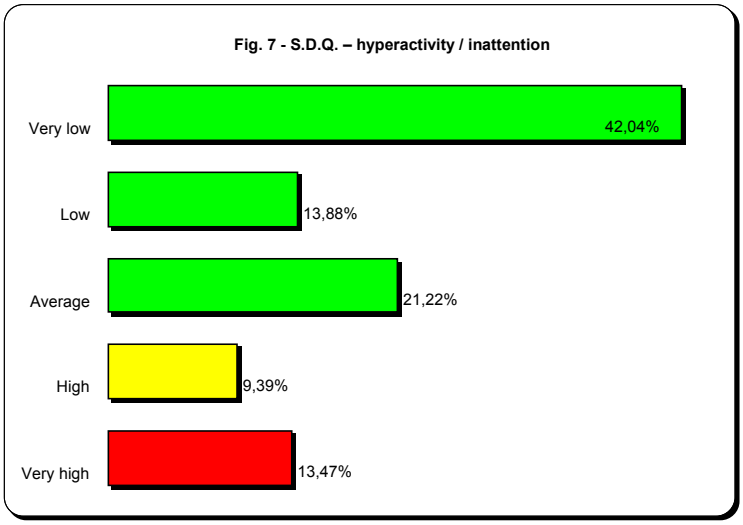
The following chart (Fig. 6) shows the distribution of standard scores obtained by the children for the scale of evaluation of conduct problems in the S.D.Q.:



With regards to conduct disorders, they show a minimum risk of occurrence for approximately 76% of the children returning to Romania, a significant risk for approximately 11%, but for approximately 14% of the remigrating children the risk of developing conduct disorders is major, hence the necessity of specialized intervention.

1.6 Hyperactivity/inattention

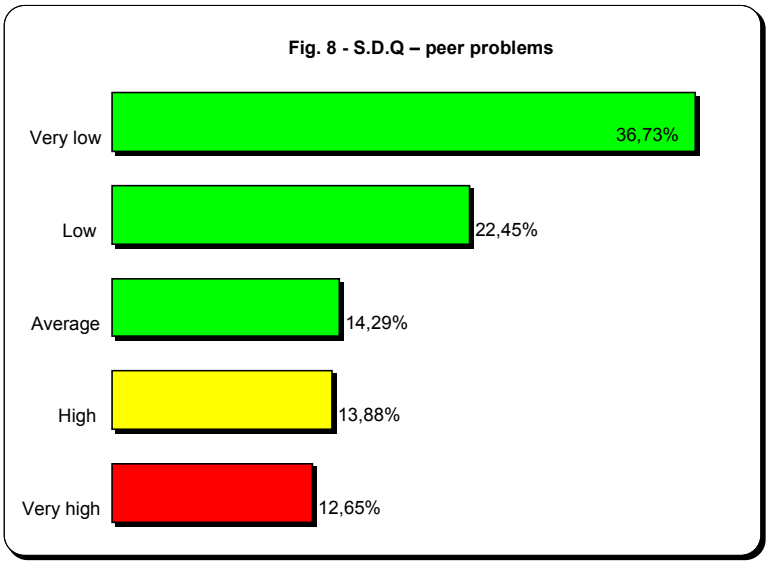
The following chart (Fig. 7) shows the distribution of standard scores obtained by children for the scale of evaluation of inattention/hyperactivity in the S.D.Q.:



As described in the chart (Fig. 7), the hyperactivity/inattention disorders do not affect approximately 76% of the children returning to Romania, but for almost 10% of them there is a significant risk of developing such disorders and in approximately 14% of the cases it is necessary to apply specialized intervention, the risk of developing such disorders later on being major.

1.7 Peer relationship difficulties

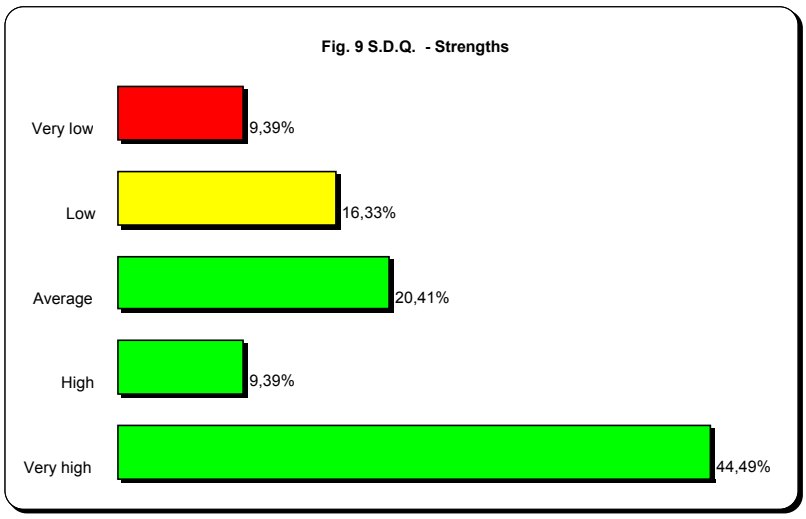
The following chart (Fig. 8) shows the distribution of standard scores obtained by children for the scale of evaluation of peer relationship problems in the S.D.Q.:



For 73% of the children returning to Romania after an experience abroad the risk of developing peer relationship problems is low, nevertheless, in almost 14% cases of children returning alone there is a significant risk, showing the necessity of additional attention and support while for nearly 13% of these children the risk of developing peer relationship problems is significant, showing the necessity of specialized intervention.

1.8 Strengths (prosocial behaviour)

The following chart (Fig. 9) shows the distribution of standard scores obtained by the children for the scale of evaluation of strengths in the S.D.Q. It is necessary to say that when reading the prosocial behaviour scale, the symptomatic scores are the low and very low scores corresponding to difficulties in developing prosocial attitudes and behaviours.



According to the statistical data shown in the chart (Fig.9), the development of prosocial behaviour is plausible for approximately 74% of the remigrating children. Approximately 10% of the children returning to Romania present major risks of having problems in identifying their own strengths and developing prosocial behaviours, requiring specialized intervention.

Qualitative findings

The focus groups with children and parents/caregivers allowed the researchers to conclude that the remigrant child has both positive and negative traits. Often times the child knows the language of the foreign country he/she lived in; is familiar with another lifestyle and is nostalgic about it; is appreciated while abroad for his/her remarkable school performances and general knowledge. At the same time the child may: have medium or high levels of anxiety; be fearful; be avoidant of relationships with adults as well as with peers; have no constant preoccupation for social relations and for involvement with groups of peers; have low self-confidence; have low aspirations, including low school expectancies; repeat at least one grade which he/she already graduated from while abroad, sometimes without understanding why.

1.1 Children

The general attitude of children towards their re-adjustment in Romania is generally a reflection of parental attitudes: they internalize the reasons stated by their parents with regards to emigration and remigration, they emphasise school performance as an indicator of re-adjustment (when asked about the difficulties faced when returning to Romania, the first elements mentioned are all related to education), they have a reserved attitude in recognizing the existence of other types of reintegration difficulties and are reluctant to discuss their feelings and in particular to ask for specialist support.

The low level of aspirations consecutive to remigration can be correlated with a decreased self-esteem, which can be explained by referencing to emigration and remigration as successive failures. Also, the student has to repeat classes which he already promoted, which is felt subjectively as a personal failure, especially if the child and parents are not told clearly the objective reasons which led to the enrolment of the child in a class behind the "normal" level according to age. Furthermore, the social and cultural reintegration problems may influence significantly the child's self-esteem.

1.2 Parents

The general attitude of parents towards the adjustment of children in Romania is centred on the school reinsertion and on the support given to the children in order to face effectively the school tasks.

Parents were considerably less interested in discussing the children's rebuilding of social relationships or aspects of psychological nature associated to their remigration.

The direct consequence of this parental attitude is a high degree of interest for supporting the child for school readjustment (including the child in additional after-school educational activities, helping the child with homework etc.) but not for his/her social and cultural adjustment.

They do not take into consideration the help of a professional (psychologist, school counsellor etc.) for the facilitation of the social reinsertion of the child and minimise the effects of the changes associated with remigration (leaving friends and routines behind, socialization issues, sometimes even the language barrier).

On the other hand, we found a high level of availability of parental support for children, parents being generally willing to make efforts to support them in these difficult times, but these efforts are limited by restrictive views on the needs of children. The lack of parental involvement in the social reintegration and cultural readjustment of the child does not reflect a lack of interest on the part of the parents but merely that they do not identify a specific need of the child in this regard.

Conclusions of the research

The children's support structure in their efforts to readjust in Romania reflects a dual relation to external and internal factors, without a clear predominance of one category of factors but demonstrating the necessary involvement of other persons (parents, colleagues, teachers, etc.).

The analysis of the SDQ data highlighted a higher frequency of peer relationship problems (due to the change of social norms, group of friends and of the rules of interaction with peers) and a lower risk of hyperactivity/inattention.

Around 10% and 15% of children returning to Romania show a significant risk of developing a specific disorder (emotional, conduct, attention, peer relationship), demanding a special attention from the family, the social environment and also specialized support. At the same time, another 10%-15% of the remigrant children show a major risk of developing such disorders, their subsequent development as well as adjustment to social and educational requirements being compromised to a great extent if not supported by specialized intervention in order to maintain their psychosocial development within the limits of normality.

With respect to the emotional problems, the risk is minimal in approximately 76% of the cases, while approximately 10% of the remigrating children show a significant (high) risk of developing emotional disorders. For approximately 14% the risk of developing such disorders is major**,** requiring specialized intervention.

With regards to conduct disorders, they show a minimum risk of occurrence for approximately 76% of the children returning to Romania, a significant risk for approximately 11%, but for approximately 14% of the remigrating children the risk of developing conduct disorders is major, hence the necessity of specialized intervention.

As described in the chart, the hyperactivity/inattention disorders do not affect approximately 76% of the children returning to Romania, but for almost 10% of them there is a significant risk of developing such disorders and in approximately 14% of the cases it is necessary to apply specialized intervention, the risk of developing such disorders later on being major.

For 73% of the children returning to Romania after an experience abroad the risk of developing peer relationship problems is low, nevertheless, in almost 14% cases of children returning alone there is a significant risk, showing the necessity of additional attention and support while for nearly 13% of these children the risk of developing peer relationship problems is significant, showing the necessity of specialized intervention.

According to the statistical data shown in the chart, the development of prosocial behaviour is plausible for approximately 74% of the remigrating children. Approximately 26% of the children returning to Romania present significant and major risks of having problems in identifying their own strengths and developing prosocial behaviours, requiring specialized intervention.

From the perspective of the resilience factors (Ionescu, 2009) the children's perception is that their personal success with regards to readjustment is due mainly to individual factors (61.07%), followed by family (15.34%) and community (15.34%) factors. The children's perception on the factors which inhibited their re-adjustment is that these are mainly individual (77.95%), followed by community (14.7%) and family (7.35%) factors.

The conclusions of the study presented in this article may help practitioners in developing models of intervention for the children affected by remigration. Also, it represents a starting point for future studies in the resilience of the children affected by remigration.

The role of family and school in self identity formation of teenagers

Lungu M.

Romania
e-mail: maria.lungu@yahoo.com

Abstract

Adolescence represents the conflict between ideal and actual values,from a moral, social, and educational vantage point leading to an outline, structure, organisation, and hierarchy of their values in relation to the socio-cultural value-system.
Identity means being the same from one moment to another, from one day to another. Teenagers are looking at this period to strengthen an identity from a personal, vocational, and spiritual perspective and even to identify themselves with a professional role. It is well-known that adolescents attempt to stand out by means of behaviour, attitudes, and especially by appearance, and style. They try to play various roles without engaging into any of them in a committed manner. This is the stage in which a frequent query is raised: "Whom am I?" What is more, teenagers display an unwished conflict by means of the internal conflict they undergo *per se*: "Should I have the initiative to do a certain thing?" On the one hand, they wish to engage in a particular action, but on the other hand, they are inhibited by their parents and teachers whose roles are to direct and limit their every single enterprise. To sum up, they would like to play an active part, but they are deterred by too much responsibility. The research we have carried out targets students with age ranges between 18 and 25, which is the stage of late adolescence.

Key words: adolescents, family, school, education, identity.

Introduction

We can find many references to the role of family and school in the self-identity formation of adolescents in specialised literature: [1],[2],[3],[4],[5],[6],[7],[8],[9],[10],[11],[12],[13], etc.

The socio-cultural and economic environment is of paramount importance since it has a direct influence on the manner in which family and school approach various education styles.

Alfred Adler, makes use of a metaphor in his book *The Understanding of Life*, in the chapter bearing the title "The Style of Life", to illustrate how two different types of trees can be recognised: "If we look at a pine tree growing in a valley we will notice that it grows differently from one on top of the mountain. It is the same kind of tree, a pine, but there are two distinct styles of life. Its style on top of the mountain is different from its style when growing in the valley. The style of life of a tree is the individuality of a tree expressing itself and moulding itself in an environment. We recognise a style when we see it against a background of an environment different from what we expect for then we realise that every tree has a life pattern and is not merely a mechanical reaction to the environment."[14]

This aforementioned conjecture can be adapted to what teenagers undergo in nowadays' society. The essence of a life pattern roots in the originating environment. An improper social environment, whether it is only a family environment with shortcomings, can lead to an unhealthy life-style. Children, teenagers born in underprivileged or financially-challenged families, deprived of adequate education, will build a life-style in accordance to the "prototype" designed for them in their childhood, in that very environment. There is, however, the opposite case in which children develop a "healthy" life-style due to a favourable climate. It may be claimed that all these major differences only lead to either a more appropriate social adaptation in relation to the current social demands, or to social maladjustment, a social and personal failure of the individual.

If this occurs in most cases, there are situations when a person, albeit growing in a problematic environment, may develop a "healthy" lifestyle which constitutes a happy scenario. Conversely, there are individuals who live and thrive in an appropriate social environment, but who, eventually, create an unhealthy or problematic lifestyle for themselves. In such cases, one or more triggering factors may arise, such as: genetic material inherited and acquired, ambition, aspirations, motivation, etc.. Adolescence is a springboard towards

adulthood, thus, teenagers assess their experience by asking two major questions related to their identity: *Who am I?* and *What will I become?*

Education achieved both through family life and school contributes extensively to adolescent identity formation. Family and school are intertwined and we cannot refer to one without including the other. In order to achieve the targeted results, there should be a close relation between them of constant communication, collaboration, support, and networking. A parent's "mission" would be to determine the child to become autonomous, independent, and able to fend for himself. Nevertheless, it is of utmost importance that parents have a certain degree of education, so that they, in turn, are endowed with the necessary skills to cultivate their children.

Methodology

The method that we have used in the research under scrutiny was that of the case study, namely the study of ten cases. The case studies were conducted from February to May 2013 targeting college students in the first and third year, respectively MA students of the West University of Timisoara.

The theoretical grid for the case studies was based on multiple sources: direct and indirect observation (as a teacher I had the opportunity to interact with students for at least one semester and indirectly, to obtain information about them from my colleagues and their colleagues), participant observation, various documents (through certain tests, quizzes or sheets - that were taken from specialised literature - namely C.S.E., behavioural expression, identity - confusion stage, my Diploma Paper, Strengths and Weaknesses, Self-knowledge, auction values, What is important to me?) and a semi-structured interview with topics mentioned *a fortiori*: adolescence, education, family, school, around which discussions were held. I would also like to mention that most interviews were conducted over a timespan of two hours. In the ten case studies we have performed the explanations were provided in narrative form.

The conjectures of the research were:

If adolescents (the students targeted) have a solid self-esteem, then they also have a well-defined identity.

If teenagers (students) really know who they are (what their skills, abilities, values, and principles of life are), what their self expectations are and those of the others, then they have a well-defined identity.

If parents/teachers are involved effectively in their relation to adolescents (grants for quality, communicate assertively, are engaged, optimistic, offering advice when they are required, etc.) then teenagers achieve success in school, in their professional life, and, moreover, they become responsible persons gaining independence both socially and psychologically.

Results

To further proceed with my analysis, a few selections were made from two case studies: I. N.C. is 19, she is a first year student in a scientific profile college. She is an only child and lives with her parents. Her mother is a housewife and her father a security guard. The N.C. couple wanted to have a perfect child, and, therefore, have inculcated a fear of failure, a fear of not being among the best. "I have little confidence in myself, and I often tend to underestimate myself. I have had a fear of failure and uncertainty since I was small, especially in elementary school. My parents have always reiterated that I should be the best and have managed to instil this idea in my head, thus, I have begun to tend towards perfection, not wanting to fail, and it is this fear that makes me insecure in my course of action (especially after I was told in the end, in an "encouraging" tone that I was not good enough by my parents). In highschool she was granted the third place award in the National Olympics, in a humanistic discipline section, and her parents, instead of congratulating her on the achievement, criticised her, pinpointing that she should have won the first prize like her friend!

"I firmly believe that I am an open-minded person, but sometimes major and drastic changes can negatively affect me. Instead I believe that people can trust me because I prefer helping others, urging them to hope for something better, to helping myself. I'm not stubborn, I have a definite sense of observation. I am ambitious and always wish to achieve more from myself. As for future plans, I trust the future, everything should be fine , but the fear of making a wrong decision is very strong. I am a rational human being, but most of the time, I am trying to find a balance between the mental and the emotional levels. Before doing something I think extensively about the consequences, and sometimes tend to analyse things to the tiniest detail which can be a disadvantage. I like to hope for the better, to dream, but I also fight for what I want. Besides all that, I like being carried away and not to oppose certain things pertaining to the future, different circumstance ."

N.C. confesses in the interview that she feels smothered by parental protection, that her freedoms are restricted and what affects her the most is the fact that her parents do not trust her. An eloquent example of their distrust is the fact that they falsely suspected her of consuming drugs and alcohol when, in effect, "it was quite the contrary", she was "a quiet teenager." Her first love was in the ninth grade and her first relationship was in the eleventh grade. Now she has a boyfriend, and it seems to be a stable relationship, although there are still

some inconsistencies. Love "influences me in everything I do". Freedom, love, responsibility, honesty and faith are of utmost importance to her (as inoculated by the family). N.C's family atmosphere is strained with many arguments, mainly because her mother is a "perfectionist " and expects everything in the house to be immaculate in terms of cleanliness. Most conspicuous is N.C's confession in the interview regarding the labels she was attributed by her parents and that she had begun to believe in them. Why did this happen? "Because they have known me ever since I was born, they are the persons who know me best. "In highschool she avoided going out on account of physical insecurities (she considered herself fat with ugly hair, therefore, she had her hair cut short and unfortunately her parents made her feed on such insecurities). She resorted to writing in order to vent out these frustration and her unrequited love. What is more, the fact that her desire to play the guitar was stifled by her parents who forbade it to her created further frustrations. She has had the same one best friend since her ninth grade. For some time, she has not cared about what others may think. She found her first college semester to be rather difficult since she graduated a philology profile high school, but managed to overcome the exam session period successfully, obtaining a grant as well. In addition, she feels very confused about college since she fears she is not going to find a proper job, fear maintained by some teachers who keep telling them that "they will not become anything career-wise." All in all, N.C. aims at exceeding herself by being "a good example for my kids and not indulge in the same mistakes that my parents made with me."

II. O.D. is 22 years old, she is a Masters student, has a younger brother than her with whom she has a pretty good relationship and to whom she was more of a mother than a sister. When she was an eighth grader, her mother went to work in Germany and she had to bear the encumbrance of all household responsibilities. O.D. defines herself as being "a person who always thinks what others expect from her." O.D's dream was to pursue a medical career, but parents disagreed on account of high tuitions fees they could not afford. She submitted application forms to several colleges and chose the one that offered her a full-grant. From the very beginning she took cognisance of the fact that the chosen faculty did not represent her in any way, however, she did not give up abiding by her parents' desires, trying to make them proud. Her parents taught her that once something is started it should also be finished. To O.D's parents it did not really matter what kind of college it was, how it would help her after graduation, whether it was suitable to their daughter or not, all that mattered was that she obtained a subsidised place in college. O.D. describes her father as being authoritarian and having expectations of her to score only the maximum grade, while her mother was uninvolved in her view: "my mom was very busy with household problems, worked very hard both at work and at home." Whenever O.D. asked her mother's advice regarding decision making, she would always receive the same answer: "it's up to you/as you wish." In order to gain financial independence, O.D. is working at a bar. The most cherished values to her are honesty, respect, professional development and involvement in as many social projects. In addition, she confesses that she feels insecure and indecisive, does not know what path to choose, especially regarding professional life.

Many teenagers struggle with a low self-esteem. They feel useless, helpless, desperate, *inter alia*, corollary to underestimating themselves and indulging in self-pity, etc.. "Home remains the main source that engenders happiness, safety and stability for a teenager, determining how the teenager relates to adults, peers or younger children, boosting his/her self-confidence, and incurring reactions to new or unfamiliar situations. Home influences most profoundly adolescent life." [15]. The fact of the matter is that if we place education in the context of the modern family, the fast pace of life and high amount of stress within our society should not be eschewed. It is well-known that people have become more money and career-oriented, leaving less time for parents to handle their children in-between their busy working lives. The question that arises is how much quality time do parents devote to their teenager children? It is often the case that parents fail to communicate with their children, despite catering to their material needs. The propensity of other parents to provide their children with home-tutoring as means of compensation for their absence is also rather common. Thus, the feeling of absence guilt is superseded by mental comfort.

In addition, there is a social phenomenon in Romania with one or both parents working abroad and leaving their adolescent children to make ends meet on their own and become responsible for household chores.
From the foregoing facts enlisted in this section of the research paper, it is reasonable to conclude that time is a factor of paramount importance in the cultivation of a child. Spending quality time, as well as a parent's general availability towards his child or children are key-factors to good communication. What is more, parents should appeal to their children with respect and love, bridging any generation gap that might occur, and not flaunting their life experience as arrogance. Any adolescent accepts adult advice from somebody he/she considers equal. Conversely, teenagers are known to refute advice and abiding by rules imposed by someone they perceive as having a superior attitude that is solely justified by their age, social or family rank.

Knowing the particularities of each age stage is very important in achieving education. Each stage comprises rules and discipline which should be well defined and internalised. The child should have strong role models to follow and, naturally, the first models to start from are the ones in the family. Hence, the idiom "children are the mirror of the family " is no haphazard.

Abiding by rules, being disciplined, following positive role models, internalising certain values and beliefs, adolescents will develop inner control effectively, which will help them preclude bad choices and going astray when parents are no longer with them. Nonetheless, in order for teenagers to develop a healthy sense of identity, parents should inculcate in their offspring strong self-esteem bolstered up by trust, appreciation, encouragement, patience to listen without criticising or judging, to provide alternatives when they wrong.
Another very important aspect that parents as well as teachers should consider, is the development of emotional intelligence - for instance, to help them identify their feelings, describe them, cultivate patience, empathy, learn how to manage crisis situations, how to control intense emotions such as anger, rage, to set short and long term goals, to direct them towards specific constructive groups in which they should be able to assume certain roles, as a sense of belonging is of paramount importance especially at this age, to avoid nagging, etc.

In other words, it is vital for parents to come to know and encourage adolescents to communicate assertively, to treat them with respect, trust, and to show unconditional love, to inculcate the young with the rules, values and principles of life. Teenagers have a critical need to be heard, to feel accepted and understood.
In practice, one of the main roles of school should be identity formation. Teaching is an informative-formative-educational process. The teacher is not only an informed transmitter (a specialist), but he also carries into effect the process of education *ipso facto,* bringing forth certain patterns of behaviour, attitudes, values, beliefs, skills, etc.. He/she must be a model of fairness, punctuality, objectivity and impeccable moral standard. In addition, the instructor should be open to proposals and wishes from learners, to listen, offer support and understanding as much as possible. It is also crucial that they disclose their personal side to the extent that it facilitates the students' learning process, and that they display an optimistic attitude, conveying trust and motivating performance.

The question that arises is whether the Romanian school itself has an identity, given that since 1990 it has been undergoing constant changes. On the other hand, school system education is an integral part of the social system and must be construed from this vantage point, i.e. the lack of an axiological system of the entire Romanian society is reflected in the school micro-context. Therefore, each teacher should reflect on what kind of education they want to instill, whether the instructor wants the students to be obedient, conformist, submissive, or wants them to develop a strong, dynamic, creative personality, and bring them all to a common denominator. The instructor may want them to be able to oppose divergent opinions or encourage them to be authentic, creative, develop a positive self-image through appreciation, encouragement, teach them to bring forth arguments to state their opinions, engage in debates on various topics, such as religious, ethnic, racial, political ones, in order to promote tolerance, non-discrimination, fairness towards diversity and fighting intolerance, focusing on the development of reflective thinking and self-reflection, arranging furniture in the classroom so as to promote communication, collaboration, and negotiation. The teacher is the one who can facilitate the process of discovering skills, abilities, inclinations, interests, motivations in view of a good professional guidance.

For a teacher, each student is like a rough diamond, and his/her mission is to polish the diamond so it shines forever. While good students prepare for success, the bright ones face life as it is, fraught with failures, frustrations, and various problems. Any teacher may be faced with the feeling that he/she is experiencing a nightmare in the class room, but he/she must realise that the situation is a nightmare if it so deemed. The art of teaching, respect for each student in turn, and gentleness, are the means by which adolescents can be changed for the better. Contemporary society is characterised by the ability to consume goods and not ideas, with the focus on the verb "to have", rather than "to be", and on role models deprived of values. Such a society entails no prospect for young people who feel confused, nor for the teachers and parents who feel alienated and disappointed by what they see around them.[16], [17]

As the great exegete and educator Comenius purported, a teacher resembles the farmer insofar as it is important that he prepares the soil, plants the seed, takes care of the plant with dedication, commitment, love, offering it favourable conditions for growth and harmonious development. However, he can never predict the outcome accurately because during the ageing process a series of disturbing factors may emerge. Perforce, the role of parents and teachers is to ensure all the necessary conditions for the development of an integral and harmonious personality. [18]

Conclusions

By the age of 18, an overall sense of identity emerges especially at a psychological level through the dimensions of character, attitude, motivation, and temperament .

Given the extension of social and professional identity schooling, a clear path is not yet outlined, on the contrary, most students face confusion. Many youngsters feel disoriented about their social status, triggered by the fact that they do not identify with the faculty or specialisation of choice, which in most cases was an extrinsic one, such as: the desire or constraints of their parents to enrol in a college beyond their choice that would grant them a bright future from a parental view. Another reason not to identify with college life as outscored by direct observation as well as the case studies, is that for some years now, college admission has been done based on

students submitting a file. Consequently, the criteria according to which each candidate chooses a particular college is generally fund-oriented. Their main goal becomes enrolling in free tuition programmes irrespective of their eligibility or lack of it for the chosen specialisation. Some students realise this fact during the first year of study and take action, focusing on the college that suits them, but unfortunately most of those who do become aware of it, prefer to continue their studies to the end, complete the college courses started, and even pursue a Masters programme in that field, guided by the slogan that all things started should be completed.

Positive self-esteem is related to school performance and quality interaction with parents and teachers. Many of them choose their parents and teachers as role models. There are, however, parents who only have "expectations" of their children, without giving them any credit for their success. Some parents claim that their children should only score the highest grade, without providing any positive feedback. Unfortunately, projecting their own expectations on their children and living through them, compelling them to abide by their prospects and interests, etc. deprives the youngsters to develop in healthy manner. "Parents expect their child to improve whatever they have done badly. It is often that parents impose on their child delusions and unfulfilled ambitions and thus force him/her to assume a role which may not fit." [19]

Parents who have constrained their children in different ways to score only high grades, who have laid too much emphasis on academic performance, have inculcated a perfectionist side in their children. Being conditioned by high grades, teenagers have developed a strong sense of anxiety, deeply-inveterate in the fear of not being number one and disappointing those around them. Consequently these teenagers are very fond of self-image, what others think about them and, therefore, live their lives constantly trying to please those around them, without taking into account their overall intrinsic motivation.

The social phenomenon in Romania of parents leaving to work abroad has changed teenagers who are deprived of the parental presence and encumbered with household responsibilities.

Some parents feed their children only food, and nothing for their souls, they do not try to comprehend their feelings without judging and criticising them, generally developing a quantitative relationship rather than a qualitative one.

Those parents who were able to instill their children a well-defined axiological system, will also create a clearly-contoured identity and a well-established internal control.

Having considered all of the above, we may conclude that in this period of late adolescence, students feel more comfortable about themselves and the way they look, they feel more confident, more independent, better organised, they are less liable to being influenced, they begin to identify their good qualities and become aware of their bad ones and of their weaknesses. Furthermore, religious and social ideas become attractive to them, some are terrified of the future and begin to realise what is important to them, ie they develop consciousness. On the other hand, many of them leave their parents' home during this period, they choose a profession and try to find a way to be financially independent, they become concerned with professional and personal development, initiate and engage in all sorts of projects. The group of friends from earlier stages in their life narrow down, some of them engage in romantic relationships or even get married.

Abstract

If one considers the psychological resilience as a process, than changes can occur all the time and it is important to establish some measurement methods to underline modifications due to the steeling effect and the variation of the ability to cope with stress or stressors. In this paper the authors presents a multiple measurement method designed to evaluate behavioural adaptation. The stressor was the noise of a dental turbine and the considered stress indicators were the heart rate, the hand temperature and the psycho galvanic response. In order to compare the different perception of this stressor, two groups were measured.

Two groups were used and the results showed differentiated behaviour according to the degree of exposure to the stressor ante-measurement and also according to the stressor significance.

The presented experiment reveals the importance of multiple measurements when reaction to stress and resilience is evaluated. The researcher also found using statistic procedures that the results are statistical significant.

Key words: resilience, stressor, measurement, statistic

Psychological resilience evaluation

According to some authors [1], the ability to cope with stressful and painful events was labeled resilience, Also, resilience can be evaluated at the individual, group or community level [2].One can measure resilience using questionnaires, but the answer to those questioners can vary according to the moment when the answers are acquired. Also, a study [3], reviewed the measuring instruments designed to asses resilience and underlined that the instruments have been focused especially on protective attitudes.

According to authors it is important to see how a person can evolve and get to higher levels of resilience. An important indicator of the resilience process is the ability to keep constant professional skills in the presence of a stressor.

The authors think that using objective measurement techniques, can improve the evaluation of individual resilience [4].

Method

1.1 Participants

In order to study the measurement methods, volunteers students from the Mecathronics Department of the Politehnical University of Timisoara and from the Dental Medicine Faculty were involved. For the purpose a group of 16 students (both genders) was selected from the first source and 29 students from the second source.

1.2 Materials

In order to measure the reaction to stress the researchers acquired the heart rate, the hand temperature and the skin electric resistance.

The devices employed for the purpose were a digital computer assisted multimeter, a pulsoximeter and an infrared non-contact thermometer.

1.3 Procedure

The stressor was considered to be the noise of a dental turbine strongly bound to the idea of pain and discomfort. The first group of technical students was not habituated to this noise, opposite to the second group of dental medicine students habituated and frequently exposed to this noise, As stress indicators the heart rate, the hand temperature and the skin electric resistance [5], [6] have been acquired in two stages: before and after the exposure to the stressor. Later the results from the two groups in the two stages have been compared.

1.4 The goal of observations

The researchers expected to have different results from the two groups regarding the physiological reaction in the presence of the stressor. The presumption was that the first non-medical group will indicated signs of high stress and the second group, the medical one will show mild reactions to the stressor indicating that they have a good resilience when this type of stressor occurs.

Results

The studied sample consisted of a total of 45 students, volunteers, females and males. They have been divided into two groups, one with medical experience and exposed to the noise of the dental turbine and the other group with random exposure to the noise of the dental turbine and only during a medical intervention. Due to the source of each group it was expected that the meaning of the dental turbine noise as a stressor to be different and to produce different physiological reaction. In order to acquire the experiment data, the group's members have been invited to relax in a known environment, in the presence of the operator. Heart rate and skin electric resistance was measured in the relaxation state and also a thermal image of the superior surface of the hand was acquired during this state [7]. After that, each student has been exposed to the dental turbine noise. Immediately after the test the heart rate and skin electric resistance and also a new thermal image of the resting hand was acquired, corresponding to the stress state.

The null hypothesis [8], was that there is no difference between the level of the heart rate, the hand temperature and the skin electric resistance when passing from relaxation state to the exposure to the dental turbine noise.

The SPSS software was applied [9], to run the paired T-test for the variables mentioned above and to find the level of significance. In this study the heart rate was labeled FC abbreviation meaning " frecventa cardiaca" or heart rate in English,, the electric resistance of the skin was labeled RED abbreviation meaning " reactie electrodermala" or electrodermal reaction in English and the temperature of the hand was labeled T, abbreviation for "temperatura" or temperature in English.To differentiate between the relaxation state and the exposure to the stressor the abbreviations corresponding to the relaxation state used the subscript "0" becoming FC_0, RED_0 and T_0.

In the following images the variation of the FC, RED and T is presented for the two studied groups.

According to Fig.1 and Fig.2 the electric skin resistance (RED) drops in the presence of the stressor for both groups, immediately after the exposure to the noise of the dental turbine. This phenomenon has a short period of manifestation and soon the electric skin resistance gains his initial value.

This aspect is important for further evaluations, due to the fact that it proves how different stressors can act on a person. The general reaction described by the sudden drop of skin electrical resistance indicates that not the significance of the stressor is important in this case, but the acoustic pressure applied suddenly triggering the psychosomatic reaction.

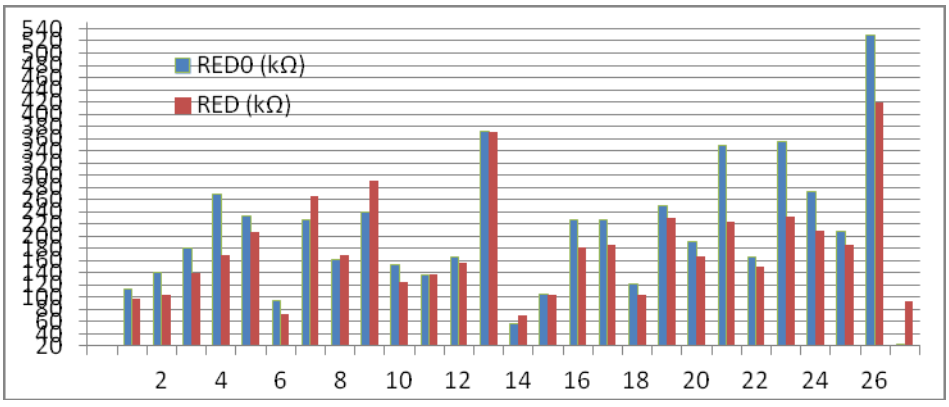

Fig.1. Medical group skin electric resistance variation before and after the occurrence of the stressor

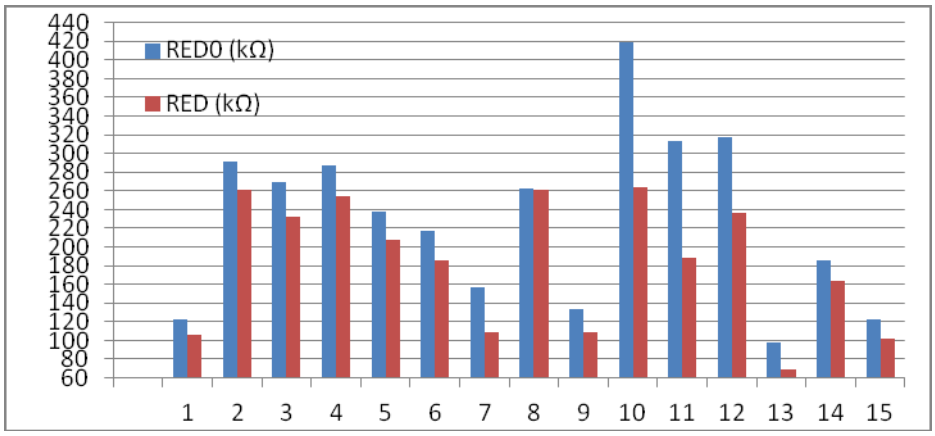

Fig.2. Non-medical group skin electric resistance variation before and after the occurrence of the stressor

According to Fig.3 and Fig.4 the heart rate (FC) increases for the non-medical group and has little or no variation for the medical group in the presence of the stressor.

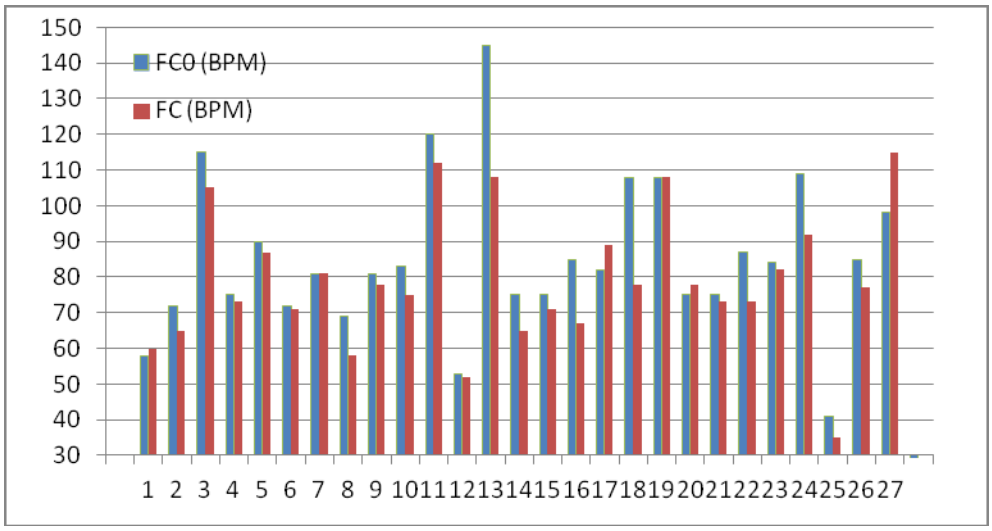

Fig.3. Medical group heart rate variation before and after the occurrence of the stressor

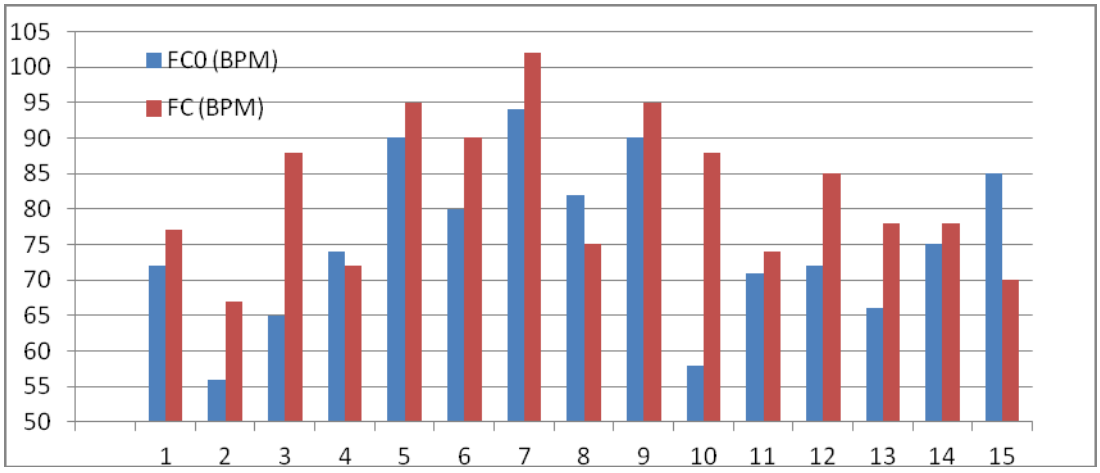

Fig.4. Non-medical group heart rate variation before and after the occurrence of the stressor

According to Fig.5 and Fig.6 the hand temperature (T) increases per general, for the medical group and drops for the non-medical group, in the presence of the stressor

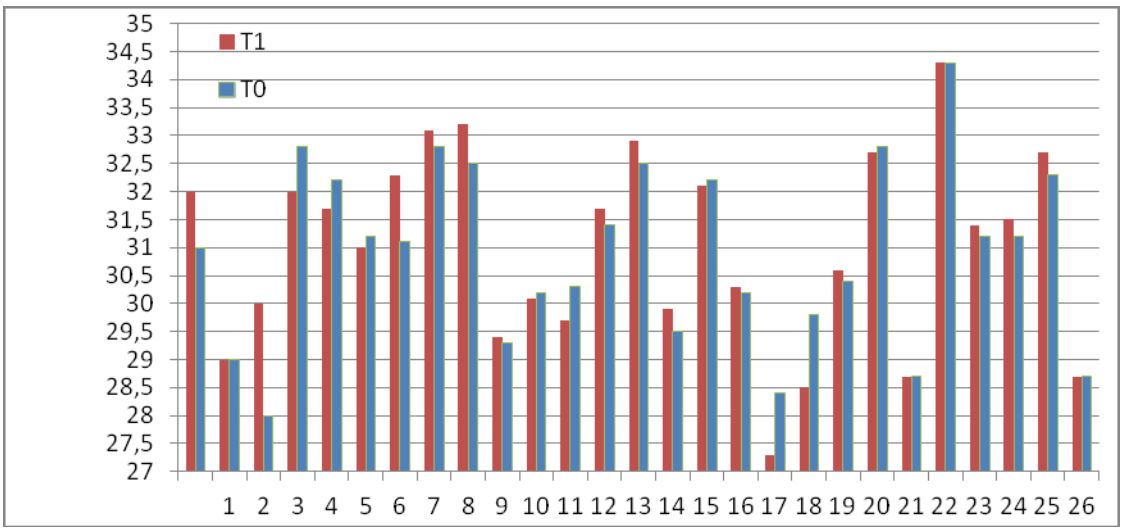

Fig.5. Medical group hand temperature variation before and after the occurrence of the stressor

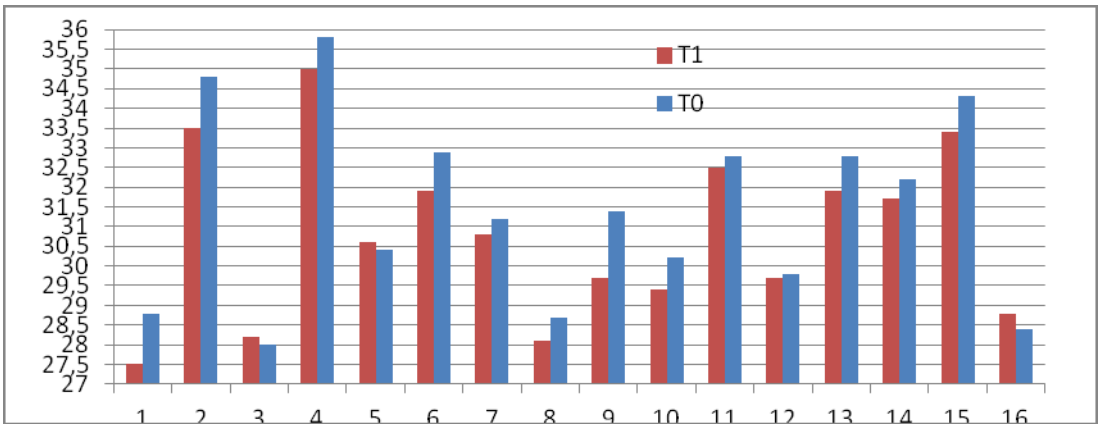

Fig.6. Non-medical group hand temperature variation before and after the occurrence of the stressor

The level of significance for the variation of the skin electrical resistance was p=0.000 for the medical group and p=0.008 for the non-medical group.

Also, the level of significance for the variation of the heart rate was p=0.0004for the medical group and p=0.02 for the non-medical group.

The level of significance for the variation of the hand temperature was p=0.492 for the medical group and p=0.001 for the non-medical group.

Discussion and conclusions

The results indicated that there is a difference between the heart rate, electric skin resistance and hand temperature values before and after the exposure to the dental turbine noise as a stressor [5], as one can see in Fig.1 to Fig.6. The authors underlined that the electric skin resistance has dropped for the both groups, according to Fig.1 and Fig.2, due to the mechanical stimulation of the auditive receptors. Contrary to the estimated results, the hand temperature generally increased for the medical group, see Fig.5, indicating a better blood flow and as a consequence, better dexterity. The non-medical group recorded a drop of the hand temperature, according to Fig.6, indicating the installation of stress [10]. Also, the heart rate increased for the non-medical group, see Fig.4 and generally dropped for the medical group; see Fig.3, showing the continuity of the professional efficiency level for the dental medicine students. The research revealed that a stress factor such as the noise of the dental turbine, produces different effects on the professionals and on the pacients.On the professional group of dental

medicine students, the research data indicated that the stressor triggers no reactions connected to pain or fear (experienced by the doctors in their patient quality, sometimes) but induces physiological reactions proving a very important aspect of the resilience: the ability to preserve or to increase professional skills under stress.

Relevance and Implications

The authors consider that the research revealed the importance of objective measurement techniques in the process of evaluating resilience, in order to sustain the use of questionnaires.

Also, the authors considers, that is very important to use multiple measurement methods simultaneously [10], [11], in order to optimize the determination of some behavioral adaptability in the frame of the individual resilience.

For the future applications of the objective individual resilience evaluation techniques, the authors envisage the use of infrared non-contact stress level measurement, due to the minimization of the degree of interference with the investigated person. Furthermore, non-contact stress level evaluation methods allows the in-situ investigations during professional activities, without extracting the person or group from their location and known working ambient.

Abstract

Resilience is a very complex and theoretical concept. It is difficult to investigate such abstract scientific concept using quantitative methods. The alternative is to investigate the meaning of resilience with qualitative methods such as discourse analysis, conceptual map or Q sorts.

In our paper we are using Q sort in order to understand the typical grid of interpreting resilience by professionals in social sciences. The Q sort is a method developed by Stephenson that correlates different points of view of the subjects. In our case the Q sort consists in 30 statements regarding resilience (extrinsic / intrinsic on three dimensions: individual, familial and organizational resilience). The subjects are 20 professionals in social sciences (social workers, sociologists, psychologists and education science professionals). The results are analyzed with PQMethod software using factorial analysis.

The outcome of the study will be a factorial model of resilience that describes the understanding of the concept by social sciences professionals. In the same time, we would like to demonstrate the usefulness of using a qualitative method in studying a theoretical concept like resilience and to stress the impact of such a particular understanding in practice.

Theoretical background

Resilience is a trendy concept. Like most of the social science concepts, it is a professional construct which means that its meaning is *fluid* and changes accordingly to its use. Several other concepts were in use to describe the same reality [1], but resilience prevailed due to its flexibility. Since its first coinage as a "bouncing back" ability, resilience changed its meaning.

In the beginning, resilience was understood as an individual trait or ability to bounce back in stressful situations. In a way, the resilience was the endurance of coping style. It means that in order to manifest itself it needed a stressor and a coping mechanism. One way to differentiate coping and resilience is to understand coping as a set of skills and responses to stress and resilience as adaptation to adverse condition. Although today we understand the resilience as a process and not only as a personal set of skills or traits, the individual characteristics are still important in assessing someone' resilience level. If we define resilience as a dynamic adaptation ("a dynamic process encompassing positive adaptation within the context of serious adversity" [2], then the process of resilience is the central issue. The process involves cognitive decisions, emotional adjustment and social interaction. In this way, someone with good coping skills could still show a weak resilience level [3].

During the last decades, the meaning of resilience did get more complex including not only personal coping resources, but external factors as well. In the paradigm of ecological functioning of persons [4], the resilience includes all resources that could be used by an individual in order to cope with stress. This means that family resources, economical, community and cultural resources as well as social and political means to protect individuals are resilience factors as well. There is a strong relation between resilience and adaptation, resilience describing a successful adaptation, despite risks and adversity [5]

For the purpose of our study, we will classify the resilience resources in three categories. The individual resources are personal traits and skills that help the person to recover or cope in stressful situation. Intelligence, assertive level and involvement are among this type of resources. The group type resources include the support of close friend and family, peer relations or the social network support. The societal resources refer to cultural factors, like beliefs systems and state policies that help people in needs to cope with difficult situations. If we take into consideration the nature of resilience resources we could also divide them into general and contextual ones. The general resources are used across all difficult situations. Some general factors are stable traits of the person. The contextual resources are employed in specific situation, for example the religious percepts could help a person to cope with an ethical dilemma.

Like all other social sciences constructs, the value of resilience resides in its specific use in practice and in developing new theories. In other words, such construct have not an important meaning in itself, but closely related to the use of it. Due to the diversity of social scientists and the specific situation in which the resilience is used we could safely assume that diverse social scientists are using this construct in specific ways.

One way to assess the meaning of resilience and its use is to investigate its use by different social scientists like psychologists, social workers, sociologist or teachers.

Purpose of the study

Our purpose is to determine how different professional from social sciences understand resilience. The basic assumption is that resilience is a construct and its meaning is shaped by professionals who use it. Finding the different meaning of resilience in professionals view will help us to determine if they assess resilience in relation with individual factors, group factors or societal ones. In the same way, we will see if they understand resilience as a general ability or as a contextual adaptation to adverse conditions.

Methods and participants

There are several methods to accomplish the purpose of the study but we decided that Q methodology is the most useful to our purpose. Q methodology was developed initially by Stephenson in order to analyze subject instead contents [6]. He understood the fact that a sample of correlated tests does not give information on underlying traits, but shows that test require similar responses. So, instead of applying a number of tests on a sample of persons, he reversed the procedure by applying a number of persons on sample of tests (statements). In this way, by using Q sorts, we could find groups of people that have similar understanding of the concept. The procedure is not new and we apply it in other situation, with the same goal, by investigating the meaning of intelligence for teachers [7] or assumptions and beliefs about discipline [8].

Specifically, our Q sort procedure required a number of statements about resilience and a number of professionals to sort them according to their relevance on a forced distribution. In our study we constructed 60 statements about resilience using a 3X2X10 design. We took into consideration three types of resilience factors (individual, group, social) and two conditions (general and specific). For each of the 6 combination we made 10 statements. The list of statements was analyzed independently by three specialists in resilience studies concerning their descriptive power of resilience construct and the representativeness for the category. The assessment was made on a 3 point scale (inadequate, somehow adequate or adequate). All statements were assessed similar as adequate both for the resilience and their category. The final statements were presented randomly and individually to the subjects. Al statements were ranked on a distribution with five categories. The positive categories were ranked +2 and + 1 and had 10 statements each, similarly negative categories were ranked -2 and -1 and the neutral items were ranked 0 (20 statements).

In the Q sort procedure the sample consists not on persons, but on statements. In our case, our sample is N=60. In our study we asked 10 professional in social sciences to rate the statements. All the subjects are university teaching staff from a social science faculty. Four subjects are psychologists, specialized in educational psychology and special education, two subjects are specialized in education sciences, two subjects are sociologists, and two are social worker, respectively special education teacher. The diversity of subjects is necessary in order to assure a diversity of perspective on the same subjects. However, the number of the subjects is not crucial and the recommendations are that they are less than the number of statements.

To analyze the output we performed a principal component analysis with Varimax rotation using PQmethod software. Traditionally, the preferred factorial procedure for Q sorts is centroid factor analysis and manual rotation of factors, but we use the principal component in order to maximize the independence of the factors and because we couldn't anticipate the number of factors. The PQmethod software is specifically designed to perform q sorts analysis using factorial analysis. The software does not provide only the factorial solution and factor loadings, but highlights significant statements for each factor.

Results

We will present date in three sections. First we will present the factor solutions and description and then we will present the characteristic statements for the factors and the differences between them, and, finally, the descriptive statements for each factor.

Using principal component analysis, we found three factors with an eigenvalue over 1 explaining 63% of variance. Using Varimax rotation we found the final solution, consisting in three factors. For the first factor there are four sorts with significant loadings, for the second there are three significant sorts, and the third has 2 sorts. The factors explain 22%, 23% and 16% of variance. The factor loadings of sorts are high, ranging from .53

to .59 on factor 1, 0.60 to 0.80 on factor two and .72 to.76 on factor 3. The correlations between factors are low (.09 to .26). The reliability of factors is: 0.941, 0.923 and 0.889.

The PQ method software is averaging the ranks of each statement of sorts that are loading the same factors and the result is an "ideal" ranking of factors for each factor. That is the most descriptive statement for a factor are ranked first and the least descriptive are ranked last on a distribution similar with the original one. We obtain a bipolar description of resilience for each factor.

For the factor 1, the most important statements are:

Parents are supportive in his/her decisions.
He/she has a supportive family.
The family relations are positive.
He /she take control over his/her problems.
He/she is confident in his/her strengths.
Parents are empathically with his/her problems.
The siblings are supporting him/her in difficult situations.

The least representative statements for factor 1 are:

He/she could rely on the society's strategies to solve efficiently problems similar to his/hers.
He/she stands for his opinions.
He/she trusts in the rightfulness of defense and protection actions of state's institutions.
He/she finds the strength and hope in transcendental powers.
He/she is a friendly person.
He/she is a sociable person.
He/she participates actively in a club.

Based on the representative statements we named this factor ***family resilience***. In the view of the subject that loads on this factor, resilience is not the results of individual actions or social framework, but is the results of a shared effort of the ecological micro-environment, specifically the family. The most important resilience resource is a strong support network in close proximity.

For the second factor, the most important statements are:

He/she is assertive.
He/she has a high self-esteem.
He/she is a sociable person.
He/she is independent.
He/she is optimistic.
He/she stays optimistically in difficult situations.
He/she is intelligent.
He /she takes control over his/her problems.

The least important statements for this factor are:

In difficult situations, he/she returns to faith.
He/she is participating in a social or religious organization.
He/she recovers quickly from illness.
He/she has a set of values and beliefs and applies it systematically.
He/she is a faithful person.
The values and principles of the culture are positive.
He/she knows the useful values and beliefs.

The subjects in the second factor stress the importance of the individual traits in resilience, but not the faith system or ethical values. We named this factor the ***individual resilience*** factor. In their opinion, the resilience occurs as a result of individual actions, based on personal characteristics. In this respect there are some traits that are quite stable and other that could be trained.

For the third factor, the more important statements are:

He/she is optimistic.
The society has preventive and remedial educational policies that are consistently applied.
He/she has positive family relations.
He/she was well informed and trained to cope with this type of situations.
He/she has a supportive family.
He/she belongs to a culture that has adequate strategies to solve this type of situations.
He/she doesn't feel accused or diminished.

The least important statements for this factor are:

His/her needs are satisfied.
The educational system promotes independence and autonomy.

He/she has good relations with the other gender.
He/she recovers quickly from illness.
He/she has good access to health services.
He/she is intelligent.

The subjects from the third factor use a mix of individual and external characteristics in order to define resilience. The external characteristics reside not only in group relations, but at societal level too. Positive attitude in a strong family and a structured society are the main traits that are interacting to successful coping. That is why we named the factor the **social-interactionist** factor.

Some of the items mark the differences between approaches. It is possible that two approaches value equally the same statement and consider it important, but more illustrative are those items that make a difference in defining resilience. We could analyze the differences between factors in term of absolute value (the difference between z scores for each statement) or in term of polarity of statements (those statement that were positive on one factor and negative on the others). In our analysis, we will include only those statements which satisfy two conditions: a polarized assessment and a difference larger than 2 z standard deviation points.

The main difference between statements from factor 1 and 2 is that the subjects from factor 1 are considering as an important aspect of resilience the values and beliefs system, an aspect that the subjects from factor 2 are considering not important (H*e/she has a system of values and beliefs* 2.37, *He/she is a believer* 2.2). On the other hand, the subjects from factor 1 are not considering personal traits very important, while the subjects from factor 3 consider them extremely important (*He/she has a high self-esteem* -2.07, *He/she stands for his/hers opinions* -2.28, *He/she is a sociable person* -3.17).

The differences between factor 1 and 3 are quite subtle. Subjects from factor 3 doesn't value that family importance stressed by factor 1, but emphasize individual traits that are not cognitive, but social *(He/she is sociable -2.07, He/she is optimistic -2.08, He/she is a friendly person -2.57, He/she could rely on society's strategies of effective problem solving -2.775*).

The difference between the factors 2 and 3 is represented by the focus on social aspect of resilience emphasized by the subjects of factor 3. On one hand, the assertiveness, intelligence and independence are seen totally different by subjects of the two factors (H*e/she is assertive 3.30, He/she is intelligent 3.11, He/she is independent 2.53)*, on the other hand the social participation and cultural values are considered important by the subjects in factor 3 and not by those from factor 2 (he/she participate in a social or religious organization -1.98, *the values and principles of the culture are positive -2.28)*.

The distinguishing statements for each factor are those statements that are important for only one factor. The statements which accomplish both a difference from others factors and a high positive value are:

For factor 1 (family resilience): *The parents are supporting his/her decisions, The parents are emphatically to his/her problems, He/she has access to effective social services (all are significant at p<.05);*

For factor 2 (individual resilience): *He/she is assertive, He/she has a high self-esteem, He/she is independent (all are significant at p<.05);*

For factor 3 (interactionist resilience): *The society has preventive and remedial educational policies that are consistently applied, He/she belongs to a culture that has adequate strategies to solve this type of situations (all are significant at p<.05).*

Discussions

The results indicate that professionals in social sciences are using the concept of resilience in different ways, with focus on different aspects and its locus. The factors suggest that there are at least three different approaches of resilience. Considering from the locus of resilience, we could speak of an **internal** approach of resilience. This approach is used mainly by psychologists and emphasizes the psychological nature of it, in terms of personality traits and individual characteristics. Due to this approach, the resilience is increased by strengthening the individual in a "therapeutic" approach of intervention. The second approach is a family or small group approach. From this point of view, the resilience is secured in a strong **small group** with supportive roles. Integration of a person in its significant group (like family, classroom or workplace) represents for those favoring this approach the best way to increase resilience. This approach is used by teachers, educational psychologists and special educators. The third approach emphasizes the **social** underlying structure of resilience, which spans from individual social skills to cultural values and society's policies. This approach doesn't contradict the other two on a basis of internal or external locus of resilience, but on the nature of it. Not surprisingly, this approach is preferred by sociologists and social workers.

One question is if the different specialists developed their understandings by accessing information relevant to their field of expertize or if the theory was filtered by their previous knowledge? Without focusing on this question, we will assume that the second option is more likely. The fact that the theory is re-constructed by each professional is possible because the construct of resilience is not clear-cut defined.

Another question was if the professionals in social sciences are judging resilience in general or specific (contextual) terms. The sort was prompted by two specific situations. However, all the professionals valued higher the general statements than the specific ones. This tells us that they are using a general theory of resilience which manifests itself across a wide array of situations and contexts. In other word, for them, resilience is not coping with a specific stressful or adverse condition, but a general active state of facing the daily aversive situations.

Our study has its limits but the results open up some questions to be studied in more detail. One of them is if there are some specific ways of intervention in helping people facing adverse situation based on the different approaches? If the field of expertize influences the way we understand resilience could we develop an interdisciplinary model of it and will it be useful?

Risk factors and protective factors in symbiotic trauma – case studies

Vasile D.L.

Bucharest, Hyperion University, (ROMANIA)
diana.vasile@psihotrauma.ro, dianavlucia@gmail.com

Abstract

Three case-studies are presented in this paper, two women and one man, who sought psychotherapy for relationship difficulties that reflects what German psychologist Franz Ruppert named *symbiotic trauma*. The symbiotic trauma represents the trauma that develops in a child who grew up with a traumatized mother and/or traumatized father. This concept is based on three theories: attachment theory developed by John Bowlby, trauma theory developed by Gothfried Fischer, Peter Riedesser, Franz Ruppert and systemic family theory and constellation method as described by Murray Bowen and lately by Bert Hellinger. In Franz Ruppert's trauma theory we can find an interested perspective on personality splitting during trauma. In his view, there are three psychological structured that emerge after traumatization: healthy structures, traumatized structures and survival ones. In the case studies, we describe these structures, their expression, and their unique mixture resulted from the combination of risk and protective factors during the clients' childhood. The traumatized structures keep the feelings of helplessness, fear of death, pain induced by the abandonment. The survival structures express self-punishing thoughts, thoughts of getting strength and power by the intellectual and rational means, or those physical ones, the swinging between avoiding and searching for good relationships, psychosomatic difficulties, work or sport addiction, self-aggression and other daily problems. Healthy structures search for the resolution of own difficulties, accepts traumatizing experiences, learn and develop.

Key words: symbiotic trauma, risk and protective factors, healthy psychological structures.

Introduction

Franz Ruppert is a professor of psychology at Munich University and psychotherapist in his own private practice. He developed his theory as a result of his practice in trauma therapy, inspired by G. Fischer and P. Riedesser and also of his practice with the constellation method learnt from Bert Hellinger, a controversial figure, in group psychotherapy. He worked with lots of different clients, with various symptoms or problems, including severe pathology as borderline and psychosis. Ruppert called what he noticed healthy, survival and traumatized parts of the psyche that result from the moment of traumatizing experience. The main characteristics of these parts are [1]:

The traumatized parts: they store the **memory** of the trauma; they remain at the **same age** at the moment of the trauma; they permanently seek a way out of the trauma situation, being still **engaged** with the traumatic experience; they unpredictably and suddenly can be **triggered.** They are a persistent trouble spot in the psyche.

The survival parts: their role is to protect the organism and the psyche in order to **ensure the survival** in the original trauma situation. They **construct and guard** the split; they work to **deny and suppress** the trauma experience: they use defense mechanisms, as **avoiding, controlling, compensating the memories and information about traumatic experience.** They control the traumatic structures and also other people (for example, burden the trauma feelings onto others); seek distractions compensating for the lack of true experience; **create illusions and produce new splits** within the psyche**.**

The healthy parts: are present in every psyche, developed accordingly to the age development. They are **capable of openly and clearly perceiving reality, of expressing and regulating feelings appropriately for present situations,** show **genuine empathy,** have the **ability to develop safe emotional bonds with others, to detach oneself from entangled bonds**, have the readiness **to assume responsibility** and **to reflect on own actions.** Healthy structures **love, know and search for the truth.** Most importantly, they are strong enough and ready to confront traumatic experiences and hope for good resolution during conflicts**.**

1.1 Symbiotic trauma

Symbiotic trauma represents the trauma that a child is most likely to suffer if he or she is born of and/or brought up by a traumatized mother and/or traumatized father [2]. "Being raised up in a difficult relationship with parents due to their own trauma that troubles the parent-child relationship, the child is forced to split in order to survive" [2]. This is more obvious in families where babies are given away, maltreated or a parent is sick and dies when the child is still very young. Therefore, the child's psyche will develop with traumatized, survival and healthy structures. The risk and protective factors influences the way the child copes with the difficult parental relationship and the help that he /she asks and gets from others.

According to Ruppert's theory, "the characteristics of *traumatized structures in a symbiotic trauma* are: feeling desperate that there is no love from mother, feelings of loneliness, fear of dying, suppressed anger, suppressed sadness. The characteristics of *survival structures* are: constant fighting and arguing to try to get in contact with the mother/father, idealizing the mother/father, feeling responsible for the parents and trying to please them or to take care of them, identifying and resonating with the traumatized parts of the mother/father, identifying with the survival mechanisms of parents, repressing and denying own trauma" [1].

1.1.1 Case study 1: Monica and her pain

Monica was the first daughter of an angry and sad mother and an isolated father. She sought help from therapist in order to improve her health and her marriage, due to constant pains in the abdomen and genital difficulties. Individual and group therapy, including constellations of intention centered on trauma, helped her to recognize her own traumas and improve her physical and emotional functioning and also to detach from the idealization of mother and father. The most important traumas were maternal physical, sexual and emotional abuse, paternal emotional and almost physical absence and identification with her mother sexual trauma. The survival strategies were: work-addiction, self-punishing ideation, clinging to people, physical pain, ideation about death, submissiveness, ignoring her needs. Monica slowly learnt to use her resources to take care of herself, to engage in healthier relationships and to lessen her submissiveness and to confront abusive situation and people.

1.1.2 Case study 2: Dora and her loneliness

Dora's mother gave away almost all her children after birth. Dora was adopted by one of the mother's sisters and her husband who could not conceive children. They were a real family for her, but she always knew that she was adopted and some siblings live with her real parents. At the age of 10, her adopted mother died. Adopted father remarried and Dora got the second adopted mother. Around 40, Dora took care of her sick and dying adopted parents and some of her disabled siblings. "No time for myself", she said. Now Dora is aged 55, unmarried, without children and she still hopes for a normal couple relationship with the man she "loves" for 25 years. But he is still married to his wife and shares his life between these two women. Dora always feels lonely and dreams of real relationships. She could finally find some close friends recently, when she started personal development and psychotherapy. For Dora, therapy and constellation method using Ruppert's perspective helped her to understand her whole life and decisions, to enjoy life more and to focus on herself and her needs.

1.1.3 Case study 3: Tom and his isolation

Tom came to therapy due to his trust in it, to stop the isolation and feelings of helplessness and hopelessness that he was having for the last year. He experienced psychotherapy and this improved his emotional states, but this time he wanted more and deeper. During the last months, he neglected his business (which almost collapsed) and he seldom came out of his house. He sees only his therapist and three medical doctors. Therapy and individual constellations of intention gave Tom some ideas about his own trauma related to his mother illness and early death, when he was only 9 and about his constant search for a happy parent to connect to. Also, the anniversary syndrome was reveled and Tom started to feel his own feelings, not his mother or his father feelings and survival strategies: repressed anger and emotional pain, rationalizing, used against his own self and well-being.

Risk factors and protective factors for clients with symbiotic trauma

In these three cases, the emotional and relational difficulties were aggravated by the following risk factors: myth of the good and loving mother, the normality of abuse in social and school settings, the low medical performance of some medical staff, low self-image and self-esteem, relationship failures, connection to mother through pain or suffering etc.

The most important protective factors that helped these clients to develop natural and assisted resilience were: intelligence, sense of humor, curiosity, school and academic achievements, relationships with colleagues and friends, social and medical acceptance of psychotherapy, openness to try new methods, strong therapeutic alliance, eagerness to go further to find their own trauma and process it to stimulate healing.

Conclusion

Individual and group therapy, using different methods and techniques including constellation of intentions help clients to use healthy structures to integrate traumatized parts within the psyche. The main elements used during psychotherapy were: patience, acceptance of survival mechanisms, enhancing client's determination and engagement for therapy (healthy structures), retaining from reactions or interpretations, using the distance and time between sessions, underlying the risk and protective factors and their role in present personality and psychological manifestations. This facilitates resilience and creates a solid basis for an appropriate and clear physical, emotional and relational functioning.

Construction and validation of the resilience assessment scale for infertile couples (rasic)

Dumitru R., Turliuc M.N.

Alexandru Ioan Cuza University, Iaşi, Romania
roxanatudorache@yahoo.com, turliuc@uaic.ro

Abstract

Based on current conceptualizations of the infertility issue and its psychological, social, relational implications and on perspective of resilience awareness as a resourceful means or a generic coping method, this study aims to build and validate a multidimensional scale for the assessment of resilience in heterosexual couples who are diagnosed with (female, male, mixed, or idiopathic infertility) infertility, and who will perform a medically assisted human reproduction procedure (Resilience Assessment Scale for Infertile Couples, RASIC). By comparing the behavior described and used in literature regarding resilient persons, we designed a set of 30 items. The items were rated by 10 experts who analyzed the content representativeness, the accuracy in expression, and its compatibility compared to the target group. Exploration of the construct validity was achieved through exploratory factor analysis using principal component analysis and Varimax rotation method. The factors were denominated based on the combination of the factor analysis results and of the theoretical foundations related to resilience. The scale was applied to 50 subjects form 25 heterosexual couples with infertility diagnosis. Exploration of the convergent validity was based on correlations between RASIC, Connor-Davidson Resilience Scale [11] and Friborg Resilience Scale [12], instruments used for measuring overall resilience. We also assessed the divergent validity by applying the Posttraumatic Development Inventory [13]. The fidelity of the instrument was evaluated in order to highlight its discriminatory value. The obtained data helped us to determine whether the tool could provide a valid measure of assessing resilience in infertile couples / individuals. Finally, we considered the theoretical and practical implications of designing and validating the RASIC questionnaire.

Keywords: questionnare, resilience, infertility, factor analysis, construct validity.

Theoretical background

Using the current conceptualizations of the infertility issue and its psychological, social, relational implications as well as the perspective of resilience awareness as a resourceful means or a generic coping method, this study aims to build and validate a multidimensional scale for the assessment of resilience in heterosexual couples who are diagnosed with (female, male, mixed, or idiopathic infertility) infertility and who will perform a medically assisted human reproduction procedure. Construction of the questionnaire is justified by the absence of such an instrument in the literature, making it difficult to directly analyze the role of resilience as for the success rates of the medically assisted human reproduction procedures. Scale development has been based on the principles underlying the resilience theory viewed as a multidimensional construct incorporating internal as well as external protective factors [1, 2, 15]. Although many factors have been proposed the mutual results of the research studies regarding internal factors focused on coping, internal locus of control, self-efficacy, perseverance [3], while the external factors included family and social support [1].

Resilience is described as a "process, a result of a very good adaptation despite threatening circumstances" [4], this concept providing us with a new theoretical framework in terms of research development. The concept of *resiliency* has been used in literature to describe three types of situations: a. individuals who had experienced a traumatic event but managed to recover very well; b. people belonging to risk groups, who had higher success than it would have be expected from them, c. people who succeed in adjusting and positively responding despite the negative aspects of their lives.

Regarding the direct correlation between resilience and infertility, studies show that resilience is an unspecific protective factor against the distress specific to infertility, having an influence on quality of life. When couples benefit from counseling, it is necessary to pay particular attention to the awareness of resilience as a resourceful method or as a generic way of coping [5]. Also, resilience was negatively associated with

infertility-specific distress and general distress. Involvement in action-based coping methods was positively correlated with resilience [6].

This study aims to design and validate a multidimensional scale for the assessment of resilience in heterosexual couples who are diagnosed with (female, male, mixed, or idiopathic infertility) infertility and who will perform a medically assisted human reproduction procedure.

Method

1.1 Scale construction

Resilience Assessment Scale for Infertile Couples (RASIC) has been designed to assess the resilience of specific diagnosis of infertility in couples who use assisted reproduction technologies. As for the scale construction, resilience has been seen as a multidimensional construct. Thus the internal locus refers to the individual's perception of being able to influence his/her own destiny, being responsible for the things following to happen in life through his/her own actions [1, 7]. Coping involves a set of cognitive and behavioral strategies in order to manage stressful situations, resilient individuals are confident they can make it to the adversity, managing stressful situations by means of solving problems and expressing emotions [8]. Social and family support was also indicated as a factor that played a role in increasing resilience [9, 10, 8]. Self-efficacy involves a belief in their own ability of self-motivation, cognitive and actional resources in order to control a specific event as well as perseverance to pursue goals in order to attain them [1].

Based on known scales that measure resilience, Connor-Davidson Resilience Scale [11], Resilience Scale Friborg [12], The Resilience in Midlife Scale [13], the items was designed on six dimensions as follows: internal locus, coping focused on problem solving, coping focused on expressing emotions, social support dimension, the couple relationship dimension, self-efficacy. Based on these criteria, we designed 30 Likert style items with six steps displaying the following rating: 0- never true, 1 – rarely true, 2 - sometimes true, 3 - often true, 4 - almost always true, 5 - always true.

1.2 Subjects

In its initial version that included 30 items, the scale assessing resilience in couples diagnosed with infertility was applied to a number of 50 couples as follows: 50 men and 50 women, with secondary education (28%) and with high education (72%), without any MAR procedure (56%), with one procedure 20%, two procedures 16%, three procedures 8%, out of which 40% with intrauterine insemination and 4% with in vitro fertilization, 42% diagnosed with female infertility female, 14% with male infertility, 14% with mixed infertility and 30% with idiopathic infertility, 12% with 1-to-3-year relationship, 6% with 3-to-5-year relationship, 28% with 5-to-10-year relationship, 52% with 10-to-15-year relationship.

1.3 Procedure

Informed consent was obtained from all the participants. Participants completed the designed scale, and other two scales that measure resilience: the Connor-Davidson Resilience Scale [11] and the Friborg Resilience Scale[12]. They also completed The Posttraumatic Growth Inventory [14].

Results

1.1 Construct validity. Exploratory factor analysis

The first steps in verifying empirical validity of the construct was represented by the exploration of the factorial structure of the collected data, in order to see if the proposed items were grouped in the hypothetical factors discussed in the literature presented before. Thus, we used principal component analysis and *oblimin* rotation method. Based on the results of the performed analysis, we retained items that showed saturation of at least 0.30 and that did not saturate in other factors.

In order to explore the construct validity, we performed exploratory factor analysis through principal component analysis. To check whether there were a sufficient number of significant correlations between items, which should the performance of factor analysis, we used Kaiser-Meyer-Olkin value, which was a measure for the adequacy degree of the target group, and Bartlett's test of sphericity. The value of 5 for KMO and the Bartlett test (χ^2=2570,73 0<0,001) verifies if the correlation matrix is different from the identity matrix. According to these values, we concluded that the items are appropriate to the factorial model, even if the KMO value is at limit acceptable because of the reduced sample compared with factors number. When we performed the exploratory analysis with principal components method through Varimax rotation, we noticed that these factors

didn't overlap with hypothetical scales and that only 4 from 6 factors had a sufficient number of items with satisfactory saturation.

The Kaiser's criteria (*eigenvalue* greater than 1) as well as the Cattell's scree plot criteria suggested 8 factor solution for the 30 items. Aiming to improve the factorial structure of the scale, we eliminated the items with saturations in two or more factors, items with factorial saturations below 0.40, and items that had communality value under 0.50. Seven items (12, 30, 4, 8, 20, 25, 28) had saturations in more than 4 factors or had communalities under the mentioned level, which why we excluded them. Also, the retention of factors was based on a combination of the results of exploratory factor analysis with theoretical foundations related to resilience in infertility.

The measurement model resulted from the item selection, according to the criteria which we referred above, included 22 items and 6 factors. For this model, the KMO indicator was equal to 0.681 and the Bartlett test's value was statistically significant ($\chi 2 = 1712.043$, $p < 0.001$). After orthogonal rotation of the factor solution resulting from the introduction of the 22 items as observed variables, the six latent factors explained 75.85% of the variance in items. The items variance percentages that were covered by each of the factors were: 28.85%, 15.417%, 10.257%, 8.464, 7.174, 5.684%. Table 1 displays saturation of the items in the extracted factors as well as the communality values. Also two from the hypothetical factors didn't bring together the exigency of items number, which why we decided to continue with the analysis with the rest of the items (20) and fixing four factors. The result of the four factors solution brought us to keeping 18 items with saturations from .54 to .95. First factor*, internal locus of control* includes 5 items, the second factor regarding coping based on *expressing emotions* has 4 items, the third factor regarding the coping based on problem solving includes 4 items, and the last factor, *social support*, has 4 items.

Tabel 1. Factor saturations (column F1, F2) communalities (column C), averages, standard deviation for the items from final factors

Items		*Communalities*			
	1	*2*	*3*	*4*	
1. I am confident that I make the best decisions related to my dream of having a child.	,859				,779
6. I believe that I succeed in accomplishing everything that I aim at, including my fertility problem.	,755				,661
19. I believe that what I do will help me become a parent.	,826				,818
2. I rather think how solve fertility problem than how it affects me.			,444		,332
3. I share my feelings about infertility with close persons.		,950			,909
22. I talk to my friends about the infertility issue.		,948			,903
7. I do my best I can in order to become a parent.	,859				,779
10. I have friends that give me support related to my infertility problem.		,870			,843
9. I avoid talking about my feelings concerning infertility.		-,623			,403
5. I offer affection to my partner despite the fertility problem.			,744		,638
23. I am satisfied with my sexual intercourse depite the fertility problem.			,420		,575
14. I can focus my efforts in order to find a solution to my fertility problem, one way or another.			,788		,670
17. I think that I am more bound with my partner since we have the fertility problem.	,481				,467
11. I feel that the infertility problem affects my couple relationship.			-,687	,319	,600
13. It depends on me to solve my infertility problem.	,316		,562		,462
26. It's hard to mentain my optimism concerning solving the fertility problem.				,575	
21. I feel furious because of the infertility diagnosis.				,656	
16. I feel that the others isolate me because of my fertility problem.				,758	,631
18. Even if everything seems hopeless, I go on with making efforts in order to fulfill my wish to become a parent.	,720			,350	,681
27. I feel that I am overwhelmed by emotions because of the fertility problem.				,758	,631

Factor 4 – 4 items (social support): 26, 21, 16, 27.
*(*Revesed items)*

1.2 Convergent validity

The convergent validity, as a facet of construct validity, was evaluated by assessing the correlations between RASIC, Connor-Davidson Resilience Scale and Friborg Resilience Scale as instruments for measuring overall resilience.

Table 2. Means, standard deviations and correlation coefficients among study variables (reliability estimates on main diagonal)

Measure	M	SD	*1*	*2*	*3*
1. RASIC	3.54	.62	.96		
2. CoDa	3.34	.44	.297**	.89	
3. RF	4.12	.53	.496**	.538**	.88

** p < .05. ** p < .001. Note. RASIC = Resilience Assessment Scale; CoDa = Connor and Davidson Resilience Scale, RF= Friborg Resilience.*

Cronbach's alpha internal consistency values are presented on the main diagonal. RASIC scale correlated medium to high with Friborg scale and medium with Connor-Davidson scale.

1.3 Divergent validity

Divergent validity was assessed by the correlation between RASIC and EPT.

Table 3. Means, standard deviations and correlation coefficients among study variables (reliability estimates on main diagonal)

Measure	M	SD	*1*	*2*
1. RASIC	3.54	.62	.96	
2. EPT	2.4	1.18	.153	.89

** p < .05. ** p < .001. Note. RASIC = Resilience Assessment Scale; EPT = Posttraumatic Growth Inventory.*

Cronbach's alpha internal consistency values are presented on the main diagonal. The data show that the two scale measure different constructs, without performing a statistically significant correlation between them.

1.4 Fidelity

In order to estimate the internal consistency of the CMF scale's scales, we used α J.L. Cronbach's coefficient. The calculation of this coefficient is recommended for measuring instruments with multiple choice items. The Cronbach Alpha coefficients for the final version of the scale consisting of the 22 items and for its subscales vary from: 0.740- 0.830. We also measured the time stability of the measurement by means of the test -retest method. After 1 month, we applied the scale to same 100 subjects.

The difference between the averages is -0.46, t (99) = -0.365 and p = 0.716, which means that there are no statistically significant differences between the two tests. The correlation coefficient between the scores of the two applications is 0.285, p = 0.004.

Advantages and limitations

The psychometric data suggest that the designed instrument may be useful for measuring resilience in couples diagnosed with infertility. From a practical standpoint the scale may be useful in the assessment and psychological counseling of these couples. However, studies are needed to validate longer versions that could be obtained by refining (in terms of psychological content and psychometrically) of items from the initial version and adding and testing new items on a bigger number of couples.

In conclusion, there are teoretical and practical implications from the development of scales to measure the resilience of the couples confronted with infertility. The scale can be used in empirical research, for a better understanding and description of the mechanisms of the development of resilience, for identifying its role as mediator [16] and/or moderator [15] between different variables. In the same time, valid and reliable instruments are needed for designing and evaluating treatment programs that aims to foster resilience in infertile couples. Interventions to promote health can assess the progress using this scales. The scale proposed in this study can be

used to measure changes in dimension of resilience of infertile couples. The scale can be used in theoretical research, for better a understanding and description of the mechanisms of development of the resilience. In conclusion, the scale appear to be valid and reliable instruments to assess resilience of infertile couples.

Abstract

The long-term situation of persons who have suffered a moderate to severe traumatic brain injury (TBI MG) suggests significant adjustment difficulties [1]. Brain injuries cause a wide variety of effects, many of which persist in the long term [1-4]. Depression, anxiety, social isolation, poor employability and interpersonal difficulties depict the evolutionary profile traced by the many studies investigating risk factors for difficult social integration [5-8].

However, some of these people are progressing well and undergoing a process of resilience despite persistent and disabling sequels. However, very few studies focused on the determinants factors of resilience of people with TBI MG, which is a major obstacle to the development of assessment and intervention strategies focused on the resilience of these persons. Unable be based their post-accident adaptation to their previous capacities, these individuals must guide and build their resilience processes using different factors from those clients for whom resilience has been documented (eg, children, victims natural disasters, psychiatric patients).

The purpose of this presentation is to explain the key determinants of the resilience of people with TBI MG that served like tags to develop a measurement instrument in the context of a doctoral project. This instrument will enable professionals working around the person with TBI MG to identify the presence of resilience factors, guiding the intervention, to measure the efficiency and prepare the moment of rehabilitation leaving. More than a measurement instrument, ERAP-TBI is an intervention tool oriented towards strengthening protective factors in the long term by establishing a partnership between the rehabilitation team and the person with TBI MG.

Keywords: Resilience, traumatic brain injury, scale, measurement, response

Problématique

Selon Gervais et Dubé (1999) [9], un traumatisme craniocérébral (TCC) représente une atteinte cérébrale causée par une force physique extérieure susceptible d'affecter l'état de conscience, les fonctions cognitives, les fonctions physiques, l'état émotionnel ou le comportement de la personne. Ces manifestations peuvent être temporaires ou permanentes amenant ainsi des séquelles pouvant affecter le fonctionnement de la personne à court ou à long terme.

L'ampleur des séquelles et leurs répercussions sur le fonctionnement de la personne varieront en fonction, notamment, du niveau de sévérité du TCC. En effet, alors que les séquelles du TCC léger se résorbent dans les semaines qui suivent l'accident, il en va autrement pour les personnes ayant subi un TCC de sévérité modérée ou grave (TCC MG). Ces personnes vivent plus fréquemment avec des séquelles permanentes et invalidantes et ce, à plusieurs niveaux. À titre d'exemples, des séquelles motrices (p. ex., hémiparésie, spasticité), sensorielles (p. ex., hyposthésie, hémianopsie) et d'autres problèmes connexes (p.ex., céphalées, étourdissements, fatigue) peuvent apparaître [2]. Au plan cognitif, les difficultés au plan des fonctions exécutives (p. ex., difficultés attentionnelles, faible endurance cognitive, problèmes mnésiques, rigidité, désinhibition) sont fréquentes [5-6;10]. Au plan psychologique, les symptômes dépressifs et anxieux sont les plus répandus. Les difficultés à réguler les émotions sont également relevées [11-12].

C'est ainsi que les personnes qui subissent un TCC MG doivent réapprendre à vivre avec des séquelles à long terme, qui dépassent le temps imparti au processus de réadaptation et l'accompagnement de la part d'une équipe multidisciplinaire. Compte tenu de la détresse vécue par les personnes TCC MG recensée dans les études

portant sur leur situation à long terme, il se pourrait que certains aspects soient négligés au détriment d'autres composantes durant la période de réadaptation physique.

D'autre part, le processus de résilience étant très peu documenté auprès de cette population, on peut estimer que les facteurs déterminants y étant associés peuvent être différents de ceux des personnes ayant vécu d'autres formes de situations déséquilibrantes considérant les pertes de capacités et les changements majeurs au plan de la réalisation des habitudes de vie. Ne pouvant reposer sa reconstruction identitaire sur des facteurs antérieurement connus et établis (p. ex., ses capacités, ses relations, ses rôles sociaux), il est probable que d'autres facteurs personnels et environnementaux soient déterminants dans le processus de résilience des personnes TCC MG. Ainsi, l'objectif de cette communication est de présenter les étapes de l'élaboration d'un instrument de mesure et d'intervention de la résilience des personnes TCC MG.

Méthodologie

Considérant les lacunes au plan de la documentation des facteurs favorisant la résilience des personnes TCC MG, la méthodologie repose sur trois phases distinctes : la phase exploratoire des facteurs de résilience des personnes TCC MG, l'élaboration de l'instrument de mesure et la validation par comités d'experts.

1.1 Participants et déroulement

La phase exploratoire repose sur la collecte de données sur les facteurs déterminants de la résilience des personnes TCC MG. Pour ce faire, une approche inductive a été utilisée : la Démarche réflexive d'analyse en partenariat (DRAP) [13]. Cette méthodologie basée sur la tenue de groupe de réflexion permet, à l'aide d'un logiciel informatisé, de colliger systématiquement les idées émises par les participants autour d'un thème et de les organiser selon différentes catégories sémantiques de façon à faciliter l'analyse du contenu. Après la rencontre de groupe, les participants doivent évaluer chaque idée selon son importance accordée dans la résilience des personnes TCC MG selon un continuum évaluatif de « 0 » à « 9 », où « 0 » signifie que, pour le participant, l'idée énoncée n'avait aucune importance dans la résilience des personnes TCC MG alors que « 9 » correspond à un élément incontournable dans la résilience des personnes TCC MG. Une analyse quantitative a permis de dégager les aspects dominants et d'illustrer les points convergents à partir des idées ayant obtenu une forte moyenne et un faible écart-type. Un total de 46 participants (personnes TCC MG, proches et professionnels) provenant de différentes régions du Québec ont participé à cette première étape de l'étude.

Par la suite, les énoncés de l'instrument de mesure ont été élaborés et organisés selon quatre dimensions pour ensuite être soumis à deux groupes d'experts ayant comme mandat d'effectuer l'évaluation relative de chacune des dimensions, d'évaluer la concordance entre les énoncés et leur dimension respective et d'administrer le questionnaire à une personne (sans TCC) et de commenter leur expérience. Des experts sur le concept de résilience, sur les traumatisés craniocérébraux ou sur l'élaboration d'instruments de mesure composaient ces comités.

Une révision de l'instrument a ensuite été effectuée en lien avec les suggestions et commentaires des membres des deux comités. Finalement, l'instrument de mesure a été administré à 71 participants TCC MG.

Résultats

Tout d'abord, le contenu des groupes de réflexion a permis d'organiser les idées énoncées en quatre dimensions. Le Tableau 1 présente les dimensions et leurs définitions respectives de même que des exemples d'idées énoncées par les participants.

Tableau 1 Définitions des dimensions et exemples d'idées associées

Définitions des dimensions	Exemples
Estime de soi Regard que la personne porte sur elle-même et sur ses capacités.	*«Il faut être persévérant et ne jamais baisser les bras devant les obstacles.»* *«La confiance en soi est importante.»* *«Le regard que la personne porte sur elle-même est déterminant.»*
Soutien Représentation que se fait la personne des facteurs environnementaux qui la soutiennent dans sa situation et qui l'encouragent dans son épanouissement.	*«Lorsque la famille comprend ce qu'on vit, ça aide parce qu'on ne se sent pas jugé.»*
Adaptation psychosociale Capacités d'adaptation et d'apprentissage malgré les épreuves et l'adversité.	*«Quand la personne est en mesure de changer ses comportements malgré la rigidité cognitive, cela lui permet d'apprendre de nouvelles façons de faire et de s'adapter.»*
Projection de soi Qualité du regard prospectif de la personne sur sa condition, associée à des projets et des objectifs à long terme.	*«Il faut s'assurer de garder un équilibre entre l'espoir et la reconnaissance des limites.»*

L'instrument de mesure créé, intitulé «*Échelle de résilience et d'adaptation psychosociale des personnes TCC MG*» *(ÉRAP-TCC)* comporte 40 énoncés, dont 10 énoncés par dimension. L'échelle de réponse est répartie en 4 points, limitant ainsi les réponses ambivalentes.

Chaque réponse est cotée selon un pointage variant entre -2 et +2. Une transformation des résultats bruts est effectuée en fonction de la valeur relative de chacune des dimensions (proposée par les experts), ce qui permet ainsi de nuancer le profil. En effet, puisque les dimensions s'organisent entre elles, certaines dimensions ont une valeur relative plus importante. L'estime de soi étant la base essentielle du processus de résilience, cette dimension possède le facteur de multiplication le plus élevé. Le soutien qui dépend de la qualité de l'estime de soi (la personne acceptera le soutien si elle reconnaît ses difficultés, mais également ses forces) est reliée à un facteur de multiplication plus faible que l'estime de soi, mais plus élevée que l'adaptation psychosociale et la projection de soi. Il en va de même pour les dimensions de l'adaptation psychosociale et la projection de soi. C'est ainsi que même si deux personnes obtiennent le même résultat brut, l'indice de chaque dimension et l'indice de résilience total varient, tout dépendant si la personne possède les facteurs préalables lui permettant de s'adapter et de se projeter dans l'avenir.

Les valeurs métriques des analyses inférentielles suggèrent un niveau de cohérence interne variant entre acceptable et élevé (alpha de Cronbach de 0,82 à 0,96).

Discussion

À la lumière des résultats obtenus, nous pouvons considérer l'instrument *ÉRAP-TCC* valide. En effet, la méthodologie de collecte de données de la DRAP assure une validation de contenu des facteurs de résilience relevés. De plus, les facteurs de résilience retenus sont ceux faisant consensus dans les groupes. Éliminant ainsi les «vécus uniques», les énoncés de l'instrument reposent sur les facteurs prédominants dans l'ensemble des groupes. D'autre part, l'évaluation des énoncés à l'intérieur de chaque dimension effectuée par le premier comité d'experts contribue également à assurer une validité interne de l'instrument.

L'instrument *ÉRAP-TCC* offre une structure multidimensionnelle unique qui permet de mieux comprendre le processus de résilience des personnes TCC MG. En fait, les dimensions proposées par l'*ÉRAP-TCC* reposent à la fois sur le contenu des groupes de réflexion, sur la recension des écrits effectuée et sur la validation des comités d'experts. Ainsi, il semble y avoir concordance entre l'instrument développé et le processus de résilience des personnes TCC MG. Toutefois, une validation externe sur un plus grand échantillon permettrait de vérifier les propriétés métriques de l'instrument et ses dimensions.

Un autre avantage de l'*ÉRAP-TCC* repose sur la transformation des données brutes en indices. Tout dépendant de l'importance relative de chacune des dimensions, le profil peut ainsi être nuancé en fonction de la réalité de chaque personne TCC MG à un moment particulier. La lecture des forces et des limites se trouve ainsi précisée, ce qui soutient la compréhension des professionnels du processus de résilience de la personne.

Cet instrument est cohérent avec les changements dans les paradigmes de l'intervention en réadaptation physique. Auparavant centrée sur le symptôme et sa disparition, le courant de la psychologie positive a aujourd'hui une influence majeure sur les interventions en réadaptation physique. L'instrument *ÉRAP-TCC* encourage ainsi l'établissement d'une relation partenariale entre la personne TCC MG et le professionnel, puisqu'un retour sur les résultats obtenus peut être fait auprès de la personne et de sa famille afin de limiter la prédominance des déficits dans la compréhension de la situation de la personne au détriment des forces et ressources de la personne. Discussions et échanges entre la personne TCC MG, sa famille et les professionnels permettront ainsi de mieux comprendre sa perception de la situation et d'intervenir sur les facteurs essentiels à son adaptation à long terme. De plus, soutenant une approche axée sur l'interdisciplinarité et l'écosystème, l'*ÉRAP-TCC* est le seul instrument de mesure de la résilience s'intéressant autant à la dimension environnementale et aux habitudes de vie des personnes TCC MG.

Toutefois, des précautions sont à prendre dans l'utilisation d'un instrument de mesure de la résilience. Il est essentiel d'éviter de considérer uniquement les résultats chiffrés pour tirer des conclusions qui seraient erronées et préjudiciables pour la personne. En effet, un indice élevé de résilience pourrait amener l'équipe ou les agents payeurs à ne pas fournir les ressources appropriées considérant qu'elle possède toutes les ressources nécessaires pour assurer sa résilience. À l'inverse, un faible résultat pourrait être interprété comme un «cas perdu» où il serait inutile de mettre en place les ressources nécessaires. C'est pourquoi cette échelle de résilience doit d'abord servir de moyens d'intervention afin de préparer la personne TCC MG à son congé, de cibler les forces comme piliers de l'intervention et d'orienter les cibles vers les difficultés. Afin d'éviter des dérapages éthiques considérables, une formation préalable des professionnels désirant utiliser cet instrument est essentielle et nécessaire. Un accompagnement personnalisé permettra également de mieux soutenir l'équipe de réadaptation physique dans l'utilisation de l'*ÉRAP-TCC* et ses résultats.

En conclusion, d'autres études complémentaires seront nécessaires afin de valider l'*ÉRAP-TCC* sur un plus grand échantillon. Des interventions spécifiques pourraient également être développées en fonction des profils obtenus. De cette façon, l'accompagnement des personnes TCC MG serait réellement orienté vers leur processus de résilience personnalisé.

Abstract

The goal of this multisite research, conducted with university students from France, Quebec, Romania, Algeria and Rwanda, was to explore relation between scores on a Risk factors scale and on the Wagnild and Young Resilience scale. The main result, except for Rwandan sample, confirms the existence of a negative relation (significant for the French, Quebec and Rumanian samples) between scores obtained at the two scales. Results also show between-countries differences concerning resilience scores and mean number of risk factors.

Keywords: Resilience, assessment, Resilience Scale, risk factors, multisite study

Researchers and practitioners working in the fields of clinical psychology, psychopathology and psychiatry took in the last decades a great interest in resilience and one major consequence was the development of many assessment tools [1]. The first instrument, the *Resilience Scale*, was published in 1993 by Wagnild and Young on the basis of the narratives of 24 women whose *level of social involvement* (as evidenced by active participation in a senior center) and levels of *morale* (mid-to-high) indicated they had a positive psychosocial adaptation, although they have lived "*a major life event"* [2, p. 167]. Prior to 1993 paper, *Resilience Scale* has been used in five studies including caregivers of spouses with Alzheimer's disease, graduate students, first-time mothers returning to work and residents in public housing [2]. The Wagnild and Young *Resilience Scale* has been used in many researches and has been translated and adapted into at least 36 languages spoken in Africa, Asia, Europe and South America [3]. In a review of instruments used to assess the resilience in adolescents, Ahern, Kiehl, Sole and Byers [4] argue that even if all instruments they considered (*Resilience Scale*, *Adolescent Resilience Scale*, *Connor-Davidson Resilience Scale*, *Resilience Scale for Adults*, *Baruth Protective Factors Inventory* and *Brief Resilient Coping Scale*) have limitations, the Wagnild and Young *Resilience Scale* appears to be the best instrument.

In their description of the process of elaboration of the Resilience scale, Wagnild and Young didn't mention which kind of *major life event* the 24 women lived. They indicated only in another paper [5] that these women had adjusted successfully "to a major loss" (p. 252). This is the reason why the present paper goals are:

- to check systematically risk factors the participants to this research were exposed to;
- to assess the participants levels of resilience;
- to correlate risk and resilience scores;
- to examine the influence of sociocultural and historical context on these correlations by realizing this research in five different countries (France, Quebec /Canada, Romania, Algeria and Rwanda).

Method

Sample

In each country, recruitment criteria were: (a) being student in the second or third year of university programs in psychology (P) or management-administration (M-A) and (b) being 18 to 30 years old. As a research conducted several years ago [6] highlighted the importance of the program the students attended, we decided to take this variable into account and have chosen psychology (a program that focuses on helping skills and understanding the psychological functioning) and management-administration (programs that focus on organizational skills, on performance). A total of 1,018 students from France, Quebec/ Canada, Romania, Algeria and Rwanda participated in this research (see *table 1*). There are more women (n = 612) than men (n = 406) and only in Rwanda the number of men (n=99) exceeds that of women (n=55). The total number of P-students (n = 561) is larger than that of M-A-students (n = 457). The average age is between 21 years and 2 months (Romania) and 24 years and 2 months (Rwanda).

Table 1 Sample characteristics

	France	**Québec**	**Romania**	**Algeria**	**Rwanda**
Sample size	370	162	209	123	154
Gender Male/Female	149/221	63/99	62/147	61/62	99/55
Program P/M-A*	237/133	99/63	93/116	61/62	71/83
Age Mean (years;month) SD Range (years;month)	21,55 (21;7) 1,62 18;5-29;10	22,83 (22;11) 2,11 19;9-29;7	21,18 (21;2) 1,08 19;6-29;6	22,28 (22;3) 1,72 19;3-29;4	24,14 (24;2) 1,94 21;1-29;7

Instruments

For all participants we collected demographic information (gender, age, level of education, program). Participants completed the 25 items of the Wagnild and Young *Resilience Scale* and the *Risk Factors Scale* [7], a 34 items inventory of major adversities encountered in life, such as parental separation, illness, bereavement, financial difficulties, etc. The data were processed using the statistical analysis software SPSS - X.

Results

The results for the *Risk Factors Scale* (see *table 2*) show that internal consistency estimated by Cronbach's alpha varies from excellent (Romania, .92) to relatively good in France (.76). Mean scores on this scale vary from 7.94 (in France) to 10.06 in Rwanda. The total scores range vary from 0 (theoretical minimum score) to 34 (theoretical maximum score). Statistical analyzes show that there are not differences in relation with gender. Apart from Rwanda, where P-students were exposed to significantly less risk factors, in all other countries they report significantly more risk factors.

Table 2 Risk factors scale scores

	France	**Québec**	**Romania**	**Algeria**	**Rwanda**
Risk Factors Scale					
Cronbach	.76	.81	.92	.64	.89
Mean	7,94	8,02	8,18	9,85	10,06
SD	4,37	4,48	4,79	3,54	5,78
Range	0-26	0-22	0-34	1-17	0-29
T-Tests	♂=♀ (n.s.) P > M-A (p=.001)	♀>♂ (n.s.) P > M-A (p<.001)	♀=♂ (n.s.) P > M-A (p<.001)	♀≤♂ (n.s.) P > M-A (p<.001)	♀=♂ (n.s.) M-A>P (p<.001)

* *P= Psychology, M-A= Management-Administration*

For a cross-country comparison, we considered the five most frequent risk factors (see *table 3*). We note that some factors appear to be more common in one country: "moving (house)" for French sample; "problems with physical appearance" and "relationship problems" for Quebec sample; "emotional difficulties, depression" for Algerian sample; "major financial difficulties in family", "learning difficulties", and "personal financial difficulties" for Rwandan sample. Other risk factors are common to two, three or even four countries:

- "death of a loved one" (in France, Romania, Algeria, and Rwanda);
- "difficult relations with parents" and "lack self-assurance" (in France, Quebec, and Romania);
- "hospitalization of a relative" (in Romania, Algeria, and Rwanda);
- "major stress related to exams" (in Quebec, Romania, and Algeria);
- "sibling birth" (in France, and Algeria).

Some of these differences are probably related to the socio-cultural and economic context. Thus, the fact that in France, families tend to live longer in the same place could explain why the move represent an important risk factor. Similarly, the fact that the availability of medical services is more difficult in Romania, Algeria or Rwanda may also explain the higher frequency of the risk factor "hospitalization of a relative".

Table 3 Most frequent risk factors

Rank	France	Québec	Romania	Algeria	Rwanda
1	Lack of self-assurance (58.9 %)	Major stress related to exams (59.9 %)	Major stress related to exams (66.5 %)	Major stress related to exams (83.7 %)	Major financial difficulties in family (72.1 %)
2	Sibling birth (56.5 %)	Lack of self-assurance (56.2 %)	Hospitalization of a relative (52.2 %)	Death of a loved one (70.7 %)	Learning difficulties (66.9 %)
3	Death of a loved one (48.9 %)	Difficult relations with parents (48.8 %)	Difficult relations with parents (49.8 %)	Sibling birth (68.3 %)	Death of a loved one (64.9 %)
4	Moving (48.6 %)	Problems with physical appearance (45.7 %)	Death of a loved one (49.3 %)	Emotional difficulties, depression (59.3 %)	Personal financial difficulties (63 %)
5	Difficult relations with parents (47.6 %)	Relationship problems (44.4 %)	Lack of self-assurance (47.4 %)	Hospitalization of a relative (57.7 %)	Hospitalization of a relative (51.3 %)

*S*cores on *Resilience scale* are presented in *table 4*. Cronbach's alphas vary: the best coefficient is obtained in Quebec (.91, comparable to that of the US original version of this scale) and the lowest are in Algeria and Rwanda (.70 and .73 respectively). The highest average resilience score is in Romania (139.99) followed by Algeria (136.56), Quebec (135.88), Rwanda (130.60) and France (122.81). It is interesting to note that dispersions are important in France and Quebec samples (from 55 to 161 and 173, the theoretical maximum being 175). Wagnild [8] defines low resilience as corresponding to a score below 121, average resilience ranging from 121 to 145 and moderately high or high resilience equal or higher to 146.

In French and Quebec samples, the men mean scores are significantly higher than women mean scores. If for Romanians students, the mean women score is significantly higher, in Algeria and Rwanda the mean women and men resilience scores are not different. Scores of M-A students from France, Quebec and Romania are significantly higher than those of P-students; for Algerian students, P-students have the highest scores.

Table 4 Resilience scales scores

	France	Québec	Romania	Algeria	Rwanda
Resilience Scale					
Cronbach	.85	.91	.86	.70	.73
Mean	122,81	135.88	139,99	136,57	130,60
SD	16,5	18.09	14,80	14,04	15,53
Range	55-167	55-173	96-169	89-161	88-164
T-Tests	♂>♀ (p=.02) M-A > P (p=.001)	♂>♀ (p=.016) M-A > P (p<.001)	♀>♂ (p=.01) M-A > P (p<.001)	♀≥♂ (n.s.) P> M-A (p<.001)	♂=♀ (n.s.) M-A > P (p=.08)

* *P= Psychology, M-A= Management-Administration*

Correlation coefficients between resilience and risk factors scores (see *table 5*) are negative and significant for France, Quebec and Romania. They are also negative but no significant for Algerian sample.

Table 5 Correlations between resilience and risk factors scores

	France	Québec	Romania	Algeria	Rwanda
Resilience and Risk factors correlation	-.161	-.167	-.309	-.107	.142
Significance	p=.003	p=.04	p<.001	n.s.	n.s. (tendency p=.08)

A particular problem is that for the Rwandan sample the correlation is positive and close to the threshold. This means that a person who has been exposed to a greatest number of risk factors is more resilient. This relationship could be explained by the presence of protective factors particularly effective. Further analyzes are needed to reach a clear answer.

Conclusion

The main result of this multi-site research is that with the exception of Rwanda – country where the mean score on *Risk Factors Scale* is highest – there is a negative relationship (significant for the France, Québec and Romanian samples) between scores on the *Risk Factors Scale* and scores on the Wagnild Young *Resilience Scale*. Results also show between-countries differences concerning resilience scores and mean number of risk factors.

Projective assessment of resilience

Jourdan-Ionescu C.

Psychology Department, Université du Québec à Trois-Rivières (CANADA)
colette.jourdan@uqtr.ca

Abstract:

Complex phenomenon, resilience is measured in various ways (Ionescu and Jourdan- Ionescu, 2011), mainly through self-administered questionnaires (*Resilience scale* Wagnild & Young, 1993; for example) to identify certain individual traits, indices of individual resilience. Presently, we consider resilience as a process taking place in an ecosystemic context, and the individual, family and environmental factors must be taken in to account when we assess the level of resilience. Social network scales and risk and protective factors scales can then be used. Few authors (Pamfil, De Tychey, Lighezzolo, Theis, Claudon, Diwo and Popa, 2007, for example) use projective techniques (*Rorschach*, *Tales test*, graphics tests) to explore resilience. We present here three projective methods we are working with: *Lifeline*, *Resilience Exercise*, *Fay Woman Drawing*. These instruments – and particularly the convergences of some common indices – allow a better understanding of the adversities faced by individual and the effective protective factors involved in the process. These instruments can give us a different picture of resilience.

Keywords: Resilience, Assessment, Projective methods, *Lifeline*, *Resilience Exercise*, *Fay Woman Drawing*

Resilience assessment and projective methods

Resilience is a complex phenomenon, a process involving person-environment interaction and protective factors moderating risk and adversity [1]. Resilience is measured in various ways [2], mainly through self-administered questionnaires to identify certain personality traits, indices of individual resilience (*Resilience Scale* [3], *Connor-Davidson Resilience Scale* [4], for example). But resilience must be understood as a process taking place in an ecosystemic context, so that the individual, family and environmental factors must be considered when assessing and understanding the level of resilience of a person. In this sense, it is important to assess risk and protective factors (individual, family and environmental ones, including social network).

If we want to better understand resilience as a process, it is important to explore how the person reacts to adverse situations, how the person integrates these experiences in his/her life and which protective factors are used. De Tychey and Lighezzolo research team uses projective techniques to explore resilience. Pamfil, De Tychey, Lighezzolo, Theis, Claudon, Diwo and Popa [5] and de Tychey, Lighezzolo-Alnot, Claudon, Garnier and Demogeot [6] illustrate the specific process of resilience in two institutionalized Romanian twin girls. Through the use of several projective tests (Royer *Story-Tales test*, *Rorschach*, *Draw-a-house*), they show that, besides the effect of torque [7], mentalizing capacity may allow a child to symbolize adversity encountered, to put it into words and send it to a third part (the development or resilience tutor) which may contain it. In another paper [8], the same team reports the development of two non-identical twins whose mother had a mental illness. Again, mentalizing (as assessed with projective *Tales test* and *Rorschach*) reveals differences in mental functioning that can explain (with different maternal investment) resilient functioning of one of the brothers. Lighezzolo, Marchal and Theis [9] use specific drawing of the "Person who has meant the most to you" to explore the importance of an identification model, the resilience tutor. This research team emphasizes the usefulness of projective methodology (interviews, projective thematic tests and drawings) "to obtain more detailed information about the mentalization mechanisms involved in generating resilience or vulnerability to a traumatic event" ([6], p. 63).

Obviously, the classic projective tests used by the research team of de Tychey and Lighezzolo are very important but I think that they can be completed by instruments that I present here, taking into account the ecosystemic approach. In this paper, we describe three projective methods that can be used with any person coming to a psychologist: *Lifeline*, *Resilience Exercise,* and *Fay Woman Drawing*.

Lifeline [10]

When we administer this test, the person has to draw and explain his/her lifeline. The subject is encouraged to draw a line of life beginning at birth (date placed on the extreme left of the sheet) and up to examination date (on the extreme right of the sheet) and then place on the line significant events of his/her life. The person has to register below the line events described as negative, and above, events considered positive. To become co-builder of the history of the person, the therapist could ask questions about each event (often a transition point from one chapter to another of the person's life; for example, "What do you remember for this particular event? ", "What is the significance of this moment of your life?") and its impact. Frequently used in art therapy, *Lifeline* also allows psychologist to start the first encounter with a person respecting the projective space. In fact, this test leaves more subjective space to the person than traditional anamnesis which aims to cover the entire history of the person. In virtually all cases, the history of life is holistic (in the sense that it considers all events), qualitative, and focuses on the experiences of the individual and his way of dealing with these events [11]. To integrate the events we live and their impact on our lives, we constantly reconsider our life to rebuild it. Some questions could complete what was not covered in *Lifeline:* if the person did not speak at all about his/her childhood, he/she can be asked about this topic at the end of the test. I want to emphasize that we used *Lifeline* to explore the experiences of parents of children with intellectual disabilities [12, 13] and the comprehension of their life by people with mental health problems [14, 15].

Strümpfer Resilience Exercise [16]

This test includes six sentences describing situations where the subject is confronted with adversity. The exercise is available in male and female forms. For example sentence, "Marion/Martin lost her/his only child, a 16-year old." Then the examiner should ask the following questions: "What is happening? What is the person doing? What is the person thinking and feeling? What does he/she want? What will happen? What will the outcome be? Looking back afterwards, what will the person think about what has happened? What will the experience mean to him/her?".

Fay Woman Drawing [17, 18]

The person has to write at the top of a white paper sheet (at psychologist's dictation or making a copy) the sentence "A lady is walking and it rains". Then, he/she is asked to draw a picture that represents what he/she wrote. Psychologists have to note the time taken to realize the drawing (time limit is 10 minutes) and the order in which the different parts of the drawing have been performed. When the drawing is finished, the person must write at the bottom of the sheet his/her first name and surname. Then, we ask questions to understand all that is presented in the drawing. The original quotation of Fay resembles *Draw a person* test (Goodenough test) with some specific elements to the situation added (lady walking in the rain). Quotation items linked to protective factors were also added.

In addition to these three projective tests, each person has to talk about his/her social network. Several versions of the social network grid exists (child, teenager, parent forms for children and for himself as a parent, adult form, person with an intellectual disability), enabling us to assess different needs of the person (somebody to listen at, concrete help, leisure).

Analysis of the information collected

In *Lifeline* analysis, we use a phenomenological methodology dedicated to descriptions of experience. It is an investigation of intersubjective reality [19]. The process involves: a) familiarization with each transcript and its content; b) comparison of ideas after reflections, categorization and articulation of the description categories; c) mapping the risk and protective factors. To take into account all the evidence from the *Lifeline*, psychologists must, in the first place, identify all events that allow (with the associated affects) to reconstruct the history of the person with the material he/she has spontaneously brought. Then, this can allow to highlight all risk and protective factors (individual, family and environmental) of the person and if he/she is aware or recognize to have support (as a mentor or resilience tutor). Finally, we must look for signs of resilience (colors, event changing from negative to positive, etc.).

To understand results at the Strümpfer *Resilience Exercise*, we must quote procedures used by the person during the test: resilience as a goal, resilient behavior, capacity to understand, resources of that person, resources under the control of others, meaning, hope to succeed, seeking for social support, positive feelings, personal improved resources, improved interpersonal coping.

In addition to classic quotation elements for graphic tests, *Fay Woman Drawing* involves quotation of some other elements: the ability to represent a person (adult/female), moving (walking), and struggling with a

negative element of the environment (rain). The presence of protective factors for the person, as well as complementary elements (as a rainbow, colors, other living beings, etc.) captures the dynamic balance between adversity (rainfall, for example) and protective factors (raincoat, umbrella).

The different information collected by the three instruments presented (*Lifeline*, Strümpfer *Resilience Exercise* and *Fay Woman Drawing*), in addition to information pertaining to the *Resilience scale* and the *Social network Grid,* are then inserted into a synthesis table to search the convergence of indices.

The ability to name experienced adverse events, the ability to associate emotions and changes in their lives, as well as the resources that are essential (social network, resilience tutor, family support, etc.) are usually present in individuals who have manifested resilience in their lives. For example, overcoming depressive episodes based on good relationships with a brother and with a person outside the family (resilience tutor), and investing her schooling allowed a young woman to overcome the death of her mother and abuse by her father when she was a child. In *Lifeline* test, this young woman puts all difficult events and adds a lot of positive events like the encounter with her first lover and, the spouse with whom she plans to buy a house at the end of her studies. The items of *Resilience Exercise* position this woman as one that can be supported by others, that gives meaning to life events and can solve problems positively. In *Fay Woman Drawing*, she draws a woman who blithely walks in the rain, who walks in the street where there are many puddles of water. She wears a raincoat, and boots, have an umbrella, and goes to the right where we see a clear sky and a rainbow. She crosses passers-by who protect themselves from the rain as they can (a man holds a newspaper over his head and, a woman has a hood).

With reference to the concept of ecosystemic resilience, the information presented here provides individual, family and environmental elements to understand resilience indices and dynamic balance between risk and protective factors and resilience.

Collected information provides key elements to understand resilience process. Resilience built on individual characteristics, family interactions and the environmental support is the natural resilience. If we want to enhance resilience, we can assist people with the support of professionals who will help them to better utilize available resources and to project themselves as resilient. Building resilience may be accompanied by professionals that support the development of individual, family and environmental protective factors. Therefore, this type or resilience can be called «assisted resilience» [20, 21]. It is a midwifery type intervention, based on the strengths (to be discovered by the person with the accompaniment of the professional) and on prevention.

Humor and mental health in the elderly

Antonovici L., Soponaru C., Dîrțu M.-C.

[1]*Alexandru Ioan Cuza University (ROMANIA)*
lorena.antonovici@yahoo.fr, camellia.soponaru@psih.uaic.ro, cdirtu@psih.uaic.ro

Abstract

The authors follow two main directions of study: 1. an exploration of sense of *humor* and *mental health* in *elders* 2. implementation of an intervention to highlight the role of *humor* as a factor for maintaining *mental health* in the *elderly*. In the first stage (n = 64) two instruments were used: the Humor Styles Questionnaire [1] which identifies four general styles of *humor* and the SF-36 [2] which measures HRQL (health related quality of life). Significant results were found only on two dimensions of *mental health* (social functioning; mental health per se) which were significantly associated with positive *humor* ($p < .050$). On the other hand, *physical health* globally correlated significantly with positive *humor* ($r = 0,39$; $p < .010$) and in particular on two of the four dimensions (physical functioning; bodily pain). In the second stage we studied the impact of *humor* intervention on subjective mental health of elderly. Level of *mental health* did not change significantly as a result of humor intervention based on a model by Walter et al. [3]. The results suggest that *humor* can be effective for mental functioning but rather could be a complementary ressource for interventions, with palliative role. From this point of view *physical health* may play a major role than *mental health*.

Keywords: Humor, mental health, physical health, elderly, quality of life

Nowadays, clinical research seems to focus mainly on mental illness, with less consideration for the role of mental health. We can notice how the inability to mourn and overcome loss plays a central role in the health equation whereas the inability to use humor or laughing does not raise similar interest.

In our lives, as on a theatre stage, we experience a constant struggle between comedy and tragedy. The role of humor becomes important in daily areas of life, as in social gatherings, choosing a life partner. However, there is still reluctance on the inclusion of humor among the areas of scientific interest. There are two major objections that can be found in scientific literature: 1. Humor is not a serious subject – it's a waste of time 2. Humor is not a scientific subject – there are no appropiate methods to investigate relevant aspects of humor [4].

What is humor?

Krichtafovitch [5] considers humor to be fundamental to human activity, having a well-defined biological component. Humor is an innate phenomenon that plays a key-role in the survival of species – though it is not the most complex of emotions, but more of a primary one [5].

Humor was generally operationalized as a multidimensional construct. From a psychological perspective, the humor process has four essential components [6]: a social context, a cognitive-perceptual process, an emotional response, the vocal-behavioral expression of laughter. In medicine there is evidence showing a range of therapeutic benefits of laughter [7].

Previous research

There is little research in the field of humor and mental health and the results are often controversial. In a study of Houston, Mckee, Carroll & Marsh [8] the elders engaged in humorous activities showed levels of anxiety and depression significantly lower compared with the elders who were not involved in humorous activities. The authors do not exclude, however, that the results might be due to the novelty of the task rather than using humor.

Another study in elders that investigated the association between mental health and several variables – humor, spirituality, self-efficacy and social support – has shown that coping humor and self-efficacy were determined for mental health [9]. Of all the variables analyzed, humor as a coping mechanism, significantly correlated with social support, self-efficacy, depression and anxiety [9].

On the other hand, following a longitudinal analysis in patients suffering from sclerosis, the results showed that there is indeed an association between humor coping and chronic illness, but significantly lower – so there is not sufficient evidence to include humor among therapeutic methods of intervention [10]. As limitations of the study, in the longitudinal analysis from one measurement to another (T1 vs T2) some subjects have been lost and subjects in T2 disease characteristics were less severe than those of T1.

Kuiper & McHale [11] introduce the self-evaluative component in humor and well-being equation. Thus, greater recognition of positive self-evaluative standards causes a higher use of affiliative humor which in turn causes higher levels of social self-esteem and lower levels pf depression [11]. Also, a high negative acknowledgement of self-evaluative standards leads to higher use of self-defeating humor that causes lower levels of self-esteem and higher levels of depression [11].

Bell, Coulston & Malhi [12] draw a parallel between mentally healthy individuals and those suffering from schizophrenia by reference to the theory of mind that occurs in humor appreciation. The theory of mind can be described as the ability to attribute thoughts and feelings to themselves and finding satisfactorily to make same inferences about others . For example, delusions of persecution and reference that occur in mental illness can lead to a misunderstanding about the behavior and intentions of others. Negative symptoms of schizophrenia can also be considered as a loss of the ability to establish appropriate social inferences. Thus, as a result of mental illness, the activation of the theory of mind can become difficult and the subject has trouble understanding jokes, humor.

A study that examined the effects of humor styles in psychopathology [13] shows that: 1. a high self-enhancing humor style decreases anxiety-related symptoms while high values of self-defeating humor style increases anxiety-related symptoms 2. whether affiliative and self-enhancing humor styles have higher values a decrease in symptoms is observed, related to mood disorders and whether self-defeating humor style is high symptoms related to mood disorders are increasing 3. high values of self-enhancing humor style causes a decrease in symptoms of psychotic disorders and with increased values of self-defeating humor style, symptoms of psychotic disorders increase.

Humor and mental health in elders

Previous research [1] have shown that people tend to use humor differently. Considering the impact and effects humor has on interlocutors, it can act in a negative or in a positive way, therefor it is called negative humor or positive humor. Studies have shown that only the latter is beneficial for mental health [13]. Declines in health is common in older adults, so that medical care is primary. Besides medication, psychotherapeutic interventions – such as humor therapy, could improve the health of the individual [3]. The research in this paper aims to highlight the link between the humor and mental health in the eldery in Romania.

1.1 An exploration of the relation between sense of humor and mental health in elders

In the medical field, one use frequently the term of "health-related quality of life" (HRQL) instead of "quality of life" as individual term. Usually, there are three general dimensions of QOL: physical (physiological), psychological and social dimensions [14].

In the physical dimension, one refers to the functioning of organs, mobility and ability to communicate [14]. Psychological dimension is operationalized as psychological well-being, satisfaction and fear vs. freedom to feel fear [14]. The social dimension takes into account the frequency of social contacts, exercise of social roles, employment situation, quality of family relationships and financial status [14]. This study is correlational and aims at revealing a possible association between humor and mental health in the elderly in our country.

1.1.1 Research hypotheses

There is an association between humor and mental health in older persons. Thus, we expect:

a. elderly individuals that have a positive sense of humor to appreciate their mental health status as being good;
b. elderly individuals that have a negative sense of humor to appreciate their mental health status as bad.

1.1.2 Investigated variables and their operationalization

The affiliative humor variable focuses on the humor that enhances relationships with others, interpersonal cohesiveness and attraction [1]. The self-enhancing humor - requires a humorous outlook on life. Aggressive humor is the tendency to use humor without regard for its potential impact on others [1] and includes using sarcasm, teasing. The self-defeating humor is a style of humor that attempts to amuse others by doing or saying funny things to the detriment of himself [1].

1.1.3 Research Instruments

Humor Styles Questionnaire [1] identifies four general types of humor relatively independent of which two positives types associated with psychological well-being (affiliative humor and self-enhancing humor) and two negative types, potentially harmful for wellbeing (aggressive humor and self-defeating humor). Rating was made on a Likert scale ranges from 1 to 4.

The SF-36 [2] is a measurement instrument of QOL (subjective quality of life). The SF-36 instrument is a generic instrument for measuring health status, comprising 36 items and 2 generic concepts - physical health concepts: physical functioning (physical activity), role-physical (limited role), bodily pain, general health (healthy / sick) and mental health: social functioning, vitality (energy), role-emotional (role limitation), mental health (altered mental status)

1.1.4 Participants

The participants were 64 elders (37 women and 27 men) from a care unit (institutionalised) and non-institutionalised, aged between 58 and 90 years with a mean age of 74 years.

1.1.5 Method

Subjects were administered two main questionnaires: humor styles questionnaire [1] and the SF-36 [2]. We aimed to correlate the results of the two scales.

1.1.6 Results

The analysis results (Table 1), shows that most responses of subjects and having the highest significance were oriented to the physical health when it was related to humor. Regarding mental health, the analysis shows that social functioning and mental health are significantly associated with humor. As for physical health in relation to humor, physical functioning and bodily pain play a major role. However, modest associations are obtained.

Tabel 1. Summary of Intercorrelations between Health and Humor

Scale	Humor Positive	Affiliative	Self-enhancing
Mental Health			
Social Functioning	.31		.30
Mental Health (per se)	.28		
Physical Health	.39*	.26	.40
Physical Functioning	.37*		.43*
Bodily Pain	.43*	.33*	.40*
QOL	.31		.32

*$p < .01$.

The research hypothesis confirms that positive humour is associated significantly with mental health in older adults only on certain dimensions of mental health. The same cannot be said about negative humour, which is not associated significantly with any dimension of mental health.

1.2 The role of humour as a factor of maintaining mental health over time

1.2.1 Method

In order to assess the role of humour as a factor of maintaining mental health over time, we have conducted a humour intervention among older adults. The intervention comprised weekly group meetings carried out for two months and it was elaborated starting from a model of Walter et al.[3]. They used humour by involving especially free association and positive evocation of the subject's biography. For our approach, we have also taken into account the various theories on humour, the theoretical perspectives on which they are grounded and that we have already mentioned.

We have measured the response to humour with the help of an observation grid. At the beginning and at the end of the observation, we have measured the mental health of individuals with the help of the above-

mentioned SF-36 Questionnaire. We have also introduced in the study a group that had been part of another intervention and a control sample, for a better insight into the humor intervention.

1.2.2 Research purpose

We aimed to follow the long-term effects of humour, in order to highlight the efficacy of a humour intervention.

1.2.3 The research hypothesis

The humor intervention will improve the individuals' mental health.

1.2.4 Variables

There are dependent variables: mental health and independent variables: positive humour – the humor intervention;

1.2.5 Instruments used

SF-36 Questionnaire (detailed in the first part of the research).

The observation grid concerned three levels: cognitive (understanding the humorous message), affective (resonation and affective involvement) and behavioural (smiling, giggles, laughter). In addition, the subjects had to assess to what degree they perceived humour in their activities, on a Likert scale from 1 to 10.

1.2.6 Participants

The intervention involved six older adults within a care facility, who have enthusiastically accepted our proposal from the beginning. The older adults (with an average age of 71) had various conditions: spondylosis, pulmonary emphysema, cardiopathy, kidney diseases, etc., as well as mental diseases (two of them suffered from depression).

The second sample also comprised subjects included in a care facility, but the centre was a different one. In this centre, the interventions comprised activities such as the following: knitting, painting, chess - activities within thematic circles.

The control sample comprised older adults from the first facility, who had not participated to a previous humor intervention. They have a rather monotonous daily schedule.

1.2.7 Intervention

The intervention – that included six older adults – was carried out for two months and it consisted of eight meetings.

- Intervention purpose: exploring the impact of humour on the self-perceived mental health of older adults in care facilities.
- Intervention objectives:
    - ensuring a positive environment, enhancing socialization and group interrelations;
    - the use of spontaneous positive humour;
    - the positive change in mood after using humour;
    - the improvement of mental health.

    Intervention progress: the intervention took place within eight sessions.

1.2.8 Results

As a result of humor intervention, perceived mental health in elderly has not substantially changed. Humor seems not to have contributed in relation to the mental health of the elderly. Elderly people who have gone through another intervention (knitting, painting, playing chess - activities conducted within thematic circles) and those who were part of the control group, obtained insignifiant results from a measurement to another (before and post intervention).

Comparison between the three elderly groups also revealed insignificant differences in the mental health during time 1 (T1) and time 2 (T2).

Conclusions and Discussions

This research aims to explore an area that today is still little studied in scientific literature compared to other fields, namely the humor and mental health. The results of our research have come to cover this area showing that there is not a significant elevated relationship between humor and mental health and therefore it is possibly that humor acts mainly as a complementary resource intervention.

In mental health, an important component in relation to humor could be social functioning: mental health in terms of social openness (social relationships with other groups of people: relatives, friends, neighbors etc.) seems to be associated with positive humor. In this case, self-enhancing humor seems to work most effectively - which suggests that first a general philosophy of life with humorous meanings may have beneficial effects on individual health.

A previous study of Nygren et al. [15] who also used to measure mental health the SF-36 instrument, indicates that perceived mental health in the oldest old individuals was associated with resilience, sense of coherence, purpose in life and being in relationship with the spiritual dimension [15]. These results were obtained only for women and not for men.

A factor of interest in the association between mental health of the elderly and humor seems to be the extent of their physical health. In old age, physical health is poor, so that it may mediate the relationship between humor and mental health more than other age groups.

Although we tried to find links between humor and physical health on many levels of physical health: immunity, tolerance to pain, heart rate, symptoms of disease, longevity - a review of several research leads Martin [16] to considering that the association between humor and physical health seems to be rather doubtful. Other authors [17] also suggest that positive humor seems to have more resonance in the physical health than negative humor that seems to be in a less strong association with physical health.

These aspects raise issues on the importance of health humor styles for health. Other factors seem to have greater importance in this relation. Humor and humor styles efficiency as singular factors in relation to health, it is an assumption that should be seen with reluctance. A study by Cann, Stilwell & Taku [18] draws attention to mediators that may arise between health and humor. The authors indicate that people who have high stable levels of optimism, hope and happiness, along with a good sense of humor, tend to perceive life as less stressful and therefor to report more positive levels of physical and mental health.

On the other hand, our study was not conducted over a sufficient period of time so as to obtain satisfactory results. We might obtain even better results if we go one step further and actually replace the intervention with a more complete humour therapy. We won't neglect the numerous variables that can occur during our research: the significant differences in medication between subjects, the different way the subjects interact with the nursing staff etc. Anyway, we tried to homogenize as much as posible the groups of subjects when it came to diagnosis and psychosocial data.

The generalization of these results is limited as a consequence of the low intensity of humor intervention and the small sample size. Future studies, including a larger group of subjects and implementing an intervention / therapy more complex and for a longer period of time, may provide better insight in humor research and mental health issues.

This research can be considered a minor step in trying to understand the contribution of humor to mental health. In our research we started from the premise that there are psychological benefits in addressing these areas. The relation between humor and mental health still has remaining undiscovered facets. This area has not fully developed its potential in terms of defining this relation in order to improve our mental life. The constructive relation between humor and mental health but also physical health role and the need to optimize the QOL, are current concerns of specialized studies in psychology today, minimizing these issues can lead to ignoring important factors in the reconstruction and redefinition of mental health services.

Abstract

Understanding the emotional management process on long term bases has received great interest in theoretical and empirical psychological research. The theoretical background of this research assumes that motivational persistence is a relatively stable characteristic of the conative system [1] and that the dynamic emotional process often impede the efficient management of daily personal experiences [2]. Study aims to understand the dynamics of emotional process by: a) identifying the role of motivational persistence and emotional management in personal changes, b) identifying internal and situational factors influencing the dynamics of affective process. Based on existing literature, we presumed that motivational persistence could interfere with negative emotional experiences and the dynamic of emotional process. We analyzed the changes of emotional process variables (intensity, overwhelming, dysfunctional thinking /beliefs, justifications, control and management) and their relationships with motivational persistence. Quantified data obtained on a sample of 239 subjects (convenience sampling), who registered for 40 weeks their negative emotions were used. The results show that motivational persistence had a general low effect on emotional dynamic process and its influence may increase if participants show a high level of control and management of emotions.

Keywords: *motivation, emotional management, process, motivational persistence.*

General approach to the long-term negative emotional management

This study focuses on the dynamic of emotions involved in the individual well-being changes and taking into account one of the recently presumed stable characteristic of the conative system – motivational persistence. From the perspective of situational factors and dispositional ones, many peoples have difficulties in experiencing well-being, due to personal emotional strategies and cognitive interpretations of different situations. More precisely, we can notice that many individuals are aware of their negative emotional difficulties but they fail to use an appropriate emotional strategy in order to experience higher levels of changes in well-being. The starting idea was that a motivational approach can lead to overcoming negative experiences, and thus the individual can engage in pursuing a personal goal that leads to healthy being.

Authors state that there is a great interest in „affective phenomena" [2] especially for their involvement in relationships, social interaction and group organization, but there is little information on when and for whom the content of emotional process can bring change in the individual perceived well-being.

Referring to the pursuing of a personal goal, Sheldon and Elliot [3] consider that in order to attain a goal and to get an adjusted level of change in well-being, there are some requirements that need to be taken into consideration: a) localization of the goal on an internalization continuum, thus understanding if that goal represents the global self of the individual, b) the capacity to actively bring sustained effort in the achievement of the goal, c) to satisfy ones psychological needs: autonomy, competence and relatedness in order to experience adjusted level of well-being.

The extended research of the self-determination theory is also known for its practical use especially because it involves different aspects of the emotional dynamics and its relationship with well-being, both in terms of quantitative and qualitative perspectives. For example, authors show in their studies that there is a significant association between well-being and emotional willingness to rely on the support of others although it involves a negative aspect, the one of emotional dependency [4] and suggests understanding the role of „work motivation" on psychological health and in organizational settings [5]. Moreover, recent research also pays attention to the „darker side" of human existence, when psychological need are not fulfilled, because „it can lead to defensive or self-protective accommodations (e.g. the development of controlling regulatory styles, compensatory motives or need substitutes and rigid behaviour patterns)" [6].

Psychotherapists mostly use a cognitive perspective to define and approach psychological problems, Dryden and Branch [7] considering that when it comes to negative emotions, we can distinguish between healthy and unhealthy ones, meaning that in certain situations (e.g. death of a relative) it is healthy to feel sadness, although this is a negative emotion. Considering the impact that negative emotions could have on individual attitudes and behavioral dominant tendencies, the authors draw an extended diagram with 17 types of negative emotions: anxiety, concern, depression, sadness, unhealthy anger, healthy anger, guilt, remorse, shame, disappointment, hurt, sorrow, unhealthy jealousy, healthy jealousy, unhealthy envy, healthy envy. The classic cognitive approach in dealing with negative emotional difficulties uses the ABC model in order to define and restructure the individual: identifying the situation, the irrational beliefs and, finally, the consequences.

With regard to emotion regulation strategies, Gross and Thompson [8] describes them as a dynamic process, one that allows a person to analyse its actions by taking into account the level of control, the manner in that they experience emotions and how they express it. In early research, health and illness were considered to be the factors that differentiate between people that experience positive and negative emotions. Currently, studies are focused on the development and testing of models that consider emotions as determinants (predictors) of functionality [9].

Considering the large amount of research that emphasizes the importance of understanding the links between the affective processes and the individual changes, we think that a programme of the long-term management of the negative emotions can lead us to clarify three directions of study: to analyse the intensity and direction of emotional regulatory strategies, to investigate whether they reduce the differences accumulated over time in relation to the wellbeing, and to determine whether they are antagonists (i.e., if were associated with a relevant psychological factor, the emotional strategies could have a similar main effect on the differences of wellbeing, accumulated over time, but in the opposite direction).

Emotions, motivational persistence and personality

Motivational persistence is considered to be a stable characteristic of the conative system, the predisposition of a person to motivationally persist with effort in order to attain a personal goal, finding personal resources to overcome the encountered obstacles along the way [10]. Research in this area consist of the study of specific concepts such as commitment (grit), concepts that are associated with personality characteristics involving stability, i.e. the pursuit of a long-term goal and involves a specific change in the overall life (eg performance, wellbeing or perceived success [11], [12], [13]. Moreover, current studies are focused on building emotions and cultivating positive emotions, because on long term they can be used as a personal shield and can stimulate a person's ability to adapt quickly to critical incidents or intense stressful events, that can lead quite naturally to finding personal resources – resilience [14], [15], [16].

Regarding the role of emotions in personality dynamics, the authors [17] sets out a number of controversial issues, among which: a) the role of emotions in people's lives - whether they structure human behavior or, conversely, are an impediment to human behavior, b) whether personality influences emotions directly, or through temperament, which would mean that emotions could be considered a predictive factor for temperament, c) the distinction between "trait" and "state", meaning that emotions are most involved in explaining dispositional or mood changes and d) the relationship between the linguistic dimension, on the one hand, where prevail terms denoting negative emotions likely to reflect the intensity with which people experience them, and emotions, on the other hand, that seem like an extension of the words, being intensified by words.

The theoretical framework of self-determination provides an integrative view of the role of motivational dimensions of personality dynamics through various facets, such as: performance indices and the effects of rewards in personality development [18] positive and responsible thinking promoted by predictive models of functionality [19] and promoting personal growth through the internalisation process [20].

Considering the general tendency to promote self-control, which leads to success and self-awareness, we wonder what are the discrepancies between actions in real situations and desired state and especially the influence of the desired condition on people's lives. We propose a different approach, one that understands the individual changes in the context of negative emotional experiences and especially the well-being changes under the impact of motivational persistence and dynamics of emotional experiences.

Method

1.1 Research problem

Based on theoretical framework regarding emotional dynamics and motivational persistence, we propose the use of an intervention program for managing negative emotions through personal diary method, in order to understand the links between personality characteristics, dynamics of emotional life and changes

recorded in perceived wellbeing. For that purpose we have developed an experimental design with repeated measurements, by filling weekly in an online form (personal diary). The main purpose was to test a model of moderation, ie: a) understanding the role of motivational persistence in the recorded changes of the perceived wellbeing, b) identification of some emotion regulation strategies that impact the strength of the association between motivational persistence and perceived wellbeing.

1.2 Main research hypotheses

1. Motivational persistence shows a general low effect on perceived well-being
2. There is a moderator effect of emotional dynamics strategies in the relationship between the motivational persistence and the perceived well-being. Emotional control and management amplifies the effect in the same direction as motivational persistence.

1.3 Experimental design

Participants (N=239) were followed over 40 weeks through a weekly online diary-based journal in order to understand their negative emotions and associated thoughts, that interferes with daily activities and functionality. An initial assessment of the level of well-being, motivation and persistence strategies used was made, and a final assessment of emotional well-being.

The use of experimental repeated measures with the same subjects allowed us to monitor the change in the perceived well-being and to statistically determine if personality characteristics and the use of experimental intervention could impact the observed dispositional difference (positive affect, negative affect and satisfaction with life). The disadvantage of the method is the risk that the boring to be installed at some of the participants during the 40 weeks. Also, some participants offered incomplete information, which made it difficult to analyse how participants have evolved over time.

1.3.1 Measures

The initial and final assessments were held in an online form and includes the following tools: Emotion Regulation Strategies (DERS), emotional control and management assessed through diary-based intervention, Positive and Negative Affectivity Scale (PANAS) and Life Satisfaction Scale. During these 40 weeks of the program, an electronic, online form was used to assess emotional dynamics. The overall measurements were used to assess the emotional dynamics: intensity, overwhelming, dysfunctional thinking /beliefs, justifications, control and emotional management.

The PMS [21] is a 24-item scale that measures motivational persistence, understood as the predisposition of a person to motivationally persist with effort in order to achieve a selected goal, finding the personal resources to overcome the obstacles, fatigue, stress and others distractors. The use of a five point Likert scale (from „*very low degree" to "very high degree")* provides insight for three key factors: „long term purposes pursuing" (LTPP), „current purposes pursuing" (CPP) and „recurrence of unattained purposes" (RUP). The internal consistency of the scales on a Romanian representative sample (N=1,636) calculated for the equivalence of 15 to 24 item is as follows: for LTTP the consistency varies from .807 to .777, for CPP varies between .742 to .777 and for RUP varies between .736 for a 7-item factor and .759 alpha consistency coefficient for a 6-item solution.

The *Emotion Regulation Strategies* (DERS) is a scale with 36 items grouped into six factors: emotional clarity, emotional awareness, difficulties in achieving a goal, impulse control difficulties, non-acceptance of emotional reactions, and limited access to emotion regulation strategies. Calculated internal consistency proved to be very high (.93) [22].

The 20-item *Positive and Negative Affectivity Scale* (PANAS) comprises two scales available for both positive and negative affects and are measured from 1 (very little extent) to 5 (very much) and shows good internal consistency, ranging from .86 to .90 for the positive affect scale and from .84 to .87 for the negative affect scale [23]. The instrument was chosen because of its international use, its fidelity and its validity [24] and, the most important reason, because can be used for a chosen period of time, depending on the chosen design or practical psychological utility.

Satisfaction with Life Scale [25] is a short 5-item scale that assesses global cognitive judgement about satisfaction with one`s life. In the present study we used this scale to finally compute a total score of well-being.

The diary-based online journal, built for this study, is semi-structured and mixes open questions, choice limited responses and general psychological measurements of the emotional dynamics (intensity, overwhelming, dysfunctional thinking /beliefs, justifications, control and emotional management).

Results and discussion

In the statistical analysis we used bivariate correlation to describe the effect of motivational persistence upon changes in well-being and hierarchical multiple regression analyses to determine predictors presumed interaction. Examining moderating effects involved three steps, as recommended by Frazier, Tix, and Baron [26]: a) the interpretation of the effect of the predictors and moderating variable, b) determining the significance of the moderator effect, and c) graphical layout of moderating effects.

Correlation analysis shows that the basic assumption was confirmed, meaning that motivational persistence and wellbeing are weak but significant associated: r (112) = - .269, p <.01. We expected that participants who record high scores on motivational persistence, will record differences in the wellbeing too, but the results show that the subjects with high motivational persistence scores have been small changes in the well-being. Then we calculated the proportion of variance to obtain a more accurate picture of the examined sample ($r^2 = 0.072$), and we found out that 7.2% of cases have significant results.

The results confirmed the our uni-directional hypothesis, but have brought to the fore a number of observations that can direct research towards new directions: a) the small significant changes recorded in the well-being could be the result of the intervention based on personal journal, so in the the future could be used an analysis of variance with repeated measurements in order to clarify whether there is a real effect of the intervention; b) psychological characteristics of personality could intervene in the relationship between motivational persistence and well-being. Thus, an analysis on a sample of equivalent groups may be used as a framework for the study.

The second main hypothesis assumes that motivational persistence, in combination with different aspects of emotional dynamics, could have an impact on changes of the wellbeing. To examine this fact, moderation models were tested, taking into account the following variables: emotional control, emotional management, emotional clarity and emotional awareness. Thus, we analyzed separately the interaction between motivational persistence and each variable, considering the presumed moderators and we called them as follows: Moderator1 (interaction between motivational persistence and emotional control), Moderator2 (motivational persistence and emotional management) Moderator3 (motivational persistence and emotional clarity) Moderators4 (motivational persistence and emotional awareness). The data indicate that emotional management and emotional control variables recorded during the 40 weeks through personal diary, did not contribute significantly to the combination of motivational persistence and changes in well-being. Emotional awareness has not contributed significantly to the relationship between motivational persistence and the differences in wellbeing. Further, the data shows that only "emotional clarity" significantly moderates the relationship between motivational persistence and changes in well-being. The value of R^2 for the interaction of the model is .087, statistically significant [F (1,108) = 0.48; p=0.001] for the differences recorded by participants in the well-being (Table 2).

Table 2

Beta and standardized Beta coefficients of the valid moderating model

Dependent variable: changes in well-being

	Unstandardized coefficients		Standardized coefficients		
	B	St.error	Beta	t	Sig.
(Constant)	5.575	2.322		-2.401	0.018
Motivational Persistence	-.435	.188	.217	-2.388	0.019
Emotional Clarity	-.362	.394	.088	-.920	0.360
Moderator3	.879	.263	.323	3.340	0.001

We concluded that there is a moderating effect of emotional clarity variable and that this occurs in the relationship between motivational persistence and well-being. Finally, we were interested in how this effect manifests itself so we looked at the lower and upper zone of the emotional clarity variable. Correlation analyzes and the scatter-plot graphic between the low (*r (41) = - .501, p = .001)* and high scores *(r (55) = - .085, p = .0539)* of the emotional clarity led us to contradictory results in that the association between motivational persistence and changes in emotional wellbeing is even smaller when recorded high scores in terms of emotional clarity.

Considering the fact that outcomes are descriptive in nature and that they provide only a general picture of how they can enhance the value of stable personal characteristics in achieving significant changes in the well, we suggest the following: consideration of some personality traits because they can become a reference point in understanding the direction and intensity of emotional regulation strategies impact, shortening the journal completion and introduction of ratings on the well-being inside thereof.

We are also aware of the fact that the hierarchical multiple regression method has low power to detect a statistically significant moderating effect and that the results are affected by sample size and the gender ratio (16% male and 84% female in the study sample).

We can easily see that there are differences between the practices recommended by scientific studies and those recommended by practitioners; whereas the latter is experiencing negative emotional problems, the researchers suggest that people should focus their efforts in daily experience situations that cause positive emotions. Although there are studies that support behaviors that are based on personal perseverance in building a natural personal shield, there are still unknown limits that can lead to rigid behavioral patterns and even pathological difficulties.

One of the particularities of this study is an effort focused on managing negative emotions; but our analysis did not take into account the distinction between healthy negative emotions and unhealthy negative emotions. Although we expected that emotional control strategies have an impact on the intensity recorded in the interaction between the well-being and motivational persistence, we need to better control the design and the recording of the responses of participants, and suggest future construction of objective measures for interpretation of qualitative data.

Secondary traumatic stress, dysfunctional beliefs and the moderator effect of compassion satisfaction

Crumpei I.

"Alexandru Ioan Cuza" University, Iasi, Romania
irina.crumpei@psih.uaic.ro

Abstract

Helping others in their time of need can be rewarding and stressful at the same time. Medical staff caring for their patients might feel compassion satisfaction, the pleasure derived from helping others in need. However, frequent exposure to human suffering makes them vulnerable to secondary traumatic stress. Dysfunctional beliefs are known to predict posttraumatic stress symptoms.

The purpose of the present study was to investigate the relationship between secondary traumatic stress, irrational beliefs and compassion satisfaction. 63 physicians and 69 nurses were surveyed to assess secondary traumatic stress, dysfunctional beliefs and compassion satisfaction.

Results show dysfunctional beliefs predict an important percent of the variance in secondary traumatic stress symptoms in both physicians and nurses. Compassion satisfaction significantly moderates the relationship between dysfunctional beliefs and avoidance symptoms in nurses. Secondary traumatic stress resilience can be achieved through interventions aimed at disputing dysfunctional beliefs.

Keywords: secondary traumatic stress, dysfunctional beliefs, compassion satisfaction, medical staff

Introduction

Posttraumatic stress disorder might develop after a person is exposed to events involving loss of physical integrity or risk of serious injury or death to self or others. As a response the person should feel intense fear, horror or helplessness [1]. Traumatic events present a large variety from car crashes to physical assaults, war and torture, natural disasters. Even a life threatening diagnosis might determine posttraumatic stress disorder [2]. A growing body of research shows that people who systematically interact with victims of traumatic events are at risk of developing a traumatic disorder themselves, becoming secondary victims suffering of secondary traumatic stress [3,4,5,6,7,8,9]. Some professional categories present a higher exposure to trauma survivors. Psychotherapists, social workers, emergency workers or health professionals are vulnerable to secondary traumatic stress symptoms.

Traumatic events tend to shake a person's essential beliefs about a safe, fair world, isolating the victim in an existential crisis [10,11]. The invulnerability illusion protecting the person from stress and anxiety is shattered; feelings of self-worth and trust in others are questioned [11]. Victims face the challenge of reconciling their previous beliefs and the realities of the traumatic event. Recovery will depend on the person's ability to resolve the discrepancy. Dysfunctional beliefs about the world, self and others might have a negative impact on posttraumatic adjustment.

Working with victims of traumatic events may have a negative impact on professionals. However helping others is also a source of satisfaction. Being part of the victims' recovery, the feeling of a meaningful work, witnessing human healing and resilience are all declared sources of satisfaction among trauma workers [6]. While secondary traumatic stress is the price of caring, compassion satisfaction is the reward.

The present study aims to investigate the relationship between secondary traumatic stress, compassion satisfaction and dysfunctional beliefs in medical staff. More precisely we hypothesize the relationship between dysfunctional beliefs and secondary traumatic stress will be moderated by compassion satisfaction.

Methodology

132 health professionals, 63 physicians and 69 nurses, from hospitals in Iasi took part in the study. They all work in emergency or intensive care units, facing difficult cases and trauma survivors on a daily basis. Only

20% of them are males reflecting the prevalence of females among medical staff. All participants signed an informed consent and answered a set of questionnaires.

Compassion satisfaction was assessed using the subscale (α = .83) from **The Professional Quality of Life Scale** [12]. The scale is a revised version of Figley's self-administrated test, developed in 1995. It contains 3 sub-scales of 10 items each, which offer independent scores measuring different concepts. **The Impact of Events Scale** [13] initially measured symptoms of direct trauma and not of secondary trauma. In spite of its original purpose, the scale is most frequently used to measure and survey secondary traumatic stress symptoms. It has two subscales that measure avoidance with 8 items (α = .71) and intrusion with 7 items (α = .89) and can be added to generate a total score (α = .84). **The General Attitudes and Beliefs Scale Short Form** [14] adapted by Bianca Macovei was used to measure dysfunctional beliefs. Its 26 items are divided in 7 subscales: rationality, self worth global assessment, need for achievement, need for approval, need for comfort, the absolutist demand for justice and global assessment of others. The last six subscales can be added to generate a total score of dysfunctional beliefs.

Results

Results show the dysfunctional need for comfort, the absolutist need of justice and the total score for dysfunctional beliefs are significantly and positively associated to intrusion symptoms in physicians. Physicians with a high need for justice also show high scores of total secondary traumatic stress. There is no significant association between dysfunctional beliefs and avoidance symptoms in physicians. Physicians with a rational, functional way of thinking report more compassion satisfaction.

Table 1: Correlations among Dysfunctional beliefs, STS Symptoms and Compassion satisfaction

Beliefs	Compassion satisfaction		Intrusive		Avoidance		Total STS	
	Physicians	Nurses	Physicians	Nurses	Physicians	Nurses	Physicians	Nurses
Rational	.332**	-.014	.018	.053	-.063	-.018	-.030	.024
Self worth	-.091	-.061	.141	.156	-.223	.118	-.052	.156
Achievement	.087	.078	.191	.213	-.116	.070	.054	.167
Approval	-.014	.098	.167	.532**	-.060	.481**	.075	.572**
Comfort	.087	.086	.271*	.278*	-.048	.159	.155	.252*
Justice	.111	-.015	.254*	.309**	.106	.226	.246^	.305*
Others assessment	-.163	.032	.055	.404**	-.056	.439**	.001	.471**
Dysf. Total	.012	.051	.291*	.421**	-.102	.318**	.132	.421**

*Note. * = p ≤.05, ** = p ≤.01, ^ = p<.10. N = 63 physicians and 69 nurses for all analysis.*

Nurses with higher need for approval, comfort and justice, with high expectations of others and higher total scores in dysfunctional beliefs report more intrusive symptoms and higher scores in total secondary traumatic stress. On the other hand, avoidance symptoms are only associated to the need for approval, high expectations of others and total dysfunctional beliefs.

Nurses show significantly more avoidance symptoms (M = 19.69, SD = 7.51) and total secondary traumatic stress (M = 34.18, SD = 14.95) compared to physicians (M = 16.87, SD = 7.64; t(130) = -2.13, p <.050; M = 28.90, SD = 11.44; t(130) = -2.29; p < .050). However, physicians show a significantly higher need for achievement (M = 13.96, SD = 2.44) compared to nurses (M = 12.86, SD = 3.39; t(130) = 2.14, p < .050). There are no other significant differences between the two professional categories.

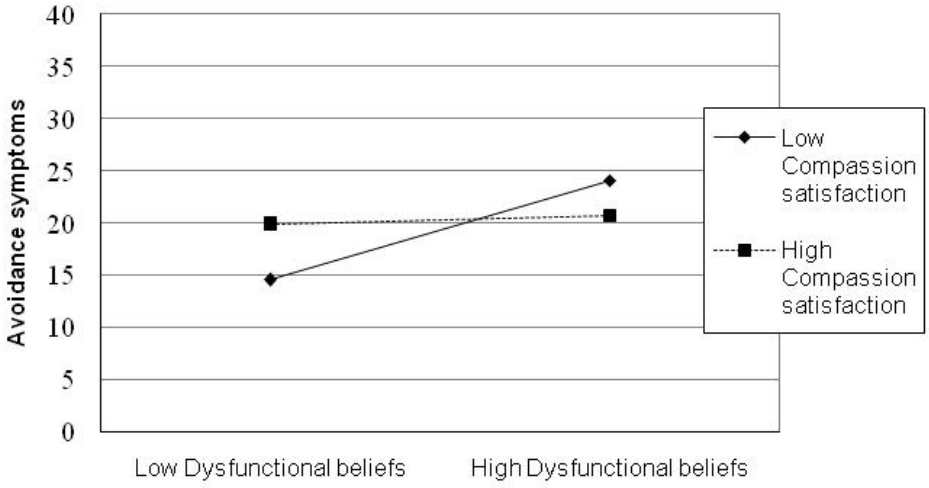
Table 2: Regression results

	Physicians						Nurses					
	STS		Intrusion		Avoidance		STS		Intrusion		Avoidance	
	ΔR^2	B	ΔR^2	β	ΔR^2	β	ΔR^2	β	ΔR^2	β	ΔR^2	β
Dysfunctional beliefs	.01	.13	.08*	.29*	.01	-.10	.17**	.41**	.17**	.41**	.10**	.31**
Compassion satisfaction	.00	.04	.00	.01	.00	.05	.01	.10	.01	.13	.00	.04
Dysfunctional beliefs*Satisfaction	.00	.07	.00	-.03	.01	.14	.01	-.13	.001	-.02	.05*	-.23*
Total R^2	-.02		.03		.02		.16**		.15**		.11*	

*Note. * = $p \leq .05$, ** = $p \leq .01$; N = 63 physicians and 69 nurses.*

Regression results show dysfunctional beliefs predict 8% of the variance in intrusion symptoms in physicians and 17% in nurses. They also explain 10% of the variance in avoidance symptoms in nurses. Compassion satisfaction significantly moderates this relationship. Dysfunctional believes also predict a significant percent of 17% in the variance of total secondary traumatic stress in nurses

Chart 1: Interaction Dysfunctional beliefs and compassion satisfaction in nurses



Nurses with many dysfunctional beliefs and low compassion satisfaction show more avoidance symptoms compared to nurses with few dysfunctional beliefs and low compassion satisfaction. However, when levels of compassion satisfaction are high, nurses show an average level of avoidance symptoms regardless of their dysfunctional beliefs. Moreover it seems that the lowest scores in avoidance symptoms are reported by nurses who have few dysfunctional beliefs and who also show low levels of compassion satisfaction.

Discussions

As hypothesised, health professionals with a high level of dysfunctional beliefs show higher levels of avoidance, intrusion and total secondary traumatic stress. This is especially true for nurses. On the other hand rational thinking helps physicians feel more satisfaction from working with people in need.

Physicians show higher levels of intrusive symptoms when they have a high need for comfort and when they have an absolutist demand for justice. The high need for comfort is expressed through the difficulty in dealing with tensed, frustrating situations. Physicians often face tensed situations when confronted to serious illness, deficient hospital infrastructure or overcrowding. This context will often disturb physicians with a high need for comfort causing recurrent thoughts and images, nightmares and other intrusive symptoms. The absolutist demand for justice is also continuously frustrated in the medical world by the evidence of trauma and disease arbitrary affecting people, with no sense of logic or justice. Medical workers who highly believe in a meaningful and fair world will have to work harder to balance their beliefs when faced with the randomness of trauma and suffering. These results are consistent with previous research on the belief in a just and meaningful world where good things should happen to good people [11, 15].

Nurses show higher levels of secondary traumatic stress and a stronger association between symptoms and their dysfunctional beliefs. Their interaction with patients is often more intimate and complex. A strong need for approval and a critical assessment of others are both associated with secondary traumatic stress symptoms. These beliefs are dynamically involved in social interaction and they influence nurses' contacts with their patients.

Dysfunctional beliefs explain a large percent of the variance in secondary traumatic stress symptoms. This conclusion has important implications for secondary traumatic stress prevention and treatment. Cognitive behavioural interventions and trainings should be created to address these important risk factors. Compassion satisfaction has a buffer effect in the relationship between dysfunctional beliefs and avoidance symptoms. The satisfaction derived from helping the patients in need is stronger than the impulse of avoiding difficult situations.

Facilitating factors and consequences of experiencing self-detachment in groups: a thematic analysis

Gherghel C., Nastas D.

Alexandru Ioan Cuza University of Iasi (ROMANIA)
claemgh@yahoo.com, nastas.dorin.iasi.university@gmail.com

Abstract

Previous theoretical reviews suggest that self-detachment, the type of psychological functioning that opposes self-centeredness, can have positive consequences for the individual and the group. We conducted a qualitative study with the purpose of exploring personal experiences of self-detachment in group activities. 141 Romanian students described a self-detachment experience that occurred in group, and answered several open-ended questions concerning the consequences of the experience and possible facilitating factors of self-detachment. Participants' answers were subjected to thematic analysis, revealing five themes at the facilitating factor level: (1) *common purpose*, (2) *agreeable and cohesive group*, (3) *captivating activity*, (4) *balanced personality* and (5) *external pleasure-inducing stimulants* and four themes at the consequence level: (1) *relationship improvement*, (2) *wish to re-experience*, (3) *positivation of thoughts and feelings*, and (4) *personal development*. The analysis suggests that positive group activities which foster self-detachment have beneficial consequences for the individual and the group.

Keywords: self-detachment, self-centeredness, group activity, qualitative analysis

Introduction

The excessive tendency to self-focus, high egocentrism and egoism are known to be detrimental to the psychological health of individuals, causing anxiety or depression [1], [2]. As a consequence, researchers in the area of positive psychology have pointed out the need of escaping the burden of the self [3], and learning ways to reduce one's self-focus and egocentrism. While character strengths like *humility* and *wisdom* have been the focus of researchers for a long time, in the recent years, the interest in state-phenomena characterized by low focus, like *flow* [4] or *mindfulness*, has increased. Another phenomenon which could facilitate self-detachment is what Haidt and his colleagues [5] name *the loss of self in group*. According to the authors, when individuals are profoundly involved in group activities, they can experience a loss of concern about the self, profound joy and a sense of high connection with others. Leary and Terry [6] name *de individuation*, conceptualized as being characterized by low self-awareness and non-individuation (as opposed to the conceptualizations that stress awareness of social identity and high conformism) among hypo-egoic states, psychological states characterized by low self-focus and egocentrism.

Despite the existence of the above theoretical considerations on self-detachment in groups (*the loss of self in group*), empirical research on the topic is scarce. The aim of the present research was to explore the state of self-detachment in groups, using a qualitative approach that could offer a vivid, profound image of the phenomenon. Although our research investigated a broader array of aspects of the experience, this paper focuses only on the facilitating factors of self-detachment in groups and its consequences at the individual and group level.

Method

1.1 Participants

A convenience sample of 179 undergraduate and graduate students attending Psychology or Philosophy classes completed a qualitative questionnaire on self-detachment in groups. We specifically chose Psychology and Philosophy students as participants to our study, because we considered them to have a high ability of introspection and to be able to provide in-depth, rich descriptions of their personal experiences. Psychology

students received course credits for their participation. Among the total of 179 participants, eight did not complete de questionnaire, declaring that they haven't experienced self-detachment in groups. Of the remaining 171, we excluded from the analysis 38 accounts which did not describe self-detachment experiences. In the final analysis, 141 responses were included (120 females, 21 males, mean age 22.59, *SD* = 4.11).

1.2 Materials and Procedure

Psychology students completed the questionnaire on self-detachment in groups, as well as a series of other instruments online, while Philosophy students completed the pen-and-paper format of the qualitative questionnaire during class. Before completing the questionnaires, all participants signed an informed consent form. The qualitative questionnaire on self-detachment in groups asked participants to remember a personal self-detachment experience that occurred when they were involved in group activities and describe it as detailed as possible. Open-ended questions on the cognitive, affective and behavioral features of the experience, as well as the possible eliciting factors and its consequences followed. The following questions concerning the consequences of the event were asked:

Did that event make you behave in a certain way or do something later on? (Yes or No) If you answered yes, what did you do?
Did you notice a change in you after the experience? (Yes or No) If you answered yes, what was the change?

As for the facilitating factors, the following questions were asked:

In your opinion, what do you think are the exterior (environmental) factors necessary for the self-detachment in group state to appear?
In your opinion, what are the internal (psychological) factors necessary for the self-detachment in group state to appear?

The completion of the qualitative questionnaire took about 20 minutes.

1.3 Data analysis

Participants' answers were thematically analyzed [7] in order to identify prevalent themes. To handle the qualitative data, we used the QDA Miner Software. The first stage of the analysis was to transcribe the responses of the participants who completed the pen-and-paper questionnaire, after which all participants' accounts were read and re-read in order to familiarize ourselves with the data. The next step was to eliminate from the analysis accounts which did not describe positive self-detachment experiences (for example, we eliminated experiences of separating oneself from the group, experiences where negative emotions like anger and sadness prevail, or accounts characterized by obvious egocentrism). Next, we started searching for repeating patterns in the data and coding them. After all meaningful parts of participants' accounts were coded, we started searching for themes which described larger portions of the data. During this stage, some initial codes were combined into one theme, and some were modified so as to create a meaningful and structured schema of the data. After deciding on the main themes and making sure they offer an exhaustive and coherent image of the whole data set, we moved on to labeling the themes and finding appropriate excerpts to illustrate them.

Results

In this article, we present only the themes identified at the facilitating factor level and at the consequence level.

1.1 The facilitating factors of self-detachment in groups

After thematically analyzing participants' responses to the two questions that concerned the facilitating factors of self-detachment in groups, five main themes were identified: (1) *common purpose*, (2) *agreeable and cohesive group*, (3) *captivating activity*, (4) *balanced personality* and (5) *external pleasure-inducing stimulants*

1.1.1 Common Purpose

Some participants named *common purpose* as a facilitating factor of the self-detachment in group experience. This theme refers to the situation when all members of the group have the same purpose during the activity, thus eliminating the possibility of conflicts arising between them. As long as the purpose of the group is common, self-detachment is likely to appear, because the individual is not forced to focus on a personal goal which could oppose the goals of other members and thus create animosity in the group. One female responder writes that, for self-detachment to appear:

…all participants must have a common purpose, and the purpose must not be a personal one.

1.1.2 Agreeable and Cohesive Group

Another factor considered by participants to have the ability to facilitate self-detachment in groups is the quality of the group itself, which must be agreeable and cohesive. Being surrounded by nice, accepting people and being part of a group that is cohesive and united could foster self-detachment. A female respondent notes:

…it is important that every member feel well in the group. As long as you are appreciated, loved and you see that no matter your mistake, the group supports you (…) probably, self-detachment will appear.

1.1.3 Captivating Activity

Another theme identified at the facilitating factor level is *captivating activity*. An interesting, attractive and soliciting activity done with the group can foster self-detachment for the members of the group, as their attention is captivated completely by the task itself, leaving no space for self-relevant, interfering thoughts.

If [the activity] is one that solicits your attention to a greater degree, then self-detachment will be stronger, writes a female respondent.

1.1.4 Balanced Personality

This theme refers to the characteristics of the individual who is inclined or able to experience self-detachment. Many participants noted personality traits which describe a balanced, positive and altruistic type of individual, as well as behavioral patterns and individual states that could facilitate the experimentation of self-detachment in groups. One female respondent enumerates the following personality factors:

…our capacity to emphasize, to relate with others and our openness towards others…

1.1.5 External Pleasure-Inducing Stimulants

The final theme identified at the facilitating factor level is external pleasure inducing stimulants, theme which includes references to aspects of the external world which have the ability to induce pleasure, relaxation and calm. Among them, participants enumerated nice weather, music, food and drinks and an agreeable environment.

For self-detachment to appear, I think that an environment as familiar, welcoming and soothing as possible is necessary, writes a female participant.

1.2 The consequences of experiencing self-detachment in groups

The analysis of participants' responses revealed four themes at the consequence of experiencing self-detachment level: (1) *relationship improvement*, (2) *wish to re-experience*, (3) *positivation of thoughts and feelings*, and (4) *personal development*

1.2.1 Relationship Improvement

Many participants wrote that after experiencing self-detachment in group, the relationship with the members of the group improved. This theme is defined by any positive progress in the relation of the participant with the members of the group, including increased closeness, understanding and affection. As a consequence of the positive group experience, some participants wrote that they wanted to be around the members of the group more, that their relation with the group had gained in profoundness and that they started to value the members of the group more than before. One female participant writes:

Spending time together in an informal setting made us know each other better and understand each other more smoothly.

As a consequence of the positive group experience, others are valued more and seen in a better light:

This happening (…) determined me to always assume that people around me have a superior potential they are unaware of, writes a male participant.

1.2.2 Wish to Re-experience

Another consequence of experiencing the positive state of self-detachment is the wish to experience the feeling once more. This theme refers to participants' desire to re-experience the emotions and the type of human interaction they had previously experienced. Through the group activity, participants learn the need to take a break, self-detach and relax. A female participant writes:

Later, I realized that the self-detachment [experience] allowed me to rest emotionally, and that when I feel tired, I should try to find these kinds of moments that give me the energy and strength to go on.

1.2.3 Positivation of Thoughts and Feelings

This theme refers to the positive changes in mood, thought and emotion experienced by participants after the group activity. The self-detachment experience helped participants see the world in a more optimistic way and feel more energetic and positive than before. One male participant writes:

The good feeling I was experiencing because of the moment of freedom in the park made me be cheerful.

1.2.4 Personal Development

Participants pointed to the fact that the self-detachment experience has not only short-term consequences, as positive changes in mood, but also long-term ones. This theme refers to the positive changes experienced by participants at the individual level, such as gaining in character strengths, self-knowledge, and strengthening their tendency to act prosocially. The group experience is a chance to learn more about oneself and about others, and make a decision towards self-improvement. One male participant confesses:

I became more sociable, friendly, compassionate, willing to help, and communicative.

Another female student talks about her gaining in resilience, self-knowledge and optimism:

After that experience I realized that my emotional states are not set in stone, that there are things I can do to escape from them, and this helped me have more trust in the fact that the chances I need to face hardship are there, and I can access them.

Discussion

The thematic analysis of participants' responses to the questions regarding the facilitating factors of self-detachment in groups and its consequences revealed profound aspects and facets of a group experience seldom studied empirically until present.

The facilitating factors identified by participants can be organized into individual, group and environmental factors. For self-detachment to appear more easily, the individual must have character strengths like altruism and optimism, the group must be an acceptable, agreeable one and have a common goal, and the environment must be an appropriate one. Learning about these factors can help us gain in understanding of the phenomenon and of the conditions under which self-detachment is facilitated or inhibited. Future experimental research on the topic is necessary to clarify the role and importance of different factors, thus opening the road to the creation of educational and therapeutic programs aimed at increasing individuals' chances to experience self-detachment and escape from the burden of the self.

Participants' answers showed that self-detachment in groups have positive effects on the individual and the group, facilitating changes in mood, the improvement of human relationships, and self-development. The present exploratory research on positive group experiences brought the first hints that self-detachment in groups is beneficial and could provide the setting for interventions aimed at reducing self-focus, rumination and negative affect. However, as the data collected is qualitative and exploratory, further research on the topic using quantitative, experimental approaches is necessary in order to clarify the degree to which group experiences can induce self-detachment and facilitate positive changes in thought, emotion and behavior.

Predictors of emotion regulation during the transition from adolescence to young adulthood

Turliuc M.N., Bujor L.

Alexandru Ioan Cuza University of Iaşi, ROMANIA
turliuc@uaic.ro, bujor_liliana@yahoo.com

Abstract

The main purpose of the investigation is to advance a possible explanation of emotion regulation strategies in terms of personality and family factors (attachment and parenting style in emotion socialization) and also demographic variables (age, gender). A look "behind the door" of the emotion regulation gives meaning and significance to those determinants whose influence – which is sometimes inferred and other times scientifically proven – becomes visible in the adaptive and maladaptive emotion management. The results obtained on a sample of 214 subjects of a mean age of 19.69 (± 4.55) support the assertion that personality structure is powerfully present in our emotional life in general, and emotion regulation in particular. In our analysis model, extraversion accounts for 46% of the expressive suppression variance. Emotional family experiences potentiate the personality factors in a positive or negative direction depending on the mother and father's emotional messages that respond to the child's emotions through reactions such as: reward, denial, punishment, amplification, neglect. The parental correlates analyzed reveal predictive significances for the negative strategies of socialization of emotions (punishment and neglect of sadness, anger) and are consistent with studies showing that the mother's emotionality indices are significantly associated with ER strategies. Age does not bring about any changes in emotion regulation strategies along the transition from adolescence to young adulthood. Instead, gender is a variable that has implications for the emotion regulation strategies - boys regulate their emotions through greater use of expressive suppression than girls.

Keywords: Emotion regulation, personality, parenting style in emotion socialization.

Introduction

According to Dunn and Brody's suggestion [1], that emotion regulation involves biological, developmental aspects as well as cognition and personality, our paper analyse concepts from each category: personality, emotion socialization strategies, implicit cognitions about emotions, adult attachment, gender and age.

1.1 Emotion regulation

Emotion regulation (ER) is a complex and multifaceted concept that shapes social skills, well-being, as well as the risk for psychopathology. It covers those strategies that a person uses to influence the emotions they have, when they have, how they live and express them [2]. In this paper, the concept will be addressed from the perspective of the process model of emotion regulation [3], [4], [5], [6] which, together with the *Emotion Regulation Questionnaire* (ERQ), has become useful and usable in the health field and beyond. ER strategies (expressive suppression and cognitive reappraisal) are determined by intrinsic/ predisposing factors (temperament, personality), extrinsic factors (family interaction), implicit cognitions on emotions and also demographic factors such as age and gender [7]; [8], [9], [10], [11].

1.2 Personality Constructs and Emotion Regulation

While consistently significant and negative links are reported between extraversion and expressive suppression (ES) [10], [12], [13], the relationship with cognitive reappraisal (CR) is significant and positive; highly extraverted individuals use CR as emotion regulation technique more frequently [7], [10], [12], [13]. Neuroticism is positively related with the ES (and is even a predictor for this ER strategy) [7], [13]. Compared to the CR, neuroticism shows a negative, weak correlation [10]. Extraversion and neuroticism are two fundamental personality traits that are reflected in the individual differences as regards positive and negative affects, cognitive

style and attitudes. These differences, however, are mediated by the CR. SE, however, has no mediating role for neuroticism, nor for extraversion.

1.3 Parental Constructs and Emotion Regulation

1.3.1 Attachment Relationship

According to the relevant literature, there are predictive relationships between attachment and ES: the low levels of communication and high levels of alienation (styles of attachment perceived towards parents, according IPPA) predict ES in late childhood and adolescence [7]. Fearful and dismissing attachment is positive predictor for ES, while secure attachment is negatively correlated. Attachment is significantly represented also in relation to CR: higher levels of communication (cf. IPPA), the avoidant and safe attachment predict CR positively while preoccupied attachment is negatively correlated with this ER adaptive strategy [7]; [14].

1.3.2 Parental Style of Socializing Emotions

Low levels of parental care and also parental overprotection are positively associated with suppression [12]. Expressive suppression of the mother is significantly associated with the expressive suppression of the child [15]. Although gender and temperamental characteristics contribute to the prediction of ER mechanisms, ER skills are significantly better when children receive a high level of positive parenting [16].

1.4 Demographic Variables and Emotion Regulation

Older people are more motivated to regulate their negative affects and even do so. ES decreases with age [9] [10] and the CR is activated more after the age of 25 [17]. According to the gender variable, men use suppression to a greater extent than women but there are no gender differences in terms of cognitive reappraisal [6], [17]. Gullone [9] confirms these data for ES but identifies gender differences regarding CR – boys use cognitive reappraisal less frequently than girls. An fMRI study of cognitive reappraisal has added information to this contradiction: there is a less intense activity in the prefrontal cortex in men than in women because men involve less effort than women as regards CR [18].

METHODOLOGY

1.1 Participants

The lot under comprises 214 subjects, 147 girls and 67 boys, aged between 14 and 45 (M = 19.69±4.55). In order to control the *type of family of origin* variable, we have only selected those questionnaires by respondents coming from families in which both parents are biological.

1.2 Procedure

Participants completed the questionnaire individually, with no time limit. The application lasted 50 minutes on average and was conducted during seminars (for students) or classes (for pupils). Throughout the application and administration of the questionnaires, the researcher was present to answer any questions and to collect the completed instruments.

1.3 Measuring Instruments

Several scales were used, corresponding to the variables involved in the analysis: personality was assessed through the *Five-Factor Personality Inventory* (Daniel David). As regards the parental style of socializing emotions, the adult attachment style, the related theories on emotions and the emotion regulation strategies, the following instruments were translated and adapted for the Romanian population: *The Emotions as a Child Scale – EAC*, the version for adults (Garside & Klimes- Dougan, 2002b), *Inventory of Parent and Peer Attachment* (Greenberg & Armsden, 2009), *The Implicit Theories of Emotion Scale* (Tamir et al., 2007), *Emotion Regulation Questionnaire* (Gross & John, 2003). For all scales used, internal consistency coefficients were calculated, and those Alpha coefficients above .70 recommend them with a view to obtaining scientifically valid results.

RESULTS

1.1 Expressive Suppression Predictors

For the first regression model, the expressive suppression criterion is explained through a four-step regression analysis (Table 1). Of the more than fifty variables included in the analysis, the results show that model 4, containing the following variables: *extraversion, emotional stability, sadness neglect by the mother, sadness punishment by the father, anger punishment by the mother*, has a statistically significant value, $F(53, 160) = 5.33$, $p<.001$.

Table 1. Results of the hierarchical regression analysis for assessing expressive suppression based on the predictors taken in the study (N = 214)

VARIABLES	R^2	ΔR^2	β
MODEL 1	.16	.14	
Extraversion			-.46**
Emotional Stability			.21*
Autonomy			.16*
MODEL 2	.34	.17	
Extraversion			-.41**
Emotional Stability			.26**
Neglect_Sa_F			.21*
Punishment_Sa_F			.26**
Punishment_An_M			.24*
Neglect_An_T			-.23*
Avoidance_Ha_M			.25*
MODEL 3	.37	.18	
Extraversion			-.46**
Emotional Stability			.31**
Neglect_Sa_M			.23*
Punishment_An_M			.27*
Neglect_Fu_F			-.25*
MODEL 4	.40	.20	
Extraversion			-.46**
Emotional Stability			.27**
Neglect_Sa_M			.22*
Punishment_Sa_F			.24*
Punishment_An_M			.25*

Model 4 adjusted coefficient of determination, adjusted $R^2 = .20$, shows that expressive suppression variance is 20% explained by two personality factors and three parental strategies for socializing emotions.

The biggest explanatory weight in the variables of model 4 belongs to personality, extraversion ($\beta = -.46$) and emotional stability factors ($\beta = .27$). Some of the parental strategies for socializing emotions have lower explanatory weights, yet they have a predictor value: sadness neglect by the mother ($\beta = .22$), sadness punishment by the father ($\beta = .24$) and anger punishment by the mother ($\beta = .25$). Of these factors, by squaring the PART coefficient, we can state that extraversion ($r^2sp = 0.09$) explains suppression four times better than emotional stability ($r^2sp = 0,02$) and 9 times better than the parental strategies for socializing emotions ($r^2sp = 0.01$).

*p< .05; **p<.01

1.2 Cognitive Reappraisal Predictors

For the second regression model, the cognitive reappraisal criterion is explained through a four-step regression analysis (Table 2). The results show that none of the four models has a statistically significant value, $p>.05$.

Table 2. Summary of the results of the hierarchical regression analysis for assessing cognitive reappraisal based on the predictors taken in the study (N = 214)

VARIABLES	R^2	ΔR^2	sig. F Change
MODEL 1	.02	.04	.07
MODEL 2	.06	.22	.16
MODEL 3	.06	.02	.47
MODEL 4	.08	.02	.10

From the correlation matrix, we can identify significant links with: reward-type answer of the mother to the child's anger (.23**), avoidance of anger (.19**) and the mother's reward to the child's emotion of happiness (.21**). As for ES, the mother's influence is also visible in CR.

1.3 Gender and Age Differences in Emotion Regulation Strategies

The differences on the demographic variables (age and gender) was measured separately (CR and ES) through the T-test for *independent samples.* The results confirm (in part) the research hypothesis: age does not distinguish between ER strategies - there are no differences between adolescents and youngsters neither on the adaptive (cognitive reappraisal) nor the maladaptive (expressive suppression) dimension. For CR and ES, the results are as follows: t (212) = .894, p> .05.

For the gender variable, significant differences only occur for ES: boys are more maladaptive than girls in adjusting their emotions, t (212) = 3.155, p <.005. However, CR does not differ between girls and boys t (212) = - .636, p> .05. Cohen d index has a mean value of 0.44 and signifies an average effect level. Hence, boys use ES significantly more than girls in regulating emotions.

Conclusions

We have a significant and negative relationship between extraversion and expressive suppression, and emotional stability is a predictor for expressive suppression. The data are consistent with the literature's findings [7]; [10]; [13].

Parental correlates are predictive variables for the negative strategies of socializing emotions; the negative parenting style has greater predictive power for ER compared with the positive style, and indices of maternal emotionality are significantly related with ER strategies. The data are similar to other studies [15]. Although in other studies communication as attachment style is a predictor for CR and alienation is a predictor for ES, we have not obtained significant data in this regard [7].

Age does not affect changes in the emotional regulation strategies along the transition from adolescence to youth. While data from other studies on ES are consistent, we have conflicting conclusions as regards CR [9]; [10].

Gender is a variable that has implications on emotion regulation strategies. Boys regulate their emotions through greater use of expressive suppression than girls, while for CR we have no gender differences. The data are in agreement with other studies [9] [19].

Our study has some limitations: (1). the respondents - adolescents and youngsters - referred to the relational aspects associated to family and parents. There is empirical evidence that adolescents, out of a wish to mitigate emotional dissonance, tend to idealize the relationship with their parents; (2). the regression analysis included a large number of variables that required a larger group of subjects; (3) the investigation is cross-sectional. A longitudinal approach, however, could capture dynamics-related aspects more accurately. Although these findings are affected by these limitations, they do offer some important information that should be considered in research on emotion regulation.

Abstract

The psychoterapeutic approach like EMDR , the sensorimotor therapy, or hypnosys, conducts the clinicians and the researcher to view the body like a therapeutic mediator.More precise this dispositive, solicitates the physiologic process to facilitate the asimilation of the traumatic experience. Like this, the researcher autor of the EMDR, exhibits the role of the vagotonic réflex to the efficacy of eye movement. Activation of the parasympathic system, to help this stimulations, disconnection induced by the hipnosis to the counsciousness, leads to an extinction of the disphoric emotions attached to certain life events, and modifies the representations and beliefs,to the point to reorganise the identity of the subject. The sensorimotor therapy, conducts the subject to feel his body and to let it enter into a defensive movement initially engaged in the traumatic experience, participating resilient in the same process.

An approach of the somatic orientation favorise a better regulation of emotions, trough the mobilisation of the somatic component of the traumatic memories (muscular tensións, aches, anesthesias, etc), facilitating to cut the links between the emotions, thoughts, and behaviours, considering the real assimilation of the traumatic experience.This way the body appears as an espace of resources, proper to the resilience.

Key words: somatic orientation, traumatic memories, disphoric emotions, resilience

Suite à la première étude contrôlée de Shapiro [1], le développement de la psychothérapie EMDR a ouvert de nombreuses perspectives tant au niveau de la clinique des traumas qu'au niveau de notre compréhension de la psychopathologie [2]. L'apport est d'ordre intégratif en ce sens qu'il amène le clinicien chercheur à tenter une synthèse difficile entre des approches traditionnellement bien distinctes, voire opposées, comme la psychanalyse, les thérapies cognitivo-comportementales, l'hypnose, ou les somatothérapies. L'EMDR incite également à prendre en compte les dernières données de la neuro-anatomie et de la physiologie [3] autant en psychotraumatologie qu'en psychothérapie.

La pratique de l'EMDR confronte sans cesse le clinicien à des anamnèses où les traumatismes psychiques prennent une place importante. Ces derniers ne sont pas systématiquement pris en compte par les thérapeutes en tant qu'étiologie principale de la symptomatologie des patients. Pourtant, ces traumatismes ont une place essentielle dans la genèse des troubles psychologiques mais aussi dans la constitution identitaire du sujet. Ils continuent même à exercer sur les individus une véritable emprise psychique.

Aspects neurobiologiques de la traumatisation

L'expérience traumatique apparaît comme une tentative d'intégration, une tentative de liaison de la part du moi d'un corps qui par définition est difficilement, voir impossible à assimiler. Le traumatisme remet en cause le fonctionnement psychique habituel et apparaît bien comme quelque chose qui désorganise le sujet sur un plan individuel et relationnel. L'impact traumatique se repère également au niveau du dérèglement neurovégétatif induit [4]. Un rôle important est attribué au système limbique qui joue une « fonction évaluative ». Le terme de neuroception proposé par Porges [5] va dans ce sens. Celui-ci définit la neuroception comme un « système subconscient composé par certains sous-systèmes neuronaux » qui évalue les situations vécues par le sujet et qui différencie ce qui relève d'un environnement sécurisant, dangereux, voire létal. Le thalamus, relais des informations sensorielles, informe l'amygdale cérébrale d'une situation dangereuse, activant à son tour l'hypothalamus. Ce dernier est en étroite relation avec le système nerveux végétatif composé principalement de la branche sympathique (activée en cas d'effort à fournir et en cas de stress) et de la branche parasympathique

qui joue un rôle prépondérant dans ce qui relève du repos de l'organisme et du relâchement. D'une manière générale, toute situation stressante se caractérise par une activité importante du système nerveux sympathique ainsi que celui de l'axe hypothalamo-hypothysaire surrénalien [6].

La difficulté, voire l'incapacité à faire-face, est bien connue en éthologie qui nous apprend qu'il existe trois types de réponses primaires face à une menace qui touche la vie : le combat (« fight »), la fuite (« flight ») et la réaction d'immobilité -ou de figement- (« freeze reflex »). Lorsque l'être humain est confronté à des stresseurs qui dépassent ses capacités à faire-face (défaut de coping), il peut être amené à utiliser cette même réponse de figement de façon automatique [7]. Des rapprochements peuvent être certainement effectués avec la notion d'« inhibition de l'action » proposée par Laborit [8]. Les réactions de fuite et de combat relèvent essentiellement du système sympathique alors que la réaction de figement paraît liée à l'activation d'une branche du système parasympathique. La réaction d'immobilité résulte semble-t-il d'un déséquilibre inhabituel du système nerveux végétatif. Si la fuite ou le combat n'est pas possible ou si la menace est prolongée au-delà des capacités résilientes de l'organisme, la réaction de figement s'enclenche. De ce blocage naissent les symptômes qui ont pour fin de canaliser autant que faire se peut la « tension somatopsychique non liquidée » au sein du système nerveux. Les symptômes sont donc le reflet d'une activation neurologique saturée.

Réponse vagotonique et assimilation de l'expérience traumatique

L'apport des neurosciences permet aujourd'hui d'approfondir notre compréhension de ce qui se joue au niveau du cerveau dans le cadre de la psychotraumatologie. Pour Levine [7], chaque évènement traumatique engendre simultanément une réponse résiliente dans l'organisme, réponse qui est le plus souvent faible au début. Il envisage l'existence adaptative du système nerveux capable de retrouver un état d'équilibre, fonction autorégulatrice pouvant être altérée chez l'individu, engendrant une sur-activation neurologique, signe d'une symptomatologie d'allure traumatique à venir. La démarche thérapeutique vise à favoriser des allers retours entre l'expérience traumatique qui hyperactive l'organisme et la réponse adaptative (régulation homéostatique) en vue d'une résolution progressive. Les données actuelles témoignent d'ailleurs de l'existence d'un système nerveux autonome résilient comme le suggère Cyrulnik [9].

Les études sur l'EMDR montrent que le système de traitement de l'information traumatique s'amorce spontanément dès que le sujet entre en vagotonie [10, 11, 12]. Le système nerveux parasympathique offre la possibilité d'activer spontanément une possible résolution « naturelle » des traumatismes psychiques [13, 14]. Il semble d'ailleurs qu'en vagotonie, l'amygdale facilite l'inscription néocorticale en mémoire à long terme de l'information jusque là dysfonctionnelle [15]. Sur un plan clinique, cela se manifeste chez le patient par une impression de relâchement, parfois même une somnolence (activation parasympathique) ainsi qu'un fonctionnement dissociatif de type hypnotique. Une partie du moi du sujet reste présent avec le thérapeute signe d'un engagement social préservé alors qu'une autre partie est reliée au passé traumatique. Il s'agit ici d'amener le patient, tout comme en hypnothérapie [16], à aborder le trauma et de le contenir dans l'ici et maintenant. Cette dissociation, pour être thérapeutique, doit respecter la fenêtre de tolérance afin de ne pas dépasser les capacités de faire-face du sujet. Autant une activation sympathique trop élevée bloque toute possibilité de traitement, autant une sous-activation empêche également toute assimilation. Précisons que les données actuelles tendent à montrer qu'une forte stimulation parasympathique permet de préserver cette fenêtre de tolérance [17].

De plus, il existe une corrélation entre cette modulation de l'activation et la qualité de l'attachement du sujet. Les travaux de Schore [14] et Perry et al. [18] témoignent du rôle primordial accordé à un attachement sain pour permettre une capacité accrue de traitement des stresseurs. Un attachement sécurisant sert de base de sécurité à l'enfant et facilite l'exploration du milieu ainsi que ses capacités à affronter des situations douloureuses. Il semble à partir de ces données que le type d'attachement du patient soit en lien avec sa qualité d'affronter l'excitation sympathique tout comme la qualité de la relation avec le patient va influer sur cette tolérance et donc sur le système de traitement de l'information. Ceci semble corroborer les travaux de Porges [5] qui mettent en avant l'importance de l'engagement social (relation à l'autre entretenue par le contact visuel, les expressions du visage, la sensorialité, etc.) comme frein à la surexcitabilité neurologique, engagement social qui serait sous-tendu par la branche ventrale du système parasympathique.

Porges [19] envisage en effet le système nerveux parasympathique comme régulateur de la réactivité et de la vulnérabilité au stress. Il s'agit donc non moins de l'importance de l'excitation du système orthosympathique que la sous-activation vagotonique qui expliquerait la réactivité aux stresseurs. Ainsi, le fonctionnement du parasympathique, en particulier de la branche ventrale, est associé aux fonctions auto-régulatrices de l'organisme.

La théorie polyvagale de Porges [5] complète notre compréhension des syndromes liés au stress et de la réponse de l'organisme. Le système nerveux autonome comprend trois systèmes réciproques, c'est-à-dire s'auto-équilibrant : 1. le système nerveux sympathique permet d'améliorer les relations de l'organisme à l'environnement grâce à une mobilisation générale du type protection et/ou défense ; 2. le système nerveux parasympathique est davantage voué à la restauration et à l'homéostasie de l'organisme. La majorité de

l'innervation de cette branche du système nerveux autonome peut être décomposée en deux sous-systèmes : 2a. le système vagal dorsal, partie la plus primitive, qui est un système de conservation de l'oxygène qui aboutit à l'arrêt, le figement de l'organisme lorsque le traumatisme est très sévère ; 2b. le système vagal ventral, système phylogénétiquement plus récent, qui soutient l'engagement social au travers entre autres des expressions faciales. La théorie de Porges propose un modèle de réponse hiérarchique dans lequel les stratégies les plus sophistiquées reliées au système nerveux le plus évolué sont utilisées en priorité : 1. l'engagement social (système vagal ventral), 2. la fuite ou le combat via le système nerveux sympathique, ou enfin 3. le figement par l'intermédiaire du système vagal dorsal.

Ainsi, au regard de ce qui a été avancé précédemment, l'EMDR et l'hypnose, et c'est ce qui fait l'essence des processus résilients, entrainent une activation du système vagal ventral qui participe à l'engagement social et à la réduction de l'excitation sympathique au travers d'un rapport à l'autre rassurant. Les stimulations usées en EMDR, l'induction hypnotique, toutes les approches visant à ressentir le corps et à le relâcher permettent d'agir sur la dépression du tonus vagal et ainsi de contrebalancer le système sympathique. Les donnés actuellement montrent que les stimulations bilatérales engendrent une diminution du rythme cardiaque et de la conductance de la peau, une légère diminution de la consommation en oxygène, une légère augmentation de la libération du dioxyde de carbone, une augmentation de la fréquence respiratoire et de la température de la peau, une meilleure cohérence cardiaque [20]. Ces modifications physiologiques signent une activité parasympathique identique à celle retrouvée lors du sommeil paradoxal confirmant l'hypothèse possible du rôle mnésique du sommeil REM. Roques [13] précise en outre que les mouvements oculaires facilitent en EMDR une libération cholinergique et contribuent de la sorte à l'augmentation des liens associatifs mnésiques. Les stimulations bilatérales alternées contrebalancent la désactivation du cortex orbitofrontal gauche ainsi que l'aire de Broca dues au stress élevé [21].

Kapoula [22], à partir de ses travaux qui portent sur la motricité oculaire en EMDR, en conclut que les mouvements oculaires sont un « moteur physiologique du changement ». En effet, une absence d'anomalie dans la poursuite oculaire témoigne d'un bon fonctionnement fluide cérébral. Par exemple, on observe suite à une prise en charge par EMDR, une meilleure fluidité des processus physiologiques qui se caractérise par une diminution du nombre de saccades de rattrapages, une augmentation de la vitesse de la poursuite oculaire et un moindre retard des yeux par rapport à la cible. Ces éléments sont à relier à une diminution de l'activité pariétale, signe d'une diminution du stress, un meilleurs accès aux souvenirs douloureux, de meilleurs échanges inter-hémisphériques.

En résumé, les mouvements oculaires favorisent une augmentation de la production cholinergique, une réduction du stress, une meilleure flexibilité mentale, une augmentation de l'élaboration psychique, une amélioration de la mémoire, de l'attention et de la cognition en général. Cette efficacité des mouvements oculaires est de plus indépendante du contexte thérapeutique et culturel. Enfin, il ressort que l'activation du parasympathique, en particulier de la branche ventrale, agit en premier sur les émotions dysphoriques par une disparition de ceux-ci. Et c'est justement cette extinction des émotions douloureuses qui agit sur les représentations et cognitions du sujet. Formulé autrement, l'abord résilient mis ici en évidence se centre en premier sur le bien-être physiologique, l'équilibre somatique et c'est celui-ci qui va engendrer ensuite des modifications dans les représentations du consultant.

Lâcher-prise pour se réassocier

Il ressort des formulations avancées jusqu'ici que le sujet inscrit dans une psychothérapie du trauma doit adopter une position spécifique au cours de laquelle il doit être « attentif et relâché » vis-à-vis de ce qui émerge de lui. C'est le lâcher-prise où se mêlent dissociation, réassociation et vagotonie. Confronté à l'intolérable, à l'impossible à penser, à l'impossibilité de réagir, le traumatisé cherche continuellement à repousser hors de sa conscience ce qui lui est douloureux. Approcher le « vortex traumatique » [7] engendre une peur qui potentialise l'inhibition de l'action et contribue au maintien du syndrome. Lorsque le sujet commence à sortir de cet état de figement, une tendance à l'explosivité est observée au travers d'abréactions importantes, d'angoisses massives, de passage à l'acte. Cette tendance va accentuer la crainte d'appréhender le souvenir douloureux et réactiver de nouveau le figement, la fuite ou l'attaque, bloquant toute résolution naturelle et adaptative du trauma. L'objectif thérapeutique est alors d'amener le patient, au sein d'un cadre sécurisant, à accepter cette rencontre avec soi-même. En EMDR, cette rencontre est facilitée à la fois par le protocole et en particulier par les stimulations bilatérales alternées.

Nous retrouvons cette même approche dans des psychothérapies telles que la Somatic Experiencing ou la Thérapie Sensori-Motrice où le consultant est amené à pister les manifestations somatiques en consultation. Puisque l'impact traumatique a en quelque sorte fragmenté l'intégrité somatopsychique, altérant toute conscience corporelle unifiée, il est nécessaire d'affronter le traumatisme par l'intermédiaire du corps, des sensations corporelles, qui peuvent devenir un reflet du souvenir perturbant et nous guider vers des ressources instinctuelles. La Somatic Experiencing ou la Thérapie Sensori-Motrice s'appuie sur la pratique du « felt sense »

élaborée par Gendlin [23], terme que nous pouvons traduire par « conscience corporelle ». Il s'agit de vivre la totalité des sensations, approche similaire à celle de la pleine conscience [24]. Travailler avec les sensations amène le patient à sortir peu à peu de la réaction d'immobilité. Comme le précise Lévine [7], « la remise en acte représente la tentative de l'organisme d'achever le cycle naturel d'activation et de désactivation qui accompagne la réponse à la menace dans la vie sauvage ». Inciter à focaliser son attention facilite une diminution de l'action du système orthosympathique et facilite un processus de décharge salutaire.

En hypnothérapie, la dissociation thérapeutique permet cette même assimilation. Pour Rossi [6], chaque symptôme, chaque manifestation émotionnelle, chaque sensation corporelle est une modalité de l'expérience du sujet et un signal qui facilite l'accès à d'autres modalités expérientielles du sujet. C'est dans cette optique qu'il faut comprendre Roustang [25] pour qui le symptôme est toujours quelque chose d'isolée de la personne en ce sens qu'il est une manifestation isolée de l'ensemble des autres modalités humaines. Le sujet en souffrance reste bloqué dans l'angoisse, assujetti à des réminiscences par exemple. Il peut être aussi assiégé par des obsessions ou des douleurs somatiques psychogènes. En invitant le sujet à focaliser son attention sur une émotion ou une sensation dysphorique, il lui est possible d'accéder à d'autres modalités expérientielles comme des pensées, des images ou des émotions autres. De la sorte, nous facilitons une élaboration heuristique propice aux changements. Rossi parle de « transduction de l'information » pour décrire cette créativité naturelle psychodynamique qui passe par une interaction entre des processus implicites et explicites. Il s'agit non pas de contrôler le symptôme tel qu'il se manifeste mais de l'utiliser comme une occasion d'explorer et de faire émerger de nouvelles possibilités de communications centripètes (entre le soma et la psyché) et centrifuges (entre le sujet et l'autre) propices au bien-être.

Généralement, les séances psychothérapiques de Rossi suivent le cycle créatif en quatre étapes décrit par Wallas [26] : préparation, incubation, illumination et vérification. La première étape, la préparation, s'appuie sur l'expérience corporelle au cours de laquelle le patient vit la totalité de ses expériences (« felt sense », [24]). On remarque à ce stade des réactions physiologiques (vibrations, tremblements, transpiration, accélération du rythme cardiaque, émotions, etc.) témoignant le plus souvent d'une activation du système orthosympathique. La seconde étape, l'incubation, consiste en une exploration intérieure (lâcher-prise, dissociation, réassociation, association libre, recadrage, etc.). Cela s'appuie sur la conscience entendue comme modalité à la recherche de la nouveauté qui prend en compte à la fois les changements environnementaux et intérieurs afin de permettre une réaction adaptative [27]. Il semble que l'accès au sens ne soit possible que secondairement. C'est au cours de ce travail psycho-corporel que la transduction de l'information paraît la plus intense et thérapeutique. Cela repose généralement sur le relâchement vagotonique qui va favoriser une reliaison des informations jusque là dysfonctionnelles aux anciennes stockées en mémoire à long terme. L'avant dernière phase s'oriente davantage vers une résolution naturelle. Comme le remarque Lévine [7]: « Une fois que vous en prenez conscience, les sensations internes se transforment presque toujours. Ces changements vont habituellement dans le sens d'un plus grand flux d'énergie et de vitalité ». Après un temps passé à vivre pleinement ce qui se joue dans son corps, le patient en vient à ressentir une issue positive : sensations corporelles agréables, émergence de nouvelles cognitions et/ou de souvenirs positifs, imagination créatrice. Ceci est la conséquence d'un travail implicite qui s'est joué lors de l'étape précédente. De nouvelles possibilités se font jour. Enfin la dernière phase, la vérification, facilite les associations entre le passé et le présent. La symbolisation ainsi que la verbalisation renforcent les effets de ce qui s'est joué au cours du travail effectué avec le thérapeute. Il s'agit d'un moment d'intégration, de consolidation de ce qui vient d'être vécu par le patient.

Conclusion

A partir d'une analyse expérientielle de diverses psychothérapies, et plus spécifiquement en s'appuyant sur la clinique qu'offrent l'EMDR et l'hypnothérapie, la question de la prise en charge du trauma amène le clinicien-chercheur à lier différents courants théoriques. Le processus de lâcher-prise, envisagé comme une dynamique psychocorporelle où se mêlent dissociation, réassociation et vagotonie, semble répondre à ce souci à la fois réflexif et pratique du difficile traitement des traumas sévères ou légers. L'intérêt est de deux ordres : il facilite des ponts entre la clinique et la neurobiologie et apparaît également comme une notion intégrative en ce sens qu'il est observable dans diverses psychothérapies qui visent la résolution de traumatismes. Il reste maintenant à affiner la compréhension de ce processus et à développer divers procédés susceptibles de l'utiliser de façon appropriée en fonction des situations cliniques. Pour ne pas laisser son patient aux abords de l'abime traumatique, le thérapeute doit s'exercer à une pleine présence pour jouer le rôle d'un contenant suffisamment étayant et devenir ainsi un « tuteur de résilience ».

Abstract

Based on the increasing interest in sociological updates, the authors (mainly the clinical sociologists) and considering the fact that the situations described become the focus of interest also the new sociologists, in terms of our approach, we consider that they have taken into account the observation made by Bertaux, namely that the life story in its particular form the memory of practical stories, has deep affinity with the situation described.

We consequently consider that all sociological approaches on a subject (mainly the especially supportive ones) should always target the specific aspect of the given situation, based on the deep understanding of that situation : the understanding of its causes, determining the prognosis regarding the possibilities of evolution of the situation.

The question in child protection for example arises due to the fact that, in order to understand a situation, its causes and possible evolution, the life story can seem opaque and devoid of useful auxiliary interpretation. Under these conditions we observed that in order to justify an action in a legitimate situation and in the best interests of the child, a useful interpretation is necessary to accompany the history of life, able to clarify concepts as is the understanding of the concept of resilience, the dynamic analysis of balance in risk factors and of protective factors.

This study is the analysis of the life history of two children who are in a position of special protection of the Roman state. It aims to reduce extreme risk to which they were subjected in terms of : assisted resilience, dynamic equilibrium analysis of risc factors and of protective factors. This study is intended as a support for professionals involved in child protection. The study may be necessary to researchers who do not aim to obtain only statistical data and in the case of an understanding of the phenomenon of children who are victims of aggressive behavior.

Keywords : biography, story of life, story of life practices, resilience, dynamic equilibrium analysis of risk factors and protective factors.

Présentation succincte des méthodes et des résultats

Il este nécessaire de préciser tout d'abord que le concept principal que nous avons utilisé est celui de récit de vie, que nous avons complété avec des éléments caractéristiques a celui de l'histoire de la vie (life history), en comprenant ici des autres documents - témoignage des personnes de référence pour les sujets, les dossiers personnels des deux enfants, les résultats des évaluations etc. Nous avons été intéressés aussi par les histoires des pratiques qui les deux enfants ont déroulées parallèlement aux leurs récits de vie avec notre appui.

Les histoires des pratiques nous intéressent particulièrement pour mieux connaitre aussi les expériences qu'ils ont vécues, leurs contextes, mais aussi les pratiques de system de la protection de l'enfant qui les ont aidés ou avec qu'ils ont été confrontés.

Pour faciliter l'interprétation des dates fournis par les récits et les histoires, nous avons appelé aussi à l'apport de la balance dynamique des facteurs de risque et de protection [2]

En raison des contraintes du Template de Congres, nous avons contracté (resserré) les informations jusqu'à la limite ou elles restent intelligibles.

Les récits de vie proviennent des deux enfants qui se trouvent sous la mesure de protection spéciale de l'État roumain en raison de risques extrêmes auxquels ils ont été soumis: A. – un garçon de 12 ans et M.- une fillette de 14 ans.

1.1 Récit d'A. bref

- il provienne d'une famille légalement constituée; sa famille était caractérisée par la violence sur le fond des consommations de l'alcool (aussi le père que la mère, ils consomment de l'alcool);
- a l'âge de 2-3 ans de l'enfant, sa mère este séparée de son père ;
- dès cette séparation ils ont commencé la chaîne des réconciliations, des querelles et des séparations. Jusqu'à l'âge de 8 ans d'A., sa mère donne naissance aux encore trois enfants: un garçon – D., plus petit qu'A. avec 4 ans (engendré avec le père d'A), un garçon – L. (engendré avec un autre homme, mais qui n'habite pas avec eux) et une fillette – A.M. (engendré aussi avec un autre partenaire, parti a l'étranger;
- à l'âge de 3-4 ans A. était rejeté périodiquement a son père. Son père a vécu dans un environnement violent, avec des individus douteux, qui pratiquaient de jeux de hasard. Il s'était vanté d'avoir fusillé des policiers. La grande mère paternelle était diagnostiquée avec la démence, le grand père paternel était violent ;
- la mère d'A. provenait d'une famille ou la mère été une Allemande sourde-muette a cause d'un accident, le père (grand père d'A) était séparé de sa femme. Le grand père d'A a changé plusieurs femmes pendant qu'il s'occupait de sa fille (la mère d'A). Cependant, un frère de sa mère se trouvait dans une Maison de l'Enfant. Les témoignages prouvent que la mère d'A était une femme intelligente, mais très agitée, très nerveuse (peut-être et à la cause de l'alcool)
- pendant 2 ans nous retrouvons la mère, avec A., avec D. et avec L. dans un Centre Maternel. Apres ces 2 ans elle a reçu un logement ANL (de la parte de l'Etat). Ici elle trouve le dernier partenaire avec qui elle engendre A.M.
- âgé de 6-7 ans, A. est obligé par sa mère soigner ses frères. D'ici il se charge de ses frères, il assume ça.
- à l'âge de 3-4 ans A. assiste à la scène ou son père a tue sa mère, âpres l'abus d'alcool qu'ils ont consommé ensemble et il s'enfuit pour demander de secours. Ses frères (D, L. et AM) dormaient.
- la sœur est placée à une cousine germaine de sa mère et les garçons sont internés dans le Centre d'Accueil en Régime d'Urgence. Ici, pendant plus d'une année personne ne parle avec eux: ni un psychologue, ni un médecin, ni un assistent sociale, juste une personne qui avait l'obligation de compléter leurs dossiers. En complétant les dates fournis par le récit de vie et l'histoire de vie avec les date fournis de l'analyse historique nous découvrons que le Centre d'Accueil, au moment du placement des les trois frères était conduit par un homme sans préparation, nommé politiquement et qui ne commençait encore ses études supérieures…
- De Centre d'Accueil en Régime d'Urgence, les frères (les garçons) sont placés dans un service résidentiel de tip familial appartenant à une ONG ;
- présente ADHD ;
- A l'école il y a des professeurs qui vont s'échapper de lui, parce qu'il était violent, impertinent, mais le dernières 6 mois il a crée l'impression de s'apaiser ;
- Il fait part d'un club privé de football, ou il a de meilleures relations avec ses entraîneurs; il est un de plus doué gardien de but de sa génération.

Pour une meilleure interprétation de l'histoire de la vie, nous avons transformé les événements de celle-ci dans des facteurs de risque et de protection, sous la forme de la balance dynamique des facteurs de risque et de protection [2]. Voila les résultats (après ce que nous avons éliminées les facteurs sur qui nous n'avons pas d'informations):

Facteurs de risque individuels	**OUI/ NON**	**Facteurs de protection individuels**	**OUI/ NON**
Problèmes de santé physique	NON	Bonne santé physique	OUI
Sexe masculin	OUI		
Niveau d'activité hors norme (anormalement faible ou élevé)	OUI		
Tempérament difficile	OUI	Tempérament agréable	
Attachement insécurisant	OUI	Attachement sécurisant	
Stratégies de coping ou mécanismes de défense peu efficace	OUI	Stratégies de coping ou mécanismes de défense très efficace	
Habiletés sociales déficitaires	OUI	Très bonnes habiletés sociales	
Faible estime de soi		Bonne estime de soi	OUI
Enfant victime de la maltraitance	OUI		
Intelligence hors norme		Intelligence moyenne ou supérieure	
		Pratique d'un sport	OUI

Facteurs de risque en famille		**Facteurs de protection en famille**	
Instabilité de la structure familiale	OUI		
Nombre élevé des enfants dans la famille	OUI		
Pauvreté des parents	OUI		
Problèmes de consommation de drogue ou d'alcool	OUI		
Violence conjugale	OUI		
Problèmes de santé physique ou de handicap d'un membre de la famille	OUI		
Perte d'emploi	OUI		
Stress parental	OUI		
Absence d'une interaction positive avec l'enfant	OUI	Interactions positives avec l'enfant	
Absence d'attentes ou attentes irréalistes envers l'enfant	OUI	Attitude positive envers l'école et attentes réalistes envers l'enfant	
		Bonnes relation avec la fratrie	OUI
		Bonnes relation avec la famille élargie	OUI
Facteurs de risque environnementaux		**Facteurs de protection environnementaux**	
Habitation non sécure	OUI		
Surpopulation dans le logement/ espace personnel insuffisant	OUI		
Fréquence élevée de déménagements	OUI		
		Présence d'un adulte significative pour l'enfant	OUI
Réseau social des parents très réduit	OUI	Riche réseau social des parents	
Réseau social de l'enfant très réduit	OUI	Existence d'un réseau d'amis pour l'enfant	
Quartier isole, défavorisée ou sans ressources	OUI	Maison et quartier agréable	

Tableau no.1 Les facteurs de risque et de protection de l'A.

A ces facteurs de risque on s'ajoute quelques uns spécifiques :

- l'absence d'intervention et d'accompagnement des services sociales primaires offerts aussi à la mère, qu'au père d'A ;
- l'inexistence des spécialistes dans les services d'intervention en régime d'urgence (psychologues, psychothérapeutes, assistants sociaux compétentes) qu'ils puissent aider l'enfant consommer son deuil, interpréter et travailler sur ses traumas.
- les nominations politiques des personnes incompétentes (sans la préparation et sans l'expérience nécessaire) pour les fonctions de chef de services sociaux (A. a resté plus d'une année dans le service d'accueil en régime d'urgence, sans qu'il soit abordé par un spécialiste, d'autant plus d'une équipe multidisciplinaire!).

Dans le cas d'A. il est besoin de (ré) construction des facteurs de protection qui puisse équilibrer la balance dynamique des facteurs de risque et de protection, mais dans l'absence des spécialistes qui coordonne cette activité peut la transformer dans un autre facteur de risque, peut-être, le plus périlleux de tous.

1.2 Récit d'M. Bref

- elle est abandonnée par sa mère a l'âge d'une année;
- âpres son abandon maternel elle est restée a son père. Mais son père, a cause de son service, laisse M. dans la charge de son frère; celui-ci négligeait sévèrement M. (pour qu'elle ne voit pas ce qu'il faisait avec sa amie, ils l'obligeaient de dormir);
- à l'âge de 3-4 ans, le père donne M. aux ses grands-parents paternels pour qu'elle soit soignée ; elle se rappelle que *„cette année a été la seule année heureuse de sa vie"* ;
- après une année passée aux grands parents, son père tombe malade et il meurt;
- elle déménage avec ses grands-parents au domicile de son père;
- âpres un an c'est le grand père qui meurt (elle était a l'âge de 6 ans);
- après plus d'un an, sa grande mère a contracté un néoplasie; ils l'ont fait un anus artificiel, que la fillette fallait le changer pendant presqu'une année (elle s'est chargée de soigner sa grand-mère en disant *„Voila combien*

de choses elle a fait pour moi!") Ce le moment ou elle pense premièrement devenir médecine. Les dernières semaines de vie de la grand-mère, la fillette dormait très peu, de crainte que la vieillarde ne meure pas seule; elle endort à l'école, ou elle a été remarque par son institutrice; cette ci annonce la sœur de sa grande mère pour venir aider M.

- a l'âge de 9 ans c'est la grand-mère qui est mort (en se rapportant aujourd'hui au cet événement elle se dit : „*Si ma grand-mère n'était pas morte, je ne serais pas ce que je suis*, *inclusivement les bonnes choses*");
- elle est parti à la sœur de sa grand-mère ; pendant une semaine elle a médité à la proposition que son institutrice lui avait fait avant de la mort de sa grande mère, et finalement elle a accepté de se loger au domicile de sa institutrice ;
- depuis deux ans elle fréquente une centre de jour ;
- elle a plus de 60 de diplômes obtenues dans les concours scolaires. Elle a souffert une grande dépression (conformément aux ses affirmations) l'année dernière, a l'occasion d'olympiade d'éducation civique ou, dans la première phase a appris qu'elle a gagné la première; deuxième jour, quand elle s'est déplacée pour recevoir son diplôme, ils l'ont dit qu'elle s'était classée la troisième;
- de plus elle écrit, elle dessine et elle peinte ;
- elle a peur de l'insuccès.

Pour une meilleure interprétation de l'histoire de la vie, nous avons transformé les événements de celle-ci dans des facteurs de risque et de protection, sous la forme de la balance dynamique des facteurs de risque et de protection [2]. Voilà les résultats (après ce que nous avons éliminées les facteurs sur qui nous n'avons pas d'informations):

Facteurs de risque individuels	**OUI/ NON**	**Facteurs de protection individuels**	**OUI/ NON**
Naissance non désirée	OUI	Naissance désirée	
Problèmes de santé physique		Bonne santé physique	OUI
Enfant présentant un défaut physique perceptible		Enfant ayant une apparence attirante	
Sexe masculin	NON		
Tempérament difficile		Tempérament agréable	OUI
Lieu de contrôle externe		Lieu de control interne	OUI
Attachement insécurisant		Attachement sécurisant	OUI
Stratégies de coping ou mécanismes de défense peu efficace		Stratégies de coping ou mécanismes de défense très efficace	OUI
Habiletés sociales déficitaires		Très bonnes habiletés sociales	OUI
Faible estime de soi		Bonne estime de soi	OUI
Enfant victime de la maltraitance	OUI		
Intelligence hors norme		Intelligence moyenne ou supérieure	OUI
Facteurs de risque en famille		**Facteurs de protection en famille**	
Instabilité de la structure familiale	OUI		
Problèmes de santé physique ou de handicap d'un membre de la famille	OUI		
Perte d'emploi	OUI		
Capacités cognitives limitées de la mère			
Stress parental	OUI		
Structuration éducative inadéquate		Structuration éducative adéquate	OUI
Facteurs de risque environnementaux		**Facteurs de protection environnementaux**	
Habitation non sécure	OUI		
Fréquence élevée de déménagements	OUI		
		Présence d'un adulte significative pour l'enfant	OUI
		Bonne utilisation des ressources	OUI
Réseau social des parents très réduit	OUI	Riche réseau social des parents	
Réseau social de l'enfant très réduit	OUI	Existence d'un réseau d'amis pour l'enfant	

Tableau no.2 Les facteurs de risque et de protection de M.

Aux ces facteurs de risque on s'ajoute l'un spécifique:

- l'absence d'intervention et d'accompagnement des services sociales primaires offerts aussi à la mère (pour ne pas abandonner sa fille), qu'au père de M. et puis, a M. même; il este possible l'inexistence de ces services (M. est reste seule avec sa grande mère malade presqu'une année, personne de ces services n'ont pas référé le cas de M. aux services publiques spécialisées).

Comme facteur de protection nous avons enregistré la maturité excessive de M. qui cherche par soi-même qu'elle comprenne, qu'elle travaille sur ses deuils répètes, ses traumas et qu'elle les assume.

Aussi comme dans le cas d'A, dans le cas de M. il est besoin de (ré) construction des facteurs de protection qui puisse équilibrer la balance dynamique des facteurs de risque et de protection, mais dans l'absence des spécialistes qui coordonne cette activité peut la transformer dans un autre facteur de risque, peut-être, le plus périlleux de tous.

Pour mieux comprendre M., voici en bas quelques ouvrages d'elle (Fig.1, 2)

Abstract

During childhood, the non-verbal communication is extremely complex – mimicry, gesticulation, graphic gestures, color, motor skill, negativism or agitation can express various thoughts, feelings, frustrations and aspirations.

Material and Method

Art Therapy, as a non-directive method, aims to reestablish the individual's harmony in relation to himself and to others. The present study included 20 children and teenagers of both sexes and from different social backgrounds, with the basic diagnosis of emotional disorders. The techniques that we used were: drawing, modeling, painting, building-up with non-conventional materials, various multimedia techniques, animation. The subjects worked both individually, and in groups, as the multiple purposes were: the harmonization and the coordination of movements, the stimulation of initiatives, the development of imagination and creativity, as well as of interaction with others.

Keywords: non-verbal communication, art therapy, emotional disorders, child, teenager, beneficiary, creative process, image, form.

General considerations

According to Elliot V. Eisner [1] art celebrates diversity, providing the children with different solving problem solutions and multiple answers to their questions. Furthermore, it teaches them that there are several ways of seeing and interpreting the world and that people can gaze through multiple windows. This diversity of approaching and solving the issues represents the path to individuality. The practice of arts leads children in finding various solutions by adapting to the changes and to the circumstances and by discovering emerging opportunities. Therefore, the purpose of art in this context is not an exercise of the already acquired knowledge upon the artistic material, but a discovery of the yet unknown.

Our aim is to uncover these new perspectives and sources of inspiration in order to advance in defining the importance of resilience in personal development. The development and the maintenance of social abilities will thus be the necessary conditions of an improved adaptability and of the capacity of personal transformation.

The recent researches have proven that the traumatic experiences are stored in mind as images and that the practice of visual arts offers the beneficiaries a unique way of expressing them consciously without a traumatic effect and a worsened condition when confronting them. We try to promote creative education/Art Therapy within the dynamic of production. This implies a complex, indirect, subtle and sometimes even contradictory approach. Any planning whatsoever would impair the vitality of the creation. The whole process requires that the artist/art therapist should create together with the beneficiaries. As we have stated elsewhere – Emilia Chirilă [2]–, the application of ideas, meaning the creation of works of art, is a process of education – self-surpassing – research – knowledge – self-knowledge – invention – creation – execution, with which the

artists are well acquainted with; it cultivates the capacity to assume the unknown and it enhances the person's adaptability, objectives both of art in general and of Art Therapy, given that the former is the essential part of the couple.

"The multimedia technique, evolving towards eloquent visual representations, incorporates a knowledge that supports perception as well as cognition. Thereby, the experience of a child or teenager related to the visual perception through animation is both cognitive and affective. After the reign of television, the computer became the main medium, while by integrating computers in a network their communicational function has prevailed over that of data processing. Paradoxically, in time and space, the visual that is commonly subjected to the aggressive insertions of innovation – namely the violent tendencies of 3D graphic – makes room in animation for a reinsertion and a reinvention of the graphic gesture, even of music. Precisely this specific interaction between the cognitive and the sensorial processes produced by the technique of animation, leads to such a discovery of one's own feelings and thoughts. Emphasizing this experience can obviously have baneful consequences in regard to children, but under the appropriate coordination by a professor/art therapist, the beneficial effects override." (Diana Drăgan-Chirilă, teză de doctorat) [3]

Neuromarketing is a developing interdisciplinary field that uses the neuroimaging technology (like magnetic nuclear resonance and electroencephalography) for studying the way in which the brain is physiologically affected by the advertisement and marketing strategies. Neuroethics is applied to the activity of the companies that influence the quality of the media (consisting of advertising agencies, web designers, television, radio, magazine and digital media companies, product and packaging designers, film, radio and TV producers etc) in order to prevent the drastic altering of consumers' behavior. They are both intended to alleviate the negative impact of advertising on the consumers. [4]

In order to establish the objectives of art-therapy, we need to take into consideration that the resilience is influenced by three major factors related to the child's personality, to his abilities and to external factors. Tolerance to frustration, self esteem (related to self confidence), personal autonomy, optimism, empathy and emotional stability are thus cultivated by the people around. [5]

The focus point is the artistic expression of the beneficiary, meaning any aspect that may lead to new life possibilities by taking part in the artistic process with the objectives of advancing towards self fulfillment and of having a meaningful life, notwithstanding the degree of disability. [6]

The educational/art therapeutic undertakings focus on several objectives:

- practicing the abilities to express one's feelings, anxieties and experiences verbally and non-verbally
- the consolidation of self-respect and of confidence in one's abilities by engaging the positive aspects of the personality
- the training of empathy in interpersonal relationships
- the development of personal problem and conflict (both inter and intrapersonal) solving strategies
- the breaking through the emotional blockages
- the optimization of self knowledge and self acceptance capabilities
- the improvement of cognitive abilities
- the release of tension, anxieties, stress
-the removal of frustrations and negative feelings
-the perfecting of already acquired abilities (collage, painting, modeling etc)
-the development of social competences

Methods and Training Materials

1.1 Methods

Our training took place individually and in groups – group activities are useful in developing the communicational and relational abilities – and the aforementioned aspects were closely monitored.

On the other hand, Art Therapy concerns itself with the information that the images have to offer regarding their author. The making of art or the production of other crafts resembles a situations test.

The analysis of the products allows the beneficiaries to attain a certain level of introspection and to "work through" their problems in a constructive manner.

1.2 Materials and techniques

We use materials and techniques that are specific for visual arts (painting, sculpture, graphic, multimedia, photography, film, animation and digital media), but also traditional ones, specific to tridimensional arts, such as pottery wheels and sculptural modeling. They are all integrated into the artistic medium through collage, natural materials and even techniques of combined arts, for instance role playing (theatre) or confectioning ceramic musical instruments (whistle, bells) and playing them (melotherapy).

The group that we studied consisted of 20 children and teenagers, of both sexes, from various social backgrounds, with emotional disorders as their main diagnosis. We made use of the following techniques: ceramic, drawing, modeling, painting, assemblage of unconventional materials, multimedia techniques, animation. We evaluated their self-image and self-esteem by means of the following instruments:

The Self Esteem Scale
The Children's Attributional Style Questionnaire
The Child and Adolescent Scale of Irrationality
The Child Attitudes and Beliefs Scale

1.3 Case Studies

Group Therapy – The children cut pieces of clay with a wire, after which they reassemble the fragments. They apply their ideas upon the finished products that they present afterwards to their colleagues. The latter are supposed to guess what the finished form stands for and what it means, by talking to each other about the images.

For instance: R.R., male, 7 years of age, "Boat"; B.C., male, 13 years: "Cock"; L.A., male, 9 years, "Cave" and "Story with a Sheet of Paper" (a beneficiary diagnosed with the Asperger syndrome takes part in group therapy alongside children with behavioral, emotional and adaptability disorders).

R.V., male, 6 years – diagnosed with emotional disorders, chromosomopathy, mental retardation with autistic accents. In therapy we used multimedia techniques, film and cartoons. During the viewing, we capture the images on the computer and we copy them in various artistic media: drawing, color and modeling. The child is properly assisted in his evolution of self consciousness and in developing his view of the medium and its functioning.

J.P., male, 11 years – diagnosed with emotional disorders, Pierre Robin syndrome, language disorders, medium/light retardation. The child is properly assisted in his evolution of self consciousness and in developing his view of the medium and its functioning. We begin with focus exercises on the small wheel, accompanied by exercises of coordination fine and gross motor skill. The whole body of the beneficiary is thus involved in the processes of form creation, decorating and painting. Therefore, they stimulate simultaneously the visual and the tactile, the spatialization and the space orientation. Results: the breaking through the emotional blockages, the overcome of inhibition by successes repeated on every level of production, the removal of frustrations and negative feelings leading to an increase of self-esteem.

M.A., male, 6 years – diagnosed with selective mutism. The child is stimulated in the problem-solving and the decision-makings strategies, in order to achieve formal diversifications. New abilities unknown by then emerge, leading to the structuring of a positive self image; the discovery of one's own abilities by means of art and the awareness of one's emotions and feelings thus attained opens new ways of non-verbal communication. The joyfulness of creating and the successes appreciated by the parents and by the people around diminish the conflicting traits of the child's living environment. The reconstructed self image and the now positive self esteem contribute towards surpassing the emotional disorders caused by the environment. For a better social interaction, we sometimes work in small groups (of 2 or 3 persons) in which each of the members execute separate phases of creation and production, according to each one's skills, in regards with a unique ceramic product. However, the common purpose of achieving the finite product is kept up throughout the activity.

M. D., female, 14 years – diagnosed with discordant syndrome, liminary intellect, low adaptability. The relief of tension and anxiety is achieved by exhibiting her drawings, alongside that of the other children of her age and by her being thus accepted by them. From her exhibited works, we can deduce an instilled state of calm and self-acceptance. In order to efficiently resolve conflicts and to optimize the abilities of self-knowledge and self-acceptance, we used a visual journal through which she expressed her feelings and thoughts. This way, she is able to both confront and censor herself successfully, developing her capacity to overcome psychic obstacles. For example, if before the therapy she posits the presence of an imaginary person: "I can't get Maili out of my mind" or "I can only speak with my friends about M., even if they can't stand it", afterwards, in her abstract works, he doesn't appear anymore, having remained at the Waldorf school.

Ş.S, male, 11 years – diagnosed with cerebral paralysis, left sided hemiplegia, slight retardation, mixed behavior and emotional disorders. The involvement of the whole in the creation process and the use of artistic techniques related to pottery (drawing, painting, sculptural modeling). By way of formal diversifications, we stimulate problem-solving and decision-making strategies and we discover new abilities, leading to the reconstruction of a positive self image and to the development of social skills. The motor acquisitions are in this case obvious also in the fact that after the therapy, he is able to ride the bicycle.

1.4 Results

While the premises of the therapeutic process were inhibition, anxiety, or depression, we achieved the following results:

- a decrease of anxiety
- diminished frustrations
- self acceptance alongside an increase of self esteem
- verbalization of activities
- improved interaction
- a progress in family and school adaptability

1.5 General Conclusion

Considering the diversity of the child`s non-verbal communication, Art Therapy is not a mere accessory method within the therapeutic process of the emotional disorders of children, but a mandatory condition of it.

La resilience : entre structure constitutive et reaction comportementale une approche psychanalytique

Ciomos V.

Roumanie, Forum du Champs Lacanien, Paris
virgil_ciomos@yahoo.com

Abstract

After a short remember of the Freud's vision of the trauma's main changes, the author proposed a differentiation between a primary resilience, adequate to several psychic reactions due to the more or less accidental traumas,a secondary resilience,adequate to symptoms characterising different psychic structures of all the human subjects, whose trauma seems to be constitutional,and a third resilience,which replaces the missing symptom, adequate especially to psychosis.He finished his text with some details concerning some clinical consequences of such a taxonomie.

Key word : resilience, trauma, neurosis, psychosis, replacement

Les débats modernes et contemporains sur le statut de la maladie « mentale » ont traversé presque tous les cas de figures, en commençant avec la distinction moderne entre la normalité et, donc, la santé, et l'anormalité et, donc, la maladie – c'est le début même de la psychiatrie, qui a conduit à la création des premiers asiles – et en finissant avec l'effacement de cette même distinction, mesure « démocratique » réclamée par le mouvement antipsychiatrique contemporain – rappelons-nous l'exigence politique de « libérer » les malades des hôpitaux psychiatriques afin de les « intégrer » dans la société. Nous nous confrontons – aujourd'hui encore – avec des prises de position « *soft* » plus ou moins proches de cette « mise en question » de la psychiatrie. Pensons, par exemple, au statut – tout à fait secondaire – du psychiatre dans le déroulement d'un procès qui soulève des questions sur la responsabilité du présumé coupable et, par la suite, sur sa santé « mentale ». Car, en France en tout cas, ce n'est pas le spécialiste qui en décide, mais le juge... Bien sûr, le juge peut toujours demander l'avis d'un psychiatre, mais la responsabilité de la décision lui appartient en exclusivité. Situation assez délicate, voire difficile, car elle suppose que, avant de se prononcer sur un tel cas, le juge a été lui-même « jugé » du point de vue psychiatrique – par quelqu'un d'autre, bien évidemment (un juge ou un psychiatre ? – nous laissons la question « ouverte ») – pour que des éléments « particuliers » de sa vie personnelle ne soient pas en mesure d'influencer sa décision. Difficulté de principe et récurrente, y compris dans le domaine de la psychanalyse où la même question se pose : par « qui » doit être analysé le « premier » analyste ?

Aussi, le défit théorique et pratique d'une différenciation « claire et distincte » entre santé et maladie reste-t-il au cœur de notre société, soucieuse d'assurer et, surtout, de dédommager tout accident initial – fût-il génotypique – ou de parcours – fût-il phénotypique. Plus encore, nous faisons aujourd'hui beaucoup d'efforts pour « régler » notre propre accident final, à la fois génotypique et phénotypique, qui est la mort. Dans ce contexte complexe, voire confus, la psychanalyse a avancé une vision méthodologique inattendue parce qu'originale par rapport aux deux attitudes extrêmes, évoquées ci-dessus. Elle nous propose, en effet, une sorte de « synthèse dialectique » entre l'attitude moderne – qui insiste sur une nette et ferme différenciation entre santé et maladie – et celle contemporaine – qui tend à effacer cette différence – en renversant, finalement, toutes les deux grâce à une nouvelle perspective, plus compréhensive. En effet, la psychanalyse affirme que nous ne pourrons jamais vraiment connaître la « normalité » psychique sans une analyse attentive de ses éléments constitutifs, qui, d'une manière paradoxale, se révèlent à nous justement à travers les maladies « mentales » et, plus précisément, dans les psychoses [1]. Ce qui reste caché – et, donc, non analysé – dans le *mixtum compositum* des actes propres aux « névrosés moyens » que nous sommes nous – c'est la dénomination psychanalytique de ceux que, plus inspiré encore, Victor von Weizsäcker a désignés par un oxymore : les « normopathes » [2] – se présente séparément et, donc, analysable dans les psychoses. Le paradoxe logique se convertit ainsi dans un oxymore linguistique. Bref, la psychopathologie des psychoses fonctionne comme un véritable spectrographe pour la grande masse des névroses. Ou, inversement, ce qui est complexe et caché dans les névroses devient simple et manifeste dans les psychoses. À l'intérieur de l'histoire de la psychanalyse, ce

changement de méthode coïncide avec le passage de Freud à Lacan. Ce qui suppose aussi un autre déplacement – avec des conséquences cliniques tout aussi importantes –, car, contrairement au scepticisme initial de Freud (qui doutait qu'il y ait un effet bénéfique de l'analyse sur l'évolution des psychoses), il exige de la part des psychanalystes – et non seulement – une réponse « claire et distincte » quant à la « question préliminaire à tout traitement de la psychose » [3]. Voilà, donc, le vrai défi : y a-t-il une résilience dans les psychoses ? Ou, plus généralement, quelles sont les bénéfices et les limites de la résilience même ?

La résilience primaire

Il est évident que la réponse à toutes ces questions dépend de la façon dont on définit le trauma. Or, de ce point de vue, la conception de Freud a sensiblement changé. Il y a eu un premier moment où Freud hésitait encore à bien différencier l'inconscient, d'une part – instance psychique qui survient au même moment que la conscience mais qui n'a jamais été et ne sera jamais réductible à la conscience – et le subconscient, d'autre part – qui se réduit, lui, à une simple expérience consciente déroulée dans le passé – fût-elle traumatique –, dont le sujet ne se souvient plus. C'est la fameuse hypothèse de la *Neurotica* [4]. En tant qu'événement traumatique et, par conséquent, insuffisamment « classifiée », cette expérience passée « hante » le présent du sujet – incapable parfois de se rappeler son propre trauma (qui lui est devenue, ainsi, impropre) – en revenant – tel un « fantôme » – pour provoquer finalement la réaction hystérique du sujet. Autrement dit, l'hystérique souffre de réminiscences « réelles », c'est-à-dire « réellement » passées. Aussi, le travail d'anamnèse – très long et délicat – que l'analyste initie – y compris sous hypnose – est-il censé justement donner un « sens » – univoque, si possible – à ce passé impropre, pour que le sujet puisse se l'approprie et, par analogie, pour que l'unité temporelle entre son passé et son présent soit finalement « refaite ». Dans ce cas, la résilience serait la conséquence d'un travail d'appropriation du passé par un présent – assisté par l'analyste – qui devrait être renforcé par un « sens » lui-même appropriant parce qu'univoque. Cependant, dans un deuxième moment, Freud a pu observer que le même événement qui provoquait – dans le passé – un trauma pour tel sujet n'avait pas le même effet – traumatique – pour un autre. Un constat empirique simple à faire, mais tout à fait essentiel du point de vue clinique. Car, maintenant, la « cause » de la réaction hystérique n'est pas l'impropre d'un passé qui « hante » le présent « déstabilisé » du sujet mais plutôt leur relation subjective ou, plus précisément, la perception *post*-traumatique que le sujet lui-même – censé être dans le présent – se fait de son passé [5, *Lettre* 69]. Cela veut dire que le rapport entre le passé et le présent n'est pas automatiquement « assuré » – ni même par l'analyste – et que, en plus, le « sens » qui devrait être « récupéré » par le même analyste – afin de « guérir », pour ainsi dire, l'hystérique – n'est pas non plus univoque. Finalement, c'est justement l'analysant qui devra l'assigner à *sa* relation à lui. Car le « sens » – y compris celui de la succession du temps – est toujours équivoque. En somme, l'hystérique souffre de représentations « imaginaires », c'est-à-dire « imaginairement » présentes. Dans ce cas, la résilience serait la conséquence d'un travail de restitution du « sens » que le sujet lui-même devrait trouver – assisté bien sûr par l'analyste, mais jamais à sa place – à une relation entre le passé et le présent, relation qui lui a provoqué des difficultés. L'accent – et, par la suite, le centre – de la cure se déplace de l'analyste vers l'analysant.

La résilience seconde

Une question assez troublante se pose alors : où est-il l'analysant au moment même où il refait la relation entre son présent et un passé qui devrait devenir, lui aussi, le sien ? Quel est le statut « topique » de l'anamnèse ? Le sujet, serait-il dans le passé ? Non, car, dans ce cas, le passé se confondrait tout simplement avec le présent. Est-il alors dans le présent ? Non plus, car dans ce cas, il n'y aurait plus d'anamnèse. Le lieu temporel de l'anamnèse n'est donc ni dans le passé, ni dans le présent : il est suspendu « quelque part » entre les deux, dans un véritable « non-lieu ». C'est dire aussi que la « topique » du sens propre à la succession temporelle – fût-il déjà connu par l'analysant ou, dans le cas échant (celui de l'hystérique), non encore connu par lui – est, à son tour, un « non-lieu » à la fois propre et impropre de la condition de possibilité même de toute relation temporelle. Lacan dirait qu'il relève non pas d'une topique primaire mais d'une topologie. Or, la condition de possibilité topologique de toute succession temporelle topique est, pour ainsi dire, plus « ancienne » que tout passé déjà présentifié car le possible précède toute actualisation, fût-elle déjà consommée, comme c'est le cas du passé. C'est pourquoi, si le passé propre des réminiscences relève encore de la mémoire, le « passé » impropre du sens relève, lui, d'une sorte d'« immémorial ». C'est à cet « immémorial » – appelé aussi « préhistorique », ou « inoubliable » (instance purement symbolique que Lacan avait « située » au-delà du « réel » du passé comme de l'« imaginaire » de sa perception dans le présent) – que Freud fait allusion dans sa célèbre *Lettre* 52 [5] qu'il avait adressée à son ami Fliess. Autrement dit, l'hystérique souffre finalement de réminiscences « mythiques » (et non pas temporelles) qu'il voudrait rendre encore présentes. Les phénoménologues ont développé cette hypothèse en stricte liaison avec le concept d'institution originaire – *Urstiftung* –, événement survenu dans un passé « transcendantal » [6]. En ce sens, la formule roumaine d'introduction aux mythes (ou, si nous le

préférons, aux comptes de fées) est plus conforme et, par la suite, plus précise que les autres car elle dit, en effet, « il était une fois comme *jamais* ». Ce qui a été « perdu » dans le présent de l'hystérique (et non seulement !) n'a jamais été *effectivement* dans un passé temporellement vécu (comme initialement présent). Ce n'est donc pas la réalité d'un passé temporel qu'il réclame, mais un passé inoubliable – préhistorique et immémorial – « situé » quelque part « avant » tout passé oublié et, donc, historique. L'hystérique a le pressentiment préhistorique d'avoir perdu ce qui, de fait, il n'a jamais eu… Personne ne pourrait le lui « restituer », ni même l'analyste. Dans ce cas, la résilience serait la conséquence d'un difficile « déplacement » du sujet hystérique par rapport à son propre mythe, impropre (qui devrait rester ainsi un simple « mythe » : ni moins ni plus). Dans un langage psychanalytique, l'hystérique n'est pas suffisamment castré par rapport au véritable mythe, impropre. Selon Lacan, son « immémorial » reste et restera un simple mythe « individuel » [3].

Nous sommes ainsi arrivés au moment central de notre exposé car nous devrions maintenant faire la distinction entre une simple réaction hystérique – fût-elle liée à un passé traumatique ou à la perception dans le présent d'un trauma passé – et une structure hystérique – qui n'a plus de liaison directe avec le temps et, par conséquent, relève d'un « trauma » constitutif « atemporel » parce qu'« immémorial », une structure à la fois propre et impropre pour tout sujet humain « normopathe », que la psychanalyse appelle « névrose moyenne ». Cette structure qui, nous le voyons bien, n'a rien de figé car elle relève tout simplement de la « condition de possibilité » de tout sujet humain qui vient au monde (les phénoménologues l'appelleraient « transcendantale ») – est liée à l'impacte du langage – véhicule de tout sens humain « immémorial » – sur le sujet humain. Un impacte qui peut être traumatique. Finalement, c'est un trauma valable pour tout Monsieur Jourdain. Si l'être humain dépasse la condition naturelle de l'animal c'est justement parce qu'il parle, parce qu'il véhicule des sens – Lacan dirait des « signifiants » – qui, à leur tour, le dépassent. C'est un constat qui, bien évidemment, n'est pas exclusivement psychanalytique puisqu'il avait fait l'objet de nombreux et importants développements bien avant Freud et Lacan, entre autres dans la philosophie moderne allemande ou dans la linguistique contemporaine française. Comment donc comprendre tout ça ? Il faudrait, tout d'abord, constater que chaque mot est fondamentalement équivoque : si nous allons chercher son sens dans les dictionnaires, nous trouverons une liste toujours incomplète de significations. Une liste qui se confond en fait avec l'histoire même de l'humanité et de sa connaissance. Qu'est ce que l'« espace », par exemple ? Mais quel « espace », plus précisément ? Celui d'Euclide ? Celui de Newton ? Celui d'Einstein ? Le mot « espace » se révèle être un simple phonème qui désigne un concept, un signifiant dont le sens « ultime » nous échappe et nous échappera toujours. Nous n'aurons jamais une compréhension complète de « nos propres » mots. C'est dire aussi que les mots ne sont pas vraiment « les nôtres », qu'ils nous viennent d'un « non-lieu » – appelé par Lacan « le trésor des signifiants » – auquel nous n'avons pas accès direct. Nous ne saurons jamais la définition de la « Femme parfaite ». En plus, nous ne la verrons jamais « en chair et en os ». Il n'y a donc pas d'accès direct à l'idée de la « Femme parfaite », ni à l'objet « Femme parfaite ». Et pourtant, nous sentons que nous l'avons « perdue ». La « preuve » c'est qu'elle nous manque vraiment. Sa perte est donc « immémoriale ». Le premier des modernes qui nous a avertis quant aux limites de la connaissance humaine a été Kant [7, « La dialectique transcendantale »] : ceux qui croient avoir accès à une idée transcendantale souffrent d'une illusion transcendantale, ceux qui croient avoir accès à un objet transcendantal souffrent d'une apparence transcendantale. Le destin de l'être humain se joue ainsi entre ces deux extrêmes que Lacan désigne par S(A barré) et, respectivement, par objet *a* [3, « Subversion du sujet et dialectique du désir »].

Voilà donc en quoi consiste le trauma initial – « préhistorique » et « inoubliable » – que l'impacte du langage sur l'être humain produit dès le début de sa vie subjective. Dès lors, sa pulsion sera toujours articulée par le langage. Elle lui parviendra d'un « en-deçà » inaccessible – *i.e.* impensable – par rapport à ce monde – le trésor des signifiants – pour le faire sortir vers un « au-delà » tout aussi inaccessible – *i.e.* irreprésentable – par rapport à ce monde – l'objet *a*. C'est le sens même du « désir », mot d'origine latine dont l'étymon est *desiderare*. Or, en latin, *sidera* est un pluriel qui désigne les astres qui habitent le ciel infini. Aussi, « désirer » veut-il donc dire « avoir perdu son astre », ce qui revient, finalement, à un « désastre ». Il s'ensuit que le trauma coïncide avec ce désastre, à savoir avec la perte d'un monde immémorial qui dépasse tout entendement et toute imagination, le seul digne d'être vraiment désiré par l'être humain. C'est ainsi que l'homme et la femme deviennent des êtres « aliénés » au langage et, par la suite, des « normopathes ». Il s'agit d'une maladie et – dans le cas échant – d'une pulsion de mort car c'est seulement par la mort que nous pourrions sortir de ce monde afin d'« atteindre », en fin, les astres et, à la limite, leur origine – le *Big Bang*. Mais quelle serait alors la preuve de cette perte de l'origine que la psychanalyse appelle « refoulement originaire » ? Pour rester encore dans les limites de notre analogie cosmo-logique, nous dirions que le refoulement qui est survenu simultanément avec le *Big Bang* nous a pourtant renvoyé sa propre « trace » – la radiation rémanente, le « reste » de cette ouverture originaire, qui correspondrait chez Freud à la *Bejahung*. Il y a donc des réminiscences qui animent, en tant que restes, notre propre présent – les restes de l'origine même. Autrement dit, l'implosion de l'origine produit quelques effets secondaires, c'est-à-dire un retour de ce qui a été refoulé. C'est la grande découverte que Freud avait faite quant à l'économie – propre et impropre – du psychisme humain. Car il existe, en effet, non seulement des phénomènes primaires – des pensées de l'entendement, des représentations de l'imagination ou des

perceptions de la sensibilité – mais aussi des phénomènes secondaires – des quasi-pensées, des quasi-représentations et des quasi-perceptions – qui nous adviennent à l'esprit sans aucun effort de notre part – *i.e.* d'une manière automatique – et qui, même s'ils arrivent parfois à se fixer dans des pensées, des représentations ou des perceptions, ne cessent jamais de « pulser » dehors (pour les psychotiques) et dedans (pour les « normopathes ») par rapport aux premiers. Au delà des nos facultés de connaissances, le retour de ce qui a été originairement refoulé se manifeste également dans notre « propre » conscience, censée être toujours « en état de veille », car non seulement notre conscience est scandée – et, donc, trouée – par le sommeil et par ses rêves – avec leurs propres formations métaphoriques : les condensations ou métonymiques : les déplacements –, mais elle est trouée même à l'état de veille par de telles métaphores et métonymies.

Comment comprendre ces automatismes – dont celui « mental » a été défini pour la première fois par de Clérambault [8] – à travers lesquels le retour du refoulé s'inscrit dans notre économie psychique ? Ce sont – cette fois-ci – les phénoménologues qui ont essayé de l'expliquer [9]. Si l'origine du langage relève d'un mythe préhistorique et inoubliable il faudrait alors rappeler quel « était une fois comme *jamais* » le statut du langage mythique. Or, toutes les grandes traditions précisent que, dans l'immémorial, il y a une sorte d'« identité entre l'être et la pensée » (et, par la suite, la parole), pour reprendre un célèbre adage parménidien. Quand Yahvé prononce un « mot » – fût-il « *Fiat lux* » –, il crée d'une manière automatique la réalité sous-entendue, à savoir la lumière même. Le « désastre » du désir humain n'est donc pas vraiment complet car le fait même que notre pensée, par exemple – et notre voix, d'ailleurs – est toujours accompagnée – d'une manière automatique – par des quasi-pensées – et des quasi-voix – s'avère être une sorte de résilience du sujet humain par rapport au mythe réel dont il est déchu. Sauf que ces quasi-voix automatiques ne se convertissent en réalité – comme dans le cas du Verbe divin – que dans le cas des psychoses où cette « réalité » se confond avec un délire hallucinatoire [1]. Cela ne les exclut pas du tout de l'économie psychique des « normopathes » car tout névrotique moyen les entend, même si, selon Lacan, il « ne prend pas au sérieux la plus grande part de son discours intérieur » [1]. Nous retrouvons ici l'originalité de la psychanalyse quant au « dépassement » de la différence entre la maladie et la santé « mentale » par leur « synthèse dialectique ». En effet, il n'y a pas de structure psychique – fût-elle celle de la névrose moyenne – qui ne soit pas « en résilience ». Car, par définition, le sujet humain reste « divisé » par rapport à la vraie normalité, qui reste toujours vraiment mythique. Les quasi-voix que les névrosés entendent et qui leur adviennent à l'esprit d'une manière automatique représentent ainsi le « reste » de l'automatisme qui « était une fois comme *jamais* » propre au Langage divin. La résilience n'est donc pas une particularité survenue dans le parcours – plus ou moins accidenté et, par conséquent, accidentel – d'un sujet quelconque : elle est constitutive à tout être humain. En ce sens, la fonction structurale de la résilience est même automatique. En d'autres mots, quand il est question de l'être humain, le problème théorique et clinique de la résilience se pose automatiquement. Aristote avait déjà défini l'être humain en tant qu'« animal inachevé », c'est-à-dire « non-terminé ». Il anticipe ainsi la définition psychanalytique du nouveau-né, qui est, par principe, un prématuré [3, « Le stade du miroir »] incapable de se nourrir, de se déplacer, etc. Or, c'est justement cette in-(dé)termination et, « finalement », cette in-finitude qui – grâce aux trous (*i.e.* aux non-lieux) qu'elles créent en lui – rend possible l'inscription des restes de ce qui gît « éternellement » en-deçà – S(A barré) – et au-delà – l'objet *a* – de ce monde.

Qu'en est-il alors des psychoses ? Si les quasi-pensées qui accompagnent toujours le discours d'un névrotique sont inscrites « quelque part » dans les trous de son discours (par principe discontinu) d'une manière imperceptible et sans susciter un intérêt particulier de la part du sujet, elles prennent, par contre, le devant de la scène pendant le délire psychotique. Nous comprenons mieux maintenant en quoi la psychose rend manifeste ce qui reste caché dans la névrose et pourquoi Lacan considère que, de ce point de vue (purement méthodologique, c'est vrai), la névrose devrait être analysée comme un « cas limite » de la psychose. La conversion des quasi-voix dans des voix étranges – voire étrangères – devient possible justement parce que le sujet psychotique n'assume pas vraiment l'ouverture originaire – la *Bejahung* – de l'au-delà propre au trésor des signifiants, y compris à son « Locuteur » ou, selon le même Lacan, au « Grand Autre ». Aussi, le fait de tourner la face devant la face de Dieu implique-t-il une certaine forclusion du Nom du Père – qui désigne ce « Grand Autre » –, le seul Nom Propre authentique et, de ce fait, inconnu et imprononçable pour les êtres humains. Car tous nos « noms propres » sont, en fait, de simples noms communs écrits en majuscules. Cependant, grâce à la grande découverte de Freud, nous savons maintenant – et toute la clinique des psychoses le confirme – que même si le sujet peut refuser sa *Bejahung* par rapport au « Grand Autre », il ne peut pas refuser le retour de son refoulement originaire. (D'ailleurs, c'est justement grâce au refoulement de l'origine qu'un sujet humain peut exister.) Car, même si, par souci de proférer un discours univoque (*i.e.* réduit à sa propre voix), le psychotique essaie de bloquer – pour un certain temps – la résilience secondaire des quasi-voix qui compensent, en tant que reste, la perte originaire, il ne peut pas les bloquer indéfiniment. Aussi, retournent-elles en tant que délire hallucinatoire, dont l'automatisme frise la « réalité ». Si les quasi-voix initiales – qui, dans les cas de névrose, ne sont pas forcloses – représentent la preuve d'une sorte de résilience seconde « normopathe », leur retour intempestif en tant que délire hallucinatoire représenterait ainsi une résilience seconde morbide – mais résilience quand même – par laquelle le sujet essaie de compenser automatiquement ce qu'il avait initialement déni. Dans un langage psychanalytique, cela signifie

que le délire devient lui-même une tentative (inconsciente) de guérison de la part du sujet psychotique, ce qui a bien sûr d'importantes conséquences cliniques pour la conduite thérapeutique du patient pendant son hospitalisation et, ensuite, si c'est possible, durant sa cure. Nous sommes bien conscients qu'affirmer – comme Freud – que le délire hallucinatoire du psychotique est une tentative de guérison [10] peut scandaliser certains professionnels de la déontologique médicale, mais, pour mieux comprendre la position analytique, il faudrait constater que cette vision audacieuse suppose finalement que la force de la résilience est beaucoup plus grande qu'on ne le pense. Plus importante qu'admettraient peut-être certains de ses propres adeptes. Car elle survient – d'une manière seconde – même dans la crise psychotique…

La résilience tierce

Il nous semble clair maintenant qu'il faudrait faire une distinction nette entre ces deux types de résilience analysés ci-dessus. La résilience primaire relève ainsi d'une simple réaction survenue plus ou moins accidentellement dans la vie du sujet. Parfois, elle a besoin d'un simple soutien externe afin de réintégrer le passé, celui d'une expérience traumatique, par exemple. À la limite, nous pourrions dire que si nous sommes vraiment énervés, il y a beaucoup de chances pour développer une réaction « paranoïaque », si nous sommes vraiment déçus, nous pourrions développer aussi une réaction « hystérique » et si nous avons, enfin, un objet qui nous a été expressément et longuement interdit, nous développerions peut-être une réaction « perverse ». Le plus souvent, ce type de réactions pourrait être dépassé sans l'aide spécialisé d'un psychothérapeute ou avec un petit soutien de quelques bons amis samaritains. Par contre, la résilience seconde fait partie de la phénoménologie propre à des structures psychiques bien répertoriées. Dans ce contexte précis, « résilience » et « décompensation » sont presque synonymes. Il va de soi que ce type – second – de résilience est « douloureux » – pour la psychanalytique, il s'agit, en fait, d'un symptôme – dont la liaison avec le concept même de résilience peut facilement échapper. Plus précisément, le fait même que le symptôme représente déjà une résilience – fût-elle « douloureuse » – peut rester souvent caché à cause de la réaction de « contre-transfert » que l'analysant peut développer face à l'intention du psychothérapeute – le bon samaritain – de lui « offrir » – plus ou moins directement – une « vraie » résilience. Aussi, pourrions-nous définir cette « résilience » offerte par le psychothérapeute – non seulement maladroite mais aussi inopportune – comme une « résilience de la résilience ». Or, ce que nous constatons dans beaucoup de cas de ce type c'est que l'analysant refuse les soi-disant « aides » ou « procédures » proposées par le psychothérapeute. Pir encore – et c'est un constat déjà fait par Freud – il s'avère que, souvent, l'analysant aime son symptôme comme lui-même. Autrement dit, il préfère sa propre souffrance symptomatique au lieu de « guérir » sagement. Nous n'avons pas le temps et l'espace de développer ici et maintenant l'explication que la psychanalyse donne à cet apparemment inexplicable – par ce qu'« irrationnel » – choix du patient. Nous pourrions pourtant anticiper qu'il s'agit d'une certaine jouissance que le patient ressent par rapport à son propre symptôme : la jouissance d'une « inhibition » de type paralytique chez un hystérique ou celle d'une « exhibition » langagière chez un maniaque, par exemple. Car, nous le savons bien, le maniaque est très « heureux » durant sa crise. Et, même s'il est difficile d'accepter, l'hystérique aussi, dans sa paralysie. Aucun moyen cognitif de persuasion n'est efficace dans ces cas-là et, par conséquent, aucune autre résilience – à part le symptôme – n'est envisageable. Pour surmonter cette situation sans issue, il faudrait trouver une petite fissure dans la structure du sujet, un déplacement dans la manière dont s'inscrit son symptôme pour qu'un travail analytique puisse être entamé. Ce qui suppose, toujours, un certain engagement éthique de sa part. De toute façon, il est clair que la « résilience de la résilience » thérapeutique est, le plus souvent, une mauvaise stratégie et que la seule résilience qui puisse fonctionner quand il s'agit de structures psychiques serait celle que le patient lui-même aurait finalement trouvée. En ce sens, les cas les plus spectaculaires restent toujours ceux des psychotiques. Nommons ici celui de Jammes Joyce, analysé par Lacan dans son séminaire sur *Le sinthôme* [11]. En deux mots : le génial romancier irlandais avait trouvé dans sa propre création le moyen de se procurer un nom – le non de l'artiste célèbre qu'il était – afin de suppléer la carence du Nom du Père de sa propre structure, psychotique. Il est assez extraordinaire de constater la manière dont les psychotiques inventent toute sorte de « symptômes » afin de suppléer la forclusion du Nom du « Grand Autre ». Nous avons nous-mêmes remarqué plusieurs cas de psychoses dans lesquels les patients avaient développé un « symptôme » obsessionnel, par exemple, un symptôme qui était censé, bien sur, les lier à d'autres personnes... Aussi, dans tous ces cas, la différence entre structure et suppléance est-elle vraiment essentielle car la destruction de la suppléance même – avec l'argument qu'on devrait guérir d'abord l'obsession avant de s'attaquer à la psychose – peut basculer le malade dans la pire des crises [12]. En ce sens, la suppléance des psychotiques serait une résilience tierce.

Self-care and resilience in the context of chronic disease. A qualitative study

Cojocaru D.

Alexandru Ioan Cuza University, Department of Sociology and Social Work (ROMANIA)
dananacu@gmail.com

Abstract

The chronic disease represents a major concern of health care systems due to the permanent and progressive nature of the disease, the high costs of care and the problems related to the patient's quality of life. The article presents and argues the importance of the self-management programs as a development strategy for assisted resilience and for supporting the empowerment of the chronically ill who are redefining their condition in terms of identifying and capitalizing their resources in order to regain control over their lives.

Keywords: resilience, empowerment, chronic illness

Introduction

The issue of health behavior is recognized, articulated and formalized as a major problem of public health programs; the new understanding of the term is related to the description of the autonomous individuals that can chose to act as a response to the illness or as to maintain their health (health behavior) [1]. "Chronic illness is, by definition, a long-term, and perhaps permanent, event in a person's life. In the classical functionalist framework, illness is characterized by dependency, regression and, through encounters with qualified practitioners, hopefully recovery. In chronic illness these features are often only partially characteristic of experience, overlaid as they are with poor or limited recovery prospects. The time-scale involved makes it important to bring into the picture a view of the illness in terms of both the stages it passes through and their interaction with the individual's age and position in the life course" [2].

Chronic illness and its challenges

The chronic illness is facing the patients with a large spectrum of needs that changes their lifestyle and, usually, constrains them into engaging in behaviors that promote physical and psychological well-being, asking them to change their relationship with health services providers, to join the medical prescriptions, to monitor their health condition, to take care related decisions, to manage the impact of the disease on their physical, psychological and social functioning [3]. Because the chronic illness requires continuous medical care, it can raise the issue of the effectiveness of care and the balance between the involvement of the medics and the involvement of the patients in the therapeutic process [4]. The participation of the professionals and of the patients in the care process represents, on the one hand, the willingness of the patients of taking responsibility of their own care [5], but it also requires the support of the care providers in informing the patients and sustaining their efforts of becoming autonomous, and also a collaborative process for optimizing their results on the long term [6]. The current approach to chronic disease care implies a complex evaluation, not only of the biomedical aspects of the disease, but also the understanding of the psychological, social and cultural aspects of health and the suffering associated with the disease [7] The sociological studies published in the U.S. starting in the 70's, years marked by the famous work of Anselm Strauss in 1973: *America: in sickness and in health*, have tried to bring to light the complex implications of chronic disease through qualitative studies conducted on chronic patients. Strauss, although does not recognize the importance of the professionals in caring for the chronic patients, considers that living with the disease has the most important dimension related to daily tasks that need to be performed, and which require managing the medical crises, the treatment, controlling the symptoms, organizing the time, preventing social isolation or managing it, adapting to the disease's trajectory, evaluating and mobilizing resources [8]. Burry talks about the chronic pain of the patient as a "biographical disruption" [9], a discontinuity or a "critical situation" in the life of the individual, that blows into the air all his assumptions about himself, about his body and about the world he lives in [10].

The occurrence of the chronic disease is accompanied by various attempts to manage and reduce its impact on the patient's life, actions labeled as "normalization, coping" or strategic management [11]. *Normalization* relates to two types of processes: on the one hand, the attempt of preserving as much of the identity and lifestyle from the period before the disease, masking or minimizing the symptoms of the disease or, on the other hand, incorporating the suffering into a new way of life that involved a different level of social functionality [11]. The strategic management of suffering refers to "skillful manipulation of social settings and appearances to minimize the impact of illness (…) but also the attempt to mobilize resources to advantage, and the setting of realistic goals in order to maintain everyday life" [1]. Different from Burry, who sets the accent on "biographical disruption", other authors emphasize the dimension of *biographical flow*, *biographical continuity* or *biographical confirmation* of the disease management [10] [12]. These authors consider the continuity as a characteristic of people's responses to chronic disease, particularly when it was installed at young ages, becoming "normal illness" [12]. Some authors consider that the most important dimension of chronic suffering is the corporal body related dimension: "At the very epicenter of the coping experience and from which other social coping processes flow, is the management of the physical problems which the chronic illness generates. The physical aspects of living such as eating, bathing, or going to the toilet are the prime focus of the experience of chronic illness, because above all else coping with chronic illness involves coping with bodies - not just for people who are chronically ill themselves but also for their families (...)" [13]. Because actions that were once automated (especially those requiring mobility, dexterity) now require an active engagement and planning, chronic disease-related physical limitations lead awareness about the socio-cultural body related performance requirements.

In the qualitative studies conducted by Strauss and Corbin, the self-care management in chronic disease conditions is described around three important dimensions [14]: (a) The medical dimension (*illness work*) refers to the effort that the patient is making in order to identify the illness's symptoms, to prevent and manage crises, to adhere to different treatments or diets, to use some medical tools etc.; (b) The *role* dimension of the management refers to all the *everyday efforts* (*everyday life work*) of coexisting with the disease, to the daily tasks of self-care and caring or the children and the other members of the family, to the efforts of fulfilling professional tasks or of rebuilding the roles – professional and familial, under the physical and social constrains imposed by the disease; (c) The *biographical and identity related dimension of the disease management (biographical work)* is often more discrete and less visible and refers to the disease associated emotions management, but also to intern efforts of redefining the identity and purpose of life of the chronically ill. The health sociology studies talk about the presence of an identity labor imposed by the chronic disease.

The self-management programs – strategies of developing assisted resilience

The self-management is a term used in the area of health education and it is associated to health promotion programs and of patient education, and refers to the strategies that a person could take in order to tackle the disease [15]. Integrating the self-management into the overall health care system is considered essential in the context of chronic disease care, because the chronic disease is incurable, and daily management of the health condition is necessary for the rest of the patient's life, it can only be realized by the patient and those in his proximity: family, friends, relatives [16]. In addition, the education for the self-management of chronic disease can majorly improve the patient's health condition and can significantly reduce the costs of care. Whatever the patient's attitude is related to his health status, even if he ignores the disease and decides to completely ignore the medical prescriptions, or he will carefully listen to his body and the symptoms and will integrate the medical prescriptions into his daily life, both of these situations are different styles of health management. Using the term health management refers to the "activities people undertake to create order, discipline and control in their lives" [17]. The engagement of a chronically ill patient in self-care practices depends on a number of factors: the type of the disease, time passed since the disease occurred, the gender, age, socio-economic status of the patient, the level of self-efficacy, the social networks of support etc. [18] [19]. The self-management notion can be studied in the context of the chronically ill adapting to the new health condition, describing "the ways that people incorporate the consequences of illness into their lives" [17] The self-management is considered fundamental in the process of positive adaptation to the disease. A series of authors [17] [20] assimilate the positive adaptation to the chronic condition with the transformation which occurs when "the burden of illness is replaced by the perception that it has enhanced the quality and meaning of life, by enabling people to experience life in a way that was previously inaccessible" (p.260). Although similar with the term coping [17] that refers to being a state of tolerating, minimizing, accepting or ignoring things that cannot be mastered, the self-management term emphasizes the area of activities that the chronically ill initiate in order to gain control over their lives, affected by suffering.

Knowing the definitions and representations that patients have on their own experience of self-care is very important because it can be valorized and incorporated into clinical nursing intervention, increasing its role of consolidating the patient's resilience and improving the quality of their lives [20].

The literature emphasizes the fact that the medical staff and the patients relate themselves to the self-management of the disease in different terms: if the professionals that represent the medical professions talk about health self-management in terms of structured education around certain dimensions considered important, the chronically ill patients relate themselves to the experience of self-care as to a "process initiated to bring about order in their lives" [17].

The patients consider the chronic disease self-management a complex process, multifaceted and nonlinear that faces fluctuations, moments of crisis and calm and is characterized firstly by its dynamic nature, of its active learning process and the exploration of the disease imposed limits. This process is described as a set of activities built around several important dimensions: Recognizing and monitoring the borders and the limitations configured by the disease, often accompanied by pain; Mobilizing material, psychological, physical and compartmental resources in order to improve the quality of life; Reconstructing the identity generated by learning to coexist with the disease; Balancing, planning and prioritizing all aspects of everyday life (which drastically diminishes the spontaneity element). The idea of self-management programs is linked to the name of Kate Lorig who considers that the patients are not only *consumers* of health care, but can also become producers of health care [8]. Although there is no consensus about what constitutes a self-management program, such the content and the methods of such programs, they are popular in the U.K., Australia, U.S., and are built around several principles [19]. Even though the needs of self-care can be very different depending on the specific chronic disease, there is a common set of needs, derived from the common symptoms and consequences of the various chronic conditions. The common philosophy of these programs is built around the idea that, despite the variation related to the effects or the impairment created by the disease, many chronically ill are capable of becoming active agents in managing their tasks, in order to diminish the negative effects of the disease and to maximize the quality of life [22]. Secondly, the idea that patients are active actors and partners in the process of disease management is promoted, ant the diverse patterns of comportment can configure diverse styles of self-management. Although the representative of the medical profession are continuously providing support in the disease treatment, the patient is the only one that can manage his health condition in the long term, and for this, it is necessary for him to acquire some skills and competencies.

The self-management program that is mostly talked about in the literature is the "Arthritis Self-Management Programme", which is a course developed by Lorig et al. [15] at Stanford University. This program is based on the concept of self-efficacy and the compartmental change, and takes place as a course during six weeks and, although used initially for arthritis ill, it is considered applicable and generalisable to a large spectrum of chronic diseases [17] [23]. Another self-management program which aims to achieve the empowerment of the chronically ill, implemented in the U.K., is the "Expert Patient Programme", which starts from the premise that, although the chronically ill is not an expert in the disease per se, he could become an expert in his own illness and in managing his own condition. Although the technical and biomedical aspects of the disease cannot be accessible for him, the management of the psycho-emotional, medical, social aspects of his disease can be learned, such as he can improve his degree of autonomy related to the medical system and to improve his quality of life.

Conclusions

The self-management of chronic disease remains a major concern of the health systems, and the way this will reconfigure the relationship between the medic and the patient remains an important topic of reflection and empirical research. The self-management programs could represent an important component of the health systems because of their potential to increase the resilience of the chronically ill and to bring important decreases in the cost of care in the health services.

Abstract

The evaluation of an interventional program for the children griefing a parent's suicide allows to explain different proximal effects which could be observed at different levels :1) Basic security; 2) Realistic comprehensions and useful knowledges;3) Inadequate behaviours; 4) Physical symptoms, nightmares, defiant dreams;5) Psychological symptoms (depressive humour, anxiety, etc) ;6) Communications children-parents, children-children;7) Capacity of social and emotional reinvestment; 8) Actualisation of new models for self and for the world;9) Self-esteem;10) Call for help behaviours, using already known techniques ;11) Cognitive skills and words, writing, drawing; 12) Cognitive discordancies, ambivalences, antagonisms;13) Breaking the isolation. Most of this proximal effects should be better validated and documented, but the teoretic model developed leed to predict, on a longer term, an effect on the resilience.

Key words: parent's suicide, interventional program, resilience.

Introduction

Les enfants endeuillés par suicide vivent plus de colère, d'anxiété et de honte que les autres enfants vivant un tel contact avec la mort. Ils risquent aussi d'avoir plus de problèmes comportementaux et plus de symptômes reliés au comportement ou à l'anxiété [1]. Ils peuvent également développer des idéations suicidaires [2]. La plupart des enfants ayant subi la mort d'un parent par suicide auront besoin un jour ou l'autre d'une aide extérieure spécialisée. En fait, l'enfant aura besoin d'aide car il n'aurait pas atteint un stade de développement suffisant pour lui permettre de traverser seul l'épreuve du deuil par suicide [3]. C'est à l'occasion de l'évaluation d'un tel programme d'intervention auprès d'enfants endeuillés par suicide, que nous avons pu développer un modèle théorique du changement qui explicite les différents effets attendus suite à la participation à celui-ci.

Description du programme évalué

La *Thérapie de groupe pour enfants endeuillés par suicide* a été mise sur pied à Laval, dans la région de Montréal, au Québec (Canada). Cette aide dite « thérapeutique » a pour but d'aider les enfants et leurs parents à surmonter les difficultés qui inhibent le processus normal de deuil chez leurs enfants. Le programme est structuré en fonction d'objectifs thérapeutiques bien précis et documentés dans un manuel [4]. Ce n'est donc pas un groupe de rencontre, d'entraide ou de soutien, comme il en existe chez certains adultes endeuillés.

Le programme est offert uniquement à des enfants endeuillés par suicide et âgés entre 6 et 12 ans. Il est animé conjointement par deux professionnels du domaine psychosocial (psychologue, travailleur social) et, idéalement, de sexes différents. Les enfants sont préalablement évalués et sélectionnés, notamment pour être redirigés vers des interventions individuelles si leur problématique relève plus du syndrome de stress post-traumatique. Le programme de groupe dure 12 sessions (de deux heures chacune) et il accueille entre 6 et 9 enfants (tous du même groupe depuis la première rencontre). Les sessions sont hebdomadaires, sauf pour les deux dernières qui sont espacées de deux semaines afin de faciliter la séparation progressive d'avec le groupe. Comme la participation des parents est vitale, ceux-ci (les survivants au suicide) doivent se joindre au groupe pour la dernière demi-heure de chaque soirée.

Le manuel du programme décrit les objectifs poursuivis, le matériel spécifique à être utilisé et la démarche à suivre. Parmi les activités prévues dans ce programme, lesquelles varient d'un soir à l'autre, on retrouve : 1) le contrat de non-suicide, 2) le jeu questionnaire *Capitaine moi-même* (un jeu sur table où le tir d'un dé détermine l'avancement d'une case à l'autre, ces cases déterminant l'accès à une carte-question), 3) le *Carnaval des animaux* (l'enregistrement d'une pièce musicale et d'une histoire), 4) l'*Île Bon débarras* (une valise où des dessins représentant des émotions très lourdes sont abandonnés), 5) l'histoire de *Chiboukayo* (une aventure tragique racontée aux enfants pour qu'ils s'identifient à des personnages), 6) des journaux de bord individuels, 7) une boîte à questions et 8) des albums souvenirs individuels. Quant au jeu du *Capitaine moi-même*, qui donne parfois involontairement son nom à tout le programme, il fournit aux enfants des occasions multiples d'expression du vécu et des émotions, en parallèle avec des moments plus légers où, fort judicieusement, les enfants sont même appelés à faire des jeux plus physiques (sautiller, courir…). La présentation graphique de ce jeu est d'une grande qualité et son aspect relativement spectaculaire a été remarqué tant par les enfants endeuillés (qui s'y précipitent) que par les participants des colloques et congrès où il a été présenté.

Méthodologie

Les fondements théoriques du programme ont été précisés, à l'occasion d'un exercice d'évaluation, et ceci à partir des écrits cliniques et scientifiques pertinents, de la documentation déjà disponible pour le programme (incluant le manuel), des rencontres avec les intervenants et les gestionnaires, des consultations auprès de collègues et d'une validation formelle auprès d'un comité d'experts. À l'intérieur de cette modélisation portant sur le programme, deux types de modèles théoriques ont été explicités : la théorie du processus d'intervention et la théorie du changement attendu chez les enfants (Fig. 1) à laquelle nous nous intéressons ici.

Résultats

Pour ce qui est du modèle théorique du changement attendu chez les enfants, l'évaluation du programme d'intervention auprès d'enfants endeuillés par suicide a donc permis d'expliciter différents effets proximaux observables chez eux et ceci à différents niveaux : 1) Sécurité de base; 2) Compréhensions réalistes et connaissances utiles; 3) Comportements inappropriés; 4) Symptômes physiques, cauchemars, rêves importuns; 5) Symptômes psychologiques (humeur dépressive, anxiété, etc.); 6) Communications enfants-parents, enfants-enfants; 7) Capacité de réinvestir socialement et affectivement; 8) Actualisation de nouveaux modèles de soi et du monde; 9) Estime de soi; 10) Outils connus/utilisés dont les comportements de demande d'aide; 11) Habiletés cognitives et parole, écriture et dessin; 12) Dissonances cognitives, ambivalences, antagonismes; 13) Bris de l'isolement. Ces éléments peuvent être identifiables peu de temps après les interventions thérapeutiques réalisées, mais d'autres éléments plus diffus pourraient apparaître plus tard. À la Fig.1, ces éléments (numérotés de I à VII, à la droite de la figure) vont du goût à la vie (espoir) jusqu'à la résilience.

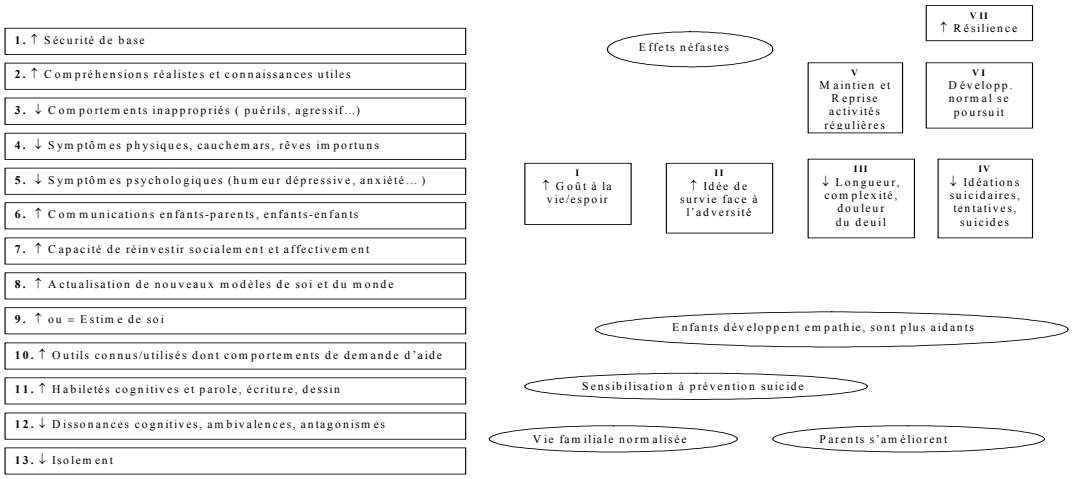

Figure 1. Modèle théorique du changement

Conclusion

Le modèle développé ici n'a pas été validé sous tous ses aspects. Ainsi, le lien menant à une possible augmentation de la résilience n'est pas nécessairement démontré. Le modèle permet cependant d'alimenter la réflexion clinique et scientifique sur tous les enjeux entourant l'intervention auprès des enfants ayant vécu un événement aussi traumatisant que le suicide d'un proche parent.

Presentation du dispositif “Theatre de la resilience”

Fauche-Mondin C.

Sous la Direction du Professeur S. Ionescu, Université Paris 8, Laboratoire Parisien de psychologie Sociale (France)
Christelle3fauche@gmail.com

Abstract

Inspired by the work of Augusto Boal, the popular education and the researches on the resilience, the « Theatre of the resilience », is an assisted resilience device type, a theatral mediation.

Evaluated in 2004 (C.Fauché, 2004 [1]) then in 2007 (C. Fauché, 2007 [2]) this device revealed itself as a protection factor for the “at risk” teenagers and in situation of vulnerability.

It was implemened as ’1h30 to 2h weekly workshops,including specific exercises combining theatre and psychology .

During our communication we will present the main characteristics of this technique: Frame of intervention, operating rules, constitution of the groups, internal frame for practitioners,coanimation and exercices.

We were refering to work on assisted resilience (S. Ionescu et al [3]) but also on Zimmerman, Brenner et Masten[4] work on teenagers résilience and observed that this activity proposed a compensatory model, fournishing supplimentary (interns and externs) ressources, but equally an ensemble of protection factors, proposing to participants a way of meeting chalanges

Keywords:Assisted resilience, protection factors, teenagers, risk, vulnerability, prevention, sanogen effect, theatre, mediations, pro-social activities.

Introduction

Cette communication a pour objet de rendre compte d'un dispositif appelé “Théâtre de la résilience”.

Cette expérience, débutée en 2003 a fait l'objet de deux recherches, l'une à court terme et l'autre à T+2 ans après l'arrêt de l'activité (Fauché, 2004[1]; Fauché, 2007[2]). Elle fait actuellement l'objet d'une recherche longitudinale regroupant 12 ateliers sur une période de 6 ans.

Depuis plusieurs années nous avons travaillé à l'élaboration de cette technique prenant en compte plusieurs dimensions telles que les ressources internes, les forces des individus et celles de leurs contextes afin de les aider à développer, en cas de cumul de facteurs de vulnérabilité (M.Rutter, 1976 [5]), un ensemble de stratégies d'adaptation, d'atouts et de ressources afin d'être moins vulnérables à l'exposition aux risques.

Se situant à la jonction entre le théâtre et la psychologie, le théâtre de la résilience se définit par rapport à son efficience et à ses objectifs.

Ni art-thérapie, ni psychodrame, ce dispositif, bien que pouvant, par certains aspects, ressembler au théâtre de conscientisation ou à l'éducation populaire, ne se situe pas non plus dans l'axe uniquement éducatif ou artistique du théâtre tel qu'il est pratiqué professionnellement ou pour le loisir.

Au cours des 10 dernières années, nous avons mis en application une méthode d'intervention basée sur l'éducation à la résilience et sur le renforcement à la fois des compétences mais aussi du soutien social et de sa perception en considérant les dimensions bio-psycho-sociales des particpants et en tenant compte de l'évolution sociale liée au développement des nouvelles technologies.

Contexte théorique

Inspiré des travaux d'Augusto Boal sur le Théâtre-Forum, de la méthode de l'Actor studio (M. Chekhov [6]), du psychodrame (Kaes[7]), de l'art thérapie (J.L. Sudres[8]) mais également des travaux de Boris Cyrulnik [9] sur la résilience, et les protocoles de résilience assistée ainsi que les mécanismes de défense (Ionescu & al. 2001[10], 2011[3]), ce dispositif tente d'offrir des facteurs de protection/ compensation à des adolescents présentant de nombreux facteurs de vulnérabilité pouvant impacter leur exposition aux risque présents à l'adolescence dans un contexte socio-économique et urbain contribuant à produire des effets néfastes sur leur développement.

De nombreuses recherches ont permis de mettre en évidence l'impact de la pauvreté et de la violence environnementale sur les adolescents. Certaines ont présenté un état des lieux des études relatives à la résilience à l'adolescence (Brenner et Zimmerman, 2013[11]) et ont montré comment l'investissement dans une activité pro-sociale, l'appartenance à un groupe ainsi que la présence de mentors adultes bienveillants extérieurs à la famille et présents sur le quartier pouvaient constituer des facteurs de protection/compensation permettant l'amorce de processus résilients.

Présentation de la technique du théatre de la résilience

Débutant par la constitution d'un groupe marginal mais non déviant, composé de jeunes ayant entre 11 et 19 ans et d'adultes - animateur et co-animateur - proposant un encadrement non-autoritaire, le dispositif théâtre de la résilience se compose d'ateliers hebdomadaires d'une heure trente à 2 heure au sein desquels les participants sont accueillis avec une règle fondatrice: la règle de confidentialité.

Cette règle est, lors de la construction du groupe, la seule contrainte imposée aux participants. La transgression de cette règle est le seul critère valable pour en exclure l'un des membres.

Cette règle posée en tout début d'atelier est explicitée et chacun y adhère individuellement face au groupe en déclarant s'engager à la respecter.

C'est à partir de cette règle que le groupe co-construira avec les animateurs le cadre (horaires, présence, respect, etc…). Elle permettra, entre autres, de garantir à chacun le respect de sa parole et d'établir un lien de confiance entre les participants.

1.1 Cadre d'intervention

Les ateliers se déroulent en plusieurs phases incluant des temps d'action et des temps de réflexion.

La séance est subdivisée en trois grandes parties : la première est consacrée à la vie du groupe, à l'échange verbal et aux propositions d'activités pro-sociales, la deuxième est un temps « d'échauffement émotionnel » constitué de la pratique d'exercices spécifiques du théâtre de la résilience, et la troisième partie est consacrée à la créativité des participants s'exprimant par les créations artistiques et improvisations sur scène.

1.1.1 Constitution des groupes :

1.1.1.1Chaque groupe se constitue par auto et/ou entre-orientation.

Les participants peuvent s'ils pensent cela pertinent, proposer à certains de leur pairs de les accompagner à l'atelier pour essayer.

Les partenaires peuvent également orienter les jeunes vers les différents ateliers pour constituer les groupes. Dans ce contexte, le type de lien entretenu entre l'adolescent et la personne qui l'oriente est crucial dans la réussite de l'orientation car le jeune investira l'atelier différemment en fonction de qui l'oriente.

1.1.1.2 Critères d'inclusion et d'exclusion :

Cet atelier est particulièrement indiqué pour :

- des adolescents âgés de 11 à 19 ans, la plus grande efficacité ayant été observée sur la tranche d'âge 12-15 ans.
- vivant au sein d'un contexte de difficultés familiales (divorce des parents, conflits et violences conjugales, nombreuse fratrie et conditions de vie difficiles, décès d'un parent, violences éducatives, défaillance de l'un ou des deux parents (alcoolisme, addiction, conduites à risque…), abandon de l'un ou des deux parents, relations difficiles et tendues au domicile entre parents et adolescent.
- Exposés à un environnement violent et à risques de type quartier défavorisé.
- Présentant des comportements auto et/ou hétéro-agressifs
- Présentant des problèmes liés au non-respect du cadre et de l'autorité
- En échec scolaire
- Vivant une situation d'adversité chronique pour des raisons économiques

Critères d'exclusion :

- Orientation contrainte vers l'atelier
- Enfants scolarisés en école primaire
- Majeurs de plus de 20 ans

1.1.2 Fonctionnement de la technique :

Les bases techniques du théâtre de la résilience reposent, entre autres, sur la division de l'espace en deux parties afin de pratiquer l'activité : Le quotidien et l'extraquotidien, délimités par une ligne imaginaire définie par l'animateur en début de séance.

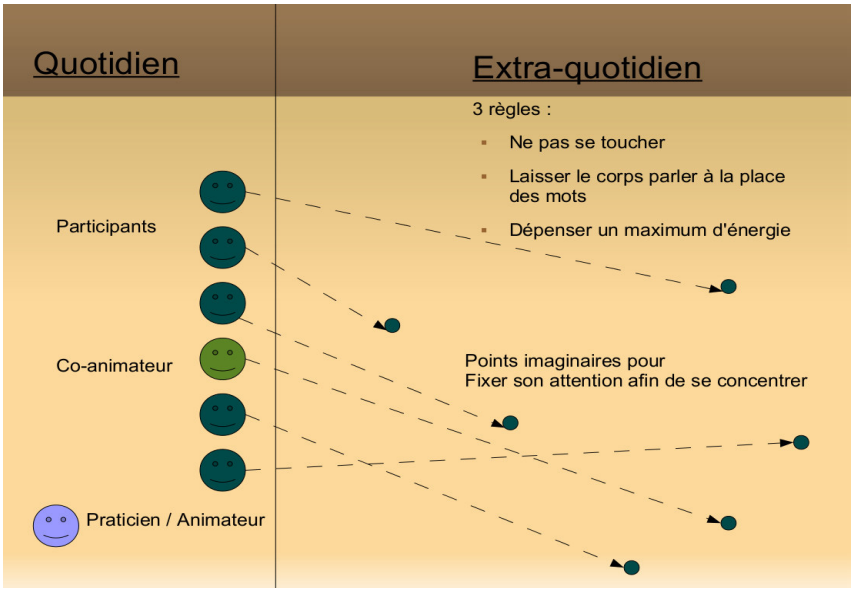

Fig.1- Illustration de la distribution symbolique de l'espace dans la pratique du théâtre de la résilience

Ces deux espaces symbolisent deux mondes différents qui sont expliqués aux participants.

Le quotidien, est l'espace de « la vie de tous les jours » où l'on s'exprime peu avec le corps et où on peut toucher les autres, c'est également un espace au sein duquel, en général on dépense peu d'énergie, dans des contextes le plus souvent scolaires - le corps est prisonnier de la sédentarité imposée par le cadre des apprentissages – ou lors des temps libres face aux divers écrans.

Par opposition, l'extra-quotidien est un espace ayant 3 règles principales de fonctionnement :

On dépense un maximum d'énergie, les participants ne se touchent pas et on ne parle pas à moins que la consigne ne le permette.

Dans l'espace de l'extra-quotidien qui représente la scène, l'imaginaire prend le relais du réel et permet l'expression dans une forme différente de celle à laquelle sont habitués les participants.

Cette technique compte plus de 150 exercices, se déclinant sous forme de jeux individuels, en binômes, en petits groupes, en demi-groupe ou en groupe complet en fonction de l'objectif de la séance. Au cours d'une même séance il est possible de transiter par plusieurs formes d'exercices qui vont s'articuler pour répondre au besoin de la séance.

1.1.3 Déroulement des séances

Les séances ne se déroulent pas selon un plan unique avec un scénario définit a l'avance mais se préparent autour de **plusieurs scénarii possibles en fonction de là ou en sont les participants** et de la où en est le groupe. Il est important d'être en **capacité de s'adapter** et pour cela de connaître et de maîtriser parfaitement les exercices mais aussi d'être en capacité d'en créer de nouveaux pour s'adapter aux besoins, voire de modifier certains exercices pour les adapter aux particularités d'un groupe.

Les exercices se décomposent en plusieurs catégories ayant chacune une ou plusieurs fonction(s) générales:

Les **exercices individuels sur scène** devant les autres participants permettent à la fois une valorisation narcissique mais aussi constituent un rite de passage permettant à chacun de se dépasser et de prendre confiance en soi.

Les exercices collectifs visant à développer l'écoute, la complicité, la solidarité ou l'harmonie au sein du groupe et travailler sur la vie du groupe.

Les **histoires et anecdotes** sur lesquelles peut réfléchir le groupe lorsqu'il est prêt afin de percevoir les différences individuelles et ne pas rester dans l'illusion du bon groupe. Mais également pour que les participants osent un positionnement non conforme aux attentes du groupe afin de revendiquer leur propre pensée et leurs propres opinions tout en étant protégés par la règle de confidentialité et les adultes référents de l'atelier

Les **exercices articulant le collectif à l'individuel** qui permettent de développer son autonomie au sein du groupe tout en se sentant soutenu par la présence des autres membres.

Les **exercices par 2** permettant de créer ou de développer des interractions privilégiés en "couple" (Au sein du collectif ou sur scène)

Les **exercices par petits groupes**, permettant de structurer du lien moins diffus qu'en grand groupe.(improvisation avec groupe choisi en fonction des affinités et du sujet qui intéresse les participants)

Les **exercices dans la division du groupe en deux** avec réunion des deux groupes ensuite pour se stimuler et s'encourager mutuellement à progresser. (effet miroir)

La **règle de confidentialité** étant le ciment du groupe, elle permet également à chacun d'oser des actions non envisagées hors de ce contexte et d'exprimer des ressentis tus habituellement.

Résultats :

Au cours d'années de pratique clinique avec des adolescents issus de tous milieux socio-culturels, nous avons pu constater la permanence de l'importance de l'engagement et de l'implication du thérapeute afin de permettre au groupe de fonctionner. Le cadre interne du praticien permettant de servir, jusqu'à la constitution du groupe et le mieux-être des participants, de « prothèse », protégeant les participants de l'angoisse du chaos qui ne manque jamais d'apparaitre lorsque le cadre interne des intervenants n'est pas suffisamment solide.

Les techniques utilisées englobent certains aspects psychopédagogiques permettant la mise en lien avec les apprentissages effectués en milieux scolaires. La place de l'école et la motivation sont requestionnée par le paiement symbolique des séances d'atelier. Les adolescents payant l'atelier en bonnes notes. Est considérée comme telle toute note, quelle que soit la matière (Dessin, mathématiques, gymnastique, français, comportement...) qui représente une amélioration par rapport à l'ordinaire de l'adolescent. Evidemment, pour les adolescents en décrochage scolaire et jeunes trop en difficulté nous trouvons d'autres paiements symboliques convenus entre le jeune et les animateurs.

Afin d'illustrer ce propos nous citerons la situation d'une adolescente se tailladant les poignets régulièrement, la réduction du nombre de marques par semaine a été une forme de paiement. Nous avions déjà expérimenté cette situation et l'engagement des participants fut tel qu'ils cessèrent les conduites les mettant en danger en l'espace de quelques mois et prévinrent l'animatrice à chaque fois qu'il firent une rechute au cours de l'année.

Les résultats principalement observés sont :

La reprise de confiance en soi, l'évolution scolaire positive, l'implication dans des activités pro-sociales, le développement de l'empathie, la réduction des conduites d'agression et de passages à l'acte violents, le développement de la créativité

L'analyse de nos résultats nous permet de confirmer l'hypothèse qu'une éducation à la résilience est possible grâce à un travail sur le développement de stratégies d'adaptation et de nouvelles compétences.

Ce dispositif a également mis en évidence un ensemble de facteurs leviers d'influence en vue de développer des protocoles d'éducation à la résilience pour adolescents à partir d'autres types de médiation. Les 3 principaux leviers identifiés comme en permettant l'efficience avec les adolescents sont :

- la constitution libre d'un groupe marginal non déviant et solidaire avec ses propres codes et ses propres rituels de passage.
- La présence d'un leadership contenant et disponible non-autoritaire et bienveillant composé d'un animateur et d'un co-animateur.
- L'utilisation d'exercices adaptés et d'une technique non-stigmatisante permettant la valorisation et la mise en réussite de chaque participant.

Conclusion

L'expérimentation de la technique du théâtre de la résilience nous a permis de conclure à une amélioration des réactions des adolescents face à des conditions d'adversité.

L'habituation, en groupe, de la prise de risque mesurée dans un contexte d'expérimentation sécure, a permis aux participants de s'affirmer et, à défaut de parvenir à mieux maîtriser leur environnement, à mieux le comprendre pour mieux se protéger.

Les activités pro-sociales qui ont émergé à partir de l'atelier ont permis aux participants de prendre une place d'acteurs valorisés dans le quartier et leur confère une reconnaissance auprès des adultes et de leurs pairs qui les croisent lorsqu'ils mènent une action.

Plusieurs types d'action pro-sociales ont vu le jour depuis la création des ateliers en 2004.

Nous en citerons ici brièvement quelques unes comme :

- La participation active aux fêtes de quartier, les jeunes maquillant les enfants et pratiquant la scupture sur ballons,
- L'organisation de concerts-spectacles « talents en fête » ayant pour but de faire découvrir les jeunes talents du quartier mais également de lever des fonds pour aider une association qui oeuvre pour la scolarisation des jeunes filles au Népal,
- l'orgnisation du colloque « violence ordinaire et résilience dans les systèmes familiaux » journée de rencontre interprofessionnelle, jouée sous forme de « conférence-gesticulée » par les adolescents et incluant les interventions de professionnels (psychologues, juge, chercheurs,...) appelés à intervenir en tant qu'experts.

L'aide et le soutien des animateurs pour la création de telles actions sont nécessaires car leur motivation et leurs compétences servent de locomotive dans un premier temps à l'investissement du groupe pour des causes qui tiennent à cœur aux adolescents.

Par la suite les adolescents développent de nouvelles compétences et s'autonomisent, créant leurs propres actions, individuellement ou en groupe, n'ayant plus besoin du tuteur de résilience provisoire que constituait momentanément l'atelier dans une période sensible de leur développement.

La fin de l'atelier n'est jamais décidée à l'avance pour les participants, c'est lorsque le jeune se rend compte qu'il a pris dans l'atelier ce dont il avait besoin, qu'il décide qu'il est temps d'arrêter. Evidemment le groupe est toujours là pour l'accueillir s'il change d'avis, comme une base arrière de sécurité, solide et rassurante, sa porte reste toujours ouverte.

Familles migrantes et handicap de l'enfant : favoriser la resilience par le recit de vie

Abstract

The aim of this paper is to present the results of an extant research in progress. The research focuses on the question of potential resilience within the migrating family unit that comprises also a handicapped child. The research data is of seminal importance for facilitating in the assistance of these families through the pertinent institutions and services available in the French speaking area of Switzerland.

The applied methodology accesses and supports the 'life story" as a buttressing factor for the family's potential resilience: through a programme called "Family journal" families meet in order to exchange the narratives of their experience with migration and handicap and in order to note of their journey's story in a diary format. This setting creates an opportunity of space-time for these families who are now able to reclaim their narratives and to become consciously aware of the resources they developed along the way. And the realization that a novel platform of transformation through learning and emancipation is accessible to them. Through further discussions we will explore some of the possible risks of the life story process such as the premature obstruction of the resilience process as well as the retreat into the unutterable.

Key terms: handicap, migration, family, resilience, life story

Introduction

Depuis plusieurs années, je travaille sur le thème des familles migrantes ayant un enfant en situation de handicap, dans le contexte de la Suisse romande [18]. Ayant d'abord privilégié une approche anthropologique (représentations culturelles du handicap), sociologique (facteurs en lien avec la migration et le handicap influençant la situation des familles) et socio-psychologique (comment les familles s'adaptent à ces situations), je m'intéresse depuis quelques temps aux parcours de vie de ces familles et à l'influence de ce dernier sur leur adaptation au handicap et à la migration. Ayant suivi une formation en recueil de récits de vie, j'ai eu l'occasion d'approfondir la question de l'utilisation des récits de vie en contexte migratoire et les liens entre récit de vie et résilience. Cette formation s'est réalisée en parallèle avec la mise en œuvre d'un projet de recherche-action visant à favoriser la résilience de familles migrantes ayant un enfant en situation de handicap, tout en apportant des connaissances sur la collaboration de ces familles avec les services et institutions en lien avec le handicap, dans le contexte de la Suisse romande. Dans cette communication, je présenterai la réflexion qui a conduit à l'élaboration de ce projet ainsi que les débuts de sa mise en œuvre. Elle sera structurée en deux temps : une première partie consacrée aux liens entre récit de vie et résilience dans les situations de migration et de handicap, et une deuxième partie qui présentera la recherche-action.

Récit de vie et résilience en situation de migration et de handicap

Pour aborder ce thème, j'envisagerai d'abord l'utilisation du récit de vie dans les situations de migration et de handicap, puis les liens entre récit de vie et résilience.

1.1 Le récit de vie en situation de migration et de handicap

En travail social, l'intervention par le récit de vie constitue une réponse à la perte de sens et de repères que peuvent vivre les individus dans un environnement social de plus en plus complexe et contradictoire [6]. Il est notamment mobilisé dans la recherche-intervention auprès de familles migrantes, dans le but de favoriser l'identification des forces et stratégies familiales, contribuant ainsi à faire émerger un sentiment de continuité entre les périodes prémigratoires et postmigratoires [15]. Dans ce type de projets, différents supports narratifs visuels sont proposés (récits, génogrammes, photos, dessins, poèmes etc.). Le récit narratif s'articule autour des

moments significatifs de la trajectoire familiale (*ibid.*). Selon Aline Gohard-Radenkovic et Lilyane Rachédi , le sens du récit est multiple : espace de création d'identités nouvelles et de transformations (des identités linguistiques, des stratégies d'adaptation, des appartenances, des valeurs culturelles), il permet aussi de négocier « les tensions entre un souci de cohésion de soi et la fragmentation d'une société » (*ibid.*, p. 10). En ce sens, il peut être appréhendé comme un espace de médiation entre soi et l'autre et entre soi et soi. Ses formes sont également multiples : récits de langues (autobiographies langagières), histoires de vie, journaux de séjours et d'apprentissage, romans familiaux, autobiographies romancées etc. Elles s'inscrivent dans des contextes spécifiques, à la fois sociopolitiques et institutionnels (formation, professions, associations etc.).

Pour la personne migrante, le récit de vie peut procéder de la renégociation de soi avec l'autre, qu'il soit migrant lui aussi, même s'il est porteur d'une langue et d'une culture différentes, ou non migrant ; le récit permet de transmettre sa propre expérience de migration [3]. Il peut aussi constituer un espace de réparation et de projection de soi [10], en s'inscrivant dans une dynamique de projet dans laquelle s'articulent les projets individuels, familiaux et sociaux. Cette fonction de réparation peut être particulièrement importante lorsque la trajectoire de migration est fragmentée, par exemple dans les situations de migration contrainte [15]

Dans l'évolution historique des histoires de vie, l'Ecole de Chicago, au début du 20^{e} siècle, envisageait déjà la migration comme un phénomène emblématique des ruptures et déséquilibres sociétaux nécessitant des réajustements à la fois individuels et collectifs [7].Dans cette perspective, le recueil de récits de vie s'intéresse à la façon dont les individus perçoivent les événements de leur vie, aux réponses qu'ils donnent à ces événements, à la façon dont ils gèrent les rapports interindividuels et collectifs et aux représentations et valeurs qu'ils construisent par rapport au monde. A l'instar de l'ethnométhodologie, le récit de vie permet d'appréhender les situations de vie telles qu'elles sont vécues et définies par les personnes [7].Cependant, il va au-delà de ce que propose l'ethnométhodologie, analyse de la vie quotidienne, en rendant également compte de la façon dont la personne interprète cette analyse et la relie aux choix qu'elle a faits (Pineau et Le Grand, 2007). Cette recherche de sens favorise l'émancipation de la personne vis-à-vis de son parcours : « Elle correspond mieux, à notre avis, à l'accès des sujets à un nouveau **savoir-pouvoir vivre** plus lucide opéré par ces activités de décentration et d'intégration » [7]

1.2 Récits de vie et résilience

Nous considérons ici la résilience en tant que « processus biologique, psychoaffectif, social et culturel qui permet un nouveau développement après un traumatisme psychique » [4]. Elle est conceptualisée en tant que résultat de l'interaction entre des facteurs de risque et des facteurs de protection (Anaut, 2012 ; Terrisse *et al.,* 2007 ; Lecompte, 2004). Les facteurs de risque peuvent être définis en tant qu'éléments individuels ou environnementaux qui ont une influence dans l'apparition d'une maladie, d'un traumatisme ou qui portent atteinte à l'intégrité ou au développement organique. Les facteurs de protection sont des caractéristiques ou des conditions qui sont à même de minimiser l'impact des facteurs de risque ou de renforcer la résistance à ces derniers. Il est à noter que la résilience ne peut être définie en tant que simple résultat per se du jeu entre ces différents facteurs ; l'individu ne représente pas seulement le terrain dans lequel s'effectue cette dynamique, il y joue un rôle actif primordial [2].

Dans un ouvrage collectif consacré aux liens entre récit de vie et résilience, Laurence Ossipow propose une différenciation les notions d'*empowerment* et de résilience : « A l'inverse de la notion d'*empowerment*, qui se centre plutôt sur la (ré)appropriation de l'autonomie pour un individu libéré de certaines dépendances, contrôles ou contraintes, l'analyse du processus de résilience rend attentif à la place qu'occupe l'altérité dans l'expérience d'un individu. Sans négliger les dimensions de la personnalité ou le contexte des traumatismes, il s'agit de se pencher sur les autruis qui apparaissent dans les propos d'un(e) résilient(e). » [20].La nuance se situe donc dans la perspective des rencontres qui ont eu lieu dans l'histoire de vie des personnes vulnérables, rencontres qui les ont aidées à faire face à l'adversité. Dans le même ouvrage, Catherine Schmutz-Brun établit un lien entre le récit de vie et la résilience à travers ce processus de reconstruction des souvenirs qui permet à la personne de se reconstruire elle-même. Nous sommes là au cœur du défi que le chercheur doit relever, à savoir de faire émerger les éléments positifs, les forces de la personne au lieu de se centrer sur les obstacles et les souffrances qu'elle a rencontrés [22].

Ninacs [16] distingue l'*empowerment* individuel et l'*empowerment* organisationnel. Le premier correspond au processus par lequel une personne s'approprie un pouvoir lui conférant une certaine marge de manœuvre dans une situation de vie contraignante. Cette appropriation implique le développement de compétences, des opportunités de participation sociale ainsi qu'une conscience critique vis-à-vis de la situation de vie (désir de changer). L'*empowerment* organisationnel se réfère au pouvoir d'agir des collectivités. Il s'appuie sur la mise en commun des compétences individuelles pour faire évoluer une situation collective contraignante. De ces deux perspectives, il ressort que la résilience s'apparente à l'*empowerment* individuel. La résilience apparaît davantage comme le résultat d'une transformation, tandis que l'*empowerment* décrit cette transformation. Mais dans les deux cas, l'interaction entre les forces de la personne et les ressources de l'environnement est indispensable.

La mobilisation du récit de vie dans une recherche s'intéressant aux familles migrantes ayant un enfant en situation de handicap conduit à un changement de perspective épistémologique: l'objectif n'est plus ici de repérer les caractéristiques des trajectoires des familles, mais de comprendre **ce qu'elles en font**, comment elles leur donnent un sens qui peut soutenir leur résilience.

Une recherche-action pour soutenir la résilience des familles migrantes ayant un enfant en situation de handicap

Dans cette partie, je présenterai la problématique de la recherche, le projet actuellement mis en œuvre et les enjeux qu'il soulève en lien avec la question de la résilience.

1.1 Problématique

L'articulation entre migration et handicap pose un double défi aux familles concernées, parce qu'il touche leur rapport aux institutions en même temps que leur rapport à leur propre histoire. Certaines familles préfèrent ne pas dire leur histoire car elles la perçoivent comme une source potentielle de stigmatisation, notamment s'il y a eu de la torture. Cette réalité renvoie à la notion de «non-dicible» proposée par Martine Lani-Bayle [12] et Boris Cyrulnik [5]. Martine Lani-Bayle distingue deux catégories de ce qu'elle appelle le « non-dicible »

- ce qui ne peut être dit car ne pouvant être compris, entendu, soit au niveau individuel, soit au niveau sociétal. Dans son ouvrage biographique « Sauve-toi, la vie t'appelle », Boris Cyrulnik (2012b) explicite cette impossibilité qu'il a rencontrée de raconter son histoire, celle-ci ne pouvant être entendue par son entourage. Ce non-dicible englobe également le refoulé, qui s'exprime parfois autrement, par la créativité ;
- ce qui n'est simplement pas encore dit, parce que l'occasion de dire ne s'est pas présentée : « La proportion de ce qui est dit ou sera dit un jour est minime, infime, par rapport au potentiel de tout ce qui pourrait l'être. Alors ce n'est pas parce que quelque chose n'a pas été dit à un moment donné, que cela signifie qu'il y a blocage ou impossibilité à le dire. C'est d'ailleurs essentiellement à ce niveau qu'intervient tout l'intérêt, voir le dit « effet émancipateur » (selon l'expression de Jürgen Habermas), des histoires et récits de vie. » [12]

Du côté des institutions, les familles sont fréquemment amenées à dire leur histoire, parfois de façon contrainte, tant auprès des instances en lien avec la migration (notamment lorsque les familles demandent l'asile) qu'auprès de celles du handicap (corps médical, prestataires de services etc.). Cela renvoie à la notion de «récit nécessaire» développée par Catherine Schmutz-Brun [21]: les cadres institutionnels impliquent des récits médicaux, psychopathologiques, défectologiques, sociaux, qui sont parfois (souvent) obligatoires. Le handicap et la migration enferment les familles dans ces réseaux de récits nécessaires, parfois même contraints: anamnèses médicales, justification de la demande d'asile etc. Paradoxalement, l'histoire des familles a peu de place au cœur des institutions, soit par manque de temps (l'intervention est surtout centrée sur les prestations à fournir à l'enfant) soit par manque d'intérêt [8].

Le récit de vie peut remplir une fonction émancipatrice vis-à-vis des contraintes liées à un parcours de migration, d'autant plus lorsque celui-ci est marqué par la survenue d'un handicap. Il a donc du sens dans un contexte de recherche-action visant à soutenir la résilience des familles concernées. Mais le recueil de récit doit se garder d'être imposé, dans un contexte où le quotidien des familles est jalonné de « récits nécessaires » autour de la migration et du développement des enfants. Le recueil du récit se doit de respecter les différentes temporalités en jeu, celle de la disponibilité (des familles et de l'institution), celle du moment du récit et celle de la mémoire familiale qui se voit proposer ici un espace-temps pour se dire, ou simplement envisager qu'elle peut se dire. Catherine Schmutz-Brun parle d'« espaces protégés ouverts à l'hétérogénéité des publics, des générations, des appartenances intersocioculturelles, des modalités narratives croisant et élargissant les champs disciplinaires pour une approche du sujet dans sa globalité » [22] Cet espace-temps peut ainsi légitimer la transmission d'une histoire lorsque celle-ci est marquée par la souffrance. La créativité que permet le Journal de famille propose aussi un autre langage lorsque la langue, la mise en mots posent problème.

1.2 Projet

Ce projet se déroule en partenariat avec un service éducatif itinérant, dont la mission est d'accompagner des enfants de 0 à 7 ans présentant un handicap ou un retard de développement. Depuis quelques temps, ce service s'interroge sur la façon d'améliorer son partenariat avec les familles migrantes, car différents défis se posent à l'intervention : isolement de certaines familles, incompréhension du diagnostic et, de là, du sens de l'intervention, difficultés de communication liées à la langue etc.

Le projet élaboré ensemble s'appuie sur la mise en place d'ateliers « Journal de famille » : développée par Michèle Vatz Laaroussi et Roch Hurtubise au Québec [24], cette approche sous forme de recherche-action offre à des familles la possibilité de se rencontrer à intervalles réguliers pour échanger avec d'autres familles tout en créant leur propre journal, qui raconte leur histoire et leur quotidien. Les supports sont multiples et ne s'appuient pas uniquement sur l'écrit, ce qui rend la production du récit plus accessible. Cette méthode s'appuie sur le concept de « Nous familial » développé par Michèle Vatz Laaroussi [24], qui a complètement repensé la façon d'appréhender les familles migrantes (il s'agit d'adopter une vision dynamique et évolutive de la façon dont les familles se réapproprient leur histoire de migration, en tenant compte de leur insertion dans des réseaux sociaux et affectifs, leurs trajectoires familiales de migration, leur mémoire familiale et leurs relations avec les institutions).

Les intervenantes du service ont participé à la sollicitation des familles (par leur savoir expérientiel, elles sont le mieux à même de savoir pour quelles familles c'est le « bon moment »). A l'heure actuelle, quatre familles de milieux socio-culturels divers participent au programme, qui se déroule en quatre rencontres thématiques :

- Premier atelier : Notre famille, c'est…
- Deuxième atelier : Notre famille au quotidien
- Troisième atelier : Des moments importants de l'histoire de notre famille
- Quatrième atelier : Nos racines, nos ami-e-s et les personnes qui nous aident

Ces différents thèmes permettent d'identifier les composantes du Nous familial (insertion dans des réseaux sociaux et affectifs, trajectoires de migration, mémoire familiale et relations avec les institutions) ainsi que de comprendre comment les familles donnent du sens à ces composantes. Toute la famille est conviée à participer aux ateliers. Ceux-ci se déroulent en deux temps : un temps d'échange entre les familles et un temps d'activité pour les membres de chaque famille entre eux. Ces deux temps permettent aux familles de prendre conscience des ressources qu'elles développent ; ils offrent aussi l'opportunité de rencontrer d'autres familles, qui deviendront peut-être des autruis significatifs tuteurs de résilience, en particulier pour les familles plus isolées. Les activités proposées permettent aux familles d'explorer différentes temporalités : la temporalité historique de leur parcours, qui s'inscrit dans Histoire des sociétés, et le temps du quotidien, avec les défis qu'il comporte, notamment lorsqu'il y a un handicap. Les familles repartent des ateliers avec leur Journal, qui permet aussi la transmission intergénérationnelle de l'histoire familiale. Enfin, ces ateliers permettent d'aborder, sous des formes d'expression symboliques, les traumatismes potentiellement liés à la migration et à la survenue du handicap.

1.3 Les enjeux

Il a été très difficile de trouver des familles acceptant de participer à la recherche. Cette difficulté peut s'expliquer par différents enjeux, à savoir l'injonction à être résilient et l'écueil du non-dicible. Dans le cadre d'un échange avec Boris Cyrulnik au sujet de ce projet, ce dernier m'a fait remarquer le paradoxe suivant : si les parents se taisent, ils transmettent de l'angoisse à leurs enfants. Mais s'ils parlent, ils transmettent de la souffrance, et les enfants ne savent pas qu'en faire. La mise en place d'un recueil de récit de vie en contexte institutionnel soulève différentes questions :

- Le « jardin secret » : lorsque le récit est collectivisé dans un cadre institutionnel, quelle place est laissée à l'intime, à ce que la personne ne souhaite pas dire ? Il s'agit d'être vigilant avec l'aspect d'injonction à dire que peut contenir un projet institutionnel.
- La « porte d'entrée » : dans une institution, il faut trouver la porte d'entrée, l'activité, la personne-clé qui permettra d'atteindre les participants potentiels au recueil. L'idée sous-jacente à cette porte d'entrée, ce levier est de créer la confiance qui rend le récit possible. Ceci est d'autant plus important qu'en contexte institutionnel le « récit nécessaire » est souvent très présent.
- Le besoin : comment le besoin de faire son récit de vie émerge-t-il ? Les acteurs institutionnels (professionnels, bénévoles) sont généralement enthousiastes à l'idée du recueil de récit (c'est le cas des intervenantes de notre service partenaire) ; par contre les « bénéficiaires » de l'institution n'en voient pas nécessairement l'utilité. Entre « intercepter » et « susciter » le besoin, le défi est de taille…
- Le récit de vie, un outil vers la réflexivité : finalement, ce n'est pas le produit « récit » qui est important, mais la réflexivité qui se met en marche lorsque le récit s'élabore. Comment rendre compte de ce processus réflexif ?

Le programme Journal de famille offre un espace-temps dans lequel la souffrance peut être déposée. Il mobilise la créativité des participants, par des canaux qui peuvent être différents de celui de la parole, favorisant ainsi l'émergence du non-dicible. Mais surtout, il permet la transmission de l'histoire de l'enfant : comme le souligne la responsable du service, certains enfants rencontrent des difficultés précisément parce que leur histoire, associée à une trop grande souffrance, est gardée sous silence. Évidemment, ce n'est pas nécessairement

dans le cadre des ateliers que des événements douloureux seront évoqués en famille ; mais la participation au programme peut constituer un déclencheur du désir de transmettre. Car, autre avantage du programme, relevé d'ailleurs par les intervenantes du service, il n'y a pas d'obligation de dire : la famille choisit ce qu'elle révèle.

Conclusion

Il aura fallu beaucoup de temps pour mettre en place ce projet, en le construisant avec les partenaires du service et en rencontrant individuellement chaque famille intéressée pour créer ce premier lien qui allait rendre la suite possible. Les défis rencontrés illustrent bien la difficulté à travailler sur le thème de la résilience dans un cadre doublement institutionnalisé qui est celui d'une recherche-action au sein d'un service. Néanmoins, le projet offre le potentiel de cet espace protégé permettant au processus de résilience d'émerger ou d'être conscientisé par les familles, grâce à la rencontre avec d'autres et à un travail symbolique sur les situations de souffrance. Si les précautions sont prises pour éviter les postures injonctives, ce minuscule espace-temps offert au sein de la société d'accueil peut être intégré aux facteurs de protection qui soutiendront la résilience des familles.

Abstract

The transition from school to working life is a critical period for all students, particularly those with an intellectual disability [1]. At the end of schooling, students with intellectual disabilities live new experiences, sudden changes, a decrease of benefits received, and a difficult access to an active lifestyle. In this study, the transition from school to working life is discussed based on the theory of resilience. The theory of resilience is focused on the risk factors and the development of individual factors, familial and environmental protection to support the person during critical periods of its development. [2] Among the risk factors include the characteristics of mental retardation, lack of information for families about the process of transition and the role that they can play, despite limited resources, to facilitate the social and professional integration. According with chosen theoretical framework, is presented a review of scientific literature on protective factors that facilitate the transition from school to working life. It focuses on the participation of students with intellectual disabilities and their involvement in the transition process. Recommendations for the transition are exposed.

Keywords: developmental disabilities, transition, working life, social and professional integration, resilience, risk factors, protective factors, ecosystem response

Introduction

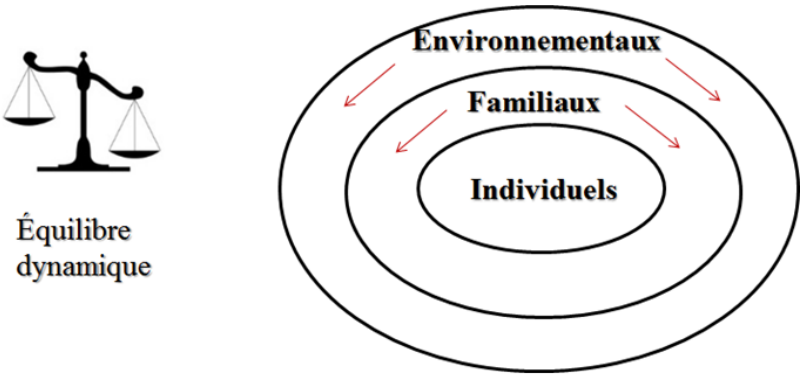
Au plan international, la prévalence de la déficience intellectuelle représente 1 % de la population [3]. La déficience intellectuelle est caractérisée par des limitations significatives du fonctionnement intellectuel et du comportement adaptatif qui se manifestent dans les habiletés conceptuelles, sociales et pratiques. Elle apparait avant 18 ans [4]. Au Québec, les élèves qui ont une déficience intellectuelle peuvent être scolarisés jusqu'à 21 ans. La période de la transition de l'école à la vie active est critique dans l'adaptation de ces élèves [5,6]. Il s'agit d'un tournant entre la fin de l'adolescence et le début de l'âge adulte où se succèdent le départ de l'école, les changements relatifs à l'emploi du temps et aux amitiés et les changements de statut social et vocationnel [7]. Une recension des écrits sur les facteurs de protection qui favorisent la participation active des élèves ayant une déficience intellectuelle à leur processus de transition est présentée. Le modèle d'intervention écosystémique axée sur la résilience est d'abord expliqué pour ensuite en venir aux facteurs de protection à développer chez les jeunes qui ont une déficience intellectuelle au moment de la transition vers la vie active. La vie active correspond ici à une participation et une contribution sociales optimales comprenant un travail à temps plein ou à temps partiel, rémunéré ou subventionné en partie, des activités de bénévolat, des activités communautaires ou toute autre occupation permettant une participation active à la société.

Modèle d'intervention écosystémique axée sur la résilience

En déficience intellectuelle, la résilience consiste à présenter le meilleur développement possible face aux adversités particulières rencontrées dans la vie afin de viser le bien-être et l'intégration sociale [8]. Elle implique le fait de « rebondir » après avoir vécu des difficultés, de persévérer et d'être en mesure de se projeter dans l'avenir avec confiance. Un élément crucial du processus de résilience en déficience intellectuelle est qu'il ne peut avoir lieu en dehors des interactions avec des tuteurs de résilience [9], le plus souvent des personnes de la famille ou de l'entourage immédiat. Pour faciliter la période de transition de l'école à la vie active des élèves ayant une déficience intellectuelle, la mise en place de facteurs de protection personnels, familiaux et environnementaux permet de soutenir le développement de la résilience. Il est ainsi possible de créer un équilibre

dynamique entre les facteurs de risque présents et les facteurs de protection à mettre en valeur pour renforcer la résilience. La figure suivante (Fig. 1) illustre cette dynamique au sein du modèle d'intervention écosystémique.

Fig. 1 Modèle d'intervention écosystémique axée sur la résilience : facteurs de risque et facteurs de protection (Inspiré de Jourdan-Ionescu, 2001 [2])



Recension des écrits

Les facteurs de protection les plus importants à développer lors de la transition de l'école à la vie active, recensés dans les écrits, sont présentés dans les paragraphes suivants.

Au plan individuel, l'intervention personnalisée visant chez l'élève la connaissance de soi (intérêts, préférences, forces, habiletés, capacités) ainsi que son engagement et son implication active dans le processus de transition est incontournable [10]. Il est recommandé de commencer tôt la planification de la transition, vers 14 ans, et de l'intégrer au programme éducatif et au plan d'intervention scolaire de l'élève [11] en favorisant la présence de tous les intervenants impliqués [12]. Le développement des habiletés personnelles, telles que les habiletés de la vie quotidienne et les habiletés sociales, est également important. Les habiletés d'autodétermination, par exemple s'affirmer, faire des choix et résoudre des problèmes, apparaissent cruciales [13,14] et peuvent être développées par l'enseignement de compétences explicites auxquelles doivent s'ajouter des expériences à l'école, à la maison et dans la collectivité. Il convient aussi de se soucier des aspects psychologiques comme le bien-être de l'élève et d'élargir ses conceptions du travail au-delà d'une source de revenu et d'un moyen d'éviter la solitude [15]. Les expériences positives et significatives pendant la scolarisation (emplois d'été, stages, bénévolat, activités parascolaires, etc.) aident le jeune à construire son identité sociale et de travail. Elles lui permettent également de connaître les occasions de participation sociale disponibles dans sa communauté, de clarifier ses intérêts et d'intégrer l'ensemble de ces informations dans un portfolio [14,16].

Au plan familial, l'implication de la famille dans le processus de transition est essentielle [7,14,16], notamment par le soutien tangible offert, les encouragements et la croyance au potentiel des jeunes. Toutefois, les parents ont aussi besoin de soutien et d'information sur le processus de transition, sur le rôle qu'ils peuvent jouer et sur les choix offerts [7]. Les valeurs du milieu familial exercent aussi une grande influence sur l'élève tout au long de son développement en lui inculquant la croyance que le travail est une attente de la vie adulte [17]. Les parents contribuent en ayant des attentes élevées à l'égard de leur enfant, en aidant à développer l'affirmation de soi, la responsabilisation, l'autonomie et la motivation du jeune [18]. Notons que la fratrie peut également offrir des occasions de participation sociale [7].

Au plan environnemental, le développement du réseau de soutien social par la création de liens interpersonnels en dehors de la famille et la participation à des activités sociales et de loisirs dans la communauté est très aidant [18]. La croyance au potentiel des élèves, la considération positive et la sensibilisation aux préjugés de tous les intervenants (éducateurs, professionnels, parents et employeurs) ainsi que de l'ensemble de la société sont incontournables pour favoriser la participation des élèves et leur intégration socioprofessionnelle [10,18]. Cela peut se faire en donnant aux élèves accès à des activités de développement de carrière à l'école [19]. La collaboration entre tous les acteurs impliqués pour la coordination de la transition est également essentielle [12,14,16]. Il est ainsi possible de regrouper toutes les informations disponibles sur le jeune et en d'assurer un suivi approprié entre les services destinés aux jeunes et ceux destinés aux adultes, de manière à faciliter la participation des élèves dans un contexte favorable.

Conclusion

L'étude, comme point de départ d'une thèse de doctorat, mise sur l'apport du modèle d'intervention écosystémique axée sur la résilience dans la transition de l'école à la vie active des élèves ayant une déficience intellectuelle. Ces élèves susceptibles d'être confrontés à de l'adversité chronique en raison de leur condition, pourront grâce à la mise en place de facteurs de protection, accéder au bien-être et à une pleine intégration sociale dans leur collectivité. Parmi les pratiques de transition, la participation de l'élève et le développement de l'autodétermination apparaissent centraux [13,14]. Or, peu d'études portent sur la participation active des élèves à leur processus de transition [20,21], et la participation réelle est peu favorisée [20,21,22,23,24,25]. Boisvert et Guillemette remarquent que l'hétéronomie, soit le « pouvoir des autres sur soi », se substitue souvent à l'autonomie des personnes ayant une déficience intellectuelle, de sorte que ces dernières ont davantage le pouvoir d'entériner une décision prise par les autres à la fin du processus que le réel pouvoir de décider de leur propre vie [26]. Pour remédier à cela, les recommandations ayant trait au développement des compétences personnelles des élèves, ainsi que de leurs habiletés de communication et d'autodétermination, le fait de favoriser leur engagement et leur place réelle dans le processus de transition en fonction de leurs goûts et intérêts, leur considération positive et la participation à différentes expériences reliées au travail sont à prioriser. Enfin, le développement du réseau de soutien social et la présence de tuteurs de résilience restent primordiaux pour augmenter la résilience des élèves ayant une déficience intellectuelle lors de la transition vers la vie active.

Abstract

We observed after several decades a return to shamanic practices in Occident. It was facilitated by the work of anthropologist Mickael Harner (1980), who, as a result of his investigations, extracts certain invariants consisting in what he proposed to call "the fundamental shamanism". The fundamental shamanism shouldnt be considered the neoshamanism,but it incorporates the main traditional techniques with the goal consisting in studying, transmission and conservation of those ancient practices.

In the frame of this communication we proposed to present this ancestral practice, with the main healing techniques in a shamanic and psychologic view.Serching the literature with a revue of the researchers focused on the psychoterapeutic impact concerning occidental subjects, and the meeting between numerous shamanic practitioners ,we tried to emphasise which way a different assisted resilience form can be integrated into occidental psychoterapeutic devices.

Keywords :assisted resilience, shamanism, psychotherapy, ritual practice,release.

Pratiques chamaniques et résilience assistée

1.1 Introduction

Nous constatons depuis quelques décennies un retour aux pratiques chamaniques en Occident [1]. Ce retour a été facilité par les travaux de l'anthropologue Harner [2, 3, 4] qui, après avoir été formé à des pratiques chamaniques, a étudié dans divers continents comment les chamanes exercent. De ses expériences multiples, Harner en a extrait certains invariants qui constituent ce qu'il a proposé de nommer le « core shamanism » ou chamanisme fondamental. De plus en plus d'occidentaux recourent en effet à des praticiens formés à ces pratiques non conventionnelles. D'ailleurs, 60 à 80% de la population occidentale recourt régulièrement aux pratiques thérapeutiques dites alternatives [5]. La maladie est en effet souvent vécue comme une crise existentielle à laquelle la médecine ne parvient pas à répondre. Cette nécessité de mettre du sens et les impasses thérapeutiques de la médecine qui ne s'attarde souvent qu'aux symptômes amènent beaucoup d'individus à se tourner vers des guérisseurs ou parfois des chamanes afin de cheminer dans une évolution personnelle, un réaménagement qui sera à même de faciliter une transformation des sujets. Se trouvent ici confrontées au fond deux logiques, une logique rationnelle et objectivante dont la médecine classique constitue un référent et d'autre part, une logique symbolique où la polysémie parle le langage de l'inconscient et des mythes.

C'est à partir de ce double constat, à savoir un retour à la pratique chamanique en Occident et le recours de plus en plus fréquent aux approches dites alternatives, que nous en sommes venus à nous intéresser à la fois aux soins chamaniques et aux remaniements identitaires lors des initiations chamaniques. Notre objet d'étude articule à la fois nos connaissances actuelles en psychologie et la vision chamanique, sans privilégier sur un plan épistémologique l'une ou l'autre vision. Il ne s'agit pas de comprendre le chamanisme au regard d'une grille psychologique mais de respecter au mieux ces deux univers. Notre positionnement épistémologique se situe donc dans l'entre-d'eux sans prendre position pour l'un ou l'autre des modèles explicatifs. Rien ne prouve en effet que les réalités non-ordinaires décrites par le chamanisme n'existent pas. Rien ne vient s'opposer à l'hypothèse de l'existence des esprits. D'un autre coté, rien ne la prouve également. Aussi, le respect de ces univers symboliques vieux de plusieurs dizaines de milliers d'années s'impose car il s'agit d'une approche ancestrale basée exclusivement sur l'expérience, sur l'expérimentation et sur leurs effets. Son ancienneté témoigne d'une certaine efficacité approuvée par ceux qui y adhèrent et recourent. Le second volet de notre recherche se propose d'appréhender ce qui a été thérapeutique au cours de/ou des soins chamaniques avec à la fois, nous le rappelons, une lecture chamanique et psychologique. Enfin, l'objectif final vise à s'interroger sur

l'intérêt des pratiques chamaniques dans notre société et la possibilité d'intégrer ces dispositifs dans nos prises en charges occidentales.

D'une manière générale, s'intéresser aux pratiques chamaniques implique le développement de ce que Harner [3] nomme un « relativisme cognitif », en ce sens que le chercheur se doit de garder à l'esprit la relativité de sa conception de la réalité, la relativité de sa cosmologie, la relativité de ses modèles épistémologiques qui l'aident à penser et faire science. Sortir de son égocentrisme théorique et éviter coute que coute d'adhérer à un « racisme épistémologique » [6] constitue un risque scientifique et le gage d'une ouverture propice à de nouvelles découvertes heuristiques.

1.2 Qu'est-ce que le chamanisme ?

Le terme de chamane est d'origine russe, plus particulièrement de la Sibérie (peuple Toungouse appelé aujourd'hui Evenk). Les anthropologues ont usité ce terme pour qualifier un ensemble de thérapeutes traditionnels (sorciers, homme-médecine, magicien, etc.) de cultures diverses. Classiquement, dans sa définition restreinte, le chamane est une personne qui s'agite jusqu'à l'épuisement et la perte de conscience. Cette altération de la conscience facilite des visions et amène le chamane à recueillir des informations provenant d'autres réalités. Cette expérience visionnaire est envisagée comme un voyage chamanique dans un autre monde que l'altération de la conscience («l' Etat de Conscience Chamanique », ECC, [3, 4]) permet de rendre visible. Le chamane est avant tout un praticien des états modifiés de conscience à même d'effectuer un travail spirituel en vue de maintenir un équilibre entre les diverses réalités. Une seconde caractéristique est le contact avec les esprits et la nature. Chaque chose qui existe dans notre réalité est esprit, ou plus précisément, chaque chose qui existe dans notre réalité est esprit dans une autre réalité que l'ECC permet de rencontrer. Le chamanisme est donc une pratique animiste qui vise à travailler avec les esprits, à les contrôler pour aboutir à une fin qui se veut généralement thérapeutique.

Harner a constaté au travers de ses investigations, que les chamanes décrivent plus ou moins «trois mondes » au sein de la « réalité non ordinaire », trois mondes ayant chacun des caractéristiques propres et ce, quelque soit les cultures : Le « monde d'en bas » est un monde transcendantal des énergies naturelles non soumis aux lois de l'espace et du temps. Les chamanes y décrivent de grands espaces naturels. Les esprits y sont représentés le plus souvent par des animaux sauvages et parfois par des chamanes décédés qui peuvent divulguer un enseignement. C'est classiquement le monde où vivent les animaux de pouvoir dont nous reparlerons. Le « monde du milieu » représente quant à lui l'aspect non ordinaire de notre environnement physique. Les énergies y sont nombreuses et donc les blocages sources de désagrément fréquents. Nous retrouvons dans ce monde toutes sortes d'esprits positifs ou négatifs (esprits des éléments, des arbres, des plantes, etc.). C'est un « monde de business » [7], en ce sens que les esprits doivent être payés au travers d'offrandes par exemple pour bénéficier de leurs services ou pour éviter leur colère. La sorcellerie se joue précisément dans cette réalité intermédiaire. Enfin, le « monde d'en haut » est éthérique et non soumis aux lois de l'espace et du temps ; les esprits sont généralement des guides spirituels qui peuvent donner des soins au chamane, lui apporter un enseignement spirituel et répondre à des questionnements existentiels. Ce monde contient aussi celui des morts en attente d'incarnation selon certaines traditions chamaniques.

En ECC, le praticien chamanique a la possibilité de se rendre dans ces différents mondes pour y effectuer un travail spirituel. Pour permettre de vivre l'ECC, le chamane a recourt à des plantes hallucinogènes (ayahuasca, iboga, mescaline, etc., [1, 8]), le chant, le tambour, ou d'autres types de percussions. Dans le chamanisme fondamental, le tambour constitue le « véhicule » qui ouvre la porte sur les autres mondes. Le tambour est en effet un outil stable qui permet de facilement court-circuiter la part rationnelle et de favoriser un lâcher-prise. Le tambour agit sur les fréquences cérébrales [3] et facilite un état de conscience modifié. Le second avantage du tambour est qu'il est plus facile de scander le rituel, le chamane n'étant pas soumis aux effets d'une plante hallucinogène qui peuvent durer plusieurs heures. Un tempo de 205 à 220 frappes par minutes permet généralement d'atteindre l'ECC et de faciliter le voyage.

Classiquement, les voyages, soins ou autres tâches chamaniques s'effectuent avec un « animal de pouvoir » ainsi que des « esprits alliées ». Ces esprits propres au monde d'en bas prennent l'apparence d'un animal, deviennent au fil du temps et de la pratique de véritables partenaires, et constituent le « pouvoir chamanique ». Des liens affectifs sont fréquemment décrits par les praticiens. Ainsi, un chamane qui a des pouvoirs chamaniques est un chamane qui travaille fréquemment avec de nombreux esprits : « Sans esprit gardien, il est virtuellement impossible d'être un chamane, car celui-ci doit posséder cette source de pouvoir à la fois vive et fondamentale pour surmonter et maîtriser les puissances spirituelles ou non ordinaires dont l'existence et les actions sont normalement cachées aux humains. L'esprit gardien est souvent un animal de pouvoir, un être spirituel qui non seulement protège et sert le chamane, mais devient son alter ego ou une autre identité pour lui » ([9], p. 84). Le chamane, aidé de son animal de pouvoir, se trouve donc protégé dans la réalité ordinaire et dans les autres mondes. Pour la pratique des soins, le chamane demande à celui-ci de lui signifier l'origine du trouble à traiter et comment y remédier. La véritable initiation est donc faite traditionnellement par les esprits. Ce travail peut être aussi effectué avec des esprits des deux autres mondes.

1.3 Etiologie chamanique des troubles et soins

Universellement, l'étiologie des maladies repose sur deux représentations fondamentales [5]: un excès de quelque chose ou un défaut de quelque chose. Nous retrouvons cette même idée dans le chamanisme. Classiquement, l'origine des maladies et autres difficultés est liée à la perte du pouvoir, la perte d'un bout d'âme, des intrusions nuisibles ou des âmes errantes (défunts) qui ne parviennent pas à quitter le monde du milieu. Le but du chamanisme est de renforcer l'âme, la force du sujet pour aboutir à un équilibre salutaire. Une relation étroite avec son animal de pouvoir garantit en partie cet équilibre. Aussi, si un animal de pouvoir quitte un individu, cela entraine une fragilisation progressive, puis la maladie [10]. Cela peut engendrer des problèmes de santé chronique, des refroidissements (grippes, etc.), des troubles dépressifs, de la malchance. Le soin consiste alors en un recouvrement de l'animal de pouvoir. Il s'agit de ramener dans la personne un animal de pouvoir. Un décès, des situations traumatiques ou des actes de sorcellerie peuvent entraîner une perte d'âme partielle. Le sujet perd une partie de lui-même et du coup se trouve incomplet, fragilisé. L'âme n'est plus intacte ou plus totalement dans le corps du sujet, d'où l'expression « perdre son âme ». Les bouts d'âmes perdus peuvent se retrouver dans les trois mondes décrits précédemment. Sur un plan psychologique, nous retrouvons les signes cliniques suivants : aspects dissociatifs, troubles dépressifs, addictions, ressenti d'un vide intérieur à combler, impression de ne plus être soi-même (troubles identitaires). Ajoutons qu'une perte total de l'âme se manifeste au travers d'un coma. Le soin consiste alors en un recouvrement d'âme où le chamane va aller rechercher le bout d'âme perdu pour le remettre chez le sujet. Enfin, une énergie nuisible peut profiter d'une fragilisation de l'âme pour polluer le sujet. Il s'agit d'une intrusion qu'il est nécessaire d'extraire. Selon Harner [3], sur un plan clinique, nous pouvons observer des douleurs corporelles, de la température, des signes d'infections, des maladies contagieuses, des tumeurs, etc. Le chamane, aidé d'un esprit allié, va donc extraire, souvent avec la bouche, ce qui est nuisible.

Lors du voyage chamanique, le chamane expose généralement à ses esprits alliés la problématique du consultant et demande conseils sur le type de soin à réaliser. La pratique chamanique attache beaucoup d'attention à l'intention qui vectorise en quelque sorte le travail. Nous retrouvons cela dans de nombreuses psychothérapies comme l'hypnothérapie [11, 12] ou l'EMDR [13]. Ceci sera abordé plus en avant dans nos réflexions sur les opérateurs thérapeutiques mis en jeux. Les principaux soins chamaniques envisagés dans le chamanisme fondamental sont donc : le recouvrement d'animal de pouvoir ou de bout d'âme, les extractions et le travail de psychopompe. Cette liste est loin d'être exhaustive car les esprits peuvent proposer tous types de procédures : travail avec des plantes, avec les éléments, les esprits du monde du milieu (arbres, esprits des lieux, etc.).

Traditionnellement, et c'est également le cas dans le chamanisme fondamental élaboré par Harner [4], ce n'est pas le chamane qui est à l'origine du soin et des effets de celui-ci. Les résultats sont imputables aux interventions des esprits qui sont le plus souvent de par leur nature des entités sensibles à la souffrance des humains et toujours prêts à aider à partir du moment où cela leur ai demandé. Le chamane joue donc le rôle d'un intermédiaire entre les mondes et consulte ses alliés pour connaître l'origine de la souffrance du sujet. Ses esprits lui font ensuite savoir quel type de soin est à procéder, soin qui peut être réalisé par le chamane (toujours aidé et guidé par ses alliés), réalisé directement par les esprits ou parfois par le consultant lui-même à qui il est demandé de procéder à tel action rituelle afin de favoriser un retour à l'équilibre.

1.4 Les opérateurs psychothérapeutiques mis en jeu

Le soin chamanique peut être envisagé comme un dispositif thérapeutique composé de praxies (gestes, mouvements, attitudes, savoir-faire) qui visent une transformation effective de l'individu au travers de contraintes procédurales spécifiques codifiées. Cette pratique rituelle est également codifiée comme une technologie qui encadre généralement une pratique de la transe. La transe constitue en effet un acte traditionnel qui opère un changement. Certains de ces états modifiés de la conscience peuvent être socialement définis et reconnus alors que d'autres sont spontanés et indépendants des normes sociales et culturelles [14]. Les modes d'induction très variés ainsi que les contextes socio-culturels participent à une multiplicité des expériences subjectives et des comportements observables.

Les praticiens du chamanisme au tambour décrivent des états de conscience divers, plus ou moins profonds ou légers, permettant d'accéder aux visions des autres réalités. Il est possible également de penser que le contexte culturel joue un rôle structurant qui peut renforcer l'efficacité de la pratique et plus ou moins organiser la transe ou son intensité. Selon le pays où le chaman exerce, des typologies propres à la niche culturelle, des pratiques, des univers symboliques plus ou moins ésotériques participent au rituel.

Cette organisation facilite un accès sécurisé à des « mondes inconnus ». Ce passage dans l'autre réalité engendre un ébranlement identitaire qui peut dans les cas les plus extrêmes aller jusqu'à la déstructuration du sujet, voire la décompensation psychotique. C'est pour éviter ou contrôler au mieux ce risque que le rituel, codifié comme une technicité, se doit d'être scrupuleusement respecté. Le rituel doit être structuré en étapes consciencieusement élaborées et pensées afin de guider au mieux le praticien dans l'exploration des mondes

invisibles, le monde des esprits. Les chants et musiques rythmées sont généralement utilisés en ce sens. L'importance de ces contraintes procédurales et de leur respect rend le dispositif efficace et favorise une réorganisation du sujet sur trois plans : organique, psychologique et culturel.

Le but du voyage chamanique est donc d'amener l'individu à recouvrer une harmonie avec son environnement ; en ce sens, c'est une démarche thérapeutique qui vise à rétablir l'intégrité du sujet en renouant avec le monde naturel dont nous sommes issus. Pour ce faire, la transe permet d'accéder à des informations provenant d'autres mondes constitués d'esprits. Le praticien vise une transformation de son existence qui va passer par une meilleure connaissance de ce qui le constitue en tant qu'être humain relié au monde naturel et « supra-naturel ». Il ne s'agit pas, comme nous pourrions le penser de prime abord, d'une simple transformation psychologique ou d'une simple réduction de la souffrance que peut endurer le sujet dans son quotidien. Le dessein est beaucoup plus large et radical : il est recherché une métamorphose de l'individu au point de faire partie intégrante de cette nouvelle réalité qu'il découvre. Les coordonnées personnelles et le cadre de référence du sujet s'en trouvent radicalement modifiés. Cette métamorphose s'apparente à une « mort symbolique », autre constante de tout rituel efficace, au cours de laquelle des facettes identitaires disparaissent au profit d'un remaniement autre.

Le consultant se trouve donc pris dans un rituel où il va s'imprégner de l'univers symbolique qui constitue la trame de fond du dispositif. La cérémonie chamanique assure en quelque sorte une communication entre l'homme et la nature, entre l'homme qui est souvent déraciné, séparé de sa part animale et ce qui constitue en fait son essence, cette même part d'animalité. Le consultant est donc invité à s'abandonner à l'expérience pour effectuer ce passage transformateur. Il est invité à se laisser porter par le travail des esprits dont le chamane joue le représentant. Il est invité à lâcher-prise.

1.5 Lâcher-prise et mouvement thérapeutique

S'abandonner à l'expérience tout en espérant une amélioration de ses maux implique d'abandonner la lutte. Le consultant doit abandonner toute lutte contre soi-même. Il doit interrompre toutes les stratégies mises en place jusqu'à aujourd'hui pour aller mieux, stratégies qui le plus souvent ne font qu'entretenir la souffrance. Il s'agit pour Roustang [15] d'introduire le sujet dans une autre forme de vigilance propice à une réorganisation de l'existence du consultant. Le dispositif de soin avec tout l'univers symbolique véhiculé amène le sujet à passer d'une perception dite « restreinte » (vigilance habituelle s'appuyant sur des repères coutumiers dualistes soumis à la conscience, à l'espace et au temps) à une autre perception plus élargie d'ordre holistique (sensorialité immédiate avec indétermination des modalités sensorielles). La première perception est discontinue et partielle, nécessitant pour fonctionner de séparer l'objet perçu de son contexte. C'est par le biais de cette différenciation que l'individu appréhende son environnement mais aussi son propre fonctionnement physique ou mental (exemples : « j'ai conscience d'une douleur dans le genou », « je suis malheureux depuis le décès de mon père »). L'autre perception que le dispositif permet d'appréhender est davantage implicite. Il correspond au premier mode perceptif que l'enfant vit dès sa naissance, une sensorialité antérieure à l'entendement. Comme le précise Stern [16], auquel on peut rattacher la notion de « conscience primaire », il s'agit d'une mode perceptif en lien avec une conscience primitive qui permet une appréhension globale de l'environnement extérieur et corporel de l'enfant au point où le bébé en vient à goûter une odeur, entendre une couleur, etc. (indétermination des modalités sensorielles). Cet abandon de soi passerait notamment par le corps à corps entre le chamane et le consultant, l'effacement de la parole, ainsi qu'un espace de dégagement de l'obligation de contrôle de soi.

Lâcher-prise nécessite de faire taire son besoin naturel de contrôle et s'autoriser à plonger dans un vécu inconnu malgré l'angoisse, la peur et la confusion. Nous comprenons cette dynamique comme une participation active du sujet à un vécu holistique, tout en se maintenant en position d'observateur sans souci de contrôle de cette même expérience. Ce processus dynamique est d'ordre dissociatif et fournit l'occasion d'une possible réassociation. La possibilité de devenir observateur de sa propre expérience, de s'autoriser à accueillir ce qui émerge de l'intérieur de soi, d'accepter ce que l'on repousse continuellement, constitue une possibilité d'intégrer, de se réorganiser et de s'apaiser. Pour ce faire, dans la pratique chamanique, le chamane doit être suffisamment présent, sécurisant, pour guider et éviter toute déstructuration psychologique. Le rapport à l'autre préserve de la folie grâce à un ancrage commun. Le lâcher-prise est souvent vécu dans l'angoisse car s'abandonner, se laisser envahir, c'est prendre un risque, celui de ne pouvoir se protéger de ce qui émerge de soi, d'où le rôle important de celui qui est déjà initié.

La question de la confiance est ici clairement posée. Pour qu'une thérapeutique soit efficace, le praticien se doit d'avoir confiance en sa technique pour amener son patient à avoir également confiance. Il est en outre nécessaire qu'il y ait un consensus autour de la technique pratiquée. Le dispositif doit être connu et reconnu ; il doit exister dans des revues spécialisée et/ou scientifiques et être pratiqué. Ainsi, faire possiblement parti du monde de ceux qui ont été initiés, voire guéris, forme un vecteur thérapeutique implicite mais puissant. Formulé différemment, les discours qui entourent la pratique se doivent de dire une vérité ou de faire office de vérité.

La confiance en la réalisation du processus de guérison s'appuie sur la nécessité de s'en remettre à quelque chose d'indicible. En participant au rituel de guérison chamanique, nous invoquons un tiers, une

nouvelle intentionnalité qui échappe à notre volonté. Nous invitons le patient à s'en remettre à quelque chose d'inconnu interne (inconscient, apprentissages, ressources psychiques, etc.) ou externe (pouvoir attribué au thérapeute / chamane ou aux esprits). La confiance tire donc son énergie d'une région de soi-même inaccessible autrement, une part de la psyché ou du corps où des potentialités peuvent se déployer. Tout comme le chamane, le psychothérapeute insuffle au profane un mouvement propice au changement. Le sujet s'autorise à se laisser porter par le champ de forces proposé. Cette dynamique est le plus souvent implicite et vise la construction d'une nouvelle réalité chez l'impétrant, voire un remaniement identitaire qui peut être thérapeutique.

Conclusion et réflexions épistémologiques

La culture occidentale donne une place essentielle à la raison, à ce qui est objectivable. Du coup, la pratique chamanique vient quelque peu ébranler nos certitudes, notre vision de la réalité et notre représentation du soin. Le relativisme cognitif, cher à Harner [13], amène le clinicien chercheur à se confronter à l'anomalité [17]. La pratique de la science s'appuie en effet sur une vision de la réalité, sur un consensus général qui définit ce qui apparaît comme une « science normale ». Les expériences chamaniques constituent des anomalies dans ce mouvement en ce sens que les phénomènes observés ne peuvent être totalement expliqués par nos modèles actuels et notre vision restrictive du monde. Une expérience anomale est du coup une expérience non ordinaire, qui ne fait pas partie de la liste culturelle de ce qui est admis et pensable. Pour Huguelit [18], chamane, ce qui est objectif, c'est ce qui est perçu, et ce qui est vrai, c'est ce qui fonctionne. Aussi, les chamanismes qui remontent à plus de 30000 ans selon de nombreux anthropologues [6] témoignent d'une certaine efficacité puisque de nos jours encore, de nombreuses personnes et beaucoup d'occidentaux d'ailleurs traversent l'océan atlantique pour s'initier aux mystères de la nature ou pour se soigner à l'aide des plantes chamaniques. Cette pratique anomale qu'est le chamanisme invite donc à penser un nouveau paradigme avec une nouvelle vision de la réalité et du soin. Cela implique pour le chercheur d'assouplir ses propres croyances, de s'autoriser à prendre des risques, en particulier celui de ne pas être compris ou d'être rejeté par ses pairs scientifiques. Ce changement dans les croyances de ce qui est vrai ou faux doit se baser sur les faits, et seulement les faits, ce qui constitue le principe même de ce qui fait science car comme le souligne l'anthropologue Narby [6], « la pratique est la forme la plus avancée de la théorie ».

Reflections on the relationship between psihotrauma (pt) and assisted resilience

Milea S.

UMF Carol Davila, Bucharest, Romanian Academy of Medical Science.

Psihotrauma, an aggressor which cannot be completely deciphered by an external observer

Introduction

Given the absence of a widely accepted definition in the field of resilience (Manciaux- 2001, Lighezzolo şi Tuchey -2004, Ionescu -2011), psihotrauma and some notions that gravitate around them, we will be working with operational formulae which are indispensable to a coherent approach to field of such complexity. Thus, we consider that:

a – Psihotrauma (PT) can be defined as: a negative psychical feeling which generates disorders and is created through a subjective processing of the external or internal reality, present or future, and perceived as a source of a prejudice seen as inevitable and unacceptable (Milea - 2014). It is not just about feelings which are obviously brutal, intense, dramatic and unexpected, as it is usually considered, but it is also about a huge number of feelings that, although apparently modest, distinguish themselves through persistence in time, repetitive character, cumulative action, the capacity to associate with and emphasize or use vulnerabilities, critical stages of development or unfavorable conjectural situations. It is Kahn's merit (1963 quoted by Fischer and Riedeser -1998/2001) to have introduced the concept of cumulative trauma.
So defined, PT brings forward the delimitation of two distinct terms: psihopatogen factors and psihotraumatogen factors.

b- Psihopatogen factors, respectively psychic distressors, include everything that causes neurobiological dysfunctions through psychological mechanisms. We are not using the term psychical disorders because, on one hand these are at the bottom of these factors, and on the other hand, psychical disorders are associated to other types of dysfunctions which cannot be ignored.

c- **Factors with psihotraumatogen potential** (not psihopatogen factors). This is a new term we propose in order to distinguish between those external or internal environmental factors which aren't pathogens automatically or directly but become so only once they have gone through the individual's filter of subjectivity and only if he turns them into PT. Different from one individual to another, subjectivity is the one which, following the processing and evaluating the external or internal reality, assigns some of its components a PT status. That means that the subjectivity of the individual is the one which identifies the factors with psihotraumatogen potential. It selects first from the wide range of psihopatogen factors. In addition to that, as the individual's subjectivity can often be wrong and see dangers where there aren't any (children offer numerous examples of this kind), the psihotraumatogen factors include situations which by nature, do not have an adverse character. As such, the range of **factors with psihotraumatogen potential** is far wider than that of the psihopatogen factors.

d- In turns, generally speaking, **natural resilience** is the process of using its own sanogen resources and those of the external environment by the subject and the capitalization of the confrontation with adverse life conditions. It is about the capitalization of the confrontation with the factors with psihotraumatogen potential and not just a simple overcoming which means that the individual emerges strengthened with what Tomkiewicz (2001) named an enrichment of their personality and Pourtois and col. (2011) called positive neodevelopment.

There are seven particularities of PT with special relevance from the point of view of assisted resilience.

They make PT a specific agressor. The definition of PT as given above emphasizes that:

1.1 PT is an outcome of the individual's subjectivity.

It is the subjectivity that assigns to some of the factors of the external or internal environment the significance of dangers or obstacles, present or future, with inevitable and inacceptable consequences. The same subjectivity is the one that can "see" a bigger threat than there really is or "invent" one without any reasonable basis thus transforming into PT what, for other individuals, is not considered as such. The other way around, subjectivity is the one that decreases significations, ignores real dangers or conscientiously accepts risks based for instance, on certain convictions or on the hope of some advantages, may they be in the afterlife. The involvement of subjectivity is by far the most significant particularity of PT because it marks anything it is related to it. That means that, no matter the nature of the internal or external factors that confront the subject, they do not become PT as long as the individual's subjectivity does not assign them such a significance.

1.2 Psihotrauma is a subjective structure with a distinct character.

The subjective nature of PT derives from the fact that it is a product of subjectivity and, as such, it is a feeling.

It has a distinct character because, on one hand, it is not the event itself the individual confronts himself with but what the individual's subjectivity appreciates it is, following its processing and the evaluation of the capacity to deal with it. On the other hand, it is the direct cause of disorders as in the succession event - psihotrauma- disorder, it has the last word. This means that PT should not be mistaken for the factors with psihotraumatogen potential that initiated it or for those it can handle or even less, for psihotraumatogen factors in general.

1.3 PT has a strictly personalized character.

It is the consequence of the fact that subjectivity is different from one person to the other. Therefore, what is a drama to an individual may well be an unfortunate event to another, a funny or even beneficial happening. This situation is a serious obstacle to the clinician, researcher, therapist or the close ones who are trying to understand and evaluate the situation, to anticipate its evolution and offer support. Even more difficult is the issue of identifying and evaluating psihotraumas in children and adolescents who not only have different needs, operational instruments and responses but are also in constant change.

1.4 The involvement of a socio-cultural dimension.

The same subjectivity causes that in the confrontation with the external or internal factors the individual involves not only the present and its whole personality but also its life experience, the quality of the attachment relationship, the moral standards and the social values it subscribes to. To all these are added the opinions of the people around, the offer or the lack of support of the community, the legislation, the feelings of guilt and shame as well as social inequity.

1.5 The involvement of thinking, memory and affectivity.

This aspect as well, differentiates PT from all the other types of aggressors. The thinking, the emotional load which accompanied its past experiences may they be traumatic or not, and their remembrance contributes directly to sorting out the present happenings and their consequences. With the help of all the above are chosen available solutions and it is evaluated their capacity to handle the situation. Actually, there is a lot of scientific literature which underlines the involvement of memory, anxiety and some possible thinking distortions that contribute to diversifying and individualizing the way in which reality is processed by subjectivity. For their importance we will mention the concept of cumulative trauma described by Masud Kahn (1963) and that of sequential trauma identified by Keilson (1979), authors quoted by Fischer and Riedeser (2001/1998).

1.6 Temporal disparity between the moment of the presence of the potentially psihotraumatogen factor, the moment of the constitution of the psihotrauma and the beginning of its action.

We here consider:

a) **The phenomenon of temporization of the transformation of the potentially psihotraumatogen factors into PT and the debut of the disorders.** Of course, the existence of an incubation period is a common phenomenon in medicine. Still, this time two situations specific to psihotraumatology should be mentioned.First of all, there is the case of the potentially psihotraumatogen factors whose harmfulness , due to various reasons – age, intellectual disabilities, education, conjectural factors etc.- is not

acknowledged, recognized or accepted by the individual for a longer or shorter period of time. Let's take for example the sexual abuse and the hyperprotective education of minors. The second mechanism which triggers the temporization of the harmful effect of PT is represented by the well known process of protection through repression, respectively, what Sillamy (1996) calls "un unconscious psychological mechanism of ego protection, through which the memories and the impressions which are unpleasant ore in disagreement with the social person are kept outside the consciousness".

b) **The remnant character**, respectively the extension of the pathogen activity of the PT long after the factors that initiated it ceased to exist. This does not only have to do with the usual confrontation with the direct negative effects of the already overcome drama. This time, there are a lot of complex conscious and unconscious mechanisms of self maintaining and psychological reactivation which can sometimes be present all life through. Memory, thinking, the emotional and the moral laws are firstly involved. Once the aggression has consumed, everything that surrounds and keeps alive the memory of the events, the reencounter with people, objects, places, words, gestures or similar events mentioned by others, the memories that generate tormenting intrusive reliving and even the protective care with which the victim id often surrounded keep the suffering alive. To these are added the dreams that can turn into nightmares and the anxious-depressive background which is part of the usual consequences of any psihotraumatogen experience.

c) **The anticipative character**. This one is a peculiar aspect, specific to psihotraumatology. It covers both the pathologic area and that of normality. It is known that the individual's subjectivity, based on the prospective character of thinking, on the self defense instinct and memory is capable of predicting dangers and the ability to face them as well as to adopt defense behaviour. It is just that such a predictive capacity is a two way street. On one hand, it has a protective factor of major importance as it offers the necessary time to prepare a certain behaviour marked by caution and the identification of defense strategies. On the other hand, the evaluation of both the risks waiting for us and that of the ability to control them is not always adequate. Therefore, there are many situations in which the danger is overestimated and the capacity to handle it underestimated which means that the individual's subjectivity may exaggerate and may confer a very dramatic connotation to a perfectly manageable circumstance or a very unlikely situation. Thus, for fear of failure exaggerated or unreasonable measures can be taken, actions whose risk would be worth taking can be blocked as well as behaviour designed to acquire various abilities or to test the ability to overcome obstacles or to self assert. All these things are very important to be taken into account by the person who offers counseling.

1.7 The involvement of specific autogenetic mechanisms meant to constitute psihotraumas.

This aspect is not singular in medicine and in this respect, the autoinmune pathology is an example. Yet, in our case we are dealing with very specific mechanisms. One very active mechanism is the already mentioned one. It refers to the fact that the individual's subjectivity can be wrong and can confer a PT status to totally controllable present or future realities.

A second mechanism involves the complex field of unsolved intrapsychic conflicts. At the origin of some of these conflicts lies the typical human ability of judging not only other people but itself as well and to start a conflict with both parties mentioned. In addition to that, the psychoanalytic conception talks about the opposition between the different instances of personality , between the conscious and the repressed component of the unconscious as well as the existence of wishes, motivations and impulses totally or partially incompatible, inacceptable or unbearable.

Comments

All the above allow us to identify within the assisted resilience a distinct field reserved to psuhotraumatology directly subordinated to the mentioned particularities specific to psihotrauma. Therefore, in this case, within the assisted resilience the following are called for:

a) A particular focus on the individual's subjectivity and not on the adverse situation.
This is due to the fact that in the case of assisted resilience the subjectivity is the one that decides not only on which of the elements of the internal or external reality are adverse but also on whether they can be faced honorably. Thus, in this case, the therapist can only act through and in accordance to the subjectivity of each individual. In this way there is room left to confrontation, training, practice and the experimentation of success and failure which are trials of an authentic resilience.

b) A strict individualization of each and every case.

c) The attention should also be moved from psihopatogen factors to the factors we called psihotraumatogen.

This should be done as the latter are, on one hand, essential for psihotraumatology, and on the other hand, are different from the psihopatogen factors. They sum up not only the psihopatogen factors that the subjectivity inherent to any individual recognizes as harmful but also those factors described as self constituted. As mentioned before these are represented by: factors which, although not harmful, considered so by the individual's subjectivity and future events considered, realistically or not, a source of inevitable and inacceptable prejudice.

d) The necessity to take into account that:

- It is not always easy to identify and, more importantly, to understand from the outside the full complexity of what makes the individual suffer and especially why he gives such importance to situations that do not seem very significant;
- It is important to keep in mind the involvement of thinking, memory and affectivity.In this case, the drama does not have only objective references. To these ones, important subjective, socio cultural, family and economic dimensions are added.

e) A special attention given to the phenomena of temporization, remanence, anticipation and autogenesis.

If the phenomenon of temporization offers time to counseling for instance, the remanence forces the resort to long term action. The anticipation and autogenesis phenomena call for a careful approach and a good knowledge of the subjectivity of the assisted ones.

Of course that, in effect, in the confrontation with the PT, the resilient procedure has to interact tightly with all the other preventive measures. Yet, the latter, more direct and, at first sight, more natural, commonly substitute the mechanisms of resilience. It is thus left aside the fact that what the individual itself accomplishes (the essence of assisted resilience) has a more effective character, more profound and more enduring than anything one could get through protective support.

Artistic languages as an educative tool to promote resilience

Mundet A., Fuentes-Peláez N., Pastor C.

Abstract

This paper presents research for improving the wellbeing of children aged between 8 and 11 living in a vulnerable social situation, who, due to the same, regularly attend *Centres Oberts, S*ocial Service Centers. The research takes place in Barcelona, Catalonia, and has two phases: the design of an educational proposal based on a preview stage and a pilot experience of the design. In this paper, we'll see output related to the second and third phase. The methodology used to develop the research is cooperative, as the participants are both the informers and impulsors of change. The aim of the research is to encourage the children's resilience through educational work using artistic methodologies as an educative tool and to unlock personal expression. The methodologies used are musical expression, artwork, drama and the spoken word. In a vulnerable environment, an artistic tool enables an immediate emotional connection, allowing them to speak about difficult and painful matters in a more constructive and way and more quickly. At the same time, it enhances the wellbeing of the children focusing on working through personal potential and capabilities rather than deficits.

In conclusion, this research is about emotional expression in vulnerable children through the medium of artistic expression. It allows easy communication to people's private areas and promotes resilience through an educational proposal. In this sense, it is important to emphasize that the educational process is more important than any aesthetical final result. Summing up, the experience confirms that an artistic methodologies approach to education working from a resilience perspective encourages personal development.

Keywords: Artistic languages, Personal expression, Creativity, Communication, Resilience, Socioeducative intervention, children at social risk, Centre Obert.

Introduction

In this article we present the results of research based on artistic methodologies as strategies that promote resilience.

The article came into being due to research developed in Barcelona with the objective of improving the wellbeing of children living in a vulnerable social situation, promoting their resilience through emotional expression through the arts. Art was a mediator in the socio-educative process of these children and had no predominantly aesthetical end.

Pain and adversity expression, together with creativity are two resilience pillars [1] [2]. In this sense, encouraging resilience means promoting this way of personal expression through the medium of art, because it allows for the interpretation of past experiences, present challenges and future hopes in a creative and imaginative way. So, it enables the communication of people who can't or don't normally communicate.

Different research has proven that creative activity promotes resilience, giving the possibility of fostering the resilience of people who live adverse situations. Social exclusion is an adversity and art can provide a symbolic re-enactment of life. Art allows people to rewrite the past, review the present and construct the future, imagining themselves in different ways and giving themselves the opportunity for change [3]. Also, when one has to confront adverse situations, speaking can often be very difficult. However, artistic expression allows them to express painful matters in a more accessible and indirect way. Resilience in the socio-educational sphere offers the possibility of communication without verbalization.

Methodology

1.1 Objectives of the research

The objectives of the research are two:

- Offer an educative proposal of emotional expression through artistic methodologies that foster resilience
- Pilot the designed educational proposal

1.2 Methodological Perspective

The methodological perspective of the research is *cooperative,* as this is highly effective in educational projects involving an intervention in a specific context and not trying to generalize. The research is a study for the transformation of socio-educational action in which the participants become active subjects for the same [4], [5]. A process for change and a transforming strategy for action.

1.3 Phases of the study

The study addresses artistic expression in the socio-educational sphere as an active promoter of resilience to improve children's welfare. This Project has two phases, the first one diagnostical and the second designing and piloting an educational proposal through a participative process of cooperative action.

1.4 Participants

The participants targeted in the research are children who live in vulnerable social conditions due to poverty and social/family marginalization, characterized by external factors of risk such as neighborhood social isolation, poor social environment and family, illiteracy, poor educational level of the progenitors, absenteeism at school or who have experienced neglect at home.

These children go to Open Centers. These are Social Services centers where children in a situation of social vulnerability go after school hours to perform activities that stimulate and foster their personal and social development.

The professionals who teach these children also participate in research, providing information on them and also on the contributions the artistic activities make as socio-educational action.

1.5 Instruments to collect information

The study uses qualitative research, collecting information via focus groups and participant observation giving all participants, children and social workers, the chance to express their views.

All the instruments formed the basis of the study in addressing how artistic languages could help children express their emotions and understand their personal perception and evaluation of the situation during the process.

1.6 Procedure

During the period of 2012-2014, we have accumulated 1 experience in 1 *Centre Obert, Grup Unió*, 2 focus groups (1 with social workers and 1 with children), and 1 participant observation (information collected in a working diary).

The experience was made more specific by putting into practice different practice sessions of 1 hour and 15 minutes a week to design an educational proposal. In each of these sessions educational activities were undertaken to identify and express emotions. They have used different artistic methodologies as socio-educational tools: artistic expression, dramatic, musical, body language, linguistic with a specific educational sequence based on:

- An introduction
- A creative activity (each week the creative activity has used a different means of artistic
- expression)
- A relaxing activity
- A summary of what has happened in the session.

1.7 Data analysis

All the information recorded was transcribed and an exhaustive process of content analysis was carried out to define categories and subcategories.

Bottom-up content analysis was applied: the first stage of analysis was textual, selecting paragraphs, fragments and significant quotes from the transcription papers. The second stage was conceptual, to identify categories and subcategories which could be inter-related. Both stages were carried out and subjected to peer review and categories and subcategories were defined when data reached saturation. The software *Atlas.ti* 6.2 was used for the qualitative data processing. A Hermeneutic Unit Editor was created in which the literal

transcriptions of the focus group (*primary documents*) were included, each category and subcategory was given a code (*code*) and textual notes were also included (*memos*).

A conceptual network (*network*) was created to analyze the data as a basis for the connections established between the codes of the hermeneutic unit and the research on artistic languages in the resilience process.

The study codes distinguish between the following themes:

a) **Emotional contents**: 1. Emotional dimension (intrapersonal communication and self-knowledge); 2. Cognitive dimension (to identify personal emotions and to think about them); 3.Behavioral dimension (educative values such as respect, collaboration or empathy as well as developing and putting into practice some social skills).
b) **Artistic strategies:** 1. Planning and contextualizing activities; 2. Having institutional support; 3. Having educational resources to create a secure space to develop and express the emotions
c) **Social worker profile**: 1. Having confidence in artistic methodologies as an educative tool; 2. Respect and confidentiality for the children's emotional work; 3. Dynamic personality; 4. Have the ability to perceive the cognitive level of the children and adjust the activities accordingly.

Results

1.1 Emotional contents:

1.1.1 Emotional dimension

The professional participants in the investigation consider that the emotional work through artistic methodologies provide the children with a wide variety of possible ways to communicate.

I believe that artistic strategies bring multiple registers to working on the emotions. Therefore, the more registers there are, the more options there are for them to express themselves and more ways to do so (Group discussion professionals).

The data confirms artistic methodologies as a beneficial mediator for working with children on Self Esteem*, the Concept of Self, Security and Confidence in Oneself*, *as well as facilitating the expression and identification of the emotions.*

*The artistic methodologies bring an injection and a first step to being able to work with the "Who am I, where am I going, what do I feel, how do I deal with things and relate to people" line of questioning (*Group discussion professionals).

1.1.2 Cognitive dimension

The **cognitive dimension** addresses the content of the emotions through the capacity to identify one's own emotions and those of others, recognize one's own potential and limitations and also be able to reflect on them all.

*Providing a space to be able to work on and think about what emotions we feel. This type of thing is very good at helping the children reflect on these things (*Group discussion professionals).

1.1.3 Behavioral dimension

The **behavioral dimension** agglutinates the way people act. In the data of the study this dimension is specified by the capacity to regulate behavior and encourage the socialization of the children with the aim of being able to change the ways of behaving which do not bring about wellbeing.

*The behavioral effects are more related to the putting into practice of artistic activity: having to collect the material used, the idea of community space, between others (*Group discussion professionals)

1.2 Artistic strategies:

1.2.1 Plan and contextualize activities, having institutional support

It is very important to have a clear idea before going in, of the overall plan of intervention, in terms of the number of sessions, their length, the length of each activity in each session, the objectives they pursue and the rules that set them out, to ensure good development. Also, the number and teaching sequence of each session

should be coherent with the objectives and the way of dealing with the emotional work of the institution one works from.

*Integrating the work within the dynamic of the centre and its educational proposal is important to be able to guarantee the maintenance of the work done and the progress made with the children (*Group discussion professionals).

1.2.2 Create a secure and safe space to develop and express personal emotions

It is important to do the sessions in a safe place, welcoming and trust inspiring, with natural light, materials available and a generous amount of space.

The number of activities planned per session should not exceed four and should follow a clear and didactic sequence coherent with the physical and emotional state of the children. The materials employed should correspond to the practice of a socio-educational intervention through artistic activities.

In relation to the space, we confirm the idea that preparing it is fundamental for developing the session. Today we have played with a new element which is reducing this space. The result has been very positive because it allows the children to establish a limit for the space, which metaphorically, implies a psychological limit. I am under the impression that this gives them more freedom, as it is culled from a smaller and specified space (Field Diary).

1.3 Social worker profile:

1.3.1 Have confidence in artistic methodologies as an educative tool;

One of the keys to the success of the methodology used is to increase confidence and security in the use of these methodologies amongst the professionals who apply them so they can transmit them to the children. One way to ensure this is specific training that acquaints them with the benefits of artistic languages as strategies of socio-educational action.

I felt highly insecure before starting*, I didn't really see or trust in where it was all going...*(Group discussion professionals).

1.3.2 Respect and confidentiality in the children's emotional work;

The children must feel that the educator is unconditionally on their side, showing love, empathy and consideration, whatever those children might be going through emotionally.

1.3.3 Dynamic attitude;

The professional should dynamically implicate herself in the activities to motivate the participants to get involved too. She cannot be a mere reporter who explains how the activities work, but must have a dynamic and stimulating attitude.

It is also important that the motivator of the activity commits 100% to it so helping boost the children's participation (Field Diary).

1.3.4 Have the ability to perceive the cognitive level of the children and adjust the activities accordingly

It has been noted how important it is that the educator be able to create alternatives to be able to adapt what was planned to the current cognitive level of the children. She should be prepared to be flexible, understanding that forecasting and planning are a starting point for what will really end up happening in the praxis.

The cognitive level of the group is low. Therefore, one must be conscious that the activities should be somewhat directed and organized. We also recommend doing simple activities. If we want to give theoretical explanations we should accordingly adjust them to the children's own language, culture and environment (Field Diary).

Conclusions and discussion

The general purpose pursued by the research was to be able to contribute to the improvement of the welfare of the children who go to the open centers working with emotional content through different activities that use artistic methodologies.

The results of the research highlight that artistic languages permit a non verbal communication which makes it easier to express certain adverse experiences. This facet is considered crucial when working with people who live in a situation of social vulnerability, especially in children. The main advantage is determined by the contribution to the emotional and personal development that contributes to the growth of the children. Nuñez and Romero [6] and Ruiz de Velasco [7] coincide with their data when they consider that artistic languages have become vital vehicles for working on emotional development.

Resilience is promoted when the expression of the emotions derived from the unfavorable social situation is facilitated, giving the opportunity to speak and express themselves to those who have not always been able to do so. Other educational values such as empathy or the frustrations connected to the work at hand are worked on at the same time as the opportunities for expression increase.

The research has allowed us to understand that artistic strategies mean benefits to the Open Centers, as well as also demonstrating that there are a series of things that should be considered to be put into practice.

An educational action directed at children between 8 and 12 will be successful according to the attitude and motivation of the professional who dynamises the interventions. It has now been grasped that the people who act in the artistic proposals with emotional content are key elements in the good development of those emotions. Marchan [8] agrees with these aspects of the attitude of the motivator, while adding the need for them to be patient with certain attitudes of the children and to know their emotions so as not to act them out.

The fact of connecting the emotions with the benefits of artistic languages to promote an improvement in the welfare of the children is of great importance, as the results of various research studies support the need to continue research on the lines of unifying pedagogy, artistic languages and emotional education to be able to support the results found up to now (Cruz, Caballero and Ruiz , 2013 [9]).

The lack of research so far focused on dealing with this theme underlies the importance of this research. Even so, in depth research should be continued to verify if the challenge of transformation and social change in this specified context area has really been achieved.

Abstract

The presentation is focused on explaining the main features of a process – systemic oriented working model in the psychotherapy of traumatic experiences. Developed on a humanistic - experiential background, the model assimilates and integrates a series of theoretical and methodological perspectives developed in various approaches in psychotherapy and also trans-generational systemic perspective on family. The model was empirically developed, based on the analysis and conceptualization of a large number of clinical cases and aims to stimulate both resilience and posttraumatic growth. Highlights regarding the subsequent theories on trauma and resilience and its use in psychotherapy are presented. The main theoretical ideas highlighting the understanding of traumatic experiences and resilience are the dissociation model ([1], [2]) and the distinction between pre-conscious and conscious periods in experiential processing ([3], [4], [5], [6]). The intervention model emphasise on: developing the working alliance from a client centred perspective ([7], [8]), use of the constructivist / information processing perspective ([9],[10]), working with the incorporated experience and the felt sense [11], working with the dissociated parts ([1], [2]) and approaching the trans-generational transmitted patterns ([12], [1], [2]).

Keywords: trauma, psychotherapy, integration, working model

The process-systemic oriented working model

The process – systemic oriented working model (PSM) is an integrative therapeutic model, aiming to be free from theoretical loyalties but fully loyal to the person of the client. It is not about proposing a new theory of psychotherapy, but rather a practical way to work synergistically with ideas already postulated separately by the most relevant schools of psychotherapy. The theoretical and practical model that we propose is submitted to the integration movement, being designed to overcome the limits imposed by loyalty towards a psychotherapy approach or other. The *process orientation* refers to the internal dynamic processes of the human being - if activated and sustained, they may lead to therapeutic change. The s*ystemic orientation* refers to: a) the view on human being as an integrated system of different facets that interact and influence each other permanently - all these aspects should be taken into account in order to better understand the human being, and for the client to better understand himself; b) to understand the human as part of a wider system, the extended family which invariably includes several generations - the consequences of previous generations` actions / traumas are reflected upon the person, and part of his current difficulties may have trans-generational causes.

PSM aims the psychic reconstruction of the individual, being concerned not only with the pathological process that determined certain psychic consequences but also with the manner by which the person can change his inner state and his future psychological path. It offers a theoretical model of understanding maladaptive emotions and an applicative model of psychotherapy. It was built through the *assimilative integration* model. The initial starting points were the Rogersian perspective of self-actualization and client-centering [1] and the Gestalt model of introjection, projection and transference [14], both as an explanation for the emergence and manifestation of maladaptive emotions and as a basis for the therapeutic intervention. The models of psychological trauma, respectively the process of psychic traumatization [15] and traumatic fragmentation [1] provided in the context a strong enough explanation of the etiology of neurotic emotionality and provided further clarifications required both on the concept of introjection and on the therapeutic goals. Concepts of conditioning ([16], [17]) and anchoring [18] were integrated into the model in order to explain how the projective mechanism and, consequently the maladaptive emotional experiences are triggered. The concepts of re-experiencing tendency [19], respectively the defense mechanisms ([20]), were included to illustrate the dynamics of the inner conflicts underlying the maladaptive emotional experiences. The family systemic perspective ([12], [21], [22])

more precisely the trans-generational transmission of some psychological vulnerabilities, complete the etiological perspective and opens new possibilities for intervention. Finally, the assisted resilience model ([23], [24]) is applied to examine the emergence of mental disorders through the complex interactions between vulnerability factors, risk factors, resilience factors and protective factors of the person - only combined they can offer a complete and comprehensive picture of the psychological functioning and methods of recovery /healing. Thus, on a humanistic-experiential basis, there were assimilated elements of psychodynamic analysis, cognitive-behavioral therapy, NLP, psychodrama, Ericksonian hypnotherapy, systemic family constellations and psycho-traumatology.

1.1. Theoretical framework of the process-systemic therapeutic model

The theoretical part of PSM aims to explore the ontology and etiology of the mechanisms and internal processes that generate the present experience of maladaptive emotions. The model is based on two assumptions sustained by other approaches (e.g. psychoanalytic and experiential): the existence of some etiological mechanisms – a personal vulnerability and its structuring processes; the existence of a phenomenological model of occurrence and manifestation of the maladaptive emotions in the present subjective experience. We identify two distinct periods for structuring an emotional vulnerability. Preconscious stage (conception – 3/5 years) is one in which the non-specific emotional vulnerability is structured and emotional symptomatic patterns are introjected, as consequences of traumatic experiences. If a child going through traumatic events will develop maladaptive emotions as an adult, depends on other factors as well: mechanisms of resilience, posttraumatic growth and relevant experiences from conscious. The key to understand the emotional vulnerability is the concept of trauma [15]. The conscious stage (3 years – 18/20 years) is one in which stable personality traits and personal preferences or existential themes are crystallized. Briefly, emotional models from the pre-conscious stage will make the person more vulnerable to the action of events occurring in the conscious stage and they will give direction to the primary, nonspecific vulnerability, emerged in the pre-conscious stage. Events from the conscious stage are the ones guiding the adult towards a neurotic type symptomatology. In the absence of a primary emotional vulnerability dating from the pre-conscious period, the action of stress or traumatic factors occurring in the conscious period will not lead to symptomatology, but rather will structure an enhanced vulnerability to stress, without involving a neurotic psychopathological component [5].

The trauma model of Ruppert [1] explains the internal subjective experience of the person affected by psychological trauma, regardless if it occurs during conscious or pre-conscious period. A person undergoing a strong emotional traumatic experience, which exceeds its capacity to adapt, has only options to survive the internal freezing or fragmentation, in which subcomponents of the personality are dissociated from the integrative instance of the ego: the traumatized part – containing the traumatic pain and energy; the surviving part – developed to prevent contact with the trauma and the associated emotions, respectively with the traumatized part and; the healthy part – unaffected by the trauma that contains the resources of growth and development and constitutes the foundation of the therapeutic intervention. Each instance is expressed in the actual inner experience of the client in a certain way and the therapist can recognize the markers of these processes. The aim is to reintegrate the dissociated parts into the client's personality for a genuine and proper functioning.

PSM states that there are three categories of etiologic factors of maladaptive emotions. The trauma suffered at early ages creates a primary emotional vulnerability, non-specific and non-differential, translated at a phenomenological level as a high availability of a person to emotionally respond in a certain manner to the intervention of environment variables. This vulnerability acquires a specific character in the conscious stage through the association with specific emotional experiences (fear, anxiety and depression). The mechanism of creating this vulnerability is the introjection. Through the projection mechanism, the person reaching adulthood brings introjections in present time and assigns them to situations /people in reality. Anchors make possible the manifestation of projections in the present. Through the defense mechanisms against overwhelming emotions, the person will avoid threatening situations, will become hyper-vigilant and will seek to anticipate them. Due to the increasingly higher difficulties to interact with reality as it is, the negative projections and expectations can become generalized. The maintaining factors of these emotional experiences are equally important and can be defined in three categories: adverse circumstances, primary (direct) and secondary (indirect, self-image related) benefits related to symptom.

Sometimes, it becomes obvious in psychotherapy that there are additional causes for the psychological disorders beyond the client's personal life and biography. A series of theories stated that trans-generational aspects may be incriminated for a part of the client`s current emotional experiences: the concept of family unconscious [25]; systemic family constellations ([12], [26]); psycho-genealogy ([27], [21], [22]). All of them postulate the following: the existence of psychological effects on the individual and on his mental health /pathology coming from the family system; the existence of trans-generational transmission processes of psychological contents. The family system is characterized by a fundamental system of emotional relationships, based on attachment relationships, which are organized in patterns; these patterns tend to be perpetuated in the

family system, on intergenerational level, based on family unconscious processes. The transmission mechanisms of these patterns are unconscious processes – the family loyalty and identification.

Application of the process-systemic model in trauma psychotherapy

PSM addresses the full range of neurotic disorders, which involve a core component related with maladaptive emotions, especially anxiety and depression. The applicative part of PSM will not try to eliminate maladaptive emotions of the client but, on the contrary will try to make him face, explore and clarify them as a "givens of existence". According to the therapeutic model that we present and apply in our clinical practice, the client, whom others consider ill or mentally disturbed, is approached as a person in a certain moment of his personal development (self-actualization) in which he feels stuck and needs support and guidance to continue.

A special application of PSM regards the therapeutic interventions on traumas, based on the conceptualizations offered by Fischer & Rieddesser [15] and Ruppert [1]. We follow the assumption that psychic wounds caused by traumatic events can be ”seen” (as in the PTSD symptoms) or ”hidden” (under certain emotional, relational or behavioral patterns, especially if trauma occurred in early development stages). The latter category requests special attention from the therapists especially when the client presents other neurotic symptoms, apparently unrelated to any traumatic events. The main therapeutic focus is on the traumatization process and the interventions are adapted to the current emotional state of the client and considering the age when the trauma happened.

1.1. The general framework of process-systemic oriented working model

The applied PSM incorporates the assumptions of the common factors model in psychotherapy. Therefore, the general framework of PSM aims to activate and use the scientifically proven factors of therapeutic change ([28], [29], [30]). We illustrate here only two of them: the role of the therapeutic relationship and the activation of the inner mechanisms that promote therapeutic change.

Using the therapeutic relationship. In trauma therapy, the therapeutic relationship activates the re-bonding process of the client – rebuilding the relationships destroyed by the trauma. It is the one that facilitates understanding of the traumatic effects and sustains the trauma perlaboration. Specifically, PSM uses the therapeutic relationship as follows: as a corrective emotional experience for the past relational and emotional patterns ([31], [32], [33], [34]); as a manifestation of the transference and countertransference, both psychoanalytically and Gestalt conceptualized ([35], [14]) – these will be used for a deeper understanding of the traumatic experience; as a new attachment relationship that provides a new secure base for the client [3] – used especially with regard to symbiotic traumas; as a frame for experiential and emotional processing, where the therapist serves as a model of acceptance and valuing the emotional experience [8]; as a fundamental framework for enabling self-reflection, consciousness expansion and client experience [36]; as a profound existential "encounter" between two people with growth and individuation effects [7]; as a way to activate client’s personality resources through identification with the personality of the therapist as a model (congruence, authenticity, presence, responsibility, respect, spontaneity, creativity, etc.) [37].

The internal mechanisms of change – are those that have been promoted by all therapeutic approaches in different terms. *The awareness* is the main therapeutic mechanism and the key inner process of the client. The process-systemic model integrates by assimilation multiple objectives of awareness (e.g. awareness on emotional and behavioral patterns created by traumatic events and on their effects in the present life; on the contact between the self and the world and on the interruptions of contact). Other mechanisms considered for promoting therapeutic change are: *emotional and experiential processing* - to articulate and symbolize the experience at a conscious level in order to identify its meanings and to create new ones; *breaking the patterns* – to create new, more flexible ways of organizing the behavior that, in turn, release the rigid ways of experiencing; *catharsis* – an essential curative factor that releases the psychic energy previously blocked in the effort to suppress the rejected parts of the self and that can, later be invested in a consciously, adult manner, in the development of new skills and in the experiential reprocessing; *interpretation* of the psychological dynamics of the client – usually used indirectly, by choosing the therapeutic tasks for the client; *activating client’s fundamental resources* – the *spontaneity / creativity* as childhood’s authentic motivational resources and the *self-observation / self-reflection (*as a main adult resources); *activating cognitive mechanisms* – to restructure the maladaptive thoughts and information processing errors, to change the client`s expectations of self-efficacy and to activate self-control; *behavioral learning processes* - to maintain the change initiated during therapy, to learn new skills and behaviors and to learn relaxation; *re-decision* - as an inner process able to create new inner experience and consecutively, a new ”life script” and thus, enhancing the personal responsibility for his own existence and experience. Their activation depends on the *experiential diagnosis* of the client and targets the moving forward of the therapeutic process.

1.2. Therapeutic strategy in processing the traumatic experience

If therapeutic intervention occurs in the immediate posttraumatic moment (crisis intervention), the therapeutic objectives covered are: to provide physical and especially, emotional safety and to facilitate the elaboration process of the traumatic experience in order to prevent it from falling into helpless emotional overwhelm, freezing or internal dissociation. In this case, ego defense mechanisms are respected and seen as absolutely neccesary attempts of the person to protect his self.

The process-systemic model aims to approach traumas on a long-term and at a deeper level. This implies combined therapeutic objectives and specific therapeutic interventions. Briefly, these are:

a. *Focusing on the ongoing experience of the client and on the experiential process*. Primary, we focus on the client's experiential diagnosis and not on the person`s diagnosis. The center of the therapeutic process is the inner emotional experience of the client, from this point of view the therapeutic general purpose being to enhance the clients' experience by introducing additional information in the representations field. Thus, the foundation of the therapeutic process-systemic model is the current experiential approach ([11], [38], [9], [10]).

   The analysis of client language is a continuous therapeutic task throughout the whole process. The therapist calibrates the specific expressive markers for different internal processes of clients and their inner difficulties and thus, can guide the exploration of the client and the optimal moments to introduce therapeutic interventions for change. As examples, the therapist should calibrate: traumatization markers; markers for unresolved feelings towards a significant person; markers for the ambivalence of the decision between different alternatives; corporal markers of emotions; markers of avoiding self-contact or responsibility; markers of trans-generational issues. The therapist uses a therapeutic language that recreates emotional stimuli in the consciousness of the clients and helps them to symbolize, regulate and express the experience. Within the process, we use several therapeutic questions to explore the client's inner experience; we pay attention to how the client speaks of himself in order to capture those statements that indicate emotional problems or inner processes. The therapeutic process aims to evoke the emotional reactions of clients in order to help them identify the impact of events, to symbolize their reactions, to discover the needs, goals and action tendencies, associated to emotional responses. Thus, clients can become aware of the connections between the external environment, inner experience and their behavior.

   Orientation of the therapeutic process to *explore the maladaptive emotions and their sources* (traumatic events); *increasing awareness* of the tendency to re-experience the maladaptive emotions*; identifying relationship and perception patterns* that interfere with the person's ability to function at the highest level of adaptation and; *creating emotional-corrective experiences for the clients* – are joined aims of the therapeutic process of traumatic experience.

   The therapeutic process is further oriented towards *deepening the experience* of the clients so that, in time, they become aware of the *maladaptive emotions and their sources*, also of their *emotional re-experiencing tendency*. The process takes place by creating experiences of deep connection with the self, of increasing the self-awareness. The process develops from the present towards the past, from current experiences towards increasing awareness and deepening it regarding all aspects of the inner experience (sensations, emotions, beliefs, behaviors, needs, etc.) and the contexts of its occurrence.

   The therapeutic strategy follows the course of the internal processes of the client until the moment when the secondary and primary emotional vulnerability were structured. Every stage (conscious and pre-conscious) is critical regarding the etiology of maladaptive emotions and raises specific issues for the therapeutic process: building different therapeutic strategies to address each period, and choosing different therapeutic techniques with curative intent. For *the conscious period*, we rely on the constructivist/information processing perspective ([9], [10]) according to which people have experiences that they have not properly processed. This is due either to too much emotional loading (e.g. the client felt so anxious at a certain moment, that he failed to process that experience), or to too much information loading. In both cases, some parts of the initial situation will be left outside the client's representation about his own experience and so there will be inadequate, incomplete representations that further will filter the experience and guide the behavior. From this point of view, the purpose of therapy is to reconstruct the meaning of experience through elaborating a more specific meaning for it. The idea is to make the client aware of his relational, emotional or behavioral patterns and their personal meanings (why they were formed, what was the meaning of their occurrence and persistence, what is missing from this inner construction, why the tendency to re-experience appears). Thus, the understanding of the experience is extended and the experience can be changed. The basic assumption is that the way in which clients symbolize the experiences determines how they feel them.

   If the client's inner process goes beyond the conscious period and moves towards the *pre-conscious* one, then in the therapeutic approach we rely on *the incorporated experience* and *felt sense* [11]. If the client

becomes aware of these corporal, pre-conceptual significances, then they become available to consciousness and therefore to reflection. Therapeutic change means changing the direction of the client's inner experience as a result of the adequate representation of these inner felt senses. The therapeutic goal is to eliminate the automatic nature of the maladaptive emotional responses that cause processing errors of the current information and, consequently the pathological functioning.

b. *Intra-psychic conflict resolution and integration of the dissociated parties due to trauma*. The therapeutic process is focused on the work with the dissociated parts of the person, based on Ruppert's model [1]. The therapeutic interventions aim at: overcoming the resistances due to the defense mechanisms; conscientiously reconnecting to the traumatized parties and to the associated suffering; re-experiencing / recalling the traumatic situations from the perspective of the present healthy resources; reintegrating all parts at the self-level.

c. *Accessing the client's internal adaptive and growth resources.* Strengthening the client`s Ego is a continuous therapeutic concern. The main strategy is re-empowering [39] the person– first, by demolishing the pathological significance of the traumatic reactions. Activating the client`s internal mechanisms will be made only in fine tuning with the client's ego capacity to "contain" and support painful inner processes. Therefore, we focus on the resilience factors – those personal resources remained unaltered by the pathological process. In the same time, there is a continuous exploration of the risks factors of the individual which may indicate intervention possibilities.

d. *Addressing the trans-generational aspects.* The next therapeutic step addresses the approach of family patterns trans-generationally transmitted, which occur in the internal emotional experience of the client and are expressed through his verbal and nonverbal language. The therapists who work with this method should be aware of the markers of these processes. Therapeutic interventions aim at raising awareness to implicit relational patterns, unconscious, existing in the family system level, followed by a phase of practicing new ways.

e. *Development of posttraumatic growth.* Even if the therapy is effective, the transformation of the traumatic inner experience is an ongoing life-time experience for the person. There can be others current events that may re-activate old patterns. Therefore, the final therapeutic goals are to make the client aware of this, to initiate the process of deliniating past from present and to promote personal growth. It regards the following aspects: the development of personal autonomy; the continuous engagement in sustaining the changes; development of new personality characteristcs (e.g. honesty, integrity, interest for spiritual values, etc.); maintaing the adult role able to enjoy his own existence and trasforming the trauma into a launching pad for a new meaningful life.

Psychotherapeutic techniques used in the process-systemic model are applied according to the therapist's objects at a specific moment of the client's internal process - an eclectic approach. The therapist can use the most effective interventions, or he can creatively, spontaneously build them but the choice has to be made according to the client's evolving experience, to the dynamic of the therapeutic process and to the evolving working alliance. The techniques are chosen to meet the client's situation and to produce him a new experience which can engage him as fully as possible.

The promotion of resiliency by counseling

Oancea C., Budisteanu B.

Alexandru Obregia Hospital, Bucharest
bbudisteanu@yahoo.com

Abstract

Defined in developmental psychology, resilience is a dynamic process whose propensity is toward a positive adaptation in conditions of adversities. The resilience draws over the importance of protective factors depending on individual on even more on his environment. A part of protective factors, especially those belonging to the individual can be consciously developed later, during life time with some outside support, e.g. by counseling through a learning semi-directive process. For estimation of quality of resilience of somebody it is necessary a global assessment of his problems, his vulnerabilities and his defending means. Departing from vulnerabilities, there may be identified the protective factors belonging to improvement of emotions management, of problem-solving, of conflict resolutions and many others. As a result of their assimilation, the counseled person will have a better efficacy, a higher self-esteem, more adaptative means. It should be reduced the impact of adversities and the risk for mental disorders. The counseling is one of the most valuable therapeutic methods addressed to those in difficulty. It offers a positive, constructivist perspective, it draw attention on the individual life with possible positive aspects. It offers the empowerment for actions and creates success opportunities. The subjects are oriented toward aspects from the realm of mental health, far from disorder. The resiliency is a concept that surpasses the developmental problems creating new perspectives in psychotherapy for all ages.

Key words: resiliency, protective factors, counseling, learning process, mental health,

Defined in developmental psychology, resilience is a dynamic process through which is achieved a positive adaptation in condition of adversities and the process of personal development is going on [1]. Through resilience there are rediscovered a state of balance, a subjective state of good, of positive adaptation, unaffected by events with whom the person is confronted. It materializes a positive perspective on human being [2]. It is promoted also the view that the resilience can be systematically build, especially in childhood, an innovative concept generator of interventions, nominated as assisted resilience [3].

Resilience is a synthesizing concept through which are assorted a succession of psychological, positive, protective factors, apparently scattered which are related by this term. Through resilience are related actions dependent from individual with that provided by its medium, which confers to interactions a plus of meaning.

The concept is born from studies on large groups of children, living in extreme condition [4] or in psychosocial risks [5] in the beginning stage of life. It was shown that the maltreatments of the children result in multiple biological and psychological deviances, which generate long-term vulnerabilities and risk of psychopathology, but these are not valuable for all. Garmezy [6] showed that a part of children maintain some qualities belonging to resilience, depending in great measure of the quality of supportive relations. The qualities are placed in zone of self-systems, in self-confidence, depending also from a relative reserve in interpersonal relations and in a rational attitude in front of problems [7].

Resilience was analyzed in life cycle, from the growing perspective, resulting in a gain, a more successful adaptation. In a larger perspective, resilience can be used in approaching of life problems, which includes psychotraumas, changes, transformations, in fact all are provocations. Resilience supposes successful utilization of personal resources in a process of surpassing the provocations. After experiencing of a difficult period it is possible, returning to the previous structure or reinstatement of a positive acting on new coordinates, what is in fact a developmental process through resilience [8, 9]. There were identified two patterns of development: the posttraumatic [10] and associated to stress [11]. On biological side resilience corresponds to neuroplasticity.

From the results of the studies about resilience, there were defined preventive approaches in defense of mental health, with targeted interventions, having a formative-educational character, materialized in many

programs centered of children and adolescents, at the optimum ages for resiliency development. They involve always a large support from outside, from the family, school and community.

Only recently, resilience was analyzed at the adulthood [12] in the case of posttraumatic stress disorders, of those living in extreme poverty, civil wars, of those whose childhood was marked by parental mental illnesses, of schizophrenia with favorable evolution and even for stimulation of a successful ageing. It was tried to introduce of the concept into life cycle, so it was considered that at any age there is some potential for growing which can be stimulated.

There were identified [13] a range of attributes which ensures a degree of resistance to pathology, as functional resilience: a close relationship with competent and caring adults in the family and community, self-regulations abilities, positive self-image, motivation to be effective in the environment (self-efficacy, self-determination), friendship and romance in peers, problem solving skills, foresight in planning, active, positive coping strategies, the capacities to confront fears directly, minimizing denial, disengagement and avoidant coping [14]. Moreover are important optimism, positive emotionality, perceiving stress in less threatening ways, ability of reframe adverse experiencing, spirituality, capacity to find a meaning in what is happening.

Very few were discussed about the use of resiliency in the therapeutic process, after psychotherapeutic model, in curative aim. There are important differences [3] because in psychotherapeutic approaches of the person, are explored in its psychopathology, drawing in evidence failures, psychological insufficiencies which will be, after that, treated through different models of intervention, psychoanalytic, cognitive behavioral, interpersonal. In the resiliency model, that of strengths, in first plane there are the individual resources and the extent to which they are put into value. For estimation of somebody quality of resilience it is necessary a global evaluation of his problems, his challenges, of the adversities, of vulnerabilities and of means of defense, the accent being placed on strengths.

In the counseling model [15], there is a preliminary stage in which the patients are accompanied for releasing from the negative affect through empathic listening. In this stage, the disturbing emotional state there are defined and assimilated. The emotional balancing and learning the management of fear, anger or other emotions represent one of the targets. In the counseling process it is developed trust, is created an interpersonal relationship which will facilitate the therapeutic process. During this time, on pass to approach of the life problems, which will conceptualized, possible with counselor support. Often there is a need for an important stage for processing of thinking and the use of reflections, interpretations and confrontations.

Finally, the subjects must be aware about his unsolved problems and about the disabilities which last behind them. The rationalization problems represent an important step forward on the way toward defining an intervention. It is followed by finding of solutions and decisions. In the majority of cases the solutions are centered on change in life. Milner and O'Byrne (2004) underline the facilitation of change as fundamental constituent of counseling [16].

The counseling is a therapeutic method which come in play with vulnerabilities, through identification of the factors which can maintain an adaptation problem in somebody life and the establishment of the procedures by which they can be removed. There are taken into consideration the positive factors, the strength, present in individual psychology which should be developed and also those which are missing and must be assimilate. In concurrence with the subject it will established the modality of growing of resilience, with the improvement of protective factors, with precise objectives as emotions management, finding a fit coping, the qualifying of the conduct with different skills as problem-solving, conflict resolution and many others. Their assimilation can be done through a semi-directive learning process with many similitudes with behavioral-cognitive therapy.

As follows, the counseled person will have a better efficacy, a higher self-esteem, more successful adaptations means, there will be reduced influence of the adversities and she will be more immune in front of obstacles. The counseling is one of the valuable methods directed to those being in an adaptations difficulty, in deadlock, even they are not in extreme situation, but in some danger as in the drug abuse. The counseling can be used only to those which address themselves, voluntarily, to a mental health professional; it cannot be applied for large group of subjects. Otherwise, the need of change is born at first in the inner space of the person. It exert a somewhat pressure toward resolution and create the interest for finding of an outside support.

The counseling offers a positive, constructivist perspective, which direct the attention toward the existence, toward adapted means. It offers the trust, the empowerment to act in reality and creates opportunities for success. The subjects are leaded to topics belonging to mental health, far from pathology. The aspects which are different from the model of assisted resilience are the approach on the emotional content, the problems clarification and the development of the means, inclusive of the strength, through qualified intervention.

Measures for assisted resilience for a group of institutionalized teenagers from Romania

Raducanu Ioana A., Răşcanu R.

University of Bucharest, Faculty of Psychology and Educational Sciences
ioana.raducanu@ymail.com, smaranda54@yahoo.com

Abstract

There are many teenagers in Romania who hardly find solutions for their professional and social future. Many entered some orphanages, institutionalized care representing their best option for the time being.

The authors tried to understand whether there is a significant difference between the institutionalized teenagers and those non-institutionalized, concerning self-esteem; whether the institutionalized ones have positive, negative or average self-esteem. We considered that self-esteem is linked to neuroticism, due to the background of the individuals.

We studied institutionalized teenagers of both sexes, aged between 16-18 years (from the "Life and Light" Orphanage) and non-institutionalized youngsters. We used three psychometric instruments: Berger, Eysenck and Berkeley tests. Self-acceptance, neuroticism and self-esteem were measured, on the five dimensions of personality.

When processing the data we collected, it became obvious there were significant differences between the two groups concerning self-esteem, neuroticism and other dimensions of personality: institutionalized teenagers have the lowest level for three of these scale. There is a strong connection between self-esteem and neuroticism for the institutionalized teenagers, negatively correlated for a 0.50 level and for those non-institutionalized w had a positive correlation of 0.37. Also, institutionalized teenagers present lower levels for self-acceptance, high level of neuroticism and low self-esteem for work, emotional and intellectual styles.

Following these evaluations, the solution might consist of efficient psychotherapy techniques to be used in order to help the institutionalized teenagers.

Keywords: self-esteem, neuroticism, self-acceptance

Introduction

Our study aims at emphasizing the importance of social background in developing the personality, at investigating the repercussions of institutionalized background on the structure of personality of the teenager and on his/her self-esteem.

Adolescence is a "bridge" between the child and the adult. Defining the concepts we deal with in this study, we need to point out some aspects:

Self-image, as revealed by Cristea D. (1999)[1], represents the subjective form through which we acknowledge and represent ourselves (as a system of abilities, relations and psycho-social qualities that give the social identity of the individual), an ensemble of traits and relations with the natural and social background. Self-image is constituted reflexively on the ground of some identity feeling and continuity of the self, prevalently lived as a state of the psychological present: "I am, I do, I have."

Self-esteem, as Duclos G. (2006)[2] states, represents the way each person evaluates himself/herself as compared to his/her own expectances and to the others and it is directly related to the awareness of his/her value.

Self-confidence is realistic and predictable, as it rests on concrete results, obtained in the past, on the real experiences a person has lived and that allow that person to predict the results he/she expects to have in the future [3]

Identity is an active process, emotional and cognitive, that helps representing oneself in a social circle, associated with the subjective feeling of permanence, allowing the person to acknowledge life as an experience with continuity and unity, thus making that person act accordingly (Doron, R., 1999)[4].

Personality represents the specific way of organizing the psycho-physical and psycho-social traits and abilities of a person. Personality has the characteristics of an axiologically and ideologically vectored structure, the trinomial entity values – attitudes – ideals being the main functional core that mediates the development of social conducts [5].

Methodology

The main objective of our study is to observe the impact of background on teenagers from orphanages, the impact on their personality the way this background influences self-image, as compared to the teenagers who live a normal life.

In addition, we want to find out if institutionalized adolescents have a negative self-esteem on all 5 dimensions (traits) of personality or only on some of them: Expressive-Self, Interpersonal-Self, Interpersonal Work-Self, Emotional-Self and Intellectual-Self.

Another objective is to find out if there is a relation between the level of neuroticism and self-esteem. We consider that a positive self-esteem helps development on all levels, the subject being prepared for the future, for adjustment to social life.

For the above reasons, we try to detect the institutionalized adolescents who developed a "negative self-image", in order to have them under specialized therapy, under the care of specialists.

The hypotheses of our study are the following:

It is possible to have a statistically significant difference between the levels of self-esteem presented by the institutionalized adolescents, as compared to the ones who live with their families.

We expect a significant difference between the levels of neuroticism showed by the two groups of adolescents.

We appreciate that the institutionalized adolescents have lower self-esteem than the ones living with their families, for the dimensions: Expressive-Self, Interpersonal-Self, Interpersonal Work-Self, Emotional-Self and Intellectual-Self.

We appreciate that there is a connection between neuroticism and self-esteem for the institutionalized adolescents as compared to the ones living with their families. The lower the level of neuroticism, the higher the level of self-esteem is and the higher the neuroticism, the lower the self-esteem is.

The model of the study

In our study, the independent variable is represented by the institutionalized adolescents, since we considered that they had to adjust to an adverse background in order to develop a positive self-esteem.

As compared to the independent variable, the dependent variable in our study is represented by the measured trait of personality, which is self-esteem.

Another variable, which is not in direct relation with the independent variable, is neuroticism.

Concepts in operation

1.1 Self-acceptance

One of the first scales for self-acceptance was given by the psychologist Emanuel Berger. According to him, there are 3 types of self-acceptance:

- *Low self-acceptance (low scores, 0-110);* Those with low scores for this scale have a low level of self-acceptance. Such a score could be interpreted as reflecting a negative opinion on himself/herself and such people also believe that others have a negative opinion about them.
- *Average self-acceptance (average scores, 111-150).* It describes the way most people are, sometimes boasting and sometimes condemning themselves. For most of the people it is a good enough reflection of their abilities and desire to get better.
- *High self-acceptance (high scores, 151-180).* Such a person trusts his abilities and considers himself a valuable person. This individual is confident he can solve any problem or challenge that might come his way and he has great vitality.

The groups of study

The study was conducted on a group of 60 institutionalized teenagers and a group of high-school students who lives with their families, all aged between 16 and 18 years. The adolescents were randomly selected from the "Viata si lumina" Orphanage in Bucharest, and from "Mircea Vulcanescu" High-school, 11th grade, Bucharest.

The group of students from "Mircea Vulcanescu" High school consisted of 30 subjects (14 boys and 16 girls), aged between 16 and 18 years. Most of the subjects in this group have a normal family life, 2 of them live with a divorced father or mother and one had only one parent due to the fact that one parent had died.

The group of subjects from the "Viata si lumina" Orphanage in Bucharest numbers 30 subjects, 18 boys and 12 girls, aged between 16 and 18 years.

Investigating methods

In order to measure self-esteem we used Emanuel M. Berger's "Scale for self-acceptance", to measure neuroticism we used the "H. J. Eysenck Inventory of Personality", only the Form A, to measure neuroticism owed to background (the phenotype), and not the genetic neuroticism (genotype) and to measure self-esteem for the 5 dimensions of personality we used the Berkeley Test, realized by Keith Harray (Institute of Advanced Psychology, San Francisco) and Eillen Donah (University of California, Berckley).

Conclusions

Following the collection and statistical processing of the data, we have noted that:

For **self-acceptance**: it is obvious that institutionalized adolescents have low scores for the scale we used to measure this variable. The low value of the score is between 0-110 and the average value they obtained, for the entire population, is 100.20. This indicates that the adolescents from the "Viata si lumina" Orphanage have low self-acceptance, well under the average for the entire population, which is 129.

As for **neuroticism**, it is obvious the fact that institutionalized adolescents have a higher level of neuroticism than the average value of the scale we used. The high score of the scale is between 16-22 (meaning neuroticism) and the average they obtained is 17, above the average of the entire population, which is 11 (stability) – and this means the institutionalized adolescents are neurotic. Those from the second group (adolescents living with their families) had an average of 3.97, well under the average of the entire population (10.48, meaning stability), an indicator of the fact that they have stability.

The results of our study showed that, at least for the characteristics we measured, the institutionalized adolescents do not form a single population, but they represent distinct populations.

The same conclusion was reached in previous studies. In order to obtain better results for the real growth of self-esteem, it is more important that the individual has success, positive results in the domains he is interested in; conditions should be created to make them get involved in different activities; to separate children from adolescents (to create smaller groups or find foster families) and to work individually with them.

Abstract

Based on personal experiences with his parents, a child develops an "internal working pattern for relationships", pattern that shall be, during his life, transferred to other persons [5]. The Type II trauma described by L. Terr addresses long lasting and repetitive weakness, helplessness and over-demand [6].

The present paper aims to highlight the role of the therapeutic relationship in the accompaniment of an adult, lacking self confidence and trust in the world. For a child who became an adult, the childhood family factors (instability of parental couple, emotional disregard, disorganised attachement to mother), produced a Type II trauma and, as a result, a resilient avoiding behaviour as protective reaction to situations perceived as traumatizing.

The anamnesis and the observation of the client, a single 32 years old man with university degree, managing his own business, revealed an avoiding personality without showing any criteria for a diagnostic of disturbed personality.The feelings of inadequacy accompanied by guilt are reactivated by a struggling couple relationship.

The main goal of therapy was centered on developing the feeling of safety as a significant part of this process during the therapeutic relationship. This approach allowed the client to rediscover himself and it was the beginning of an assisted resilience process. Working on the traumatical memories was possible after the evaluation of the existing resources and after building new resources.

The therapeutic attitude increased the client's confidence in change and facilitated a new relational dynamic.

Keywords: disorganised atachement, trauma, therapeutic relationship assisted resilience.

Theoretical assumptions

The attachement theory explains the uneven development of resilient and mentally healthy personalities, as well as the one of the predisposed to anxiety and depression,or predisposed to develop a false ego, or presenting vulnerability to psychical afflictions [5]. The attachment develops into a multilateral adaptation process. For the child, the emotional attachment to his mother is needed for survival [4], and the way the parents treat him establishes the directions in his development [5]. The relations of the child with the adults have great importance because the attachment relationship is maintained requesting an adaptation form despite its disfuncti,onality. The studies on child development show the constance in pattern of the parents-child attachment even for the relationships of the child with other persons[4]. The child rejection by his mother inflicts an attachment trauma. According to the classification system of L. Terr, Type II refers to repeatedly traumatized persons. The Type II persons are overwhelmed by multiple traumas in such a degree that they are incapable of separating an traumatic event from another [3]. The anxious-avoiding attachment is developing in the conditions in which the child does not have any certitude that he will get a positive answer to his attention and care demands but, on the contrary, he is expecting rejection. Once developed, the attachment pattern aims to persist. While the child is growing, the attachment patern becomes a self feature, which means that it imposes as it is or as another related form in any social relationship developed. The model of himself, that is built, reflects the parents images of himself , images that are communicated not only through the way each of them is treating him, but also through what each of them is telling him. These models of a parent and of one self, in interaction, come to function at the level of the personal subconscious[5].

If the human potential allows vulnerability in front of adverse events, then it also allows positive influences, fact that opens the possibility for assisted resilience.

1.1 Case description

The client requested an appointment in January 2012, reasoning difficulties in the couple relationship. I underline that he is still in therapy. The conflicts in the couple relationship, the ambivalence of the partner and her demands expressed as expectations have reactivated in the client the feeling of inadequacy accompanied by guilt.

The anamnesis underlined the following information: the first borne between brothers, the age of the mother at birth 35, the age of the father 63. He grew in an hermetic and extended family, conservative, with a physically absent father due to his occupation, with a housewife mother emotionally instable, with a one year younger sister and with a mother side puissant grandmother that took over the role of the leader ,

The father, uninvolved and emotionally unavailable for the education of the children, was never considered the head of the family and he was never involved in taking major decisions

The mother, full of resentment and anxieties, was almost unaware of the client's needs and when she was receiving his signals she was answering either late or unapropiate.. "Since i was a Little boy, my mother made me feel like an Antichrist. She was telling me I was guilty even for the car engine stoping. I was guilty for everything bad that was happening, thus I was not present. " Being convinced that he is the "bad one", he became trustful that his parents will change their attitude if he becomes "good". Lacking the marks for what being "good" means, his tries without a positive answer led him to social isolation.

The absence of the father and the incapacity to understand the unpredictable behaviour of his mother, generated incapability, desorientation, culpability and fear. The inadequacy of parental attitude, the incoherence of the strategies for maintaining discipline, the lack of support, all led to the affectation of the attachment processes, to the development of anxiety, accompanied by lack of concentration and decrease of performance in school activities. His way of interior development remained marked by lack of trust and by rejection. The weak comprehensive function of the mother, of the father and maternal grandmother, led to the development of an disorganized attachmet, expressed through behaviors such as blocking, interrupting or retreat in the relationships, on the background of an emotional load marked by generalized anxiety.. The unclarities and the role confusions made the child's feelings of insecurity grow. The first major family crisis they faced, in which they were threaten to loose their house, appeared when the client was 16 years old. This lasted 10 years. At 22 he looses his mother and at 23 his father is passing away. For evading the confusión of feelings (disapointed love, anger, incapability, guilt, shame), in order to cover the traumatic experiences, to fight and repress the symptoms of somnolence and fear and to escape insensitivity and the feeling of inner void, starting with the age of 24 he began alcohol and Ecstasy consumption. In his attempt to deny the trauma he had developed behaviours that were creating him the sensation of control over his own life. The fear of criticism and disapproval were activating the draw back mechanism that was learned and consciously used as a defence reaction in the situations percepted as being traumatizing.

The emotional conflict of the client was proven to be the lack of trust in himself and in the world as well.

1.2 Therapeutic intervention

The tharapeutic intervention was specially adapted to the client's needs. The technique of not applying any technique or clinical evaluation instrument was proven to be the best technique..

A first therapeutic goal was to build a feeling of trust based on a mature and safe therapeutic relationship and to clarify the kind of unsolved conflict. Approaching the traumatic memories became a secondary stage. Anamnesys was centered on discovering the client's resources and mechanisms of defence for creating more options. Not being receptive to techniques, teaching theory proved to be useful to the client. Starting with the major influence the mother has in the child's development reframing the ""inner maternal model" was necesarry, through understanding the mother's life context, her experiences and personal history that determined her to adopt the caring maternal style she practiced. The lack of emotional support she needed herself when she became a mother, the lack of maternal care that herself experienced during her childhood, diminished the resentment, the feelings of anger and incapability felt by the client in the relation with his mother.. The interruption of the verbal and emotional "flux" of the client and the reframing of the events made the rupture from the past and the anchorage in the present possible. Admitting the fact that the traumatic events ended and strengthening the" here and now" reality, diminished the anxiety feeling of the client.. The accessing of the functional resources(home safety, financial Independence), of the physical resources(the capacity to maintain ones health) and of the psychological resources(inteligence, sense of humor, creativity, intrinsic motivation for change,and avoidance mechanism) made the implementation of polarity opposing avoidance in the social relations of the client possible. This offered him alternatives, balance and avoidance control through maintaining the ability to realize it when proven useful.

1.3 Results

The process of assisted resilience allowed the client to center and rediscover himself, to find a new way of life, to act in a non-selfdestructive manner and to try out opening up to others.. Accessing the feeling of love for the parents is still painful, because it remained without an answer during childhood, but, what makes the interruption of suffering possible is the compasión feeling that involves a change in attitude towards reality, source for a positive self transformation of the client. The client gave up alcohol and Ecstasy consumption, has stimulated his self analyzing capacity and generated behaviour and emotional changes that had an echo in his professional life, in the social relationships and in the couple's relationship.

Conclusions

The capacity of the client to survive, to develop in an unfavorable environment, and to get oriented in disorganized life conditions are the proof of a resilience natural process that was enriched by an assisted resilience..

The therapeutic attitude of unconditional acceptance, the compliance with the client's rhythm and the trust in his potential for change stimulated the confidence in himself and in the world and his capacity to initiate and maintain authentic interpersonal relationships.

Abstract

Our paper presents the results of a research study following the victims of incest undertaken in France. The main aim was to better understand the victims assuming a responsive becoming, in particular in concerning their relating to their own parenting. The results point to the inference that the determining factor in their becoming was their encounter with a significant other who proved to have an influential and formative sway as far as the victims ability to surmount their psychological wounds.

While some professional and/or institutional aid is said to have augmented at times their suffering, it was really the attendance and significant role of a transitional adult, an authentic resilience-tutor figure, who is often invoked as the seminal influence in their process of psychological remedial. These results confirm the conclusion that it is favourable to provide for a caring significant other beyond the legal dictates, in order to allow them to reclaim their worth through a humane interaction. The significant other is presumed to be a person who listens well, with no interruptions, expressions of shock or judgmental remarks.

Key words: incest, transitional adult, post-traumatic disorder, resilience

Contexte

1.1 De la complexité de l'inceste

1.1.1 Définition

Il n'existe pas « un » inceste mais une multitude de situations d'inceste, chacune étant singulière, liée à un processus de déstructuration psychique, sexuelle, filiale et engageant des enjeux particulièrement complexes selon le profil de l'auteur ; âge et sexe de l'enfant victime et ses ressources antérieures ; place dans la fratrie ; type et durée des abus; positionnement de la mère au sujet de ces violences ; capacité de l'enfant à révéler ; mesures de protection mise en place ; reconnaissance de la gravité des faits par le père comme par la mère ; etc.

1.1.2 Devenir des victimes quand elles révèlent

Les victimes peuvent ne pas révéler (par peur, par honte, par culpabilité, par incapacité à se dégager de l'emprise de l'auteur et à se penser victime, par perte de toute confiance en autre). Certaines qui y parviennent ne sont pas nécessairement crues et protégées. Lorsque la situation est judiciarisée, différents dispositifs peuvent être mis en œuvre qui font intervenir une multitude de professionnels différents (éducateurs, psy, juges, avocat, assistants-sociaux, experts, etc.). Il peut s'agir de mesure d'accompagnement en milieu ouvert (AEMO) ; de placement en établissements de l'Aide Sociale à l'Enfance : foyers, familles d'accueil ; en établissement spécialisé pour les filles victimes d'inceste Maison d'accueil Jean Bru (Agen).

Conséquences post-traumatiques

1.1 Croyances et méconnaissance des conséquences de l'inceste

Si de multiples progrès ont été faits dans la connaissance de la maltraitance, il reste une croyance selon laquelle les enfants maltraités se plaignent, s'effondrent et *doivent* inévitablement présenter des troubles majeurs

en immédiat. Or la pratique clinique amène à constater que bon nombre d'enfants victimes n'expriment pas de façon massive leur souffrance : ils ne se plaignent jamais directement mais le plus souvent à travers leur corps, véritable médiateur de leur souffrance psychique. Cette modalité particulière d'expression traumatique fait que beaucoup d'adultes ne la repèrent pas pour ce qu'elle est. Certains, par un processus de clivage post-traumatique, parviennent à survivre sans trouble apparent mais sont susceptibles de s'effondrer psychiquement des années plus tard : l'adolescence, le temps de la grossesse, la naissance de leur enfant sont des périodes propices aux reviviscences, tout comme celle correspondant à l'âge atteint par leur enfant au moment des abus. Cette méconnaissance de l'expressivité post-traumatique conduit à de multiples croyances selon lesquelles si l'enfant ne manifeste rien, c'est qu'il ne souffre pas ou qu'il n'a rien subi ; que passé la période de l'enfance l'oubli s'imposerait (particulièrement pour les enfants les plus jeunes) ; que cela ne servirait pas à grand-chose de les informer des procédures car « ils n'y comprennent rien » ; qu'il faut attendre « l'élaboration d'une demande » pour que le travail thérapeutique puisse se faire ; que le placement et la séparation matérielle protégeraient l'enfant (alors que l'abus sexuel est un poison psychique qui continue d'agir même quand l'auteur n'agit plus etc. Les réactions habituelles des proches et de certains professionnels peu habitués à la clinique du psychotraumatisme chez l'enfant, sont ainsi bien souvent de banaliser, voire de dénier les troubles. L'enfant se retrouve alors seul, sans personne pour panser ce vécu traumatique.

1.2 Incidence des troubles psychotraumatiques sur le devenir des victimes

L'effraction psychique et corporelle que représente l'inceste a de multiples conséquences : somatique, Intra-psychique, intersubjectives, scolaires, familiales, sociales.

1.3 Mieux comprendre les ressources des victimes d'inceste

1.3.1 Initiative de cette recherche

De 2010 à 2013, le laboratoire PsyNCA, EA 4700 de l'Université de Rouen a été chargé par l'association des Docteurs Bru (ADB - promoteur de l'étude) d'étudier les représentations de la parentalité chez des jeunes filles victimes d'inceste, en les mettant en regard des aides reçues.

1.4 Méthodologie

Il a été décidé de rencontrer des jeunes femmes victimes d'inceste (âgées de 20 à 38 ans) et de leur demander de parler de leurs représentations de la parentalité et de son évolution depuis leur enfance ; ceci, en cherchant à repérer l'impact que les aides reçues ont eu sur ces représentations. Cette étude a été menée auprès de trois groupes de jeunes femmes, dans le respect des règles éthiques et déontologiques des recherches (recrutement par appel à participation).

1.5 Outils utilisés

Questionnaire à questions ouvertes permettant d'organiser les trois cohortes ; **deux entretiens de recherche clinique,** visant à repérer les représentations de la parentalité imaginée, fantasmée dans l'enfance et l'adolescence, éventuellement dans l'expérience parentale à l'âge adulte ou dans le refus de faire cette expérience, ceci, dans leurs liens avec les prises en charge; un **test projectif** (dessin de famille de Corman) pour repérer d'éventuels décalages entre discours manifeste et discours latent ; une **échelle diagnostique** (la MINI).(*Mini International Neuropsychiatric Interview. La version française du M.I.N.I. a été développée par Lecrubier et ses collaborateurs en 1998.)*

1.6 Résultats

1.6.1 Participation importante

132 personnes ont spontanément fait part de leur volonté de participer à cette recherche ; de nombreuses autres ont indiqué l'importance de mener cette recherche, tout en ne souhaitant pas y participer. Parmi ces 132 jeunes femmes 71 ont renvoyé le questionnaire initial.

- 23 ont participé aux deux entretiens, parmi ces répondantes
- 10 jeunes femmes n'ayant pas été placées
- jeunes femmes ayant été placées par décision judiciaire, en foyer généraliste ASE, dans un contexte d'inceste
- 9 jeunes femmes placées, par décision judiciaire, à la MAJB

1.7 Spécificités de l'impact sur la parentalité

Si toutes ces femmes ont un désir d'enfant, certaines expliquent ne pas souhaiter devenir mère en raison des abus subis. Toutes décrivent les incidences de l'inceste sur leur représentation de la parentalité. Celles devenues mères témoignent des conséquences de l'inceste dans leur façon d'être maman, qu'il s'agisse des soins de nursing, comme du portage psychique de leur enfant.

1.8 Importances des conséquences post-traumatiques

Cette étude rappelle que l'impact de ces souffrances post-traumatiques est majeur et se manifeste depuis l'enfance avec des modalités différentes : 100 % des femmes interrogées présentent ou, ont présenté, au moins un trouble au *MINI*

13 % ont présenté et 87 % présentent actuellement un PTSD
39 % ont présenté et 21 % présentent actuellement des troubles dépressifs
35 % présentent des troubles anxieux
15 % ont présenté et 8 % présentent actuellement des troubles de dépendance à l'alcool
8 % ont présenté et 4 % présentent actuellement des troubles de dépendance à des drogues
8 % ont présenté et 4 % présentent actuellement des troubles de la conduite alimentaire
65 % ont présenté et 49 % présentent actuellement une phobie sociale
60 % ont présenté et 61 % présentent actuellement des troubles suicidaires

1.9 Facteurs de survictimisation et de résilience

1.9.1 Facteurs de survictimisation

Les femmes indiquent différents facteurs d'aggravation de leur souffrance que nous citerons dans l'ordre d'importance :

- absence de reconnaissance de ce qu'elles subissaient : déni, banalisation ou évitement des proches de confiance (fratrie, parent non mis en cause) et/ou des professionnels.
- positionnement ambivalente ou déprivante de la mère à leur égard
- fonctionnement judiciaire (lenteur des procédures, expertises multiples, logique pénale axée sur les auteurs)
- multiplicité des ruptures de leur cadre de vie (familial, social, scolaire)
- psychiatrisation de leur vécu (hospitalisation contrainte, traitements et thérapies imposées)
- stigmatisation à l'âge adulte : crainte de solliciter de l'aide à des moments importants (grossesse, maternité) ; stigmatisation négative à leur passé de victimes d'incestes dès que les professionnels en sont informés

1.9.2 Facteurs de protection

- ressources antérieures aux abus ayant permis à la jeune fille de se construire une confiance en l'autre et une estime de soi-même suffisamment positive
- rencontre et reconnaissance de leur vécu par **un** adulte « transitionnel » :
  - enfant : fratrie, pair, enseignant, infirmière scolaire, médecin, éducateur
  - adulte : proche, conjoint, professionnel
- positionnement du parent non mis en cause de façon protectrice et sans ambivalence
- reconnaissance des faits par l'auteur
- reconnaissance sociale de leur vécu de victime d'inceste et de leur souffrance sans stigmatisation
- apport d'un soutien et une protection d'abord au sein de la famille (père, mère et frère et sœur et famille élargie)
- Capacité à se penser victime sans se figer dans cet état
- Devenir mère (12 femmes parmi 16 femmes devenues mères, soit 75 %.)

Conclusions et perspectives concernant la parentalité

1 Pas de facteur prédictif

Aucune variable évoquée (type inceste, durée, modalité de prise en charge, révélation ou non) n'est, à elle seule, prédictive d'un devenir positif pour ces victimes, en particulier au regard d'une parentalité plus ou moins « sereine ».

2 Importance d'un adulte transitionnel comme facteur de résilience

Cette étude montre que les jeunes femmes témoignent bien davantage de **l'importance positive et restauratrice psychiquement, d'une personne** dans leur parcours de vie (enseignant, pair, proche, médecin, infirmier scolaire etc.), que d'une modalité de prise en charge (placement, AEMO, thérapie)

3 Absence de répétition inéluctable

Avoir été victime d'inceste ne condamne pas ces femmes à répéter les violences subies et n'implique pas un destin de « mauvaise mère ». Le processus de parentalité et la façon dont elles peuvent se penser « mère » (même si elles ne le deviennent pas dans la réalité), participe, dans un certain contexte spécifique, à leur restauration psychique.

4 Importance des troubles post-traumatiques tout au long de la vie

Troubles présents tout au long de la vie, avec des modalités d'expression variables.

1.1 Parentalité

Si devenir mère peut avoir un effet positif, toutefois, ce statut réveille des blessures anciennes. Ce qui conduit à pointer l'Importance pour les femmes de rencontrer au cours de la grossesse, lors de l'accouchement et en périnatalité, des adultes qui puissent les aider. La confrontation à leur enfant, à son devenir déclencher des mouvements d'identifications et de projection source d'une grande souffrance pour la mère et faisant courir de grand risque à l'enfant (difficulté d'attachement, liens insécures) Le devenir mère réveille aussi la nécessité pour ces mères la faille laissée par des conflits familiaux non résolus (importance du lien à la mère.)

1.2 Perspectives

1.2.1 Mieux comprendre les victimes en connaissant mieux l'impact de l'inceste sur le vécu de la parentalité

Nécessité d'évaluer, <u>à tous les âges de la vie</u>, les troubles somatiques et psychiques des victimes d'inceste et leurs incidences dans leur devenir adulte et sur les liens avec leur enfant (meilleure formation des pédiatres, des gynécologues, des sage-femmes de l'impact de l'inceste sur le vécu de la grossesse, de l'accouchement et des premiers liens à l'enfant)

Concevoir des dispositifs de prise en charge qui ne se fondent pas exclusivement sur la notion de « protection matérielle » de la victime et prennent davantage en compte les dimensions psychiques de l'inceste et ses conséquences.

Adopter une approche contextuelle et systémique avec les notions de facteurs de vulnérabilité et de facteur de protection. Cela permettrait de restaurer un tiers de confiance (proche non mis en cause, pair, professionnel) pour que l'enfant victime, comme l'adulte qu'il deviendra, puisse trouver des tuteurs de résilience en capacité de l'entendre et de le soutenir sans le condamner.

Limiter les intervenants et les ruptures successives imposées à l'enfant qui ne font que l'insécuriser davantage et le culpabiliser.

Information et formation des professionnels Prendre en charge des enfants victimes d'inceste nécessite, des **compétences spécifiques** et des moyens adaptés à cette problématique ; en particulier cela suppose d'ajuster les dispositifs d'aide aux différents temps du vécu traumatique.

Reconnaître sans condamner

Ces jeunes femmes témoignent de l'importance d'être reconnu à un moment de leur vie, ne serait-ce que par une personne, dans ce qu'elles ont subi. De cette reconnaissance, viendra l'inscription possible de cette enfance traumatisée dans leur histoire et la mise en récit de ce qu'elles ont pu subir. Il s'agit d'un véritablement engagement éthique à l'égard de ces enfants (filles et garçons), lien humanisant indispensable pour qu'ils puissent vivre, grandir, construire leur vie d'adulte et devenir sujet de leur histoire.

Art therapy an effective means in the psychological resilience

Rusu M.

Romanian Academy, Iaşi Section,The Institute of Economic and Social Research "Gh. Zane" Iaşi, România.
marinela1808@yahoo.com

Abstract

Art therapy is a modern way to approach *resilience* and its beneficial effects in supporting and strengthening the individual's personality, were first observed and subsequently experienced since the 1940s. Since then, art therapy has become an established therapeutic intervention with unexpected positive effects, on the various dimensions of personality. This paper will present the modalities of art therapy as a means of *resilience,* presents also *the principles* that guides it and the psychological effects in relation to resilience.

If we want to mention some of the issues that respond to the art therapy resilience we can remember: ego support, stimulating the individual development/maturation, better mental organization, ability to withstand the stress, improve self-image and self-confidence, developing intercommunication and overcome anxiety, gain cognitive skills, prevent/improve speech and speech disorders.

Art therapy can address *all stages* of age and persons at risk, such as substance abusers, the marginalized and the elderly. Art therapy involves more communication, self expression and connection. Can be put into action in more forms of art: painting, theater, dance, collage, modeling or photography, creative lyrics, stories and role playing.

Being part - more or less – of the whole of means of resilience, art therapy aims to relieve stress or traumatic events, opening to a world of harmony, beauty and balance, contributing to personal development. Education for solving *expression-repression* conflict is essential in art therapy.

Keywords: *resilience, art therapy, anxiety, creation.*

Introduction

The effects of psychological trauma on individuals are very different, and that attracted the interest of researchers on the factors influencing these differences. The general ability to overcome various tasks, difficult or painful events, is the result of a natural resilience process that takes place without the help of mental health professionals.

Thanks to the research conducted for half a century, it is now possible to use intervention strategies that facilitate the development of resilience also to the persons at risk of developing mental disorders due to life situations which. In this case, we speak of an **assisted resilience**, which is achieved with the help of specialists. Assisted resilience is devoted to a new clinical approach and proposes techniques and programs that can be used in many situations, including: child abuse, unemployment, natural disasters or genocide.

Resilience - the factors that influence and also define it:

Some concepts are proving to be essential in defining the phenomenon of resilience. Some of them are as follows:

a. Adaptability.

Smith and his collaborators (2000)[8] proposed a classification of adaptability of a person, depending on the response he/she has toward change: **passive adaptation**, **reactive** or **anticipatory adaptation** (Smit, Burton, Klein & Wandel, 2000)[8]. Developing the positive coping skills throughout life involves developing resilience (Martin-Breen & Anderies, M., 2011)[4].

b. Positive deviance

Positive deviance emphasizes that within any group of people there are some individuals who "function" better than their peers (also called "positive deviants"). If the strategies used by these individuals could be isolated, meaning to check exactly which strategy is useful in a particular situation, other individuals may benefit from specialized training to successfully surpass difficult situations.

Differentiation toward the normal resilience seems insignificant in such circumstances. However, *positive deviance* outline its conclusions from normative approach (Spreitzer & Sonenshein, 2004)[9]. Looking at the situation from the perspective of theories of resilience, we notice that reporting is done individually.

c. Emotional Intelligence.

Resilience represents a *meta-competence* that highlights the environmental opportunities and individual factors toward a situation perceived as problematical, in order to restore balance (Tusaie & Dyer, 2004)[10]. With the aim of using the individual and social best factors to the problem, the person must first make judgments about the complexity of the problem, on the emotions he/she feels. Therefore, in the absence of an acceptable level of emotional inteligence, we can not talk about resilience.

d. Coping strategies.

Coping is the function that acquires a cognitive structure when it is intended to shape the emotional state. Constant use of the adaptive, coping strategies is a predictor for the manifestation of the process of resilience (Martin- Breen & Anderies, M., 2004)[4].

Art therapy - an effective means in the psychological resilience.

Art therapy is an alternative therapy that is addressing specifically to children and adolescents reluctant to traditional methods. This method, however, can be applied to adults who manage to overcome personal problems, knowing themselves better, having more self confidence and overcoming some limitations of communication. Art therapy is recommended also to addicts, marginalized people and elders.

This type of therapy involves the participation of many art forms: painting, theater, dance, collage, modeling or photography, with a beneficial effect on people. The purpose of art therapy is to remove the stress and trauma experienced by a person, opening to a different universe (the harmony, beauty, uninhibited expression) leading to his personal development. Through this therapy, a person becomes more human, simply because no longer repress his feelings and emotions.

Art therapy involves more communication, self expression and connection. Art is at the same time a source of liberation which helps overcome certain problems and personality transformation.

Finally, art therapy supports the creation and development of the creative spirit in all of us. Even if you don't have a specific medical condition or have been through trauma, art therapy can be a way of self-discovery, offering wellbeing and comfort. This therapy is a new type of approach to physical and mental disorders, which although appeared in antiquity, began to be practiced only in the 1930s in England and the United States (K. Machover, 1949)[3].

The experiences of the past and the dreams for a different future, can be expressed by art therapy. The images created by a patient through art reveals his true personality. American researcher Loretta Pickford (2013)[6] considered that the artistic productions can help patients to express and utilize unconscious aggression, and also to sublimate sexuality. Works of art can enable a patient to integrate the fragmented aspects of his previously own personality, which makes possible to "restore" the unity and harmony that creates the ego. The fact of watching (to question or admire, to evaluate or criticize) a work of art helps a distinct focus, and at the same time, gives a detachment from personal problems considered serious and insurmountable.

Art has been used since antiquity and the first "therapists" who have implemented this method were Plato, Aristotle, Plutarch and Pythagoras recommending art as a therapeutic tool. Patients are advised to paint in nature, developing their creativity and experience of positive emotions. But not any art form can be applied anyway. Depending on the condition of each patient, he/she will be directed to a specific art form.

It can be said that the art therapy comprises two different sides (Rubin, 1984)[7]:

1) individual therapy - ***creating art***, which involves the use of imagination and introspection client/patient and
2) the therapeutic effect generated by the contact with ***authentic art*** (well-known artistic creations - paintings, famous songs, great choreography, movies, etc.). However, some artworks may have less pleasant effects. For example, contemplation of Leonardo Da Vinci's famous painting *Gioconda,* produce unsettling effects and should be avoided by agitated people. Instead, the works of painters Jacques-Louis David, Poussin, Manet and Renoir have a positive therapeutic effect.

One of the most popular art therapies is **painting**. Whether if there is an intensive program (are visited museums, taking contact with great works of art), whether it addresses a painting course, this is still one of the most successful therapy in treating certain psychosomatic disorders and also, the anxiety states. When you go to a course in art therapy you don't have to be a specialist in art. You just have to be passionate about beauty and have a desire to express yourself freely. So, we can choose many forms of art: drawing, sculpture, theater, dance, stories, music, puppets and masks.

Artistic forms such as theater and dance set the body in motion and acts as a valve. These art forms help to remove anguishes and fears. Art helps the patient to take distance and see things more objectively. ***Music*** helps develop communication and creativity, and puppets theater reveal the hidden emotions and removes inhibitions.

In summary, we can say (Machover, 1949, Naumburg, 1953)[3] that during art therapy sessions, the subject :

- has the opportunity to express himself and to low the psychical tension;
- establish relations with the group (into the dynamics of the group) and psychotherapist;
- reshapes his attitude towards himself and towards others;
- the child learns in an attractive and funny way about/and how to handle different life situations. The therapist is always careful to provide challenging tasks that foster learning but do not overwhelm the child. There are used motor and sensory games and activities that seek to stimulate initiative, looking for a solution, for expression of desires, and acquiring awareness of his own body. An important principle is to promote the winning independence, helping the child to overcome passivity.

Art therapy gives the opportunity to:

- support ego,
- stimulate development,
- facilitate maturation generally,
- contribute to the physical organization, such as being able to operate in conditions of stress without being affected.

Particularly interesting are the effects of art therapy on children (J.H. DiLeo, 1973, M.T. Levick, 1983)[1], that can lead to:

• improve mood by modeling self-image and self-esteem;
• developing intercommunication (with colleagues and peers in general);
• overcome anxiety;
• provide a sense of comfort with these activities;
• building the capacity to react appropriately in different circumstances of everyday life;
• employment skills;
• education and cognitive capacity;
• development and training of general and good motor skills;
• prevent/improve speech and speech disorders;
• developing and training the sense of form, color and artistic expressiveness.

Art-therapist role is to:

- recognize and respond to the manifest and hidden aspects of the child's productions;
- help him to create emotionally expressive materials;
- facilitate the development of children's creativity.

Conclusions:

Art therapy is another way to remove trauma, frustrations and problems of life of a patient, whether child or adult. As a way of resilience, art therapy is an effective aid, support and method of solving internal conflicts.

Sports as a protective factor in adaptation to disability.

Sikorska I.

Institute of Applied *PsychologyJagiellonian* University, Cracow [POLAND]
i.sikorska@uj.edu.pl

Abstract

The article represents the results of a pilot study involving Polish disabled athletes that succeeded either as amateurs or professionals. The purpose of the research project was to examine the role which sports play in the process of individual adaptation to disability. The value of sports in the life of disabled athletes was investigated in such categories as: motivation to practise sports and the effects of participation in sports. Positive adaptation to disability was measured with such variables as: satisfaction with life, resilience, personal values and courage.

The project involved a study group of 30 disabled athletes (M = 26.5 years of age) and a control group consisting of 30 healthy young adults (M= 25.9 years of age). The measurement tools included: the Resilience Scale for Adults by Friborg et al.; Satisfaction with Life Scale by Diener, Emmons, Larson, Griffin; Personal Values List by Juczyński and Courage Scale by Sikorska.

As regards the courage factor, disabled athletes demonstrated a significantly higher level of endurance (t = 2.1921, df=58, p=0.0324). As highly assessed values, respondents would often choose the following: being useful to others (z=2,74, p,=0,00061), courage and firmness (z=2.26, p=0.0239). The reason they most frequently provided for taking up a sport was "encouragement from colleagues" and "a desire to be fit". Adventure, making new friends and better self-esteem were in turn identified as the most frequent effects of engaging in sporting activities.

Key words: disability, sports, adaptation, resilience

Introduction

1.1 Adaptation to disability

Physical disability carries a number of emotional implications resulting from damage to an individual's body. Psychologists of rehabilitation emphasise the importance of the transition period between disease and disability. They suggest that the period directly following treatment, when a person involved in it is neither a patient (not any more) nor someone meeting all the criteria for disability (not yet), should be called a moratorium. This period is characterised by increased anxiety about the prospect of continuing one's life and adapting to disability[1,2,3]. The challenges involved in the process of adaptation include three crises described by W. Wolfensberger [4,1]. First, persons with disabilities experience the novelty crisis, which emerges when their plans and expectations about their future lives collapse. The second crisis affects their personal values. This manifests with a conflict between their refusal to accept their own disability and their striving to maintain a positive image of themselves. The last challenge that follows, namely the reality crisis, emerges as a response to the existing social and economic conditions in which persons with disabilities have to function.

Resilient reintegration, namely the acceptance of the limitations brought about by disability and further development that results from it, is regarded as a form of reintegration that is most conducive to adaptation after losing one's fitness. It is regarded as a sign of both resilience and the ability to positively cope with crises that persons with disabilities have to face in their lives [5,6].

1.2 Sports as a protective factor

Numerous researches demonstrate a correlation between physical fitness and motor activity, and on the one hand, growing self-esteem and self-agency and the improvement in the perception of oneself and one's physical capabilities, and on the other, a decrease in one's anxiety, stress and depression levels (7,8,9). Physical ability correlates positively with mental health, self-esteem and well-being. Team sports, since they increase

one's resilience, are particularly believed to reduce the risk of the incidence of depression. Participation in sports enhances resilience and facilitates the process of adaptation to one's disability [1,2,1]. As regards the process whereby disabled persons redefine their own identity, we may assume that they do so, as it were, by regaining their resilience assets. This assumption allows us to draw upon the existing models of external and internal assets in the resilience developing process [11].

The first external asset includes supportive and caring relationships with one's own environment. When doing sports with other people, persons with disabilities may face interest, care and support from their coaches and team-mates, which in turn may help them to develop the following interpersonal skills: collaboration and communication, empathy and the ability to solve problems. The bond that thus develops stimulates one's interpersonal skills.

Goals and efforts to achieve them are inherent in sports. Coaches that demand a lot and team-mates that expect just as much from the team set a standard that disabled athletes will aspire to. The fact that people from their direct sporting environment show belief in their strengths and capabilities becomes a motivating factor conducive to coping with their fatigue or self-doubt. Requirements instil in them a sense of personal strength and identity and a sense of agency and self-awareness.

Last but not least, they also instil in them a sense of belonging, and a sense of participation in major events raises their optimism levels and makes them perceive their lives as coherent and meaningful. By taking part in sports competitions and by meeting other athletes both home and abroad, they confirm their value in the eyes of other people, which facilitates the process of their social affiliation and participation in society.

As regards self-discipline, which is part and parcel of anyone's striving for mastery in sports, we may safely argue that it shapes their character: it develops their endurance, helps them overcome their weaknesses and becomes the way to develop themselves [1, 12].

Method

The project involved young athletes with disabilities, 30 participants in total, including 21 men and 9 women (M = 26.5 years of age). 77% of participants had been disabled for more than 10 years. As regards their type of disability, 40% of participants had spinal cord damage, 30% had paralyses and pareses, 27% had limb deficiency and 3% partially lost their eyesight. 80% of respondents practised sports on a competitive level and took part in competitions. The sports they did included: skiing (10 people), cycling (9 people), swimming and fencing (4 people), basketball (3 people) and other sports, including rugby (5 people). Several respondents practised more than one discipline. The control group consisted of 30 people, healthy and young (M= 25, 9 years of age), 90% of whom practised sports as leisure.

The research project aimed to answer the following question: Do athletes with disabilities differ from young and healthy adults in terms of resilience, life satisfaction, courage and values they uphold?

The measurement tools included: the You and Your Life Questionnaire by Jelonkiewicz, Kuhn-Dymecka and Zwoliński [13], the Polish adaptation of the Resilience Scale for Adults by Friborg et al.,[14]; the Satisfaction with Life Scale by Diener, Emmons, Larson, Griffin,[15]; Personal Values List by Juczyński [16] and Courage Scale by Sikorska [17].

As a tool designed to study resilience, the You and Your Life Questionnaire consists of twenty items and covers six factors, such as self-perception, the perception of one's future, personal strength, structured style, social skills and resilience. A respondent takes a stance by choosing an answer on a five-point scale ranging from utterly positive (with expressions such as “always” and “well” that give five points) to utterly negative (with expressions such as “never” and “unclear” that give one point).

The Personal Values List includes two sub-scales, one of which refers to the symbols of happiness (e.g. a large circle of friends, good economic conditions) and the other refers to values (e.g. love, wisdom). A respondent ranks five items selected out of ten according to the level of their importance, ranging from the most important (five points) to the least important (one point).

The Courage Scale in its pilot version consisted of sixteen statements comprising four sub-scales such as endurance, authenticity, optimism and courage. A study involving 105 people (both healthy and disabled) was used to calculate the reliability of the scale, and Cronbach's alpha for the test amounted to 0.77. Possible answers on a point-five scale ranged from “completely agree” (5 points) to “completely disagree” (1 point). The tool's preliminary statistical analyses demonstrated that the scale required further improvements.

Respondents were asked to complete tests and questionnaires and send them back by e-mail. The project was carried out in the winter of 2013.

Results

The most frequent *reason* why disabled persons began doing sports was their desire to keep fit and continue their previous and healthy lifestyle (43%), encouragement from their disabled colleagues (40%),

information available at treatment centres and encouragement from parents or teachers (13%) as well as information in the media (10%). Several respondents provided more than just one reason. The *effects* of doing sports, from respondents' subjective point of view, included: the opportunity to make new friends (90%), growing self-confidence (90%0, the opportunity to do something adventurous (90%), a form of rehabilitation (80%), social recognition (33%). Several respondents mentioned more than just one effect..

The groups involved in the study do not differ in terms of their *life satisfaction* levels. The median in both groups gives an average result (in the standard ten scale: disabled athletes M = 6.4, young adults M = 6.8).

The statistically relevant difference can be identified with regard to *resilience*, concerning the *structured style* factor (two-tailed test, $t = 2.3088$, $df = 58$, $p<0.05$).

With regard to *courage*, disabled athletes achieved results indicating a significantly higher level of the *endurance* factor ($t = 2.1921$, $df = 58$, $p = 0.0324$).

With regard to *personal values*, athletes attached a significantly higher importance to the symbol of happiness *useful to others* ($z = 2.74$, $p = 0.00061$) and the symbol of value *courage and firmness* ($z = 2.26$, $p = 0.0239$).

Conclusions

1. The factor that explains the significant similarity between the two study groups with regard to their life satisfaction is that are in their early adulthood, that is, a period in their development that brings natural optimism and hope for a better future. The fact that disabled persons, too, were happy with their lives demonstrates that they coped well in the process of adaptation to disability. Moreover, sports as a stimulating factor conducive to happiness were present in both study groups. They also had a regulating effect and acted as a diary (competition and training camp dates) for disabled athletes.

2. Competitive sports entail the necessity to discipline and control oneself and to keep one's rhythm of life in order, which manifests itself through the results that illustrate a higher level of structured style and endurance in disabled athletes. Sports as a factor that organises the lives of people involved in the study may have influenced areas such as making plans, overcoming one's own limitations, courage and endurance.

3. Disabled athletes attach more importance to such values as being useful to others, which may demonstrate that they recognise the importance of social interaction in the process of adaptation to disability. The necessity to overcome the disability-related external and internal limitations of one's own may have helped them recognise such values as courage and firmness.

The results achieved by disabled athletes demonstrate that they have a number of personal qualities typical of resilience. Striving to achieve one's goals, regardless of obstacles, is undoubtedly one of them. These persons in particular that did sports before acquiring disability show the desire to continue doing sports despite the completely altered circumstances of their lives. The qualities of a resilient person include: the ability to regain equilibrium after the critical event they have experienced and the ability to grow and develop as a person [18,19]. The study group demonstrates a high level of the following resilience qualities: life satisfaction, optimism, endurance and social focus.

The results achieved by disabled athletes should also be interpreted in the light of positive psychology. which lays particular emphasis on individual resources, strengths and values conducive to development. Of particular relevance in this context is Barbara Fredrickson’s concept of positive emotions and their broadening effect. Fredrickson claims that resilient persons demonstrate a positive attitude and experience more positive emotions in comparison to their less resilient counterparts [20] Consequently, such emotions as enthusiasm and optimism enhance their health assets and are conducive to overcoming obstacles. We should mention that respondents also demonstrate a high level of individual assets described by positive psychology, such as courage and endurance. Such assets help individuals, both healthy and disabled, to develop and actualise themselves. Positive psychology propounds that every person has the ability to strive for and achieve a sense of life satisfaction and happiness [21].

The task of psychological support for persons facing the consequences of health and fitness deficiency is to accompany these persons in the process of adaptation to a new life. Dobrzańska-Socha draws upon Hoff to claim that “people cannot live in perpetual crisis, as the resulting anxiety is too painful and a person experiencing it must take action to find one way or another to resolve it”[3]. It seems that, for persons that adapt themselves to disability and must therefore redefine their own identity, sports may become a factor conducive to overcoming their mental crisis. Sporting activities that make life meaningful again, new social experiences and new emotions may act as a factor that develops and enhances resilience.

"Treasures of the winning couple" program for young children in Israel: body-mind coping skills for stress reduction and enhancing resilience

Tal-Margalit M.[1], Spanglet J.[2]

merav-ad@smile.co.il, c.l.jspanglet@gmail.com

Abstract

Life is comprised of positive experiences and stressful situations. Exposure to the latter frequently leaves us overwhelmed and traumatized. In Israel, constant security-related threats increase the need for the development of coping skills and strengthening of innate resilience, particularly for children and the adults in their lives.

We developed 'Treasures of the Winning Couple: Mr. Body and Ms. Awareness' for this purpose. It is based on Tal-Margalit's STREAM model (Somatic Therapies, Resilience Enhancement, Awareness & Movement) which combines the Somatic Experiencing ® trauma healing approach with Dance/Movement Therapy [1].

Our program presents practical body-mind tools designed to help children acquire the competence and life-skills needed for building resilience. Children, teachers and parents gain self-regulation skills together while developing a common language to cope with life's pressures.

The 'Treasures' in the program trigger the senses through various channels. Each is presented by an original poem, a unique illustration and a movement expression while naming the treasure. Imagination, metaphors with which children can identify, together with movement exercises, connect children to their natural resilience. Furthermore, use of mindfulness, developing self-regulation, improving coping skills and self-management create an integrated presence for them, individually and within their environment. Children use movement and awareness of physical sensations as natural resources; natural 'treasures' that help them feel better. A survey accompanies the program allowing evaluation of its efficacy. Results from a pilot sample will be presented.

Keywords: movement & mindfulness for children, Child Resilience program, Winning Couple, Stress reduction, STREAM model, EFS.

Background

Scaer [2] claims that young children are often less resilient due to their experience of "little traumas". Understanding the neurophysiological dynamics of these experiences on children is vital.

In Israel, children contend with a security situation that exposes them to significant stress. Research points to the effects of prenatal, maternal-infant bonding, and infant attunement on the lifelong capacity of the infant to modulate arousal and promote homeostasis [2]. This is particularly relevant when developing an intervention program for promoting resilience for children at risk. Children, especially today need to acquire skills to cope and be prepared for future challenges quite early in life. More than ever, resilience is critical for success. [3]

Theoretical Basis for the Program

Our scope of practice emphasizes the neuropsychology of trauma and resilience. Levine and Kline (2007) [4] refer to children's body/mind reactions when faced with threatening experiences and the use of Somatic Experiencing trauma therapy in strengthening resilience (Levine and Kline, 2007 and Ross, 2008) [4], [5]. Imprinting of neurological patterns in children is heightened by traumatic events. Intelligence, emotional resilience, and ability to self-regulate develop in the context of the face-to-face relationship between child and caregiver, i.e., 'neurobiology of attachment' [6].

The theoretical constructs linking body-mind integration and resilience are varied and support the diverse elements of the program. Knowledge acquired by researchers in neuropsychology and by therapists, together with Dance Movement Therapy, theory and practice, is foundational for the development of STREAM, which is the basis for the "Winning Couple" [1], [7], [8]. Motor movement, dance and music all influence brain development and stimulate neurogenesis, leading to improved learning, emotional balance and self-regulation in children [9], [10], [11]. In addition, studies have demonstrated that creative dance instruction can be an effective intervention for teaching self-regulation skills. Thus, yoga, martial arts and creative dance have proven to be useful ways to strengthen and teach self-regulation to children (Hart-Booth, 2012) [12]. Plummer (2012) [13] remarked on the connection between mindfulness play, stress reduction and self-regulation. Mindfulness training in schools contributes a to a positive association between individual practice outside the classroom and an increased sense of well-being [14].

The BASIC PH model [15] is important for identifying coping strategies and resilience building. We recognized that embodying faith and spirituality resources within an intervention program provided an integrated body-mind-spirit experience for participants and improved their coping [7]. This approach serves as the basis for techniques integrating the belief systems of children to promote coping.

The STREAM Model, as described above, incorporates Dance Movement Therapy (DMT) and Somatic Experiencing® (SE) in a group setting. It is an integrated body-mind psychotherapy model for relieving stress, healing trauma and enhancing resilience.

The theoretical foundation for the "Winning Couple" program is the same as that for the STREAM model, which incorporated findings from contemporary neuroscience, and features a psycho-physiological perspective of trauma and resilience as well as theories of body-oriented psychotherapy and Dance/Movement Therapy. The "Upside of Trauma" concept [1], is based on Positive Psychology [16], the BASIC PH model of coping resources [15], and Post Traumatic Growth (PTG).

Therapists and researchers [17], [18], [19] maintain that body-oriented treatment models that "speak the language" of the primitive parts of the brain via sensation, perceptual experience, somatic responses are essential in building resilience. Working with bodily sensations and with the "felt sense" [20] is crucial to arriving at self-regulation and integration. Tal-Margalit adds the use of movement with motoric and somatic discharge using "Riding the Wave" [8] within the "Window of Tolerance" [21] to ensure self-regulation.

STREAM research identified six body-mind resilience characteristics [1]: 1. body-mind integration; 2. self-regulation and relaxation; 3. vitality and aliveness; 4. empowerment; 5. sensing body self-boundaries; 6. using coping resources.

"Treasures of the Winning Couple" Program

The text included in the sections or subsections must begin one line after the section or subsection title. Do not use hard tabs and limit the use of hard returns to one return at the end of a paragraph. Please, do not number manually the sections and subsections; the template will do it automatically.

1.1 A Salutogenic Approach

Using neuropsychology and body/mind reciprocity in building resilience, our approach reaches diverse child populations. Focusing on the vitality and innate resilience that children universally possess enables them to rebound from being overwhelmed; movement, a child's natural resource, is a central element of resilience. In its essence, the program is both culture- and religion-sensitive. A key element is its employment of embodied faith and spirituality, the EFS model, for encouraging their use as coping resources for children [7].

Goals of the program for children and their parents and teachers:

- To learn about the potential of the body-mind connection in life
- To acquire new understanding about stress coping and resilience
- To develop the ability to identify ongoing situations of stress and trauma, and their effects
- To acquire useful coping tools for stressful situations, skills for self-regulation, and life skills
- To discharge survival energy stored in the body as a result of living through threatening experiences

1.2 Population

The program serves elementary school children. Some live in a "war zone" in the south of Israel and others are at risk living in maladaptive families. Together with their parents and teachers, they have an opportunity to experience the joy of movement while discharging tension and building resilience.

1.3 The Program in Practice

The children learn stress reducing body-mind tools to help them acquire life-skills and coping tools for enhancing resilience. The program consists of 12 meetings with children, parents and homeroom teachers. Through enjoyable activities, they learn to help themselves under stressful situations and acquire more regulated nervous systems. The abstract concept of body-mind connection is a difficult one for children to comprehend. Puppets and illustrations of Mr. Body and Ms. Awareness (mind) depict this combination.

The body-mind experience is actualized through mindful movement and movement games with various stimuli. The body's resources, i.e., the treasures of the "Winning Couple", serve as self-help tools for self-regulation and coping. The children experience the 'Treasures' in the form of movement and games, and deepen their experience through other senses and creativity. Via poetic and colorful illustrative treasures, imagination and metaphors, the children identify and clarify abstract concepts.

Workshops include sharing verbally within the group and processing what transpires during and between sessions. Examples of real life situations where they have used the treasures, are shared. They are encouraged to use the treasures at home and in school. Suggestions for applying the treasures for daily life are given to the teachers after each session, facilitating assimilation of the concepts and treasures as coping skills in everyday life.

1.4 Structure of the Program

During each session one or more treasures are introduced. A session begins and ends with the movement ritual and new parts are added weekly. Psycho-education about stress and its impact on bodily sensations is included, as well as raising awareness of pleasant sensations while in movement, at play, or verbal sharing. The movement ritual becomes an important self-regulating tool and a cohesive experience individually and as a group.

Summary

By providing skills to improve positive coping and resiliency of children, their ability to cope can be improved (Gurwitch and Messenbaugh, 2005) [22]. This is the goal of the "Treasures of the Winning Couple". We have begun research to evaluate the program's effectiveness for helping children to be more resilient. Longitudinal research will be conducted to assess its sustainability.

Resilience indicators in psychotherapy

Vîşcu L.-I.

"Eftimie Murgu" University of Resita (Romania)
loredana_drobot@yahoo.com

Abstract

Resilience is a concept that is hard to define, this being the reason for the lack of a definition widely accepted. Still, specialists have agreed on two essential points: the resilience characteristic to persons who have lived and continue to live traumatic events and have a good adaptability and reliance and the resilience as consequence of interaction between the person, his/her family and the social environment.

In psychotherapy resilience represents a subject that is approached through the studies of researchers and practitioners as Bohart and Tallman (2010), Hubble (2010), Seligman (2002), Delage (2002, 2004) etc.

Resilience indicators in psychotherapy are those products of client activity, which represent starting points for the therapeutic process. Such indicators are observed by the psychotherapist in the dialogue with the client about past and present events. Resilience indicators are the expression of the client's strong points and the intervention based on these strong points is considered essential in therapy and prevention (Seligman, 2002). As examples of resilience indicators we can mention: products of art-therapy (drawings, paintings and schemas), poetry and journals. The following can also be considered resilience indicators: activities, which in the past brought success and recognition; the client's valuing (for example: sports activities with medals or the participation as member of a national sports team). In therapy another indicator of resilience is considered to be the client's safe attachment, but not all clients present such an attachment, the therapist's task being to build together with the client such an attachment through the therapeutic relation.

In conclusion, resilience indicators may be considered common factors in psychotherapy and an inexhaustible resource of study for psychotherapists and more

Keywords: resilience, resilience indicators, common factors in psychotherapy

Introduction

The study field of resilience has been developed in the research plan and in the clinical practice plan and the bio-psychology layer has become the most clear one [2]. Bonanno (2004) has defined resilience as the ability to maintain a state of normal equilibrium in the face of extremely unfavourable circumstances. Thus to develop resilience, the person must have an understanding of its determinants. Various factors such as beliefs, attitudes, coping strategies, behaviours and psychosocial cohesion as suggested as favorable in offering protection or endorsing resilience in the face of trauma. People who are considered resilient show insight, initiative, humour, creativity and independence. All these qualities are gathered in the dynamic category. There may be discontinuities in resilience as people, situations, opportunities and environment change. [5] the field of resliences has known development in the research domain and in the clinical one, and its bio-psychosocial branch has become the most studied one.

The concept of resilience has also been used in psychotherapy and has been correlated to the client's self-healing potential. The psychotherapeutic change is the therapists and the client's task and begins with the updating of the self-healing potential. This may be updated in difficult situations in the life of persons without specialized help [3]. Thus the question of demanding help from specialized persons doesn't determine the client's stigmatization in the social domain, but there is also another category of clients that cannot benefit from psychotherapy.

Persons that prove to be resilient need the help of another person, from his family of from a close environment called resilience tutor [1].

The ability to change is developed and practices by the client in the psychotherapy office under the guidance of a psychotherapist. Thus art-therapy has found use in meeting the concept of resilience. The products of art-therapy determine the stimulation of the client's creativity, an increase of self-esteem, the connecting to other persons and the creative process which are in a close relation [4].

The indicators of resilience represent, from the psychotherapy perspective, products of the client's activity, for example, products of art therapy, writings, journals, drawings or other artistic creation. In the same category of resilience indicators we can also include the results of activities from the client's past.

During clinical practice, it was noticed that the true anchors in the updating of the client's potential comes from the client's professional development, medals obtained in different professional or sports competitions.

Psychotherapy based on the client's strong points, also has consequences in the building of the person's resilience. One of the founders of psychotherapy based on strong points, with an origin in positive psychotherapy [5], Norine Jonson, uses interventions based on competencies. From a methodological point of view, in order to collect information the following instruments are used [4]:

- A questionnaire for parents regarding the teenager's strong points;
- A questionnaire for the teenager regarding his strong points;
- A questionnaire of parental practices, which starts with a question regarding the positive parental attributes of his mother and father.

Resilience has been classified in natural resilience and assited resilience. Natural resilience starts from individual characteristics, inter-familial interactions and interactions with the subject's environment. The study of resilience, of knowing the factors involved and the subadiacent processes allow the construction of assisted resilience. In psychotherapy, the client and the therapist both know assisted resilience.

An exemple of this kind of resilience will be presented in a case study.

Methodology

As it has been mentioned, not all clients have the possibility to activate their potential of self-healing and need specialized for the construction of assisted resilience. The study case presented is a reflection of addiction and resilience. Addiction refers to a lack in control, a repetition of behaviour, dependency and all its delirious effects. Resilience refers to overcoming life situations, traumas and surviving the life's challenges.

In the following rows, there are five sessions of psychotherapy presented, the client still being under therapy.

A young man aged 23 presented to the psychological office 2 months after giving up drug consumption (cannabis). He began to consume drugs around the age of 12 while being a member of the gymnastics national group. It can also be said that he was national vice-champion in gymnastics. At the age of 13 he was sent home. A period of 10 years followed when he started to consume cannabis, he gave us high school, started stealing money from home to procure drugs and he frequented a group, where his friends were criminals, killed themselves or went to jail. The client is aware of the consequence of drug consumption and he decided to become clean, having support from his family. Thus, he refused to come out of his room for six weeks, during the withdrawal period, with panic attacks, agitations, deliration. At night he couldn't sleep alone in the room. After six weeks we came to psychotherapy accompanied by his uncle.

During the first session he was agitated, pale, with his eyes in tears, speaking about his panic attacks. We kept on repeating "Who I was and who I am". He was preoccupied in bringing his friends to therapy. A motivation to heal was observed, but also the potential to self-heal. The success from the past was considered resource for psychotherapy and the client's strong points. He lived with his grandmother and with his uncle, his mother being in Spain for work. During the withdrawal period, his mother was home and he decided to stay with him until the problem is solved. His father left time, when he was a little child.

The therapeutic objectives were established during the first therapy session:

- The creation of a safe attachment;
- The access to internal sources;
- The strengthening of the self.

The first session also represented the construction of a therapeutic relation with the respect of the client's needs. The client was reinsured about confidentiality, of the support he will receive and that he won't be alone. The worry regarding his friends and the manner in which these will be helped was not eliminated, but it underlined the importance of helping the client.

During the second session the client's resources were discussed by remembering his past success. Thus began the construction of the assisted resilience with the client through:

- The development in a psychological plan, despite the long period of drug consumption;
- The development of abilities to adapt and "rebirth" from withdrawal;

The client was encouraged to restart practices and to identify the manner in which he could go back to school. He was also remembered that there are times in which he will fell ok and times with difficult situations.

In this context resilience may be considered an adaptive result, without the presence of mental disorders, even if there are proper situations for the development of such disorders.

At the third session the client had a good general state and had a backpack with his sports equipment. He followed my advice and contacted his former trainer, being received for practices. The same trainer helped him in continuing his high school studies starting with the nest year at a sports high school.

During the fourth session, the client gained in weight 500 grams, the purpose being that next year he will be able to compete. He expressed even a desire to participate in the national competition "You will soon seem me on TV". As during after every session the client was created realist expectations and trainings were a means for him to renter the world, not necessarily do performance. At a certain moment, the client showed a registration on his cell phone of him executing a jump and his trainer congratulated him. The recording was considered an indicator of resilience and the need to go back to consuming may be left behind just by watching the video.

During the fifth session, the therapeutic relation was strong enough to work on an exercise of muscle relaxation, called "favorite spot". The client learnt to relax and to suggest practicing the exercise every day. The client was satisfied with the progress realized and to come regularly to therapeutic sessions.

Conclusions

Regarding the connection between resilience and addition, there modalities of interpretation were identified [4]:

- Addiction perceived as a failure of the resilience process, the client didn't find the necessary resources to overcome unfavorable events. For example, some women who were sexually abused may become addicted while others not (are resilient);
- Addiction as a paradox form of resilience, often a point of support to more forward through life's difficult situations;
- Clients that gave us additions, during the first stage consumed substances to adapt to the reality, after years he wants to give up and finally he has to readapt to the environment.

During this therapeutic process emotions were used and resilience indicators were considered to be: restarting his practice, the trainer's encouragement and his colleagues' and the video. The therapist suggested a correlation of indicators of resilience mentioned with the living of positive emotions. For addicted persons there are two variants in the case of remission: a total abstinence or a regress to substances consumption.

The client was encouraged to fix realist objectives and he learnt to accept himself, to consider the 10 years a life experience and to value himself in the readapting process to the familial, sportive and social environments. During the discussions with the client he was valued for his effort and he learnt to see his realizations, no matter how small these were. The therapist insisted on establishing realist goals in his professional life. The therapeutic relation was the basis on which therapeutic goals were reached.

The therapeutic process had as starting point the client's strong points. An update of his potential was made to suggest the restart of trainings and visits to the gymnastics team physician. An acceptance and understanding of his trainers and colleagues determined him to change. The client wasn't stigmatized and had the understanding of his team for a gradual dosing of his effort. After 4 weeks of practice he was proposed to go to winter cantonment. The family was instructed not to remember him about his past experiences with drug consumption and to strengthen any positive change.

The therapist must identify any event of situation from the past and present that reflects the client's potential and to encourage him in a positive manner. Anchoring in the reality is a process realized with the support of the group and of his family. Resilience indicators are realist anchors for a functional adapting of clients and may be considered common factors of counseling and psychotherapy. The resilience indicators belong to the client and are discovered by the therapist during the therapeutic process through a therapeutic relation.

Abstract

In the present article, we wish to point out how Mooli Lahad's method of the Six Part Story-Making can be used in order to activate inner resources, and to help the child differentiate himself from his conflicting parents. We started from the central idea that, through creating a personal story as method of assessment and therapeutic intervention, we can understand the types of resources and coping styles of children.

The first part of the paper will present the results of a comparative study between the type of resources identified in the stories of 20 children coming from recently divorced families, and the stories of 20 children coming from intact families. The second part of the paper will present two case studies in which we were able to set the therapeutic objectives starting from the Six Part Story-Making Method.

Keywords: divorce, children, resilience; basic ph coping model, 6 PSM method

Introduction

How the child will respond to the traumatic event of his parents' divorce depends not only on the personal risk factors, but also on the coping strategies. The factor with the highest risk is holding the child in the parental conflict and creating alliances of a parent with the child, against the other parent.[1] [2] [3]

Our practical experience with such cases, along with other various existing publications [1] [4] pointed out that there are several factors that can reduce the negative effects of divorce and increase the child's resilience, such as: the intensity and duration of the parental conflict, the quality of parental practices, the parent-child relationship, as well as the individual characteristics of the child (temperament, self-esteem, level of development, coping strategies).

Stimulating the positive individual traits is essential to the field of resilience factors. The child's resilience can be developed and perfected through the adult's protective and positive action and by reducing risk factors.[5] Moreover, special attention needs to be paid to the manner in which the child's resilience and the individual coping style can be increased during the divorce period and afterwards .[4]

Basic Ph Coping Model was created by Dr.Mooli Lahad and can serve as meta-model for understanding coping and resilience.[6] The model suggests that there are 6 characteristics or dimensions at the heart of one's personal coping style: belief, affect, social, imagination, cognitive, physiological. Every person has the innate ability to use each dimension as part of his coping style, yet most people tend to rely only the comfortable coping methods they developed across time.

Although The Six Part Story-Making is a projective method frequently used by many therapists, it was not validated as a method to determine one's coping strategies. [7]. Lahad's shows how Basic Ph can serve as meta-model for understanding coping and resilience [6].

Methodology

In this study, we wanted to identify the types of coping strategies present in children from recently divorced families.

For this study 40 children with ages between 7 and 11 were tested using The Six Part Story-Making model. The subjects were divided in two groups, as follows:

The control group was made up of 20 children (13 boys and 7 girls) aged between 7 and 11, without a history of divorce.

The second group was made up of 20 children (14 boys and 6 girls) aged between 7 and 11, all with a recent history of divorce. All children had a normal cognitive development and did not have any psychiatric or neurological problems.

They have been tested by The Six Parts Story Making model. Only the results found in both assessments were taken into account in the statistical analysis.

The dimensions under examination in the children's stories were as follows: Belief and values, Affect, Social, Imagination, Cognitive, Physiological; coping resources, thematic level and conflicts areas. [6].

Results

All results obtained after scoring the stories created by both subject groups were worked through with the SPSS program. Frequencies for each of the dimensions were compared across groups using T-test analyses of variance to determine if children with a history of divorce could be differentiated from children without history of divorce. According to the descriptive statistical analysis and to the T Test applied in order to compare the two groups, significant differences ($p < 0,01$/ $p < 0,05$) were registered between the groups for several scores.

Discussions

The statistical analysis of results showed that there is no statistically significant difference between the two groups of children, regarding the use of the following coping modes: Affect, Social, Belief, Physiological, Physiological (-). There is a difference however in the Cognitive coping mode and the Affect (-) coping mode, between the two groups, but these differences are not statistically significant. Statistically significant differences resulted in Social (-) coping mode and Imagination.

For children without a history of divorce, the themes that were most frequently emphasized throughout the study were the one concerning social relations and assuming social roles in life, respectively, the need to relate and communicate with the others (high scores in Social coping mode).

They registered few minus scores, which were statistically insignificant, for Social and Physiological coping modes. This might indicate that these children do not feel difficulties in their relationships with the others and experience positive feelings of confidence in themselves and their families. They express their emotions in an adequate manner that does not involve any aggressive emotions towards themselves or of general destruction, as it occurs in children with a history of divorce. For the Cognition dimension, the control group of children obtained significantly higher scores comparative to the group of children with a recent history of divorce.

Children coming from recently divorced families, often appeal to imagination as a coping method. Additionally, they got statistically significant more minus scores compared to the control group, for the Social, Affect and Physiological dimensions. This result suggests that they experience feelings of social isolation, conflicts and inner tension.

The minus score in Affect coping mode obtained only by the group of children with a history of divorce, coupled with the minus score in the Social coping mode, suggests the fact that they do not possess good emotional self-regulation, and that they have unrealistic expectations, given their own life experience.

Correlating these minus scores with the dramatic overall atmosphere of the stories, the frequency of conflicts and of themes (the theme of the saviour, the confrontation between the forces of good and evil), which were identified in the stories of children with a history of divorce, emphasizes once again the fact that they experience the feeling of being responsible for their parents' divorce and that they take on an essential role in restoring the parental couple.

Identifying the coping modes configuration, the relevant themes and conflicts which cause difficulties, aids therapists in establishing intervention programs for children who experience divorce. Starting off from their stories, through dramatization, children can be helped to develop more efficient coping strategies, to activate those inner resources that help them differentiate from their parents, to become more assertive, and to increase their self esteem. The final objective is that of helping them develop resilient personalities. [6]

Clinical examples

1.1 Boy, Michael, 10 years old

Parents had divorced 6 months before. Michael and his 15 years old sister were entrusted to their mother and now live with her. There was a long period of fighting between the parents. The husband did not wish for a divorce, and even threatened her with suicide. Michael sometimes visits his father, although he would not want that sometimes. When he returns from his visits to his father, Michael rejects his mother and sister. He

refuses to speak to his mother about his father. He says he is his father's only friend, because his father tells him so. Michael is impressed by the fact that his father lives alone and does not want to see him upset. The boy does not accept his parents' divorce, and he holds his mother responsible for this. He does not know which parent to believe and during those moments he feels sad and upset.

1.1.1 The Six Part Story

The hero is the Man-Dog, Ham Man. (I) He is playful. He helps you when you get bored or when you have nothing to do. (S, A) His mission is to cheer me up or entertain me when I do not know what to do, (S, A) when I am upset or sad and go to my room (A). When my sister scolds me (S-) I get sad (A) and Ham Man appears and we play video games together.(I). His help is a bone, Osman.(I) It has feet and hands and it is always creative. (I) Ham Man can hold it in his mouth to ease his help. (C) It also has glasses so that he is not discovered. (I) It has a wig, too. (Ph) The obstacle is Cubineg. (I) Neg comes from negative. (C) It's a cube I used to play with when I was little and threw it against the walls, (Ph) or at anything, and the cube did not like that (A) and wanted to take revenge. (I) Action: Cubineg tries to prevent him and throws a bag of meat at him, to make him go to it and not come to me. (C, I)

In the end, Ham Man arrives and makes me cheerful and makes me be no longer upset (I, A) Osman and agent Fly come to his help. (S) The agent flies to the meat (Ph) and takes it.(C) Ham Man goes to the helicopter (Ph) and the helicopter brings him to me. (C)

The analysis of his story according to the Basic PH model led to the following coping style: Imagination (9) Affect (6) Cognitive (5) Physiological (4) Social (3) Social - (1) Belief (0)

Michael uses imagination and expression of emotions as main coping modalities, which are mostly dysphoric. He is very focused on himself and his need to be helped to face solitude and sadness. He experiences conflicting states at the level of relationships.

The objectives we followed in our therapeutic program were gaining better self awareness, strengthening the self and differentiation, stepping out of his loyalty to his father, accepting the divorce. We initially used his coping modalities, through exercises of visualization, metaphorical expression through drawings, stories, dramatization. We then approached aspects of relationships.

Throughout the therapy, which lasted for eight months, Michael gained more confidence in self-expression and developed a better ability of self awareness. He learned to be more responsible for himself and less responsible for those in his family.

1.2 Girl, Adina, 9 years old

Adina's parents are on trial for child custody. She has a 6 year-old brother. Adina watched the conflicts between her parents, at the present moment being caught between two reference systems, in which each parental figure tries to communicate that he or she is the most suitable for taking care of her raising and education. Adina finds herself in alliance with her mother and holds father guilty for the divorce, projecting on him her mother's discontents and not her own. Although she would like to spend more time with her father, Adina chooses not to answer his requests in order not to upset her mother.

1.2.1 The Six Part Story

The hero is a girl (C) from a village, daughter of an ex carpenter(C). He was not able to work anymore (Ph). The girl had a gift, (B) she would weave very beautifully (Ph) and so she worked instead of her father (S).She would weave cloths. (C.) Her mission was to help her father (S). No one helped her. Afrodita, the goddess of beauty (I) also knew how to weave beautifully (Ph) and when she saw how neatly Corina would weave, (C), the goddess (I) took it as a challenge (S-).

The goddess (I) comes on a golden cloud and tells (C) that, if she dared her, now it was her time to dare her on a kind of a fight (S-): Who weaves most beautifully? (Ph). The goddess (I) got angry (A-) that the girl was the one to weave more beautifully, (Ph) and transformed her into (I) a spider that would weave (Ph) its web all its life without receiving any admiration ever (S-).

The analysis of her story according to the Basic PH model led to the following coping style: Physiological (6), Cognitive (5), Imagination (5), Social (2), Social – (3), Affect – (1) , Belief (1)

Adina uses as main coping modalities action and physiological satisfactions (compulsive eating), coupled with imagination and cognitive abilities. She experiences very intense conflicts at the relationships and affective levels. If she finds herself behaviourally in an alliance with her mother against her father, the analysis of her story theme points out to the need of helping her father and the threat she perceives in relation to the competing maternal figure.

The objectives to be followed through therapeutic program are improving her ability to express emotions, strengthening the self, and stepping out the alliance with her mother against her father.

Conclusions

The study using Mooli Lahad's "Six Part Story" Method emphasized the existence of significant differences between coping styles and thematic levels in children coming from divorced families and children coming from intact families.

Identifying the blocked resources in children with a history of divorce offers the therapist suggestions for shaping intervention programs suitable to the child's individual needs. Dramatization on the basis of the stories they create, enhances the children's abilities to differentiate from their parents and facilitates their detachment from parental conflicts.

Integrative treatment of depression and its impact on quality of life and resilience in cancer patients

Zarie G.

Romania
zariegabriela@gmail.com

"Success is going from failure to failure without losing enthusiasm." Winston Churchill This is easier said than done. How do you maintain enthusiasm when you are exhausted, discouraged, frustrated, or completely alone? How can you do this?

Abstract

Introduction

The aim of the study was to reveal the impact of the integrative treatment of depression on different domains of life quality in cancer patients, due to the increasing body of studies concerning the domains of the quality of life and resilience factors.

Methods

In the study were included 130 cancer patients with a comorbid depressive disorder, which followed for 6 months several therapeutic options: 76 subjects (58,5%) only antidepressants and 54 subjects (41,5%) antidepressants plus different support psychotherapies. For the evaluation we used Hamilton Depression Rating Scale (HAM-D) and WHOQOL World Health Organization Quality of Life Scale. Statistical processing of data included the T-test (Student) for dependent samples, Kolmogorov-Smirnov test and Kruskall-Wallis ANOVA. The results were considered statistically significant for $p<0.05$, which corresponds to a 95% confidence intervals.

Results and discussions

After 6 months of integrative treatment the level of depression decreased from severe (54,6%) and moderate (38,5%) to mild depression in the majority of patients (59,2%), with a complete simptomatic remission in 11,6% patients. Concerning the quality of life, all the differences had strongly statistic significances ($p<0,01$,) the most important enhancements being in the domains of the psychological health (86%) and physical health (73%).

Conclusions

Cancer associated emotional distress conduct to an important decline in all the domains of the quality of life. Integrated therapeutic interventions contributes to the enhancement in quality of life as a whole, especially in the domain of psychological well-being, recommending it as a valuable approach to increase patients resilience too.

Key words: cancer, depression, integrative treatment, quality of life, resilience

Introduction

It is an increasing body of studies concerning the quality of life (QoL) and resilience factors in depressed cancer patients subjects of integrated psycho-social and pharmacological treatment .A review of Galway 2012 on 3309 studies concerning psychosocial interventions to improve quality of life and emotional wellbeing for recently diagnosed cancer patients revealed that psychosocial interventions comprising information combined with supportive attention may have a beneficial impact on mood and QoL in an undifferentiated population of newly diagnosed cancer patients.(1)The World Health Organization (WHO) defines quality of life as a subjective perception that an individual has of his position in life, in a cultural setting and in a set of values in which he lives, in relation to his goals, expectations, standards and concerns. It is a broad ranging concept affected in a complex way by the person's: physical health, psychological state, personal beliefs, social relationships and their relationship to salient features of their environment (2).

Resilience was defined within the developmental psychology as a variety of psychological resources providing power of resistance when a person faces critical life situations or demands(3) . More specifically Werner (1995) distinguished three contexts for protective factors:1. personal attributes, including outgoing,

bright, and positive self-concepts;2.the family, such as having close bonds with at least one family member or an emotionally stable parent; 3.and the community, such as receiving support or counsel from peers. (4). Latter, Rutter began to argue that resilience was a process, not a trait, and it is created when the protective factors initiate certain processes in an individual, like: building a positive self-image, reducing the effect of the risk factors and breaking a negative cycle so as to open up new opportunities for the individual. And as a process which changes through time, researchers should use qualifiers such as "relative" and "variable" to describe resilience (as in his definition above), rather than any term that might imply absoluteness (5). In his more recent reviews of the literature, Rutter defined resilience as relative resistance to psychosocial risk experiences (6,7). This approach focuses on a range of outcomes, not just positive ones; it does not necessary expect that protection lies in positive experience and does not assume that the answer lies in what the individual does about the negative experience at the time (how he or she copes with it (7).

In the field of psycho-oncology resilience is among variables that improves personal feelings in cancer patients and helps them to be inclined to try to stay alive and also leads to a better understanding of the factors promoting well-being (8). For instance, a study done by Gotay et al. on patients with breast, stomach and lung cancer showed that resilience is related to better quality of life and low levels of depression(9).

Another study examined pain in cancer patients who were undergoing radiotherapy and the results showed that resiliency is a strong predictor of quality of life and adoptability in patients (10).

Resilience was not usually measured yet in patients with neoplasms; but depression is a frequent occurrence, recognized and treated by physicians. Treatment of depression relays mostly on medication, but various studies (including the one presented below) have relayed the importance and positive impact of psychotherapies in the treatment of depression. Psychotherapy has been shown also to increase several aspects of life quality. Therefore, it could be surmised that interventions meant to reduce depression , results also in the improvement of the protective factors which strongly connects with resilience and enhancement in quality of life domains.

Methods

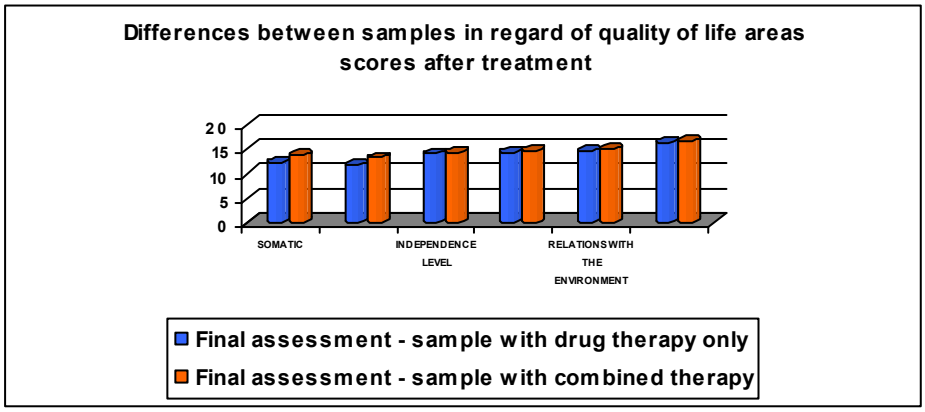
Below is presented a study carried out in Timisoara City Hospital on 130 cancer patients with a comorbid depressive disorder, which followed for 6 months several therapeutic options: 76 subjects (58,5%) only antidepressants and 54 subjects (41,5%) antidepressants plus different support psychotherapies (Cognitive-Behavioral Therapy -13 patients 10%, Family Systemic Therapy -13 patients-10% and Group therapy - 28 patients-21,5%). *The cognitive-behavioral intervention adapted to cancer consisted in:* explanations concerning emotional reactions generated by cancer; clarifying the informations connected to diagnostic and therapeutic procedures ; cognitive restructuring techniques; monitoring and replacement of negative thoughts, with rational explanations; stress management; relaxation techniques followed by guided imagery or autohipnosis.The family systemic therapy adapted to cancer used an approach based on structural (Minuchin)(13) , transgenerational (Bowen, and Onnis)(12,14,15), and systemic (Mara Selvini-Pallazoli)(16) models. Group therapy consisted of an open group with an educational, coping abilities training and social-emotional supportive prophile, with all members participating at at least two meetings /month for a minimum 12 weeks. Instruments used for the evaluation were: Hamilton Depression Rating Scale (HAMD) with 17 items and WHO Quality of Life The World Health Organization Quality of Life assessment (WHOQOL-100) with 6 domains: physical, psychological, social relationships, independence level, environment and spirituality. It also includes 1 facet examining overall quality of life and general health perceptions . Statistical processing of data included Shapiro-Wilk's test and Student t-test.The paired *t*-test was used to assess the responsiveness to clinical change of scores on the WHOQOL-100 at baseline and post-treatment in the different groups.(11)

Results and discussions

Neoplasms are generally associated with emotional distress that ranges between normal feelings of vulnerability, sadness and fear to psychopathological symptoms with life-impairing intensity, like depression, anxiety, panic, somatization, paranoid ideas, social isolation and existential and spiritual crises. The emotional distress associated with neoplasms impacts on the quality of life of the patients, especially in the psychological and general well-being area.

In regard of the quality of life, the results of the study has also shown that combined treatment (drug plus psychotherapy) has better results than drug treatment alone.

Figure no. 1. Differences between samples in regard of quality of life areas scores after treatment



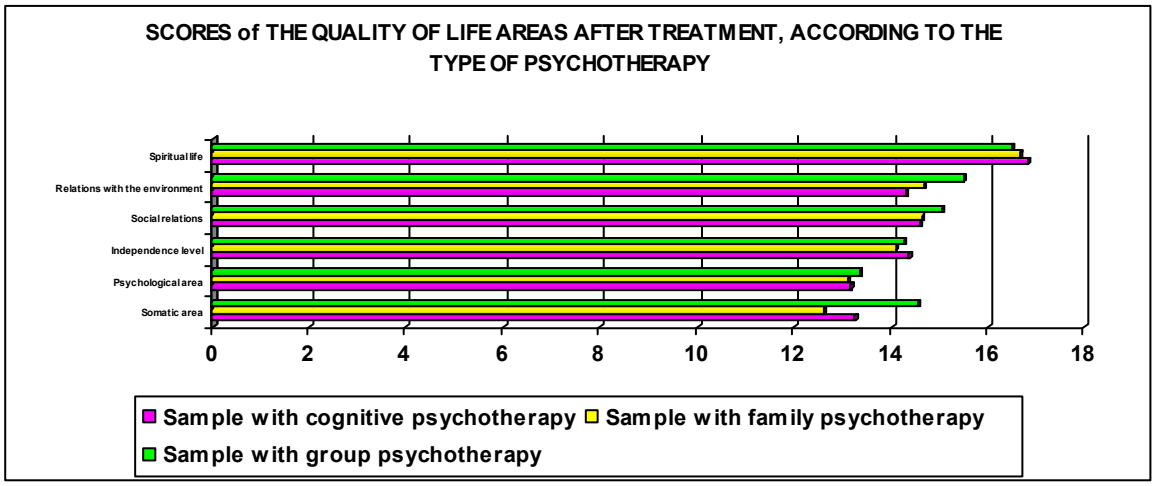
The study has also examined the results of the various combinations of drug and psychotherapy, according to the type of psychotherapy.

Improvements in the domains of Qol , based on beneficial efects of interventions on protective factors, may also seem, according to the modern opinions that , resilience as a process mai facilitate the adaptation to the cancer distress . The results are presented below.

Table no. 1. ANOVA results – comparison of after treatment scores for the samples on types of psychotherapy

QoL Scale Areas	Average score after treatment			Rank differences (H, 2, N = 54))	Statistical significance
	Cognitive psychotherapy	Family psychotherapy	Group psychoterapy		
Somatic	13.25	12.61	14.56	H = 15.61	p = 0.000
Psychological	13.17	13.12	13.36	H = 0.71	p = 0.70
Independence level	14.37	14.09	14.27	H = 4.33	p = 0.11
Social relations	14.60	14.65	15.06	H = 0.39	p = 0.82
Relations with the environment	14.31	14.69	15.49	H = 9.31	p = 0.009 Statistically significant
Spiritual life	16.81	16.66	16.48	H = 3.48	p = 0.17

Figure no. 2. After treatment scores on QoL areas, for the samples, according to the type of psychotherapy



The results of the study realized in Timişoara City Hospital has shown that the Quality of Life in the psychological area has better improved in patients with cancer following a combined treatment for depression: medication and psychotherapy, as compared with patients with cancer following only drug treatment (86% versus 46%). The areas of life quality better responding to this combined therapy were somatic health and social relations. Especially behavioural-cognitive therapy (in association with drug therapy for depression) has shown a significant improvement of psychological and somatic state of patients, and a significant (but by a lesser degree) improvement of patients' relations with the environment and their spiritual life. Family psychotherapy (in association with psychothropic drugs) has managed to promote the reduction of depression and anxiety's intensity in all patients and significant improvements in the psychological and somatic areas and relations within the patients' families. Also, group psychotherapy has helped half of the patients to improve their relations with the external environment and a third of the patients have reported an improvement in the level of their spiritual life, from average to good.

A large systematic rewiew and meta-analysis to date on the effects of psycho-social interventions including individual psychotherapy, group therapy, psychoeducation and relaxation training on emotional distress and QoL in cancer patients demonstrates that these interventions produce small to medium effects on emotional distress, anxiety, depression and health related QoL, the response being more important as the therapies were prolonged more than 6 month (17) .It was found that in the group with less than 12 months awareness of cancer, there was positive relationship between resilience and quality of life in emotional dimension. In other words, by the growth of the cancer, changes in emotional aspects of quality of life are not the same as in the first year; and in this regard, it does not show a meaningful relationship with resilience. Perhaps, this is due to the fact that the patient gradually finds out that dealing emotionally with this problem cannot help him/her (18).The majority of studies that examine cancer and resilience are cross-sectional which limits causal inferences, thus is not clear whether resilience makes peoples less distressed or less distress makes peoples more resilient in face of adversities. Another limitation of previous studies is that they have relied on measures, such as hope and optimism, which are proxy to resilience rather that measures that were developed to assess resilience (19) Other studies done on cancer patients show that high levels of resilience help patients in useing positive feelings and emotions to pass unfavorable experiences and return to favorable condition and quality of life(20). Social support was found to be related to mental health in cancer patients and to act as a buffer to cancer distress and cancer related worries (21). Recently it has been hypothesized that social support might be related to resilience and that the relationship between social support and distress may be mediated by resilience (22,23). A study of Jung Ah min et all (2013) suggests that psychological resilience may independently contribute to low emotional distress in cancer patients. The relationship between resilience and emotional distress was also significant in the subgroup of metastatic cancer patients. Psychosocial interventions to enhance resilience might provide useful approaches to overcome cancer-related emotional distress(24). Independent studies and systematic reviews emphasize that psychologically-distressing problems created or exacerbated by cancer can be effectively addressed by psychosocial and peer support interventions (17, 25).In our study psychosocial intervention significantly improved QoL especially in the domain of psychological and somatic state.

Further studies are required in order to clearly determine the role and action of the various combinations of drugs and psychotherapy, but the results support the importance of implementing psychotherapeutic interventions in oncology patients.

Conclusions

Though few studies have been conducted in Romania on the problem of resilience and cancer, there are studies and programs aimed at reducing depression and increasing the quality of life in patients with neoplasms. Even if we call resilience a *process,* initiated when the protective factors (personal attributes, the family and the supportive community) are mobilized to reduce the adverse factors like cancer and to open new opportunities for the individual, or a *mediator* between social support and cancer related emotional distress, integrative psycho-oncological interventions succeed to reduce the distress and to increase the resilience and quality of life in cancer patients.

Intervention de type resilience assistee ecosystemique

Jourdan-Ionescu C.

Département de psychologie, Université du Québec à Trois-Rivières (CANADA)
colette.jourdan@uqtr.ca

Résumé

Après avoir fait une distinction entre les concepts de résilience et de résilience assistée, la présente communication visera à définir les principes d'élaboration d'une intervention écosystémique axée sur la résilience, notamment par le développement de facteurs de protection trans-adversité. Une étude de cas permettra d'illustrer comment partir des résultats d'une évaluation mixte de la personne (questionnaires et méthodes projectives) pour élaborer et mettre en place une telle intervention. Les résultats obtenus à l'*Échelle de résilience* (Wagnild et Young, 1993), aux *Échelles de facteurs de risque et de protection* (Jourdan-Ionescu et al., 2010), à la *Ligne de vie* (Jourdan-Ionescu, 2006) et à l'*Exercice de résilience* (Strümpfer, 2003) permettront de sélectionner les cibles de l'intervention écosystémique axée sur la résilience, de la co-construire et de superviser sa mise en place. La co-construction d'une intervention de résilience assistée basée sur les résultats d'une évaluation mixte est applicable dans tous les milieux et peut être intégrée aux programmes de perspectives théoriques différentes.

Mots-clés : Résilience, Modèle écosystémique, Intervention, Résilience assistée

Quelques précisions sur la résilience

La résilience est « Le processus qui fait que, face à l'adversité, face au traumatisme ou face au stress, des individus, des familles, des groupes d'humains s'en sortent, ne présentent pas de troubles psychiques, continuent à vivre comme avant (ou presque) et peuvent même présenter un fonctionnement psychique meilleur qu'auparavant » [1]. Parmi les exemples d'adversités, nous pouvons citer : une situation de maltraitance, une maladie, un accident, un deuil, une perte d'emploi, etc. Si, au départ, la résilience ne concernait que les individus et leurs caractéristiques personnelles (comme l'estime de soi, la flexibilité cognitive, la régulation émotionnelle et l'humour), la résilience concerne maintenant aussi les familles et des groupes d'humains comme un groupe de travailleurs d'une usine ou les habitants d'une commune ou d'un pays. Le résultat inattendu auquel la balance dynamique entre les facteurs de risque et de protection (individuels, familiaux et environnementaux) aboutit est que la personne ne présente pas de trouble psychopathologique diagnostiqué, s'adapte et reprend son développement et même dépasse les attentes (voir la trajectoire de résilience proposée par Richardson, *Fig. 1*).

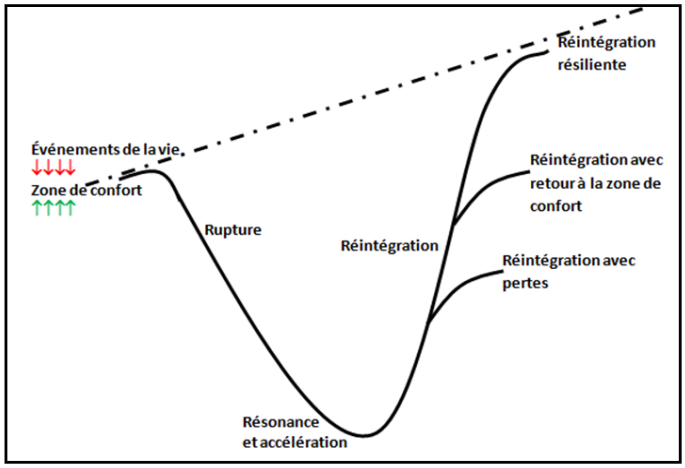

Fig. 1 Évolution après un traumatisme (d'après [2], traduction libre de Hamelin et Jourdan-Ionescu)

Passage de la résilience naturelle à la résilience assistée

La résilience naturelle, telle que nous venons de la redéfinir, se déroule sans l'intervention de professionnels de la santé mentale [3]. Par contre, la résilience assistée se caractérise [4, 5] par :

- la mise en évidence et le développement des potentialités des personnes à risque;
- le dépistage des ressources existantes dans l'entourage de la personne;
- la mise sur pied de programmes de prévention en partenariat;
- la mise en œuvre d'une stratégie d'intervention de type maïeutique.

Comment faire pencher la balance dynamique du côté de la résilience?

Pour cela, il faut viser à diminuer l'impact des facteurs de risque tout en augmentant l'action des facteurs de protection présents afin de développer les potentialités [6, 7]. De plus, il faut ajouter des facteurs de protection trans-adversités [8]. On appelle facteurs de protection trans-adversités des facteurs de protection qui s'avèrent efficaces envers plusieurs adversités à condition de les adapter, de les moduler à la spécificité de ces situations (par exemple, pour une situation de maltraitance affectant un jeune enfant, une personne venant d'apprendre qu'elle a une maladie grave ou une autre confrontée à l'Alzheimer de son parent).

Citons quelques exemples de facteurs de protection trans-adversité :

- une bonne estime de soi, l'emploi de l'humour dans le but s'affilier avec autrui (facteurs individuels);
- le soutien des parents, l'intérêt des parents envers les résultats scolaires de l'enfant, une bonne ambiance familiale (facteurs familiaux);
- un bon réseau de soutien social, la présence d'un mentor ou d'un tuteur de résilience (facteurs environnementaux).

Le modèle de développement d'interventions de résilience assistée (voir la *Fig. 2*) implique tout d'abord d'évaluer les facteurs de risque et de protection de la personne dans une perspective écosystémique et son niveau de résilience naturelle. Pour cela, différents instruments peuvent être employés : échelles de résilience, de facteurs de risque et de protection, grille de réseau social, méthodes projectives, etc. Une fois la résilience naturelle évaluée, il faut choisir les cibles d'intervention en partenariat avec la personne. On visera à diminuer les facteurs de risque (évidemment, ceux qui sont modifiables) les plus dérangeants pour la personne et on augmentera les facteurs de protection qui peuvent l'être. Si possible, on aidera la personne à découvrir d'autres facteurs de protection favorisant sa résilience. L'intervention écosystémique est toujours co-construite en partenariat avec la personne qui oriente l'intervention en fonction de ses besoins et préférences. En ce sens, elle ne peut être qu'individualisée et doit toujours s'appuyer sur tous les systèmes de vie de la personne (facteurs individuels, familiaux et de ses environnements scolaire ou professionnel, services de santé, loisirs, regroupements associatifs et communautaires). L'intervention de résilience visant à assister ou à développer la résilience de la personne peut alors être mise en place et supervisée. Ceci permettra à la personne de continuer le processus de résilience de manière autonome et d'aider des personnes à risque de son entourage à s'engager dans ce processus (diffusion).

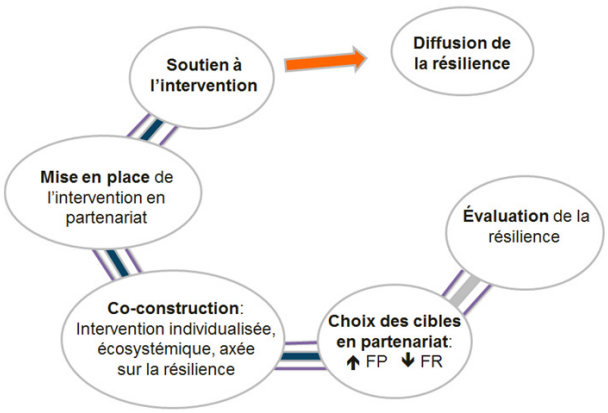

Fig. 2 Modèle de développement d'interventions de résilience assistée [9]

Nous illustrerons l'application de ce modèle à partir des résultats de l'évaluation d'un jeune homme, Victor.

Vignette clinique

Victor a 21 ans et deux mois et est étudiant en sciences. Il est en couple depuis bientôt trois ans, mais il vient d'emménager en appartement avec sa copine. Il fait une demande car il est anxieux (il dort mal, n'a plus d'appétit, se demande comment l'avenir va se passer).

L'évaluation de la résilience naturelle de Victor est réalisée à l'aide de trois échelles (*Échelle de résilience* [10], *Échelle de facteurs de risque* [11], *Échelle de facteurs de protection* [12]), d'une *Grille de réseau social* [13], et de deux méthodes projectives (*Ligne de vie* [14] et *Exercice de résilience* [15]).

Résultats

Le score de Victor à l'*Échelle de résilience* (134) le situe dans la moyenne des étudiants de son âge. Ses résultats à l'*Échelle de facteurs de risque* montrent qu'il rapporte peu de facteurs de risque (4, alors que la moyenne des répondants est le double), mais il faut noter que ce sont principalement des facteurs de risque familiaux. En ce qui concerne l'*Échelle de facteurs de protection*, il obtient un score total inférieur à la moyenne (21), surtout en raison du faible nombre de facteurs familiaux.

La *Ligne de vie* représentée par Victor (*Fig. 3*) met en évidence un événement marquant dans son enfance, le décès de sa maman. Il avait seulement sept ans lorsqu'elle est morte après avoir été longtemps malade. Suite à cet événement, il a été mis en pension par son père. Il inscrit ces deux premiers événements du côté négatif. Son frère (plus âgé de quatre ans) est resté à la maison avec son père. Heureusement, comme son père adorait le sport, il l'avait inscrit auparavant dans une équipe de football, ce qui a favorisé son développement physique et moteur, lui a permis de rencontrer des amis et un entraîneur soutenant, ainsi que de se valoriser par le sport.

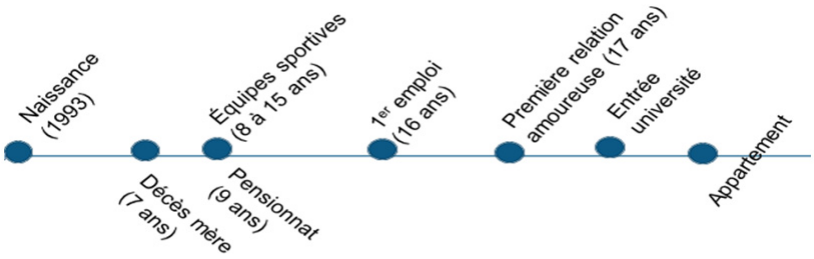

Fig. 3 Ligne de vie de Victor

Victor passe ensuite rapidement à d'autres événements positifs, d'abord son premier emploi (occasion de gagner de l'argent et de se révéler fiable) et sa première relation amoureuse. Il met ainsi en valeur son accès au monde adulte. Puis, il inscrit son entrée à l'université et finalement, il hésite pour son installation en appartement et place cet évènement à cheval sur la ligne (comme pour le mettre à la fois entre le positif et le négatif).

Victor affirme que son réseau social lui procure satisfaction, mais dans sa *Grille de réseau de soutien social* (*Tableau 1*), son père et son frère apparaissent très peu présents. Sa conjointe se révèle essentielle (pour l'écoute, la résolution concrète des problèmes et les activités plaisantes). Ses amis sont aussi importants, tout comme ses grands-parents paternels.

Tableau 1 Grille d'évaluation du réseau de soutien social de Victor [13]

	Se confier	Aide concrète	Activités agréable
Père	-	1	-
Mère			
Fratrie	-	1	-
Copine	**3**	**3**	**3**
Amis	2	3	3
Grands-parents maternels	2	2	1
Intervenants	-	-	-
Enseignants	-	-	-
Autres, précisez :	-	-	-

L'*Exercice de résilience* [15] – qui explore les réponses face à des mises en situation d'adversité – révèle que Victor recherche la résolution du conflit, fait preuve de mentalisation, favorise l'apprentissage à partir des erreurs, l'intégration de l'adversité et qu'il cherche à retirer du positif des situations.

Par exemple, face à la mise en situation « Ron vient d'être mis à pied », Victor répond aux questions :

- *Que pense et que ressent la personne? Que veut-elle?*
  « Ben, tout dépendant du type de personne que Ron est… eee… faudrait qu'il fasse le bilan de pourquoi il a été mis à la porte et de ce qui a mené à ça… mais… pis de tirer… de tirer l'positif de son passage là et essayer de voir ce qu'est-ce que le négatif était. »
- *Que va-t-il se passer? Quelle sera l'issue?*
  « Il va chercher un nouvel emploi… eee.. en tenant compte de tout ça »
- *Plus tard, en y repensant, qu'est-ce que la personne pourrait penser de ce qui s'est passé? Que signifiera pour elle l'expérience qu'elle a vécue?*
  « Il va être content, car… eee… il gagnera plus dans son nouvel emploi, ça l'a obligé à se dépasser ».

Suite à l'évaluation réalisée…

Actuellement, on peut conclure que Victor présente un niveau moyen de résilience naturelle. Même s'il a vécu une enfance difficile (décès de sa mère et pension très jeune), il a comblé les manques par de très bons résultats scolaires et la pratique de plusieurs sports. Il fonctionne bien, a une conjointe et poursuit des études universitaires tout en travaillant pour les payer. Son score à l'*Échelle de résilience* le situe dans la moyenne par rapport aux jeunes de son âge. Ses facteurs de risque familiaux – tout comme l'absence de facteurs de protection familiaux – s'expliquent par la coupure qui s'est produite entre lui et son père et son frère qui ont vécu ensemble alors qu'il était en pension durant toute sa scolarité. Son père et son frère sont très proches, alors que lui vit toujours coupé d'eux. Il est très autonome, fier de ses réalisations et déterminé. Lors de l'*Exercice de résilience*, on constate qu'il emploie des stratégies qui l'amènent à retirer du positif des situations d'adversité. Il affirme être satisfait de son réseau de soutien social.

Par contre, Victor exprime qu'il ressent de l'anxiété dans sa demande. Ceci se confirme, à la fin de sa *Ligne de vie*, quand il parle de son installation en appartement avec sa copine. Il révèle alors que s'il est content d'avoir emménagé avec elle, il se questionne beaucoup sur l'avenir, sur sa capacité à faire face à ce qui va suivre… et notamment le fait d'envisager d'avoir des enfants.

Élaboration d'un plan d'intervention de résilience assistée écosystémique et individualisée

Victor a participé à l'élaboration de son plan d'intervention de résilience assistée en ciblant les facteurs de protection qui lui semblaient les plus importants : abaisser son niveau d'anxiété et avoir une image rassurante de père. Nous avons co-construit une intervention écosystémique favorisant l'action de facteurs de protection individuels (1, 2), familiaux (3, 4) et environnementaux (5, 6):

1. accroître sa capacité d'expression des émotions, renforcer son estime de soi, augmenter sa capacité d'identification au rôle de conjoint et de père; facteurs à développer grâce à un suivi psychologique permettant à Victor d'explorer l'impact du deuil de sa mère et de la séparation d'avec son père et son frère, ainsi que son angoisse face à l'avenir.
2. augmenter sa capacité de contrôle et diminuer son niveau d'anxiété en réalisant des activités de relaxation avec sa conjointe, notamment pour améliorer son sommeil. De plus, le fait de partager cette activité avec sa copine lui permettra de le faire dans un contexte agréable et d'avoir du soutien pour intégrer cette activité dans sa vie quotidienne.
3. se réconcilier avec son père et bénéficier de sa présence comme soutien. Pour cela, il pourrait aller le voir pour regarder avec lui des matchs de football, puis souper ensemble.
4. se rapprocher de son frère qu'il connaît à peine en réalisant régulièrement des activités agréables avec lui qui a aussi dû faire le deuil de sa mère jeune.
5. afin de diversifier son réseau social, Victor peut faire davantage de sports collectifs, pour rencontrer des nouvelles personnes comme lorsqu'il était jeune. Actuellement, il fait du cyclisme l'été dès qu'il a du temps et de la raquette l'hiver avec sa conjointe. Il ne fait plus partie d'une équipe sportive, ce qui lui avait permis de s'en sortir quand il était jeune.
6. enfin, il devrait tenter de se trouver un mentor (homme, père de famille) soit dans le cadre de ses études (un professionnel de la profession qu'il désire exercer) soit dans le sport (un entraîneur, par exemple) qui pourrait lui servir de modèle d'identification paternel, mais qui pourrait aussi le soutenir pour le rendre plus confiant face à l'avenir.

Telle que présentée, la co-construction d'une intervention de résilience assistée basée sur les résultats d'une évaluation mixte est applicable dans tous les milieux et peut être intégrée aux programmes de perspectives théoriques différentes.

Abstract

PROBLEM: One of the best therapeutic practice that support resilience in adolescents with suicidal attempt and severe mental disorders is dialectical behavior therapy. OBJECTIVES: To measure the implementation of this therapy and assess its impact in young people with suicidal behavior. METHODS: The implementation of the program is evaluated by two independent evaluators. The structure of the program implementation, the intervention protocols proposed and matter products are used as indicators. The impact of the treatment is evaluated in 28 teens (M = 15.9 years, SD = 1.26) receiving therapy in Quebec psychiatric setting. The research design is based on a pre-test and post-test group without control group. Measures are taken before and after a 20 week program with an assessment of life skills, suicidal behavior, self-mutilation and symptoms of borderline personality. RESULTS: A high rate of agreement between evaluators (program structure = 90.1%, kappa = 0.78; intervention protocols = 93.8%, kappa 0.82 and matter product = 90%, kappa = 0.64) was found between Quebec and U.S. programs. Correlation analysis showed a significant relationship between the decrease symptoms of borderline personality and improving mindfulness (r = -0.43), emotional control (r = 0.55) and distress tolerance (r = 0.73). The linear regression analysis shows that the distress tolerance contributes significantly reduce the symptoms of borderline personality disorder (β = -0.67, p = 0.001). The hierarchical regression analysis indicates that the reduction of the symptoms of borderline personality is related to an improvement of the first mindfulness (β = 0.67, p = 0.01), then emotional regulation (β = 0 , 75, p = 0.01) and finally, the distress tolerance (β = -0.67, p = 0.01). The model explains 56% of the variance. CONCLUSIONS: The results indicate that this therapy has been well applied in Montreal and had an impact on reducing the symptoms of borderline personality enhancing life skills. The order in which these skills are taught is important.

Keywords: adolescent; suicidal behavior; self-harm; borderline personality; Dialectical Behavior Therapy; life skills; implantation; impact.

Introduction

Le suicide constitue la deuxième cause de mortalité chez les 15 à 19 ans au Québec [1]. Pour chaque suicide à l'adolescence, il y aurait environ 100 à 200 tentatives de suicide [2]. L'adolescent présente aussi des comportements d'automutilation. Même si ces comportements ne sont pas accompagnés d'une intention de mourir, certains d'entre eux sont associés à une dangerosité et à des décès possibles. Ils sont estimés à 18 % chez les adolescents américains [3]. Diverses études ont mis en évidence la cooccurrence de troubles mentaux chez les adolescents morts par suicide [4-7]. Selon Jacobs du *Harvard Medical School*, les individus présentant des comportements suicidaires et d'automutilation peuvent être partagés en deux groupes, l'un présentant des troubles dépressifs, l'autre présentant des troubles complexes associés habituellement à des symptômes de personnalité borderline [8]. Une des meilleures pratiques thérapeutiques soutenant la résilience chez les jeunes appartenant au deuxième groupe est la thérapie comportementale dialectique [9]. Cette prise en charge de l'adolescent et de ses parents vise essentiellement l'acquisition de compétences afin de faire face à l'adversité de la vie [10]. La présente étude québécoise rend compte de l'implantation et de l'évaluation de la thérapie

comportementale dialectique chez des adolescents qui présentent des comportements suicidaires et d'automutilation avec des symptômes de personnalité borderline.

Description du programme implanté et évalué

La thérapie comportementale dialectique, développée par Marsha Linehan de l'Université de Washington, est un programme d'intervention indiquée s'adressant aux individus présentant des comportements suicidaires et d'automutilation avec des symptômes de personnalité borderline. Ce programme s'inscrit dans la troisième vague des thérapies cognitivo-comportementales puisqu'il met l'accent sur l'utilisation des stratégies d'acceptation et l'enseignement de la mindfulness. La mindfulness est généralement définie comme étant la capacité de maintenir volontairement et de façon soutenue son attention sur l'expérience du moment présent, et ceci, sans juger cette expérience. Dans ce programme, les comportements suicidaires et d'automutilation sont conceptualisés comme une conséquence d'un dysfonctionnement de la régulation des émotions. Ce dysfonctionnement est expliqué par une vulnérabilité émotionnelle sur le plan du tempérament qui est exacerbé par un environnement nuisant à l'apprentissage de l'autorégulation des émotions. Pour diminuer le dysfonctionnement de la régulation des émotions, ce programme cible l'apprentissage de compétences psychosociales permettant à l'individu de mieux réguler ses émotions. Dans un premier temps, les compétences sont apprises grâce à une intervention de groupe. Dans un deuxième temps, cet apprentissage est réalisé grâce à une thérapie individuelle visant l'intégration et l'application de ces compétences dans la vie quotidienne. Dans un troisième temps, cet apprentissage est effectué par un soutien téléphonique visant la généralisation de ces compétences dans la vie quotidienne de l'individu. Dans un quatrième temps, une supervision d'équipe hebdomadaire obligatoire est mise en place pour assurer la qualité des interventions de groupe, individuelles et téléphoniques.

Dans la présente recherche, le programme est offert à des adolescents de 14 et 17 ans en milieu psychiatrique québécois présentant des comportements suicidaires et d'automutilation avec des symptômes de personnalité borderline. Le programme offert s'échelonne sur 20 semaines et est dispensé par une équipe de professionnel en santé mentale. Durant cette période, les adolescents assistent chaque semaine à une rencontre de groupe de deux heures pour l'entrainement aux compétences. Ces groupes sont fermés et composés uniquement de filles. Ces rencontres sont animées par quatre cliniciens, dont deux sont responsables des adolescentes et deux sont responsables des parents. Durant cette rencontre, les adolescentes apprennent et pratiquent les compétences proposées. Le contenu du groupe de compétences est divisé en quatre modules et chaque module porte sur une compétence précise : la mindfulness, la tolérance à la détresse, la régulation émotionnelle et l'efficacité interpersonnelle. Les adolescentes assistent également chaque semaine à une rencontre de thérapie individuelle d'une durée de 50 minutes avec leur thérapeute primaire. De plus, le thérapeute offre une aide d'urgence par des disponibilités téléphoniques durant les jours de la semaine.

Méthodologie

Cette étude a reçu l'approbation du Comité d'éthique à la recherche et comprend deux volets.

1.1 Volet implantation

Est-ce que l'analyse des critères de succès confirme l'implantation de la thérapie? Un devis de recherche descriptif pour évaluer l'implantation du programme en milieu psychiatrique est utilisé. L'implantation du programme est réalisée par six intervenants. Cette évaluation touche l'intégrité du programme (structure, protocole et matériel). Des observations systématiques et participantes sont réalisées et l'examen de ces observations est basé sur des critères de succès. Ces critères permettent d'évaluer avec un taux d'accord inter-juge de deux évaluateurs les retombées de l'implantation du programme.

1.2 Volet évaluatif

Est-ce qu'une diminution des symptômes de la personnalité borderline et une amélioration des compétences sont observées après la thérapie? Et, est-ce que l'amélioration et l'utilisation des compétences est associée à une diminution des symptômes de la personnalité borderline après la thérapie? Un devis de recherche avec pré-test et post-test sans groupe contrôle avec 28 adolescents qui ont reçu le programme est retenu. Le diagnostic est émis à partir de l'entrevue clinique du psychiatrique, de l'entrevue au Kiddie-Sads-PL de Kaufman et al. (1997) et de l'entrevue structurée du DSM-IV pour l'axe-II de Frist et al. (1996). Les comportements suicidaires, d'automutilation et de symptômes de personnalité borderline sont évalués à partir du *Borderline Symptom List* de Bohus et al. (2009). Deux approches sont proposées pour évaluer les compétences psychosociales. La première suggère l'évaluation globale de l'utilisation des compétences à l'aide du *DBT Ways*

of Coping Checklist de Neacsiu et al. (2010). La deuxième approche suggère de mesurer chaque groupe de compétences du programme pour identifier la contribution individuelle des compétences psychosociales sur le dysfonctionnement de la régulation des émotions. Les questionnaires retenus sont : le *Five Facet Mindfulness Questionnaire* de Baer et al. (2006), le *Distress Tolerance Scale* de Simon et Gaher (2005), le *Difficulty in Emotion Regulation Scale* de Gratz et Romer (2004) et l'*Inventory of Interpersonal Problems* de Barham et al. (1996).

Résultats

1.1 Volet implantation

Les résultats indiquent que le programme implanté respecte le programme original dans une proportion de 90,1 % ; un accord inter-juge avec un kappa de 0,78 est obtenu entre les deux évaluateurs. Les résultats montrent que le protocole de traitement respecte les étapes du protocole général dans une proportion de 93,8 % ; un accord inter-juge avec un kappa de 0,82 est obtenu entre les deux évaluateurs. Les résultats révèlent que le matériel québécois respecte le programme américain dans une proportion de 90 % ; un accord inter-juge avec un kappa de 0,64 est obtenu entre les deux évaluateurs.

1.2 Volet évaluatif

Les résultats révèlent que l'amélioration de la mindfulness, de la régulation des émotions et de la tolérance à la détresse sont associées à la diminution des symptômes de personnalité borderline chez les adolescents (Tableau 1). De plus, une régression hiérarchique suggère que l'ordre d'enseignement de ces compétences joue un rôle dans les gains thérapeutiques observés. La séquence d'enseignement des compétences trouvée confirme que pour optimiser l'impact du programme, la mindfulness devrait être enseignée en premier, que la régulation devrait être enseignée en deuxième et que la tolérance à la détresse devrait être enseignée en dernier. Le modèle explique 56 % de la variance (Fig. 1).

Tableau 1 Corrélation entre les valeurs résiduelles obtenues aux variables dépendantes (n = 28)

Variables	Prétest		Posttest				
	M	*ET*	*M*	*ET*	*t(27)*	*p*	*d*
Compétences de *mindfulness*	99,4	19,0	121,9	21,1	7,04	<,000	1,33
Compétences de tolérance à la détresse	2,1	0,8	2,8	0,9	3,07	,001	0,66

Conclusion

Ces travaux témoignent de la complexité de mener une recherche d'implantation et d'évaluation en milieu psychiatrique québécois chez des adolescents difficiles à traiter et à haut risque de comportements dangereux. Malgré ces défis, la présente étude a contribué à l'implantation de la thérapie comportementale dialectique auprès de ce groupe. Par ailleurs, cette étude s'inscrit dans un désir d'évaluer les interventions psychologiques et de mettre de l'avant une pratique clinique qui repose sur des données probantes. L'ensemble de ces efforts a permis la réalisation d'une recherche novatrice permettant l'avancement des connaissances. En effet, le résultat principal de cette étude est la mise en relief du lien existant entre l'apprentissage des compétences psychosociales enseignées et les gains thérapeutiques observés chez les adolescents après ce programme. Cette étude permet de mieux comprendre comment certaines notions intégrées aux thérapies cognitico-comportementales de troisième vague, comme la mindfulness, le non-jugement et l'acceptation, semblent jouer un rôle important dans le rétablissement d'adolescents qui présentent des comportements suicidaires et d'automutilation avec des symptômes de personnalité borderline. Ces résultats sont ainsi porteurs d'espoir pour l'intervention axée sur la résilience de jeunes qui étaient jusqu'à récemment considérés réfractaires aux traitements psychologiques. Il demeure que cette étude est basée sur un devis de recherche sans groupe contrôle qui utilise un protocole d'évaluation constitué uniquement de mesures auto-rapportées et qui comprend exclusivement des filles.

Abstract

Following the shelling of Qana (April 1996) which killed 104 people including 39 children and 24 women, and medical centers for psychological counseling for children victims of war and their families were established in Beirut and South Lebanon (Tyre, Nabatieh). These centers were designed on the same base like centers of medical and psychological consultations operating in France. Children and adolescents are treated with outpatient psychotherapeutic support. A multidisciplinary team of psychiatrists, psychologists and social workers support children who visit the centers. Since December 1996 until February 2014, 3,730 children and adolescents were followed-up which represents 27,000 consultations. Of these, 3730 were directly exposed to stress.

Key words: children victims of war, psychotherapeutic support, resilience construction

Evénement traumatique et travail de mentalisation

Un cas clinique, le cas de Hassan illustre les situations rencontrées dans le cadre de ma pratique.

En juillet 2006, lors des bombardements israéliens, Hassan âgé de 4 ans se trouve à Cana. L'immeuble où il s'était réfugié avec ses parents et sa sœur Zeinab s'écroule. Rabab la mère de Hassan réussit à sortir de sous les décombres son mari handicapé Fadi, son fils Hassan. Pendant qu'elle était à la recherche de sa fille Zeinab, elle confia Hasssan qui dormait dans ses bras à un voisin. Celui-ci croyant que Hassan était mort l'emmena dans une maison isolée où se trouvaient toutes les personnes décédées lors du bombardement. Cinq heures plus tard l'enfant se réveilla. Il était entouré de cadavres autour desquels les chats et les chiens rodaient. Il se mit à hurler, pensant que sa mère et son père l'avaient abandonné. Un jeune homme l'entendit. Il l'emmena chez sa mère. L'enfant saignait. Il était gravement atteint à la tête. Rabab la mère de Hassan, blessée au bras marcha seule avec son fils durant deux heures sous les bombardements israéliens. Arrivés au premier poste des Forces de Sécurité, la Croix Rouge transporta Hassan et sa mère à l'hôpital où ils reçurent les soins nécessaires.

Quinze jours après la tragédie qui a coûté la vie à Zeinab, la sœur de Hassan, j'ai rencontré l'enfant et ses parents. Durant l'entretien, Hassan s'exprime facilement. Il coopère, affirme bien dormir, ne jamais être triste. Il lui arrive rarement de pleurer. Hassan dessine une maison, des tanks israéliens, des hommes de la résistance libanaise qui tuent les Israéliens. Selon lui, sa sœur Zeinab est au paradis et il ne souhaite qu'une seule chose « mourir pour la rejoindre le plus rapidement possible ». Il ne présente aucun symptôme sur le plan clinique.

Interrogée à l'école trois mois après la tragédie, son enseignante affirme qu'il s'agit d'un excellent élève et tient le discours suivant :

« Je n'ai pas constaté que la guerre avait des effets négatifs sur le fonctionnement psychique des enfants… J'ai constaté que les élèves étaient très fiers des martyrs de la résistance …Il y a même énormément d'élèves qui sont fiers d'avoir eu leur maison détruite ou d'avoir perdu un de leur proche… Beaucoup d'entre eux souhaiteraient s'entraîner dans les camps militaires pour affronter Israël… ».

Cet enfant que j'avais rencontré en 2006, m'avait poussée à réfléchir et à me poser les questions suivantes : S'agit-il d'un enfant résilient ? Sera-t-il confronté à la désorganisation psychique ? Qu'adviendra-t-il si plus tard Hassan décide de ne plus être attaché au même idéal politique et religieux ?

Il y a 2 ans, Hassan et sa mère sont venus me voir au CMP à Tyr. Hassan se plaint de douleurs abdominales importantes sans aucune cause organique. Durant la consultation, Hassan qui a 7 ans ne peut pas rester assis plus de quelques minutes. Il se lève souvent, marche, déchire les dessins des enfants accrochés au mur puis s'assied pour se lever de nouveau peu de temps après. Hassan évoque ses peurs : peur d'être seul, peur

qu'on tue ses parents comme on a tué sa soeur. Il me raconte qu'il aime se défouler en cassant les objets, se décrit comme agité à l'école.

La mère quant à elle présente une angoisse de séparation importante associée à des symptômes dépressifs.

Je suis amenée à leur proposer une thérapie mère-enfant pour leur permettre de verbaliser leurs angoisses. Par ailleurs, Hassan bénéficie dans le cadre scolaire de séances d'art- thérapie.

Cette vignette clinique illustre bien le fonctionnement psychique des patients traumatisés. La décharge dans l'action constitue une particularité du fonctionnement de Hassan. Elle masque un éprouvé trop violent, source de maux dangereux et permet d'évacuer hors du psychisme une réalité impensable.

Le déni chez cet enfant ne pouvait se maintenir qu'accompagné d'une fuite motrice pour lutter contre la douleur mentale insupportable**.** Joyce McDougall [1] affirme que les patients qui présentent des somatisations et des agirs comportementaux ont besoin de rechercher dans la réalité externe « une nourriture perceptive adéquate ». Les perceptions venues de l'extérieur agissent ainsi comme des interprétations calmantes venues du dehors. Le surinvestissement du factuel constitue un contre-investissement anti-traumatique. Les solutions par l'agir, auxquelles peuvent être assimilées les manifestations psychosomatiques renvoient à une faille dans le processus de symbolisation. « Elles recèlent toutefois » précise McDougall « une lutte pour la vie, et notamment pour la survie psychique de l'être ».

La thérapie a permis à la mère et à l'enfant d'entreprendre le deuil de Zeinab. J'ai été amenée six mois après le début de la prise en charge à travailler avec le père. Le père dans son récit a évoqué plusieurs événements *séparés dans le temps.* La forme narrative du récit a permis que puissent se retisser des liens entre ce qu'ils étaient avant le décès de Zeinab et ce qu'ils sont devenus par la suite. Les capacités de mobilisation psychique du père, c'est-à-dire les instances de transformation et de médiation, ce que Kaës [2] appelle l'intermédiaire, en tant qu'il assure une fonction de « reprise sur une rupture maintenue » ont joué un rôle important dans l'évolution psychique de la mère et de l'enfant. Elles ont favorisé le travail de l'histoire et ont empêché l'évènement de s'inscrire en traumatisme.

Caractéristiques de la prise en charge des enfants de la guerre

Dans nos différents centres la clinique de la violence et du traumatisme se donne à voir dans sa richesse et sa diversité. Le psychologue est souvent confronté non seulement aux conséquences de la violence de la guerre mais aussi à la violence des parents à l'égard des enfants, violence des professionnels dans les institutions à l'égard des enfants, violence des enfants entre eux, violence de la société à l'égard de nos patients.

Violence et mentalisation nourrissent donc la réflexion des thérapeutes qui travaillent au Centre d'accueil de l'enfant de la guerre.

Le chemin que j'ai parcouru avec mes patients m'amène à m'interroger sur les spécificités de la prise en charge psychologique des enfants de la guerre et de leur famille. Comme dans tout suivi psychologique, la rencontre avec le patient est singulière. Chaque intervenant se présente comme un élément d'étayage possible prêt à se laisser utiliser comme objet contenant pour tout ce qui est difficile à supporter pour les familles. Le souci de l'autre est prédominant. L'autre avec ses valeurs, avec sa culture nous impose des rythmes qui ne sont pas les nôtres et qui entravent nos désirs. Ce n'est qu'à condition de reconnaître l'altérité, que le penser avec sera plausible et que le travail dans l'entre-deux du lien pourra être possible.

Dans le cadre de cette rencontre, le dispositif offert va renforcer les structures et les processus qui sont à l'interface entre le psychique et le social et qui aident à l'autoconservation aussi bien qu'à l'adaptation, renforcer l'aire transitionnelle de Winnicott. Il s'agit donc d'une relation qui laisse la place à la créativité et à la symbolisation. Elle confronte le soignant à des affects violents de colère, de honte et de culpabilité. Dans ces situations, comme le précise Winnicott [3], le thérapeute doit être un témoin compréhensif de la détresse de l'enfant. Sa reconnaissance non angoissée de la période difficile dans laquelle se trouve l'enfant-ce que Winnicott appelle « la compréhension favorable » est en soi-même une intervention

Mais souvent lorsque le patient est en danger le thérapeute ne pourra se contenter de l'intervention classique. Il faudra nécessairement impliquer l'environnement des patients et concevoir des actions pour transformer les environnements. C'est ici que notre travail devient difficile. Je pense ici essentiellement aux enfants carencés affectivement placés dans les institutions.

Pour permettre à ces sujets traumatisés de se reconstruire, les pratiques d'accompagnement comprennent nécessairement un travail de co-pensée avec nos partenaires. Il faut donc solliciter les différents acteurs qui entourent l'enfant et leur faire prendre conscience de l'importance d'un itinéraire de résilience.

Dans le traité de résilience assistée qui vient de paraître, Jean-Pierre Pourtois et Huguette Desmets [4] , Professeurs à l'Université de Mons fixent les critères qui permettent de distinguer les institutions de résilience : l'autorisation de la créativité, le respect de la temporalité du sujet, et le questionnement des procédures que l'institution produit. Il est important que les procédures ne fassent jamais l'objet d'une application routinière

comme c'est le cas dans les structures sociales d'aide traditionnelles. Dans celles-ci la force des habitudes et la contrainte des normes laissent peu de place à l'initiative personnelle du sujet.

Ce travail de co-pensée se révèle fructueux dans notre partenariat avec certaines institutions où les professionnels saisissent l'importance pour les patients d'établir un lien positif avec leur environnement proche et d'être accompagnées dans un développement résilient si celui-ci est possible.

Toutefois le bât blesse lorsque le lien social n'est plus possible, lorsque comme le dit André Green le rôle structurant et organisateur de l'autre se perd.

C'est le cas de beaucoup de nos patients n'ayant connu que des situations traumatisantes, suivis dans notre association pour la plupart depuis 15 ans, en situation de grande souffrance parce que vivant dans un contexte qui les disqualifie socialement. Il règne chez ces sujets une impression profonde d'inaccomplissement au sein de la communauté humaine et la conviction continue de ne plus pouvoir s'intégrer au sein de la société. La haine à l'égard de la culture envahit le champ psychique.

Je pense aujourd'hui en particulier à Odette, Elissar, Khalil, Georgette et à beaucoup d'autres. Georgette répète à chaque séance les propos suivants :

« Je déteste ce pays. Il ne te donne rien lorsque ta famille est inexistante. Il ne m'apporte rien, ne laisse aucune place à la différence. J'étouffe physiquement, psychiquement. Les libanais ne peuvent vivre que dans la guerre. Ils sont en guerre avec eux-mêmes, en guerre avec la société. Je veux partir. C'est une société qui absorbe. Soit tu te noies, soit tu te quittes. Ce pays ne connaît pas l'intermédiaire. Je veux partir et ceux qui ont choisi de rester, qu'ils se débrouillent, qu'ils assument leur choix ».

Se pose ici tout le problème de la déliaison sociale. Comment fortifier le moi de ces sujets lorsque l'étayage par et dans le socius est impossible ? Comment promouvoir la résilience de ces patients, leur permettre de tisser un lien identificatoire à l'ensemble humain lorsque les tuteurs de résilience et les réseaux de soutien sont absents ?

Conclusion

Je voudrai postuler ici l'existence d'un système anti-traumatique chez les enfants résilients. Dans ce système interviennent des facteurs individuels comme la constitution du sujet mais également des facteurs liés à l'environnement familial et social de l'enfant. Le développement précoce satisfaisant constitue la pierre angulaire de ce système.

Par ailleurs, dans les situations de guerre, les stratégies d'intervention que met en place le psychologue contribuent á renforcer la résilience des patients. Le thérapeute par sa capacité de penser doit parvenir à contenir ce qui est exprimé de l'angoisse des patients et à le leur restituer sous une forme assimilable qui puisse donner lieu à une transformation de leur psychisme. La liaison consistera en cette activité de transformation. Mais parfois, malgré le travail thérapeutique, la violence du destin continuera à agir à l'intérieur de soi en ne trouvant aucune transformation, aucune transaction, aucun déplacement possible. La réalité externe avec son effet de discontinuité nocif dominera la scène. L'entourage ne pourra pas jouer son rôle de pare-excitations. Seule ici le travail de la culture sera décisif pour la continuité de la vie psychique, travail de culture qui tentera de trouver les mots pour décrire l'expulsion hors du monde civilisé, la barbarie des actes. Il permettra à certains sujets d'assumer leur mémoire pour qu'elle devienne une mémoire dynamique pour l'avenir.

Abstract

The paper presents the evaluation process of the projects financed by MOL and by the „Foundation for Community", *a MOL Program for Children's Health"*. The program has been implemented for 5 years, during which 7357 children and adolescents had the chance to benefit from art therapy and emotional therapy. The beneficiaries of the project were children and adolescents under 18 years who had different deficiencies, chronic disorders, children recovering after severe disorders or children with permanent severe disorders (for example tumours, psychiatric disorders, lymphatic, endocrinologic, respiratory, digestive, motor disorders etc.). The evaluation of the projects submitted is a complex process, having very strict evaluation criteria. The evaluation team is formed by experienced specialists in the fields of psychology and special psycho-pedagogy. The criteria used for the scoring of the projects are presented (the formal and professional requests). The main objective is a proper, efficient evaluation of a project, in order to select the best projects, so that as many children and adolescents as possible can benefit by emotional and art therapies, leading to resilience and psychological and physical wellness.

Introduction

The paper has the purpose to present a health program with a significant national impact, regarding the emotional and art therapies for children with disabilities, chronic disorders and at risk for different problems. At the national level, the objective of this program is to promote the alternative therapies, such as emotional therapy and art therapy, complementary to the medical, social, psychological, psycho-pedagogical and educational services. It is not easy to define what can be included in emotional and art therapy, because the majority of the therapies influence the emotional experiences and these experiences can be expresses in a variety of artistic ways.

Our experience shows that many therapeutic activities are able to improve the physical and psychological states and to help building resilience in the persons being at risk. Art therapy can be related to the concept of resilience. Some authors stress the possibility of discovering indicators of resilience in the artistic performances of the patients who had suffered a trauma and were involved in a program of art therapy [4]. The processes and mechanisms through which art therapy contributes to the development of resilience are related to creativity, to the ability of creating something new and special, leading to a positive effect on the self-esteem. The making of an artistic product or the simple process of artistic experience gives the person the opportunity to express his intimate feelings which, in some cases, especially in children, cannot be easily verbalized. Resilience is more than just an adaptation to adverse conditions or just surviving them. A person is not resilient besides the adverse conditions, he is resilient due to these conditions. The experience of extreme stress can help the person to discover the strength which he might not have been aware of, to do things he did not think he was able to do. *The MOL Program for Children's Health* finances the projects that involve art therapy and emotional therapy. These methods are the best for discovering and developing resources and hidden talents and for learning new techniques and approaches for problem solving.

1.1 Art Therapy

This form of therapy teaches children, adolescents and even adults to freely express their feelings, thoughts and preoccupations. It facilitates creativity and confidence in one's own capacities. All these are possible through the guidance of specialists, in the process of assisted resilience. Art therapy is a strong

"instrument" used in the therapy of children suffering from cancer [1]. It enables emotional expression, imagination and it is indicated for the ill children and in the strengthening of resilience [6].

1.2 Emotional Therapy

The emotional therapy must not be confused with the Emotion-Focused Therapies (EFT) or with Rational Emotive Psychotherapies (REPT), where the focus is on the emotional experiences, the patients being helped in identifying, expressing, exploiting, transforming and managing emotions. In the case of children and adolescents, the mechanism through which emotions are controlled or influenced is different than the one used in the emotion-focused therapies. The mechanism is an indirect one, implying therapeutic activities which offer the opportunity to process the emotions connected to the illness or disability.

1.3 Art Therapy, Emotional Therapy and Resilience

Group art therapy and emotional therapy gives the children and adolescents the opportunity to meet other persons dealing with the same or similar situation and to approach problems in a secure environment, where other people (children, adolescents, adults) can understand the difficulties related to different traumatic situations. This fact is very important for building resilience. In all therapies, not only art therapy, the therapist is the mentor of resilience.

1.4 Strengthening the resilient factors through the MOL Program for Children's Health

The research shows that certain school, family and environmental factors can modify, alter or even reverse the expected negative consequences of some situations experienced by the children and that these children can develop resilience in this risk situations [2,3]. The program aims to enable all the factors that can have a role in the development and strengthening of the beneficiaries' resilience, involving as many persons as possible in this process: family, caregivers, specialists from different domains. It does not focus only on the problem and the child, but on the whole environment of the child, promoting a systemic approach.

Methodology

The project does not consist in a simple intervention, on a specific target group. It has a broad approach, thus the methodology is a complex one, implying a variety of interventions designed for different target groups.

1.1 The target group

The target group is formed by children and adolescents under 18 years, who suffer from a disability or a chronic disorder, children recovering from a severe disorder, children having a permanent severe disorder or children at a high risk for developing a somatic or mental disorder (children with a psychiatric disorder, children passing through a mourning process, children who suffered emotional/physical trauma, adolescents with addiction problems or children form fostering centres). The target group is not a specific one, including a variety of disorders and difficulties. During the 5 years (2009-2013) of the *MOL Program for Children's Health* development, 90 projects were financed and 7357 children were included in these projects.

1.2 Selection of the participants/beneficiaries

During time, there are more and more associations and specialists who aim to support the families of children with special needs and at risk. Thus, the number of art-therapists and specialists in the domain of mental health, psychology and special education who use this type of therapies has also grown. We will present the target groups from different years, according to applications and funding. Considering the various types of disabilities and chronic illnesses, they were grouped in the following way:

1.2.1 The target groups in 2012

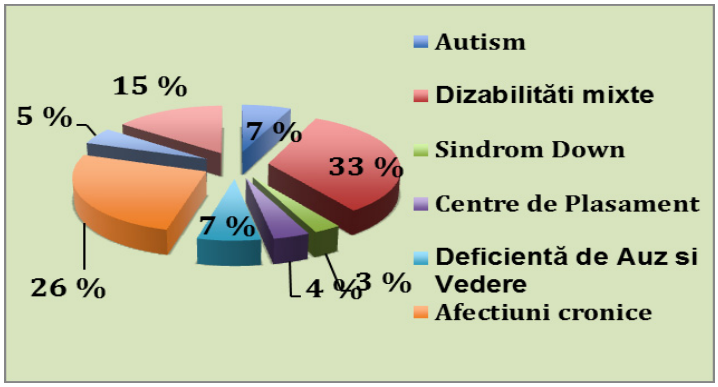

Figura 1. *The distribution of the target groups of the applicants (Funding for Children's Health, 2012), N=3994*

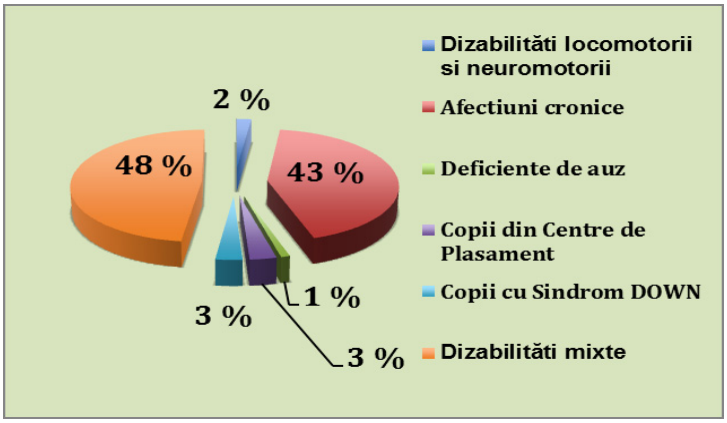

Figura 2. *The distribution of the children who benefited from MOL funding in 2012 (N = 778)*

In 2012, the majority of the projects had as target groups children with Down Syndrome, children with different disabilities and children and adolescents with chronic disorders (Table 1). In this year, out of 12 projects applying and targeting children with autism, none received funding. The most frequent target groups which were financed were the mixed groups.

Tabel 1. *The number of applications, financed projects and type of disabilities (2012).*

	ASD	Down S.	Mixed	FC	Sight and Hearing deficiency	Chronic disorders	Locomotor and neuromotor disorders	Others
Applications	12	6	49	6	6	25	1	3
Financed projects	0	1	9	1	1	6	1	0
					Total of projects receiving funding			19
					Total applications			108
					Rejected projects			2

ASD – Autism Spectrum Disorders
FC – Fostering Centers
Others: emotional and behavioural disorders, speech and language disorders, respiratory disorders

Target groups in 2013

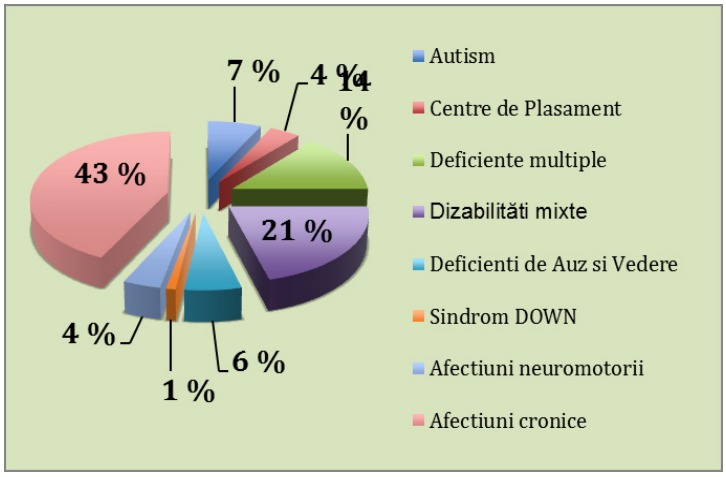

Figura 3. *The distribution of the target groups of the applicants (Funding for Children's Health, 2012),N= 4527*

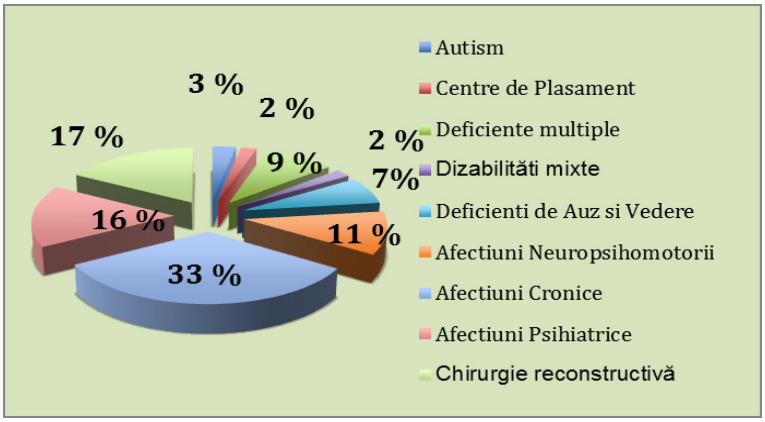

Figura 4. *The distribution of the children who benefited from MOL funding in 2013 (N = 590)*

In 2013, the majority of the projects had as a target group the children with mixed disabilities and chronic disorders. When comparing the target groups from 2012 and 2013, we can observe a significant rise in the number of the target groups with chronic disorders. In 2013, the projects targeting the Down syndrome and mixed disabilities did not receive funding. We need to mention the fact that the classification of different disorders is not one hundred percent precise. Tables 1 and 2 show that the target groups of children with Down Syndrome was much smaller in 2013 than in 2012, but this is also due to the fact that we formed a new target group, the one including children with multiple disabilities, where we can include the Down Syndrome as well.

Table 2. *The number of applications, financed projects and type of disabilities (2013)*

	ASD	Down S.	Mixed	Multiple	FC	Sight and Hearing deficiencies	Chronic disorders	Locomotor and neuromotor disorders	Others
Applications	12	3	30	25	7	7	41	6	2
Financed projects	1	0	1	2	1	2	7	3	1

Total of projects receiving funding	18
Total applications	150
Rejected projects or projects without a specific target group	17

ASD – Autism Spectrum Disorders
FC – Fostering Centers
Others: two types of therapies (reconstructive and plastic surgery), respiratory and speech deficiencies.

1.1 The formal base of the project

Currently, there are 150 projects, out of which 18 winning projects need to be selected. In comparison with the preceding years (2009-2013), the number of projects is significantly higher. There are even more projects than in Hungary. This is a proof of a high interest in children and adolescents' physical and mental health. Each applicant aims to offer social and psychological support for the ill children, adolescents and their families, proving, in most of the cases, seriousness, devotement and professionalism.

1.2 The evaluation of the projects

1.2.1 The evaluation process

The evaluation of the projects is a strict process, having different stages and involving many specialists. The evaluation has two phases. The first phase is the formal one, implying the consideration of formal requests and the second one consists in the professional evaluation. It involves two-four specialists from the fields of psychology and special psycho-pedagogy. A project can receive a maximum score of 100 points. The scoring is based on rigorous criteria, being only a landmark for the jury. It does not mean that the funding of a project is only decided based on the high score.

1.2.2 The evaluation criteria

1. The previous experience and results of the NGO regarding emotional and art therapy programs.
2. The selection of the target group and the evaluation of needs.
3. The project's feasibility and the achievement of the objectives.
4. The effects aimed by the project and the measurability of the results.
5. The project's framework, the methods used and the time management.
6. Originality and efficiency of the procedures used in the project.
7. The previous research experience of the project's leaders.
8. Evaluation of the financial planning, regarding the effects, costs and feasibility.
9. The congruence between the program announcement, formal requests and spreading of the information to a larger audience.

The majority of the criteria are published on the association's site www.pentrucomunitate.ro and they are part of the application form.

1.3 Methods for strengthening resilience

The most frequent used therapies in the projects focus on the combination of many techniques and therapies. This fact is easy to understand if we consider the different needs of children having different disorders, For example, combing family therapy with play therapy is considered an efficient combination for strengthening children's resilience [5,7]. Other types of therapies which were financed were the therapies with animals (dogs, horses), meloptherapy, therapy based on photography, painting, drawing, dance, sport, multi sensory therapy (Ayres) combined with art therapy, pottery, therapy based on movie-making, emotional therapy+art therapy, adapted to different diseases (for example cancer), hydrotherapy, narrative therapy, play therapy, psychodrama, theatre, eurythymia, occupational therapy, experiential therapy.

1.4 Results evaluation

The evaluation of the result is made by each Association, using individual evaluation methods. In most of the cases, the questionnaires are common. They are adapted to the program, to the children's needs and types of disorders. They evaluate not only the effect on the children, but also the satisfaction and the effect on the professionals (for example, in the case of paediatric oncology – the doctors, the nurses) and on the caregivers involved in the projects. The global evaluation of the entire project is based on a questionnaire regarding resilience. The data are in the analysis phase.

Conclusions

Usually, this kind of therapies is used for a longer period of time (except for the camps), leading to the development of resilience. The children and their families are passing through a long process, having enough time and space to build a therapeutic relationship. We consider this relationship the base on which resilience can develop.

Besides a formal, professional evaluation, in order to score a project, the role of the evaluators consists mostly in the observation of some invisible, but relevant aspects of the projects. These aspects are difficult to score and to be evaluated formally.

In the evaluation process, a cornerstone is the efficiency of the therapies and their attunement to the children and adolescents' needs, the ability of approaching new techniques in a creative and efficient way. We also consider of great importance the building of physical, professional and technical conditions for the development of this kind of programs in different regions of the country. The evaluation needs to be as efficient as possible, leading to the selection of the best projects, the final purpose being the physical and psychological wellbeing and the development of resilience of the children involved in the projects.

Abstract

Deaf children having an impairement in hearing and speach are considered at risk to have difficulties in language, communication and relationships across the life span. Confronted with trauma of implantation and wearing hearing devices (that make them also dependent on technique in perception and interactions with their environment) those children need an early systemic approach to promote resilience processes.

The research – action project called "The play breaks the silence mask" targeting deaf children with cochlear implant or hearing aids, aged between 3 and 18 years. It was designed by the "Audiosofia Association" and funded in 2014 by "Community Foundation" and MOL Romania. The activities were coordinated by seven professionals volunteers (psychologists, speech therapists and teachers) in Bucharest in a residential kindergarten and a private medical clinic. The paper presents the partial results obtained from group therapy play sessions, attended by a total of 77 children aged between 3 and 7 years (12 deaf children interacting with peers - the 65 hearing children, most of them having emotional, language and learning difficulties). Through the play and drama therapy, children in this project have had the opportunity to express themselves freely in a safe therapeutic place.

The 15 therapeutic meetings were divided in rhythmic and physical activities (embodiment), activities of painting, drawing and modeling (projection) and storytelling dramatization (role), aiming at paradigm embodiment - projection - role (EPR). At the final drama representation, in the end of the program, each child (choosing his role in the play,) proved to be valuable in the group interactions and capable actor in front of parents, friends, teachers and specialists. The results are discussed in terms of the assisted resilience concept.

Key words: cochlear implant, hearing aids, assisted resilience, play therapy, drama therapy, embodiment-projection-role (EPR)

Introduction

"Increasing numbers of deaf children receive most of their education in general education classrooms. These students may not have easy accesses to peers and adults with whom they can communicate; consequently professionals have expressed fears that these students will be socially isolated and lack opportunities to develop the social competence for success.

The dynamics at play between various factors in a deaf child's development are complex, multiply determined, and subject to influences that cannot be predicted. Risk, protective factors, and resilience can be seen as independent, though related, constructs. Children experience different levels of risk. Some children with limited internal resources and born into impoverished families struggling with mental health issues may be at very high risk; those with great internal resources born into families that are well supported and capable may experience less risk.

Deaf children have long been considered a population at risk for difficulties in developing social competence because of the negative effects of hearing loss on language and communication development. This is particularly true for deaf children of hearing parents.

More recently, researchers studying the development of Theory of Mind suggest that language focuses children's attention on mental explanations of behavior and provides them with a vocabulary for abstract concepts such as thoughts and feelings (Schick, de Viliers & Hoffmeister, 2007). Such a vocabulary, in turn, plays an important role in understanding the feelings, motivation and actions of others that is essential to the development of social relations. The lack of full accessibility to language and communication therefore can negatively influence deaf children's social development.

Although the literature in deafness is limited, there are a number of factors that are important in helping deaf children to achive a variety of kinds of successful outcomes. Rogers, Murir and Everson (2003) have provided an excellent review of the literature in deafness and resilience. There exist only a few studies and most of these are theory-based or use a case study approach. However, these authors identified 13 factors that they grouped into three general categories of "assets". These are:

a. Interpersonal Assets, which include a good sense of humor, caring, responsible and committed to worthy goals, a strong sense of social bonds, emotionally self-perceptive, awareness of strengths and comfort with solitude.
b. Environmental, which include quality time caring mentors in school, positive learning partnerships with peers in college, supportive family environment and rich opportunities for participation in the community
c. Behavioral Assets, including self-advocacy, self-reliant, goal-directed behaviors and persistent solving, and authentic presentation of self." [6]

Goals

"The play breaks the silence mask" aims to increase the resilience factors of deaf children. It especially addresses to children with hearing loss (with cochlear implant or hearing aids) aged between 3 and 18 years through a program of play and drama therapy. Involving the professionals volunteers (psychologists, teachers, speech therapists) in this project gives him a strong character for research - action, both being achieved simultaneously.

From the perspective of the concept of assisted resilience the project proposed by the team of professionals, to introduce the appropriate therapeutic elements, for identifying resources for all children participating in the project and their potentiation.

Through two kinds of techniques, play and drama therapy, children are able to externalize emotions, to express themselves, to access their inner feelings, ensuring a preventative mental health character for project. The aim is to improve the quality of life of deaf children in the hearing children community, their valorization, increased self-esteem, stimulating nonverbal communication skills and awareness of the needs of these deaf children by families and communities. Participants in group therapy are both deaf children and hearing children. The rationale for the project was designed in this manner is to succeed in reaching another very important purpose: normalization and acceptance of deaf children hearer community.

Hypothesis

The way for the deaf and hearing children communicate without barriers is play and body movement. Play and drama therapy offers this opportunity. So they can find common language of nonverbal communication, which will come out the affinities than the barriers that separate them.

Methodology

On the first project's step an intensive program was planned for 77 children (5 with cochlear implant, 7 with hearing aids and 65 with normal hearing) aged between 3 and 7. A lot of children with normal hearing have behavioural, emotional, learning and language difficulties.

No. Group	No. Deaf children	No. Hearing children	Age (years)	Total number of children
1	2	16	3-5	18
2	2	16	3-5	18
3	3	16	5-7	19
4	2	16	5-7	18
5	3	1	3-5	4
TOTAL	**12**	**65**		**77**

All the 15 sessions were divided in physical and rhythmic activities (embodiment), painting and modeling (projection) and drama and stories (role), based on the EPR developmental paradigm (embodiment-projection-role) [4].

Each therapy group received 15 sessions (one per week for 60 minutes). During the period 22nd January to 30thApril were operating in the 5 therapy groups, and during the period first of May to15th August to run the activities of other two groups. Interlace will be held two national cochlear implant summer camp, for two weeks during in August 2014.

Working techniques used in the project were specific to play and drama therapy: drawing, painting, modeling in clay and plasticine, play with miniatures, handling puppets, play with sand, multisensory stimulation, making and painting masks, role play, storytelling, theater techniques, improvisation techniques. . Each therapy session was divided into three essential parts:

-1) beginning and heating activities (15 min)
-2) the activities for the specific theme (30 min)
-3) closing activities (15 min)

At the beginning of the first session were agreed rules of the group, who were reminded at each meeting in order to ensure a secure space for all participants in the group. This manner of conducting sessions used to children with a predictable framework meant to provide confidence. The end of the meeting was marked each time specifically to facilitate exit from the play activity or of the dramatic reality.

Results

Preliminary results were obtained after completion of the first phase of the project. On the first step were attended 12 deaf children and 65 hearing children. Activities of five therapy groups were held in two different locations: Section 6 Recovery audio- verbal disabled children (residential kindergarten) belonging to IFACF - ORL "Prof. Dr. Dorin Hociota" and private medical clinic "Otomed Medical Center" from Bucharest. The five therapy groups were coordinated by a team of six volunteers (psychologists, speech therapists and teachers) supervised by the project coordinator.

The results indicate that the initial objectives in terms of increasing resiliency factors were achieved.

- Since the first meeting was a significant improvement the communication strategies of the deaf and hearing children also
- We have improved the difficulties regarding the possibilities of expression by removing the many barriers of communication
- Ritual-risk evaluation sheets indicate a getting the balance right, meaning that a significant progress in terms of taking initiatives anxious children
- Degree of acceptance and tolerance towards those with hearing children increased, participating equally to all proposed activities
- Every child has made a contribution to group activities, strengthening the sense of belonging to the group
- Introverted and anxious children being able to fully unfold before the group and with it, they become less inhibited
- Extroverts and hyperkinetic children's manifestations have adjusted so as to accept the group.
- Specific embodiment, projection and role play have removed some barriers, supporting the development and strengthening weak sides are the most striking
- Children participated with great pleasure and medical meetings as the process advanced, became more open, more creative and uninhibited
- A sense of humor is one of the important resilience factors, and it has appeared at every meeting
- Through the theater every child had the opportunity to show off his strengths to the group, parents and community
- Parents feedback were positive assessments regarding the immediate effects of therapy on children
- Parents have realized the need for children to express themselves in various ways, not only through the language
- The professional team has undergone training and practice constructive play and drama therapy techniques, providing the quality of assisted resilience
- Nature of the research project, action and volunteer training is done simultaneously, a process underway

Comments

Strategies and techniques of play and drama therapy is an appropriate way to approach deaf children. They had the opportunity to develop communication skills other than speaking, had the opportunity to meet in

play the hearing children, to be appreciated in group, had learned the importance of teamwork. They had the joy of their contribution into the group and learned how to observe certain rules. Internal resources of the children were stimulated and encouraged by group, thus preventing certain exacerbated or inhibited events to expression of emotions. Were given the opportunity of sharing common experiences, and their senses were stimulated in various ways. They experienced new situations and have learned that it's normal and natural to make mistakes in a space and safe environment, surrounded by trust people. The professional team was prepared to manage and contain the emotions whatsoever they were.

Deaf children's thinking in general is very concrete, their mental structures are very accurate, which reduces the possibility of the creative, inventive and artistic side. By participating in this play and drama therapy project they had the opportunity to explore and experiment this side also, resting left. Given the considerations mentioned, deaf children with speech and language difficulties, are ideal candidates for this therapeutic approaches styles.

Conclusions

Partial results indicate the positive effects on the resilience factors of all children who participated in therapy groups. In Romania are becoming more and more deaf children receiving cochlear implants or hearing aids. They are integrated into regular schools and their needs are major in terms of communication by any means. Through play and drama therapy can be provided the assisted resilience of these children. Given these issues, it's proposed to continue this project in the future.

Group resilience, community support and associative behavior – lessons learned from a grant scheme program

Ciumăgeanu M.[1], Predescu S.[2], Tar G.[3], Stan V.[4]

Abstract

Associative behavior is largely related to both increased group and individual resilience. Associative behavior is linked with other behavioral and emotional variables that are linked to increased personal and group resilience - togetherness, helping others, sharing hope and other positive future oriented feelings. One might consider that reciprocal positive modeling is one of the main factors that shape both individuals and groups to be resilient. The paper discusses from a qualitative point of view the resilience factors that were involved in groups that attended a small grant scheme of the "For the Community Foundation", where the authors are member of the grant-awarding jury. In depth qualitative interviews were performed with winners of the grants (two subgroups – multiple winners and single winners) and were contrasted with groups that were rejected (multiple rejections, several years in a raw and single rejecters). Quantitative analysis reveals a strong increase in context-oriented resilience-related behaviors for multiple winners, but also some counterintuitive mobilization of individual resilience factors in the multiple rejection groups. There were no medium and long-term modification in the single winners or rejected groups. In the discussion part, the authors imply a link between community support and group resilience and the urgency of the development of small-grant schemes in the Romanian NGO environment from a resilience point of view.

Introduction, conceptual issues

Nowadays, positive psychology and the resilience movement have moved the focus of study in the well being of children from psychopathology oriented variables towards the exploration of critical issues connected to health promotion and prevention. If sometimes variables such as the child behavior, unconscious processes and thoughts can contribute, along with the attachment patterns, to maladaptive behaviors and poor emotional health, wouldn't we expect to conclude that similar combinations of factors can contribute to positive and adaptive behaviors?

Resilience can be considered an essential topic of positive psychology, defined as "the ability to thrive, mature, and increase competence in the face of adverse circumstances or obstacles" [4]. One can sustain the necessity of a broader perspective, which implies an explicit negative and adverse context that opposes the individual – form this point of view, resilience is a "process, [a] capacity or outcome of successful adaptation despite challenges or threatening circumstances... good outcomes despite high risk status, sustained competence under threat and recovery from trauma" [8]

Short and simple, resilience can be defined as a *dynamic process encompassing positive adaptation within the context of significant adversity [7]*. Historically, the concept was initially brought into discussion linked with the study of surviving severe mental illness (both in the study of afflicted individuals and their children [2][3].Emmy Werner's studies encouraged further research on resilience to include multiple conditions such as socioeconomic disadvantages, parental mental illness, maltreatment, poverty, chronic illness and catastrophic life events, in a systematic search for protective forces that could differentiate the children with healthy and resilient adaptation profiles from those who were less well adjusted.

One of the main issues that emerged, as research was progressing, was that of internal vs. external factors that influence resilience. Subsequent research yielded three sets of factors important to the development of resilience (1) characteristics of the children themselves, (2) aspects of their families, and (3) characteristics of their wider social environments [9]. In the last quarter of a century, the focus of empirical research shifted away from the identification of protective factors towards their conceptualization and understanding. Instead of

understanding with child, family or environment may contribute to positive outcomes, the focus is nowadays on how such factors can contribute to positive outcomes (Luthar,1999).

The Romanian context

Romania as a micro- and macro-context (family and community level) is an appropriate target for studying resilience issues. Socio-economic inequalities, family distress, poverty, poor mental and medical quality of care, at least in comparison with other member countries of the EU, are a basis for identifying a *context of significant adversity* for a large proportion of the young population. Specific cultural issues (the existence of two Romanias – a urban, cosmopolite one and a rural or small-town disempowered Romania, significant marginalization or stigmatization of Roma people, people from the LGBT subculture or people with mental health problems) bring together a very specific context of adversity.

Living in Romania is a matter of overcoming negative narratives regarding hope and disempowerment, especially at the rural marginalized end [1]. Romanian children are occasionally subject of resilience studies, especially adopted children [5], for example, but there is no coherent line of study of resilience factors involved, either to compare them to large scale studies, or to attempt to identify specific cultural context-related variables.

The Romanian macro-context is, for the moment, one of the most ignored variable – one legitimate research question is if the manipulation of community or societal variables could lead to increase in resilience resources accessible to children or youngsters. Analyzing such hypothesis is quite spurious, since there are a lot of possible mitigating variables. Therefore, the results of our inquiry is more heuristic than definitive, but it could lead to some interesting speculation about supporting communities in becoming more resilient.

Associative behavior & community support in Romania

Four decades of communist regime potentially destroyed the candid associative structure of Romanian communities. Associative traditions of the Romanian rural society or of the urban ones (related mainly to Hungarian, German or Jewish communities, more representative for the urban communities, even if urban civilization got a boost for Romanians between the two world-wars) got lost or become either obsolete or perverted. Romanian associative life got a new (and one might say fresh) start after the fall of the Communism in 1989. NGO's and civil society – as potential hope sharers and bearers – became slowly a growing partner of the resilient child.

Large organizations, inspired or powered by their international counterparts (as Save the Children Romania or Romanian Angel Appeal) have already more than two decades of programs for children and adolescents, and their programs had several locally and internationally acclaimed successes. These large NGO's, however, sustain a top-down approach and sometimes participate more to alleviating distress at the beneficiary level (children especially) and not directly supporting resilience empowering measures – at least, from a subjective point of view of the authors, there is no covert focus on resilience in the programs of the large NGO's, and a lot of the activities of these organization is focused on the funding that is available – Romanian Angel Appeal, for example, started as an NGO focused on the well-being of Romanian HIV positive children and has now a large focus on youth and children and on autism developing policies, Save the Children started with the endorsement of the Children Rights Bill, and has now several programs focused on internet safety, prevention of violence and child trafficking, but also in mental health prevention and parenting.

Large funding for projects in behalf of marginal communities, of children in distress or for specific issues is available at the moment, especially through the instrument of the European Funds. These schemes of funding risk, however, to leave a lot of blind spots at local level, since only large scale NGO's or local administrative structures, usually at county level, have the manpower and knowledge to access and administrate these funds. Community-level programs and local initiatives are still scarce, and micro funding (either provided by local charities, by the local administration or by other funding agencies) is seldom and inconstant.

Taking into account all the above-mentioned features, small grant scheme programs and micro funding is one of the missing links that could account for a boost in community solidarity and possible increased resilience. Small grants are, at least in theory, more suited for mobilizing both formal and informal resources and to encourage proactive initiatives at the direct beneficiares level. Continuity in micro-funding is also a premise that the targeted population, through an increased level of awarness of existing support, is more involved in searching for further resources and is a good hope-instilling initiative.

The programs of the "For the Community Foundation" – an NGO supported by MOL (MOL Group is a integrated oil and gas company from Hungary, operating in more than 40 countries) are in line with the logic of micro-funding and with the supporting of small initiatives at the community level. The program of the foundation called "MOL Program for Childrens Health" started in 2009, offering micro-funding with a maximum of 20.000 Romanian Lei per application, the rough equivalent of 6.250 USD. This program is one of

the very few offering micro-funding for projects that aim the childrens well-being in Romania, and it is the only that is offering such financial support on a constant basis nation-wide.

In the last five years, the program had a constant growth in the number of application, even if the total amount of funding was the same, around 90.000 USD, accounting for a maximum of 20 integral or partially funded projects. In 2013, more than 150 applicants competed and 18 of the projects were funded. As members of the jury, the authors of the present paper inquired how this project could foster community growth and increase resilience both at community and individual level.

A qualitative study

Taking into account that the project is already in its fifth year of activity, the authors had the possibility to inquire about its impact at community level. Both winners and apllicants that were rejected were approached by the research team and asked to answer a survey.

Abstract

The MOL Child Healing Program is aimed for NGOs organising adventure and arts therapy activities for promoting psycho-social rehabilitation of chronically ill children.

In case of chronically ill children the programs offer a possibility to better struggle mental and physical stress caused by the hospital residence period. The development for mentally and physically handicapped children is a daily need lifelong and can raise the life quality for themselves so as for their families. For them these special development therapies become more motivating than routine exercises. The adventure and arts therapy programs are part of the primer prevention in case of children and youngsters considered as risk group from the point of view of mental hygiene.

MOL Child Healing Program has become a regional support program offering financial support since 2006 in Hungary having granted already more than 280 projects.

Keywords: adventure therapy, art therapy, chronically ill children, psychosocial rehabilitation, resilience

Introduction

MOL Child Healing Programme is aimed to support non-profit organizations providing adventure and art therapy programmes to promote the psycho-social rehabilitation of chronically ill or physically or mentally handicapped children as well as the children and youth considered to be a risk group concerning mental health. The MOL Child Healing Programme has been providing support for more than 280 rehabilitation programmes since 2006.

When children are fighting chronic illnesses the rate of success also depends on how vulnerable and sensitive they are to risk factors, whether they have a kind of capability for flexible resistance, or resiliency. A number of different protective factors can give a chance for the person affected by a risk to avoid the unfavourable outcome. The assumed protective effect of the MOL Child Healing Programmes can also be interpreted or examined on the basis of the models defined by Garmezy and his associates [1], the compensation model, the challenge model and the immunization model.

The intervention methods supporting the adaptive fight types of the MOL Child Healing rehabilitation programmes show a strong similarity with a lot of key notions of resiliency, such as insight, endurance, self-reliance, establishing relationships, taking initiatives, creativity, moral sense and sense of humour [2].

Two sample projects are introduced below in detail.

Relationship therapy between children and parent with psychodynamic movement and dance therapy

In a central Children's Clinic of Budapest (Heim Pál Hospital) a pioneering project the elements of psycho-dynamic movement and dance therapy were introduced by the Ladder Foundation in a series of sessions for parents and their children to foster relationships therapy. At the beginning of each section both the children and their parents participate in the block of movement therapy exercises, then the children and the parents proceed with the therapy in separate groups. The therapy with the children includes movement, and expressions of the self through drawing and painting, while the work with the parents is carried out verbally.

The programme is aimed at working with the children not in an isolated, but with the therapeutic involvement of the parents, which makes the process more efficient. With the families where the child's problem has developed as a result of the corrupted child-parent relationship, this method is especially effective. Concerning diagnosis the combination of the groups is quite varied as the groups integrate children with different difficulties at different levels, but fighting with different conformity, integration, behavioural and emotional disorders is a problem for nearly each of them.

The process develops in 8 executive weeks, each daily session takes 1.5 hours, and in the middle of the course there is a one-day intensive consolidation programme. The framework of the process is rendered by a starting and a final interview with a parent. The group sessions are held under the joint leadership of a psychologist and a dance and movement therapist. The parent group is led by a psychologist and psychotherapist pair.

As a result of the group sessions most of the children become free of their earlier symptoms, or they have to cope with fewer symptoms. There is also often feedback from the parents if they have also undergone changes as a result of the sessions, which makes changes for the children also easier. One of the main changes they experience in their everyday lives: They understand each-other easier, carrying out the tasks become „smoother". As a result they can spend more quality time together, which against makes their relationship stronger. Many people are unable to express their love or affection nonverbally, in the language of touches. However, through the exercises during the movement therapy they have to touch each-other, which also brings their souls closer, makes intimacy deeper, and opens up new channels of communication. The group leaders often experience that the parents explore a new side of their children.

The psychodynamic movement and dance-therapy is a self-recognition and therapy method approved and accredited by the Hungarian Council of Psychotherapy, where movement, feeling and experiencing the body are in the focus of the correction process. If people move, they sense and accept their body in a new way, it may contribute to looking at their life-history in a different way, too. While realizing and making aware ourselves of our own feelings the global sensations become more varied and diverse, which helps us differentiate and realize our feelings and open up a way for self-reflexion on a physical (body) level. The movement exercises are structured, planned and themed well enough to bring the members into a psychological work situation; at the same time they are flexible and free enough to let their relationship dynamics evolve and their individual solutions break through. Falling out of their usual patterns and roles they can experiment with new points of views which can help them to utilize this skill in their everyday lives as well [3].

Summer camp program for children living with spine curvature

Vertebra Foundation was created to support those living with spine curvature. The Foundation strives to reduce the psychological burdens of the young people having undergone an operation or those suffering from the permanent wearing of corset by providing them proper information, organising community and relationship-building activities and by offering community experience events. By revealing the joyful side of a life in corset, the most important aim is to get the children to participate in a long-term cooperation after they have had positive experiences even though they were wearing their corsets, and the 23-hour corset-wearing should become reality even for those who had had problems with wearing it earlier [4]. To achieve this goal the motivating force of the community, the peer-impact and the combined power of the positive experiences are unified.

Our summer camp called „Scoli camp" has been organized for 10 years, and since 2010 winter camps have been added to the programme as well.

The bigger part of the camp activities include special physiotherapy mixed with different games, competitions, various sports activities and self-knowledge sessions all led with the conscious application of therapeutic recreation methods.

An important asset in the camp is the helpers or specialists (special needs teachers, physiotherapists, as well as orthopaedic specialists and mechanics) and the great number of the task leaders, the adults who earlier used to wear a corset themselves.

During the last 10 years a total of 850 persons experienced the adventures of the camp and the number of the children and the youth participating in the programmes throughout the year amounts approximately 150.

The most important result of this period is to show the people, to make the society aware of the conservative way of treatment of the spine curvature, i.e. the corset. This is closely related to the effect mechanism of resilience: if the person concerned knows what is to come, what to expect, it will not affect them as a shock, and on the other hand they do not have to face too many negative reactions coming from outside, therefore the trauma caused may be much less as well. As a result during the long years of treatments the psychical resources of the individual do not have to be wasted on self-pity, or resolving the problems of self-esteem, but the person can see himself/herself, the illness and its treatment from a different perspective. What earlier seemed to be such an enormous sacrifice and trauma what the individual was unable to come to terms with can become also an advantage as a result of the camps (among others). The young person can overcome

their own limits, finds in it a new challenge, a positive potential. They are motivated not only by healing, but also by the challenge, whether they can do it. For an adolescent it is a big achievement to look back at the end of the way and to be able to say: I did not believe I'd be able to do it, but I have done it! I have overcome myself! Such a trial of strength provides immense energy, confidence and healthy self-evaluation, and such experience for the challenges later in life that the person can safely reach back and rely on them

Children's cooperation in the treatment is also an achievement, that in spite of all the difficulties and failures they persevere, they chose the more difficult way instead of simple rejection and resistance, and later, even if medically there is no justified improvement, they can regard themselves as „hero's", winners, as they have overcome obstacles that many adults would not have been able to do. The child in corset knows their power, can fight, and knows what it means not to give up. Such a serious tour de force brings about positive changes in the personality of the child as well: they become more mature, more determined.

Conclusion

The psycho-social rehabilitation programmes of MOL Child Healing Programme can be interpreted as a protective device for the persons participating in it, as an intervention to promote the individual's flexible resistance.

Romani mobilities as resilience strategies: trans-atlantic expectations, lives and journeys

Acuña Cabanzo E.

Cultures of Mobility in Europe [COME], Freiburg University (Germany)
esteban.acuna@eu-ethno.uni-freiburg.de

Abstract

Recently, the labels 'Gypsy' and 'Nomad' have resurfaced in politician appearances, newspaper and journal articles, literary oeuvres, and other discourse pieces. Once again an avalanche of mediatic attention, centered on human trafficking, poverty migration, deportation, squatting and criminality, has relied on generalizing representations that mask the complex realities of Romani groups and their movements. The proposed paper's objective is to revise current approaches and state the need of a theoretical stance that can encompass, and not reduce, the diverse mobile strategies that can be revealed by means of biographical narratives. The argumentation picks up on the recent scholarships that focus on 'migration', 'mobilities', 'nomadism' and other related conceptual terms, with the aim of linking daily practices and experiences with 'global' trends, 'mobility regimes' and geopolitics.

The paper has been divided into three parts. The first section briefly recreates the genealogy of the "Gypsy" and the "nomad" idealized figures in academic discourse, followed by a description of recent trends in the study of the movements of Romani groups. The second section presents an excerpt of the author's fieldwork following trans-Atlantic Romani mobilities, concentrating on family dispersions and personal journeys. Descriptions are based on ethnographic tracing using documentary evidence, participant-observation, 'go-along's' and biographical interviews. Finally, the conclusion argues for fresh perspectives, a debate that allows discussions beyond binary terminologies and disciplinary divides that impede dialogue. Thus, move beyond a sedentary/mobile simplification; account for resiliences and adaptations that are part of the history of Romani groups in the form of mobile practices, connections, exchanges, and displacements.

Keywords: Mobilities, mobile ethnography, Roma, nomadism, trans-Atlantic migration, resilience processes.

Introduction

Recently, the labels 'Gypsy' and 'Nomad' have resurfaced in politician appearances, newspaper articles, literature pieces, journal papers and other discourse pieces. Certain physical traits or lifestyles, such as being 'nomad', 'homeless', 'black haired' or 'skinned', 'dirty', and 'criminal', keep being associated with social and moral hierarchies, homogenizing diverse populations around the globe. The movement of Romani groups has been consistently simplified as either 'nomadism', 'labor or poverty migration', 'welfare tourism' and sometimes 'diaspora'; especially now when last year's so called 'summer of hate' evidenced the power that these universalist constructs hold to sway public opinion, guiding policies and actions.

This paper's first section is concerned then with the role of these categories in public and academic grounds. It describes contemporary trends in the study of population movement among Romani groups, elucidating a possible way to not only de-construct the consequences of these assumptions and analyze critically both meanings, practices and politics involved [1]; but see these diverse mobilities as part of social capital [2], as a field of possibilities that can be translated into strategies that have concrete effects on life courses and community formation. For this purpose, the second and main part explores the lives and journeys evident in case studies of Trans-Atlantic movements. Given the complexity of the concept of resilience, this paper relies on it as an analytical tool that allows us to underline a "systems' capability to effectively absorb, respond, and recover from an internally or externally induced set of extraordinary demands" [3]. I use 'system' with complete conscience that it refers to sentient groups or individuals with their own expectations and agency. In this light, the conclusion argues that the extreme cases analyzed are examples of the complexity and diversity of mobilities of Romani groups beyond fixed categories, crucial to comprehend their trans-national dispersion, their endurance and their creative adaptiveness.

The 'racialization of mobility' among Romani groups

Given the short amount of time given for this presentation, I have chosen not to go through the categories used to label Romani groups and other itinerant populations according to alleged mobile practices or lifestyles. Previous works [4] [5] [6] have underlined the importance of the contents of these 'universal' metaphors and the practices of exclusion and racialization that arise from their enmeshment in daily life. Paloma Gay y Blasco calls this the "gendered and racialised", "exoticising and orientalising", "thematic repertoire" [7] elaborated around the 'Gypsy' category. This discursive weapon, quickly reworked to justify spatial segregation, is strongly tied to the idea of 'whiteness' as the top of a social (and spatial) hierarchy that is actively reproduced and contested in daily relations [8] [9].

Academia has not been exempt of reproducing, shaping and transforming the existence of the 'Gypsy-Nomad' tropes. Several works that concern populations stigmatized as such have announced the deep relation between academic texts and these generalizing trends [10] [11] [12]. Most of the historical documents available have been gathered by institutions that helped to create the 'Gypsy' "stigma", resulting in the burial of the intrinsic diversity of Romani groups under "definitions used by authorities" (e.g. *Travellers; nomades; ambulants; bohémiens; Landfahrer; woonwagenbewoners)* that came mostly from western European countries [11]. Early works in 'Gypsy' studies seems to recreate a "unique ethnographical sketch" [11], similar in some ways to the "thematic repertoire" discussed earlier.

Struggling with the presence of racial categories, only until the 1970's did critical accounts of spatial practices of Romani groups stated the need to separate cultural forms apprehended by a "nomadic-economic community" from the analysis of group formation of an "ethnic community" [13]. These first arguments were based in the existence of an "economic nomad" "who turn[s] their mobility into a form of asset", taking advantage of market variations [13], that is not necessarily equated with all populations under the 'Gypsy' label. Past dichotomies ("mobility" and "sedentism"; endogamy and exogamy, etc.) are then considered "rather as continua which strategies are adopted to successfully cope with constraints which are also not entirely rigid" [14]. After the final decade of the XXth century, analytical differentiations became more complex. The simultaneous consolidation of "Gypsy politics" cultivated a fertile ground for a critical revision of the 'nomad' label as part of claims of a "sedentary mode of existence" as an inevitable development that leads to civilization and the birth of the modern nation-state [15].

Following the spatial and mobility turns, latest works on how diverse Romani groups move and connect have delved into different theoretical frameworks and perspectives to transcend this limitations. To finish this section, I would like to mention what I call the three basic lines that have developed their own terms and themes for empirical analysis: (i) Focusing on Roma migration, the first line emphasizes long histories of being linked to a particular place for generations as well as questions of displacement [16] [17] [18] [19] [20]; (ii) the second line, coming from Diaspora Studies, states the need to account for "diasporic modalities": particular way[s] of conceiving ´the Gitanos, Gypsies/Roma´ or `the Gitano/Gypsy/Roma people´ […] as a community as well as a distinctive pattern of sociopolitical relations" [21]; (iii) finally, the most recent line concentrates on the diversity of what they call "nomadism" [22], "ambulant lifestyles" [23], "itinerant lifestyles" [24], etc., and has picked up both on the 'mobility turn' and 'neo-nomadism' [25].

A trans-Atlantic picture of Romani mobilities in three case studies:

The following case overviews are short excerpts of biographical narratives gathered through multi-sited ethnography during the last year, 2013, both in Toronto (Canada) and Bogota (Colombia). Their richness allows to consider how 'mobile' ethnographic methods and critical accounts of the "mobility turn" terminology can continue fueling the debates I described earlier by motivating dialogue between stances.

1.1 The Cristo family, Colombian survivors of the Holocaust…

Tosa and I have known each other for more than six years, but it took us that much time to sit down and talk about his family's history. "The parents of my mom had arrived in Germany, leaving the [Greek] island of Corfú. […] Then, mi mom was eight or nine years old and my father was five or six years old. […] my mom [had] traveled with her parents to visit some [her] grandparents" "As time passed, two or three years later, the war started and my father's family was killed, I don't know if in a gas chamber or in those camps that Hitler built to kill all the people". "The kids were placed in a railway carriage […]" "When they had to stop, they had to get off and they gave them a portion of bread or some bit of soup. They didn't give them anything else. […] that way they endured cold, endured hunger, and they suffered a lot and cried. But they had a lot of panic too, much fear […]

"They met other gypsies and they formed a big group and they managed to escape. But they weren't elders […]" Among confusing memories he tells me how his father's cousins manage to get into a boat heading to the Caribbean; exactly when and how he does not know. Some of his father's 'cousins', he says, were not his

immediate family, but Roma from other places. After several tribulations they land in the port of Barranquilla, where they found members of the *Mighai* vitsa: "[…] they arrived from Cuba. They settled down in Barranquilla and had installed business. […] they spoke Spanish perfectly, while my father's group, Soviets, imagine with whom could they talk?" There they started a new life, learning language and ways from the newfound 'cubanos'. His brothers were born next and his father began an itinerant career as smith, boilermaker, welder, livestock trader, among other skills. Not wanting their children to experience such kind of suffering again, her mother kept her grief to herself, trying not to tranmsit that sadness to her children. Paradoxically, in the Americas, even though their dispersion goes from Argentina to the United States (not everyone stayed in Colombia in the years that followed), connections are still strong, and some of the members of the *Ruso* or *Russaiko vitsa* are now leading activists, pastors and businessmen.

1.2 Crossing the Ocean during the Cold War:

O. always greeted me in Spanish, with a smile. *Ame sam Lovara Rom*, he says proudly. "So my father got anyway the conscription. My mother died in the first bombing […] by the allied forces. […] so we have no choice, father don't want to leave us alone and to grow up as you say, orphans. Therefore we had to run, we went to Slovakia. […] From Slovakia when the situation was heat up, we went anyway to Croatia, Yugoslavia. […] When the situation was bad they went to Romania. From Romania, when it come the liberation from the Russian army they moved back to Hungary." Then came the after-war period: "We had to move [from] one road to the other […] even one province to the other to make business. […] Selling, buying horses and other kind of livestock […]". "You have to do everything on your own, if not you die. […] In my life, my time, I had no childhood. […] a child has to use adult mentality in order to survive." Later, while working as a mechanic, the Hungarian Revolution brought the fears of fascism back. O. and his cousins crossed the Austrian border and jumped from one refugee camp to another until they reached the Netherlands.

There he learned English, while he worked in other factories, and prepared to embark in his first Trans-Atlantic voyage, from Rotterdam to Canada. After receiving ´landed immigrant status', given his application as a political refugee, O. was taken by train first to Calgary, but continued his travels always looking for a better job. After living in Montreal for 25 years, he decided to try his luck in the United States and even reached Mexico. "No more USA, forget it, it was anyway delusion of grandeur, dreaming". My conversations with other activists who knew him, told me about his role as a Roma intellectual in Montreal, given his educated background. O. is now a respected elder among the Hungarian Lovara in Toronto, renewed by the recent wave of asylum seekers that arrived from Central and Eastern Europe. His talent with languages and intellectual curiosity has not only helped new arrivals to find a place, but been a crucial part of the Canadian activist scene.

1.3 From Hungary to Canada: the beginning of the XXIst century

A. and his family all joined the conversation around the table. His life started in the late seventies in a small Hungarian village. His father's family used to peddle from market to market. Eight years later his mother claimed custody and he moved to the city. "[…] a world just opened up and I knew a lot of different things […]". His mother worked in factories in socialist times, "she was the one that encouraged us, me and my brothers, that we need to learn, that we need to be educated." Still, even though his fondness of reading, school was not an easy place. "[…] I didn't know what is racism. My mother didn't want to tell me these things. I felt they didn't like me somehow, and I didn't know the reason [small laugh]". "Socialism ended when I was fourteen".

"I met my wife" he said later; "Junior happened", said her with a refreshing laugh. A. stepped out of school to be responsible, and joined the factories: "[…] it was always a short time. […] I was sure at that time because I am a Roma […] as soon as they had to fire somebody, I was the first." "[…]we had to move all the time.[…] We were always trying to find a better place to live, because most of the times we had these racist neighbors that just cannot stand Roma." A. later worked in retail and even in fast food chains. Finally he found a niche in the Roma self-government but "I had to stop working there because of serious attacks […] it happened three times […] my family was near, they saw everything." The situation became unbearable. After his brother left for Belgium, another attack happened, "[…] they just beat us, even my children". The family did not think twice, and followed him to Brussels. It took almost a day by car. Not being eligible for asylum inside the EU, several months later A. decided they will follow his brother, again, to Canada. After the long flight they were question by an immigration officer, "[…] he remembered him saying 'damn it, one more refugee family'". A.'s fortune smiled later, he was able to get help from lawyers provided by Toronto's Roma Community Center, where he became an active member. A couple of months later, one of his messages greeted us on Facebook, "Our family was accepted on Humanitarian ground just this morning!"

Conclusions:

The American continent, for centuries, has acted as a shelter for populations that seek for new chances. Perhaps this is one of the reasons that Trans-Atlantic voyages of Romani people throughout the twentieth century can give us insights not only on the situations that forced or encouraged the decision to take such extreme measures, but on their abilities to endure, adapt, and thrive through mobile strategies. This paper's argument comprises two parts, given that experiences are better comprehended both in terms of an individual sense of identity and located within labels that shape their experiences and journeys. Expectations and aspirations encounter power relations and structures. Through the narratives, this text brings an "*interactive* concept in which the presence of resilience has to be *inferred* from individual variations" [26], reinforcing the importance of diverse mobilities as turning points or assets during traumatic events.

In the three narratives we can find past relations with mobile economic strategies that can be labelled as nomadic or itinerant, considered part of Roma life, even if the business and experiences themselves differed in nature. Later, even though in the three cases there is persecution, violence and fleeing, only A.'s story is officially classified as 'Roma asylum seeking'. Tosa's family did not have access to this resource, and O. had luck when he was received asylum as a 'political refugee'. In the three cases, though, persecution is felt deeply as part of being Roma, and crossing the Atlantic means stepping out of its grasp.

There are indeed other movements evident in the narratives that cannot be classified so easily. Boat travel goes from unregistered arrival to the Caribbean, to finding a job as a waiter on board. Job-seeking spans from finding business as craftsmen to looking for jobs in factories and other possibilities. Border crossings occur in different moments in life, and have very different connotations, both for the protagonists and onlookers and controllers. To link the first and second part of this argument, these movements become Roma (in this case 'Gypsy', or 'Cigane', or 'Gitano') only when the discursive 'thematic repertoire' feeds particular quotidian or extraordinary actions.

Finally, these movements themselves, even the ones in the direst circumstances, generate spaces of creation, transformation and renewal of ties. In Brubaker's words, they create moments of "groupness" [27] where expectations brought from their previous lives meet a new context. The Cristo family and O. found, even after such traumatic experiences, their place among the kinship and business ties that other Roma groups had established in the Americas. O. and A. find, in activism, a way to reinvent themselves as part of both their economic strategies and their belonging, now as part of the educated lot that can guide political claims. Moreover, it is through these diverse mobile strategies that families or individuals not only leave or shift a space where social boundaries and power relations cause danger and fear, but create opportunities and belonging. As the life-stories evidence, generalizations or reductions of Roma movement to culturally specific perceived practices are not useful. In shifting realities, resilience can very well mean the capacity of starting anew.

A gypsy and traveller journey through foster care: emotional resilience versus the experience of being shamed

Allen D.

Edge Hill University, England
allend@edgehill.ac.uk

Abstract

Over the last five years, social care departments in Britain have attempted to transform the way in which fostering services are delivered. Arguably, the most important development is to promote opportunities for children to live with friends or family members. However, whilst this recommendation has been implemented with a diverse range of children, the placement of Gypsy and Traveller children with Gypsy and Traveller carers has not always been realised.

Guided by the philosophical assumptions of interpretative phenomenological analysis, this paper reports on the experiences of 6 Gypsy and Traveller women who lived in foster care as children. Based on the testimonies provided, it reveals how the experience of growing up in foster care, away from the Gypsy and Traveller community, can be inextricably linked to a resilient experience of cultural isolation which is not always contained within childhood.

Keywords: Gypsies and Travellers, Looked after Children, Resilience, Lived Experience, Friends and Family Foster Care

Introduction

One of the most important aspects of social care practice relates to the support of children and young people who live in the foster care [1]. In addition to the complex roles and responsibilities which accompany this task more generally, there is a requirement that where a child is unable to live with a birth parent, then in the first instance consideration must be given to them living with a family member or friend [2]. Although the legal frameworks are different in each country in Britain, they all allow for children to be placed directly from home, and require local authorities to provide appropriate support according to the circumstances of the case so that cultural and biological links to families can be maintained [3 & 4]. However, for all the good intentions of these directives, it is reported that this duty rarely extends to include Gypsy and Traveller communities [5].

Before moving on to explore this matter further, it is important to note that people who are frequently referred to as "Gypsies" or "Travellers" in Britain actually constitute a rich and diverse group of communities who each go under different names, and often distinguish themselves sharply from one another. Although a fuller exploration of these differences might be useful, any additional detail is beyond the scope of this paper. For readers new to this topic, the book *'Social Work with Gypsy, Roma and Traveller Children'* [6] provides an accessible foundation from which to better understand the unique challenges experienced by Romani Gypsies, Roma, Irish Travellers, Scottish Gypsies and Travellers, Welsh Gypsies, New Travellers, Showmen, Circus People and Boat People within a British context.

Understanding why these communities may not be included in friends and family placement planning is complicated. One potential reason is located within a stereotypical perspective that has emerged from a general ignorance, or projected racism within the population at large. Frequently characterised as being "socially deviant" within the media, it is argued that this representation has become manifest in social care practice [5]. In 2013, statistics in England revealed that Gypsy and Traveller children were not only overrepresented within the fostering system, but that they were 3 times more likely than any other child to be taken into foster care [7]. Whilst there are broader issues to consider when interpreting these statistics, the concern remains that social care practitioners can often view Gypsy and Traveller communities and cultures as objects of concern. This level of concern, or general antipathy, is just one suggested reason why Gypsies and Travellers are not being considered as suitable foster cares [5]. However, whilst it could be argued that this perception could increase the risks associated with the cultural segregation of Gypsy and Traveller children living in foster care, it is also clear that,

for the most part, the experiences of these children have not been studied in any depth. As such, the allegation that social care practice might be institutionally prejudiced is contested [8]. In order to shed some light on the extent of this reported concern then, this paper summarises the experiences of Gypsies and Travellers who have lived in care as children.

The research

This paper reports on a larger study that utilised interpretive phenomenological analysis (IPA) [9] to uncover the lived experiences of Gypsies and Travellers who lived in care as children. Within the context of the current paper, the experiences of 6 women are described. 1 woman was a Romani Gypsy, 4 women were Irish Travellers, and 1 woman was a Showmen. Each lived in foster care in England between the 1980s and 2000s.

Each person was invited to describe their experiences in any way which suited them. 3 women chose talk about their experiences in a one to one interview, 2 people chose telephone interviews, and 1 person chose to describe her experiences through poetry. In line with the theoretical framework of IPA, the analysis presented in this paper is discrete in the sense that the interpretative account provided is a close reading of what people have said. Any editorial elision by the researcher is indicated by three dots (...) and significant pauses are indicated using bracketed numbers; for example, '(3)' would indicate a three-second pause.

1.1 Feeling and becoming different

Each person explained how their early childhood experiences of being a 'Gypsy' or a 'Traveller' had reinforced their cultural identity, and created an indelible imprint which cemented an understanding of how their customs and mores were unique. Each remembered how they were taught to be separate from, and suspicious of, wider non-Gypsy/Traveller influences.

'Growing up we soon learnt that [non-Gypsy] people hated us. They hated us and they hated our culture.'

Reflecting on these lessons, each person remembered that when they were removed from their families and placed with non-Gypsy/Traveller foster carers, their sense of vulnerability became acute. Instead of feeling safe, each person described the perceived need to conceal their Gypsy or Traveller identity so that any cultural difference did not make them targets of anti-Traveller racism:

'The kids at my new school picked on me because of my [Irish Traveller] accent. I told my foster family but they didn't care, so I thought oh well, I won't speak with an accent anymore that way no one will know I am a Traveller. I wanted to make the Traveller me invisible.'

1.2 A war against becoming settled

Despite attempting to conceal their identity, each person explained that they remained victims of racism and abuse. Over time, and as the perceived need to assimilate minimised, each person described how they began to feel guilty for abandoning their culture. In order overcome these feelings of guilt, each person described an obligation to maintain their Gypsy or Traveller identity:

'I got back [from school] to the foster house and watched telly. I remember having chewing gum in my hair from the girls at lunchtime, I saw Kyle Minogue on the telly, and I decided that I was going to be like her. I suppose I just wanted to feel normal and I went upstairs [and] cut my hair.... (3) (Laughing) fuckin idiot aren't I. Anyways it didn't work and [the girls at school] called me all the more. I had made a right job of my hair all sticking up all over the place but from that day, I decided that I am who I am and that's the way it is. A Traveller through and through (laughing) I found out that I fight good as well. Me da would have been proud.'

Within the limits of the power that was available, each person described how an ideological commitment to a Gypsy or Traveller identity reduced their preparedness to accept cultural change, and increased their resilience to undermine the conventions associated with their new experience. For 4 people, this confusion became manifest in aggressive behaviour:

'I didn't do anything that the carers wanted me to do. I feel bad about it now because I used to give them real trouble. I think that I must have been restrained every day. But I thought that if I did what they said, I would become like them.'

For 2 others, self-harm, emotional and social isolation became a coping mechanism:

'When it all got too much and I started to cut myself and I refused to speak, no one helped me…They didn't know the pain I felt in my heart from not knowing who I was, from being, from being (7) (sobbing) from being treated like animals, worse than animals. No one cared about me as a Traveller.'

In each instance, the individual attempts to maintain a Gypsy or Traveller identity were labelled with broader anti-Traveller stereotypes. Instead of responding to this behaviour with empathy, each person recalled how their carers attempted to achieve control and the assimilation in more extreme and abusive ways:

'You [felt] your life was nothing; you were nothing (8). They used to beat us (5).They became random acts of violent racism, physical violence, sexual violence, emotional and psychological violence. They thought they could beat our ethnicity and cultural identity out of us.'

1.3 Contaminated and shamed

Even though resilience enabled each women to survive their journey through care, they each explained that their ability to subvert the mores of the dominant society has gone unnoticed within their own communities. As adults, each person explained that they remain isolated by a community which views them as being contaminated by non-Gypsy/Traveller influences:

'When I left care, I tried to get back in with my family. My Uncle and Aunty took me on and let me live in their [caravan] for a while. When we went to fairs and that, all the boys would all look down at me and call me dirty. They knew that I had been in care and they all thought that I was like a [non-Gypsy] girl. That I had been having sex, that I had been to nightclubs and that I had taken drugs. You see, the [non-Gypsy] people look at us and see what they think are Gypsies. The same way the Gypsy boys looked at me and saw a [non-Gypsy] girl. Because what they have seen on the television, and that, they think that I am dirty, and because of this, no man in his right mind would marry me. If someone did, they would be outcast.'

Despite demonstrating great resilience to cultural assimilation as children, they remain, as adults, alienated and shamed by stereotypical assumptions about their childhood experiences. Despite remaining resilient towards the traumas of childhood, each explained that they have never been supported to overcome the feelings of complete cultural abandonment and isolation; a sense of loss and confusion which continues to haunt them to this day:

'In my soul there is a hole that nothing can quite fill.
I've searched across the miles, for me time has stood still.
I'm still that convoy member, Travellers across the land.
We have morals and we're Christian, our loyal moral band.
We believe in freedom, in love and light and hope.
Even though I keep searching, I cannot sit and mope.
I have these precious memories and future happy dreams.
So, one day I hope to find my kin, and then my life begins!'

Discussion

An introduction of the experiences of Gypsy and Traveller women who lived in care as children has enabled this paper to reveal how the experience of cultural isolation can have long lasting and harmful implications. Based on the testimonies provided above, it could be argued that social care professionals can easily become constrained by prejudice, thus substantiating the concerns of Cemlyn et al., [5]. Where this occurs, a lived experience of a life in foster care might be lost to wider racist generalisations; the same types of generalisations which are used to justify the decision to take Gypsy and Traveller children into care in the first place [6]. To overcome this challenge, it is clear that if a transition into, and out of care is to become safe and effective, cultural continuity must become a centralised feature of any care planning process. In other words, it is essential that Gypsy and Traveller children experience continued cultural inclusion. While effective placement planning for Gypsy and Traveller children might only be achieved through friends and family foster care [2], where this is not possible, there remains an urgent need for professionals to spend time with the child to listen and talk to them, as any reasonable parent should [3]. In all cases, this requires a shift in emphasis which sees Gypsies and Travellers less as objects of concern, and more as culturally proud and resilient children who might be losing their identity, their sense of cultural pride, their customs, and their distinctive way of life. As shown by research carried out in the Republic of Ireland [10], paying more respectful attention to the heritage and lived experience of Gypsy and Traveller children is the only way to promote resilience, protect transitions, and reduce the risk of cultural isolation.

Conclusion

The testimonies included in this paper hold out the hope for a developed understanding of the unique challenges faced by Gypsy and Traveller children living in foster care. Whilst it is hoped that the presentation of these experiences will prove useful in highlighting the role of resilience in the face of adversity and shame, it is recognised that unless a Gypsy and Traveller culture, identity and heritage is respected in Britain, sustainable opportunities for friends and family foster care may never be realised.

Why Roma migrants leave or remain settlements? Different strategies of survival and adaptation among Roma in northern italy.

Manzoni C.[1]

[1]*University of Milan-Bicocca (Italy)*
c.manzoni3@campus.unimib.it

Abstract

Since the 1990s, major political and economical transformations are modifying the distribution of Roma population within Europe. In particular, some Roma families chose to migrate to Western European countries, adopting transnational trajectories to improve their living conditions. Many of them do not enter the regular housing market and find a shelter in urban slums, in the suburbs, with very poor housing condition. Research on Roma migration from Eastern to Western Countries tends to emphasize the structuring role of slums. Literature stresses that slums make Roma visible, and tend to turn them into the main public problem for local politics, decreasing work opportunities and inclusion of Roma migrants.

Based on a research carried out between October 2009 and September 2012 inside slums in Turin (Italy) as well as in Romania and in Bosnia, this paper shows different strategies of survival and adaptation of Roma migrants living in settlements. Through ethnography as well as the reconstruction of life stories, I explored the mechanisms that explain why they remain in settlements, or why they leave them. The core of reflections is the analysis of different factors that Roma take actively into account when they strategically decide where to live.

Keywords: Roma camps, slums, housing careers, exit process, strategies.

Introduction

The presence of Romani population in Italy is estimated between 140,000 and 160,000 people [1], [2], representing a small percentage of the population (0,2%). Sinti and Roma groups have been settled since 15th century [3] and different migratory arrivals are crucial elements for the understanding of the diversity of this "minority groups galaxy" [4].

Scholars dealt with a variety of policies, regulations, and laws designed to face the Roma issue in Italy, focusing on the governmental constrains on nomadism. The emphasis is based on the effects of nomadism on the housing policies expressly aimed to Roma [5], [6], [7]. Thus the majority of researchers analyzed the space of camps which, created in the Eighties, were justified as a strategy both to protect nomad culture and to circumscribe the Roma population in specific areas. Scholars analyzed the role played by camps in preserving and reinforcing the spatial segregation and social marginalization, providing a refuge for people without rights [8].

The representation of Roma by media as a security problem was legitimated in 2008 by the Italian government which declared the Nomad State of Emergency. The main goals were: to intervening on hygienic, sanitary and social degradation of illegal settlements and authorized camps, promoting the rule of law, fostering suitable living conditions, safeguarding both public security of majority and people living in these settlements.

Focusing on the criticism addressed to the 'nomad camps' paradigm I argue that it produces a new polarized debate between housing solutions as an alternative to camps and - on the individual level – the exit pathways. The exit process played such an important role that eviction and closure of camps were recurring electoral issues as well as a favorite objective of the local agenda [9]. However, little attention has so far been paid to the exit process, and it seems to be a demonstration that leaving a Roma settlement is always better than living inside it, and is a normal process when housing offer grows up.

The aim of this paper is to stress on different strategies of survival and adaptation of Roma living in camps or slums. In particular I will focus on why and how people living in these settlements choose to leave or remain there. In order to develop these topics, the article starts from the housing condition of Roma living in the city of Turin. The questions will be answered by a part of the empirical findings of a Ph. D dissertation which was discussed in July 2013.

Methodologically it is a multi-sited ethnography research [10] carried out between October 2009 and September 2012 in Turin (Italy), Romania and Bosnia. Roma narratives explore the variegated world that circulates inside and around settlements, and the meaning of camps and slums for their inhabitants. The focus is on the analysis of their experiences, a concentration of ambitions and restrictions.

The presence of Roma groups in Turin

The 1960s arrival in Turin of the first Romani Yugoslavia as well as the second flux in the late 1970s required the intervention of the municipality to solve the security issues related to that population. The municipal Nomadism and Emergency Settlement Office was officially created in 1982, although the city of Turin had dealt with the presence of Roma since the 1970s. The municipality action was twofold: on one side new camps were created and equipped, on the other the presence of Roma and Sinti living in urban slums was tolerated by the regulation of these areas. According to the Regional law of 1993, during these years four camps were equipped: two of them for Sinti, and two for Roma coming from Balkan area. Nowadays the Sinti areas are still the same, while settlements for Balkans Roma have been dismantled and replaced elsewhere over the years.

Since the end of the 1990s and starting from 2000s Romanian Roma migrated to Turin. They settled down close to rivers because they could not afford the rental costs and all the municipality camps were already filled.

The main nationalities of Roma in Turin are Romanian, Bosnian and Serbian. In particular illegal slums are mostly inhabited by Romanian Roma while Bosnian and Serbian Roma are living in municipality camps. Besides the physical places where these two groups are living, another difference between Romanian and Balkans Roma is related to the juridical condition: many Roma coming from Balkan areas are still undocumented, while Romanian Roma are EU-citizens.

Camps and slums: magnetic areas or temporary places?

Each area -camp or slum- is an actively place [11] which combine a variety of political, social, Each area -camp or slum- is an active place [11] which combines a variety of political, social, institutional, and juridical features that structure the daily life of their inhabitants. During my research, I analyzed different settlements characterized by different institutional levels: equipped camp and illegal slums. I compared those different places sizing up the effects of these differences on the inner social organization and the daily life of their inhabitants. As scholars underlined, Roma settlements are often placed in marginal spaces, polluted, dangerous, and lacking all the essential services (water, electricity), where social exclusion and ethnocultural stigmatization is reinforced.

Through my ethnographic analysis came to light how is useful to specify the double aspect of segregation. Indeed spatial marginality of Roma serves the double purpose of spatial confinement and control by the social majority , but is also a strategic plan used by Roma for protecting themselves. Settlement inhabitants try to keep invisibility as a strategy to maintain social capital with the city, exploiting its resources [12]. Camouflage is important also because visibility produces strong effects on living conditions, such as evictions in case of illegal settlements.

Despite the condition of spatial and social marginalization, conflict and deprivation inside these areas, not everybody dreams of moving away. This lack of correlation depends on several factors: first of all a person who was born or has been living for years in these settlements reveals a difficulty to imagine himself elsewhere. According to Appadurai [13] the ability to aspire depends on the amount of significant experiences. Although settlements display physical features of temporariness and precariousness, for someone these areas take on a permanent meaning, while for others they are just a strategic place where spend some time saving money.

The equipped camp which I analyzed is an area thick of a strong network of relations, wherein everybody knows more or less everything about everybody, and wherein knots of relations are defined mainly but not exclusively by familial linkages. For some families a sense of security is provided by the support of moral or financial solidarities. The camp is perceived as a community of shared norms, values and interests. The settlement appears as a well acquainted place and many inhabitants perceive as distant the possibility to leave the camp. Even though for someone moving away is desirable, from a cost-benefit analysis it seems unattractive or not interesting enough. This because there are some adaptive mechanism, some strategic choices, some priorities which establish the degree of freedom within the people who are acting.

Living inside the equipped camp is often the result of a strategic propensity to stay close to the extended family. Space is easily changeable, fitting to the needs of new families: when a son gets married one can add a caravan for the new family. The camp is so wide that inhabitants can banquet all together without any restriction. Another important positive aspect is that socialization and social interaction is easier in the camp than in a flat. For these reasons leaving the camp produces the fear of loneliness and isolation. In addition inhabitants do not have significant external relations or friendship networks. Living there may be seen as a sign of community

strength and strong bonding social capital. Moreover for some Roma the settlement is a front for illegal trafficking: people excluded from the labor market take refuge in the informal economy.

Different is the situation of the slums which I analyzed. They are characterized by the same physical deprivation as the equipped camp. Nevertheless, slums are not a real community of inhabitants; for the Romanian Roma who are living in the slums I found that the proximity to the extended family is not so important. This difference is also reflected in the spatial organization within the settlements where slum-dwellers are not concentrated in the same area or even reside in different urban slums. Roma migrants who are living in the slums move independently and interact within the city, they construct and maintain networks of privileged relations with local population. If for Balkan Roma living inside the municipal camp the main resources are provided by exploiting known and established network of their own settlement, for Romanian Roma who are living inside slums survival depends almost exclusively on the ability to take advantage of the resources offered by the city.

Living inside the camp or the slums, allows to reduce rent price and save money; inhabitants do not have to pay any rental cost or consumption. Thereby staying there for long time increases the idea that cost of home management is a waste of money. As time goes by, investing money in a home is perceived as a useless cost. Many Roma migrants have left home for overseas and transnational behaviors such as the import of remittances justify a temporary and precarious accommodation in a slum.

Another characteristic of both camp and slums is the constant presence of several actors: municipal offices of Nomadism and Emergency Settlements Office, policemen of the Nomad Patrols, social workers, educators and volunteers of different NGOs. All these actors transmit information, facilitate services and allow a connection to the social networks. They provide support and constitute a relationship capital. Cultural mediators facilitate access the health care, enroll children at school, convey a whole range of information that would be unknown. The negative effects produced by the presence of all these actors are the increasing of dependence on assistance [14], [15].

In addition to desires and strategies there are also different structural constrains: for many inhabitants living there is the only alternative imposed by juridical or economical conditions. Several institutional limitations are linked to the possibility to move away: many Yugoslavian Roma living in Turin are undocumented. This condition contributes to further exclusion by restricting access to the services and opportunities which authorities grant for integration; obviously they cannot rent a flat or buy a piece of land. Individual motivation of exit are linked to all these elements. In the cases of slum-dwellers emerged that, despite their EU citizenship, not everyone has the option of renting an apartment, because they lack the necessary guarantee of a employment contract or because of economic vulnerability.

Conclusion

Through the analysis of housing career of Roma migrants leaving the settlement I moved the attention from the physical space of the camp to the frame of the agency of the social actors.

Starting from the perception of what the settlement represents for its inhabitants the analysis shows how a slum is a temporary area while a municipal camp is often perceived as a definitive one. This difference highlights the disadvantage elements of the equipped camp compared with the slums: a more structured situation of dependence.

An important remark is that the time spent inside a settlement – as stressed by the homelessness literature – produces a progressive adaptation to deprivation and consequently a loss of resources and capability [16]. The motivational resource to move away is progressively replaced by passivity and resignation; the time frame is limited to the present. For these reasons, the availability of economical capital is not sufficient to determine the exit process that requires both a strong motivation, and the capacity of autonomy and long-range planning.

A few steps away: two schools, two different worlds. The capacity of resilience in the calòn identity building

Persico G.

Università degli Studi di Milano – Bicocca
g.persico@campus.unimib.it

Abstract

The paper aims to show the role of hidden curriculum in the construction of the "Calón identities" in two schools of a Brazilian neighborhood, through the analysis of the standard curriculum organization and the interactions among school directors, teachers and parents (particularly the semi-itinerant workers).

Key words: Brazilian Calòn, schooling, multiculturalism, *hidden curriculum*

Theoretical framework

This paper intends to explore the identity attribution processes currently developing in two Brazilian schools placed in the same neighborhood, regarding the residing Calòn families. The job of many of the Calòn families requires a semi-itinerant living on the federal territory; therefore the education of their children often is marked by absenteeism, learning gaps, missed learning goals, failures. Facing this issue, the two schools tested different ways to consider and involve the Calòn families. Different were also the effects, and afterwards we'll have a look on how and why resilience processes were activated, or weren't.

We refer here to a theoretical background based on three main approaches. First of all we refer to the literature about the presence and the effects of the *hidden curriculum* (e.g. [1], [2]). We consider the school not only for the didactic contents but also for all those material and immaterial elements it's build by such as spaces, times, bureaucracy, school year, meeting with parents, symbols etc. According to the theories and further development of critical pedagogy (e.g. [3], [4], [5], [6]), all those elements act as a *pedagogical device* (e.g. [7], [8]) producing meaning, practices of *subjectivation* (e.g. [9]) and attributing identity at a tacit level. Within this theoretical choice we consider Romani, Sinti and Calón as active subjects: in dealing with the Institutions, they can have some influence on the social process that define their recognition as interlocutors. We'll also refer to those authors who consider education as *political action* (e.g. [10], [11], [12]) able to foster the democratic principles that define the need to safeguard the fundamental children's rights. From such a perspective, school as a democratic institution (e.g. [13]) should organize itself, in order to be able to guarantee the conditions for a positive schooling to each and every student.

Research methodology

This research is the result of a fieldwork realized between 2010 and 2013 in a neighborhood inhabited by a conspicuous Calòn community and by Gagé (non Calòn), in a town a few kilometers away from Goiana, capital city of the Goias State. Literature about Roma groups has repeatedly stressed the need to adopt a methodological approach able to guarantee tools for reading the particular contexts (e.g. [14], [15], [16]). Therefore we decided to follow an ethnographic method through long periods of participant observation both in the neighborhood and in the schools. In particular we chose to realize semi-structured interviews with the school directors, long-time teachers, a few semi-itinerant Calòn parents, and the local and state representative in charge for fostering the ethnic minorities' rights. For a fully developed analysis we took into account official acts issued by the two schools, but they're not going to be analyzed here. In our perspective a comparative analysis of the two schools can show to what extent the organizational culture of a school can affect both the identity attribution process (e.g. [20], [21]) and the schooling regarding some social, economic, and cultural specificities of the considered groups.

Two schools, two worlds. Data analysis

From being a sex market addressed zone, thanks to the dwellings that Calòn and *moradori* families has built on their own, and the small businesses they're running, the whole surrounding area turned into a residential district.

The first school building, enlarged in the course of time, keeps a simple and warm appearance. Most of the educational team has been working together in the same school for several years, some of them since its opening.

The issue of itinerant students begins now to concern the teaching staff. Those students leave the Montero school, stay in Santa Caterina for several months, and don't apply for other schools there. That causes evident gaps that need to be filled. At first it looks like there's no answer to that: enrolling students at schools in Santa Caterina is a parents due, Montero school can't directly deal with that. On the other hand teachers can't simply pass them, overlooking their major learning gaps. Back to the earlier years, to face this issue the school got in contact with a leader of the Calòn families. Later the direction, in agreement with the teaching staff, decides not to deal with Calòn community as a whole. Actually there are Calòn students that attend classes the whole school year. Slowly the school and the itinerant families starts to know and to speak to each other. A meeting is set, with the involvement and participation of the *Subsecretaria.* (Local Education Agency at a district level). The aim is to exchange views in order to find feasible solutions, according to the current regulations, the teaching plans, and the families' working needs.

Every teacher takes charge of setting up ahead the educational material required to complete the annual teaching plan of the subject. During their absence, the itinerant students can thus do their homework and send it by mail to Montero school. It has not been immediate to succeed and get the envelops with the homework done. It has been rather an aim to pursue, as people interviewed told us.

> *Now the families tell us in advance when they're supposed to leave and they ask whether we could* "liberar fulano" *(set the kid free). According to the time left to the end of the school term, and to the missing evaluations, we suggest a leaving date so that it fits to their working season and to the student's success. (Interview realized with the A. Manoel school headmistress. Brazil, June 2012)*

The teaching staff cooperates, and establishes the tests dates right in the beginning, so that students can be not overcharged at the end of the school term, and teachers can evaluate them adequately. In the same way, parents who can't afford a person for tutoring their sons prefer to postpone their departure. Some of them are illiterate indeed, and can't provide a proper help with homework.

The itinerant students issue is taken into account as well by the staff of the adult education evening classes (EJA - *Educação Jovem e Adulto*) (Interview realized with an EJA teacher from Montero school – June 2012) given in the same building: the teaching program is intensified during the months they're not away. By doing that, once the school term is over and evaluations are done, youths are free to go to work and come back to school for the following term.

The trustworthy relationship that has grown over the years between school and families led to encounters, mutual support, requests for help or collaboration, even beyond the school institutional function (e.g., the school tableware loan for Calòn celebrations in the neighborhood).

In spite of a federal legislation and the recent resolution of 17 May 2012 that ensures norms and protection specifically to the right to education for itinerant minors and minorities in the country, the course of action of the Montero school isn't bound to general guidelines. It rather follows a course of action named *jeitinho brasileiro*,(That's an expression for the way of doing things pragmatically by circumventing rules and social conventions.) that is, "Brazilian knack".

Let's have a look now to our case study's second school, the Abram Manoel.

The outer space is wide and the concrete building is slightly larger than Montero's. As in the latter, students here wear neat and color uniforms. The headmistress who welcomes us has been having tenure for 13 years, and she's been teacher, and daytime and evening teaching coordinator. Regarding the cohabitation of Calòn and Gagé she maintains that there are not major problems. There 's been only an isolated case of a future student whose parents refused to enroll her for the presence of Calòn students in the school.

She says about Calòn:

> *Missed school days and fickleness are the main problems. They often miss classes, don't keep up with the school rhythm, barely can stay four hour in the classroom, and their parents are very protective. If a child doesn't turn up, parents say he's been ill in order to cover him […] Here the law sets as bare minimum 200 school days, but sometimes they don't even attend the half of them. […] They already miss the end of the school term, and come back after two months from the next term beginning. Nonetheless they miss further classes. It happens to get medical certificates from time to time, but they look to be in such poor health in their justifications... […]. Sometimes we either phone up, turn up at home, or summon the parents, and we should fail the students, but in the end we take pity on them and nevertheless pass them. They tell us that*

south, where they go, they get discriminated and their children enrollment is often denied by schools. We don't know whether it's true, and whether they even tried. […] That's why we always support who's worthy, set the tests and close the school term in advance. For we have pity on them. […] (Interview realized with the A. Manoel school headmistress. Brazil, June 2012.)

Among the many disparities between the two schools, one stands in the relationship established with the families. In both cases, school professionals highlight the parents participation. Parents concern themselves with their children schooling: they do participate at meetings, show up at parent-teacher interviews, ask their relatives to replace them when they are busy. Nonetheless, this same kind of relationship leads to opposite effects. In the former case the ongoing exchange let the respective needs emerge, so that the two sides can find common answers, and build a trustworthy relationship even beyond the school institutional functions. In the latter case the headmistress perceives the parents' concern as solipsistic, *with no openness to face and solve problems*. She said:

If they were the 70% the school should take it into account, and even modify its calendar, but they're few as opposed to the student body.

In her view these *problems* don't question *curriculum*, and neither the schooling organization, instead they affect specifically the families of Calòn students, a minority compared to the whole student body.

Abramo Manoel and Montero schools are about five hundred meters distant, but one has the impression to get in parallel universes. Let's proceed in an orderly fashion. Two school cultures, divergent and multifaceted, come to light with different manners to face the "Calòn issue". It is difficult to assess to what extent the respective histories of the two institutions has affected their course of action, not only towards *ciganos*. A first hypothesis: Montero school, born as an outpost in what was then a marginal context, struggling for its very existence, had to develop a more flexible organizational culture, able to overcome hurdles by spotting creative solutions. To the contrary Abram school has been historically present in the neighborhood. It is never had the need to devise itself anew, establishing through the years its own operating methods. Second, most of the Montero's teaching staff is part of it since the school birth, was present and active in the positive change of the area: thus they can rely on a strong team spirit and on strong bonds with the local families. That is not the case for the other school. Last but not least, a few teachers set up home in or next to the neighborhood, living personally the history of the approach between *Calòn* and *moradori*.

Unlike Montero school, the Abram did not develop specific strategy to face the learning problems of Calòn students, bound to their families' itinerant work. The solution against this clear critical state has been lowering the required level in terms of learning goals. The reason of this choice is the will to "help" Calòn students, without considering, on the medium and long term, the side effects not only on individuals, but also on the whole school community. Lowering expectations leads to an even lower output. What is missing here, is the very concept of schooling: it is a duty, just as it is a right to safeguard, and the parents' profession can not be an excuse for not doing it.

In the needs assessment of the students the particular profession of Calòn parents is not taken into account as a major element, so that the school could take on a new organization to foster everybody's attendance. On the contrary, that is seen as an insurmountable hurdle to deal with only through makeshift actions, following the "lesser evil" logic.

Conclusions

The question to raise at this point is: are the school professionals, with their imagery and consideration about Calòn families, still trustworthy as peer interlocutors? The same situations recur in the speeches of the teachers from the two schools, but for the former, e.g., a celebration in the neighborhood is a good chance for sharing time beyond their professional role, for the Abram's colleagues that's *"a bloody mess that ends up with some fightings"*. The intervention tested by the Montero school is neither the only nor the best way to overcome the observed problems but it's the outcome of a process that deserves our attention. First of all the recognized critical state is not unilaterally ascribed to the Calòn parents: their profession, although different from the most common kinds of job, is taken into consideration in its economic and social prominence for the families and the neighborhood life. The school perceives itself as part of the problem and possible driving force for a solution. The skilled the teaching staff can look beyond abstract rules, with no practical solutions, and on one hand they speak directly with the families, on the other hand they bring back the issue on an institutional level. Involving the Education Agency turn out to be crucial because it implies the statement that the duty/right to education is a responsibility of the families as it is of the State. If Calòn children don't go to school and don't learn that is not merely their problem, but it concern their parents, their teachers, their classmates, and the institutions. The spotted solution is kind of radical: both the right to take up an itinerant profession, and the achievement of learning goals have the same dignity. The terms for mediating are crystal-clear and that fosters the imagination of feasible alternatives: they may not be totally successful, but they do lead to further chances to succeed.

Beyond bereavement: exploring resilience in gypsy and traveller families following bereavement

Rogers C.

Institute of Diversity Research, Inclusivity, Communities and Society,
Buckinghamshire New University England
carol.rogers@bucks.ac.uk

Abstract

There are an estimated 3000,000 Gypsies and Travellers in Britain. Despite Romany Gypsies, Irish Travellers and Scottish Gypsy-Travellers being recognised as distinct ethnic groups, in recent decades these communities have faced increasing challenges to retaining their culture and traditional nomadic lifestyle with significant impacts on their health and wellbeing. In addition to facing inequality and discrimination Gypsies and Travellers experience significant health inequalities and have a life expectancy which is considerably less than surrounding populations.

Bereavement is a significant health concern for Gypsies and Travellers with considerably higher levels of suicide, maternal and infant mortality, miscarriage and stillbirth than in wider society. Multiple bereavements can result in long term health implications including depression, anxiety, and increased risk taking behaviours, including alcohol and substance misuse and complicated grief reactions in adults. In addition the close knit nature of Gypsy and Traveller communities means that the death of a relative is felt with great intensity articulated by some research participants as an event with which they "never come to terms". The significance of bereavement and loss within these groups can therefore result in a continuum of loss and complicated grief throughout the lifespan.

However, the effects on children of significant loss, or living with carers who are experiencing bereavement remain largely unrecognised, despite the increasing research evidence which explores the connection between early childhood experiences and later life chances.

This paper presents emerging findings from my on-going PhD studies exploring the bereavement experiences of Gypsies and Traveller families, and considers resilience in relation to the bereavement experiences of this marginalised ethnic group.

Key words: Gypsy, Traveller, Bereavement, Resilience.

Introduction

'What doesn't kill you makes you stronger' (Irish Traveller woman in her late fifties Roger's unpublished data).

The statement above made by a participant in my on-going bereavement research reflects the stoic nature and resilient attitude found within Gypsy and Traveller families and communities experiencing hardship. Moreover, it summaries acceptance of life-long challenges and adversity faced by Gypsy and Travellers living a marginalised lifestyle within mainstream society.

Living on the edge of mainstream society British Gypsies and Travellers (the standard terminology used in the UK to refer to members of the ethnic group included in European policy documents as 'Roma' communities, see further: Council of Europe (2012) [1] remain largely hidden or invisible. Whilst there is limited space in this paper to detail all the risk factors faced by these communities, they are vulnerable across all aspects of the life-course. Including experiencing high rates of premature death. Hence bereavement and complicated and long-term unresolved grief underpins high levels of mental illness (depression and anxiety) in Gypsy and Traveller communities.[2,3] However despite the challenges faced Gypsies and Travellers, community members, and particularly women have been found to have a very stoic attitude towards life [4,5] as illustrated in the opening quotation. However this paper sets out to question whether when faced with repeat bereavement, communities are behaving stoically or exhibiting psychological and social resilience?

Resilience relates to an individual's capacity to recover from adverse life experiences including trauma and high levels of stress [6].The complex lifestyles led Gypsies and Travellers (i.e. often experiencing poverty and homelessness or insecure accommodation) typically involves experiencing high levels of trauma and stress,

both on an individual level and also collectively as members of a marginalised ethnic group. Thus Gypsies and Travellers have been identified as being vulnerable to both individual and 'cultural trauma' through their communal experience of membership of a group whose traditional ways of life is increasingly criminalised and stigmatised in sedentary post-modern society. Individual vulnerability is therefore exacerbated by collective cultural trauma which impacts on social dynamics, emotions, spirituality and the resilience of those involved and additionally, can have intergenerational impacts on coping mechanisms leading to increased emotional vulnerability. [7]

This paper explores research participants' capacity for resilience by considering the risks and protective factors faced by Gypsy and Traveller families. In order to set the scene it is important to clarify who are Included within this definition

Who are Gypsies and Travellers?

In Britain, 'Gypsies and Travellers' is a generic term used to identify members of ethnic groups who are traditionally nomadic. Defining who is a Gypsy and Traveller is however relatively complex, with different formulations found in planning law, which is based on nomadism (as still practised by a considerable number of Gypsy/Travellers in the UK) and under the Race Relations Acts which provides protection for individuals who are members of ethnic groups. It is important to recognise that there are a number of distinct groups commonly included within the generic term Gypsies/Travellers, e.g. English Romany Gypsies, Welsh Gypsies, Scottish and Irish Travellers, Show People, (Fairground Travellers) Bargees (barge or boat dwellers) European Roma and New Travellers [8]. For the purpose of this paper the term 'Gypsies and Travellers' is used to refer simply to English Romany Gypsies and Irish Travellers the largest of these populations in Britain.

Despite estimates that there are approximately 300,000 Gypsies and Travellers in the UK, [9] they remain a largely hidden community in mainstream consciousness. In part this invisibility is used as a protective strategy by the communities, to maintain their distinct cultures and heritage and also to prevent assimilation into the sedentary society.[10]. However, invisibility also keeps them marginalised and misunderstood by the wider population, creating a dichotomy of views, from the historic and romanticised notion of glamorous beauties leading a nomadic lifestyle with horse drawn wagons in country lanes, juxtaposed against the more recent stereotypical view of 'dirty' and 'dishonest' people living in illegally parked caravans. [5,11] The reality is in fact more complex as may be expected of a marginalised community who have experienced a long history of prejudice and discrimination dating back to the Sixteenth century when they were first identified as present in the UK.

The separateness and lifestyle choices favoured by many Gypsies and Travellers, which is often at odds with mainstream sedentary society, has resulted in a complex and difficult relationship between Gypsies, Travellers and the state. [9,10,12]. Consequently increasingly repressive laws and social and economic exclusion has led to Gypsies and Travellers having the poorest life chances of any ethnic group in the UK [14,15], Furthermore the marginal physical places occupied by many Gypsies and Travellers often adds to the high levels of exclusion they experience, increasing their vulnerability across all aspects of life, in particular in relation to accommodation, heath, education and employment risk [16]. This is particularly evident when considering the poor health status and rates of premature mortality found within Gypsies and Traveller communities when they are compared to mainstream populations, including individuals with low socio-economic status. [2]When this multi-factorial exclusion is added to a high rate of multi-generational premature bereavement from accidents or preventable deaths etc, it means that the individual and socio- cultural significance of death remains at the forefront of Gypsies and Travellers experience.

The impact of bereavement on Gypsy & Traveller communities.

Although death and grief are universal, the place of the dead in society, mourning rituals and the manifestations of grief vary greatly across cultures.[7,17] Thus culture, societal traditions and beliefs create understandings about death, and provide a framework for bereavement behaviours through determining the influence that the dead have on the lives of the living. [18, 19, 20]

Whilst death remains central to shaping the behaviours of Gypsies and Travellers, often played out through strong cultural traditions and religious beliefs; within the community there also appear to be explicitly contradictory models of bereavement behaviours, with overt expressions of loss, lavish funerals and complex death rituals, whilst the experience of 'grief' (defined as the emotional response to bereavement and loss that has both physical and psychological consequences that may impact on health[21,18] itself stays firmly hidden and is often unresolved for many years. [5.,3] In order to understand the phenomenon of long-term complicated grief it is necessary to understand the close knit nature of the Gypsy and Traveller families who are typically defined through a collective culture with each person's well-being and identity connected to membership of their family and kinship group rather than primarily operating as an autonomous individual.

The close-knit nature of Gypsy and Traveller life (which in many ways remains unchanged from the models found in pre-industrial rural societies) means that following a death, public displays of grief, and open recognition of the enormity of loss both to private individuals and the community at large, are central to both demonstrating the value of that person and acknowledging the ways in which life is changed forever by the loss of a community member. Failure to respect these social norms is almost unthinkable for the vast majority of Gypsies and Travellers, with individuals often travelling for many hundreds of miles to 'show respect' and support a recently bereaved family. Not uncommonly a funeral – regardless of the age of the deceased person, or the circumstances of their death – might attract several hundred mourners. Moreover should a breach of 'respect' such as sending flowers or attendance at the funeral or at the 'sitting up' with the family the night before occur, (even if social breaches may have existed in the past between families), individuals would behave in such a way report that they would feel both personally diminished and risk of social ostracisation.

So why does this central focus on death and appropriate behaviours remain so crucial to Gypsy and Traveller identities? Firstly, the relatively unchanging family structures and 'traditional' values common to the overwhelming majority of Gypsies and Travellers means that there is an exceptionally high level of contact between kin groups on a daily basis. This is in complete contrast to the majority of 'Western' communities where families tend to be smaller, more disparate and geographically dispersed. Thus, an individual might spend their entire life living alongside their parents and siblings, on a caravan site, with their own children growing up, marrying and having their own family whilst living either at the same location or geographically nearby. Hence almost by definition, living in an extended family unit, the repercussions of birth and death are likely to have a greater impact and deeper resonance than for individuals who are unable to live in such close proximity to their wider family. The close kin-ship structure of Gypsy and Traveller communities means that the death of a relative is felt with great intensity, articulated by some research participants as an event with which they "never come to terms". The significance of bereavement and loss within these groups can therefore for some people result in a continuum of loss and grief throughout the lifespan, particularly (as touched upon below) there are cultural factors which preclude seeking external psychological help with unresolved grief, leaving sufferers with no option but to 'cope' stoically, or resort to 'self-medication' such as alcohol or drugs to numb the pain of loss.

Resilience factors within Gypsy and Traveller communities.

Having outlined the factors which lead to increased grief reactions, amongst Gypsies and Travellers it is time to consider the strong protective factors which aid resilience and survival for individuals experiencing repeated trauma. Many of these resilience factors, like those which exacerbate risk of unresolved grief, are embedded within their close family networks. Rutter 1981[22] identifies a number of domains (both personal and environmental) by which individual capacities for resilience can be measured against the dominance of risk and protective factors within each person's life. Personal domains include personality traits and gender, capacity to cope with stress factors and change and family influences, whilst environmental factors include living conditions. It is impossible to separate personal and environmental factors where Gypsies and Travellers are concerned, as their nomadic traditions are increasingly compromised and an insecure living environment may be a significant cause of stress, with fear of eviction, prejudice and persecution common concerns amongst research participants. In addition, poor and dangerous living environments account for a number of intergenerational sudden unexpected deaths such as those associated with traffic accidents or poor environmental health. Negative family circumstance can also result from accommodation change with families being 'broken up' and unable to live in the close proximity that they are used to. In addition, bereavement will also have a significant effect on family with changing roles and responsibilities. [3] Thus, whilst the closeness of family is a strong protective factor associated with resilience, changes in circumstances such as those outlined above can also create additional stress factors. Rutter's (1981) consideration of personality traits and gender roles is particularly pertinent to Gypsy and Traveller families as he highlights psycho –social stressors in male patients, particularly those linked to family discord, proposing that males are more vulnerable and less resilient than females to stress. Evidence of male responses to family bereavement stressors within Gypsy and Traveller families in my research (and earlier literature), repeatedly note high incidences of risk taking behaviours and bereavement-related suicide; supporting Rutter's proposition of increased male vulnerability. In contrast Gypsy and Traveller women are often responsible for keeping the family together and demonstrate a stoic or resilient attitude of ' just getting on with it' (Irish Traveller woman aged 45, Roger's unpublished data)

Overall, whilst positively correlated resilience markers are clearly found within Gypsy and Traveller culture and traditional family structures: predominantly secure emotional attachments, strong relationships; the availability of emotional support; security, and a structured family environment with clear and consistent boundaries. [22,6] all of which were noted by respondents as fundamental to Gypsy and Traveller values; the overriding cultural need articulated by interviewees to "protect family at all cost" may, as normatively practised, be detrimental to developing personal support and resilience. Thus, my current research findings strongly suggest that the desire of Gypsy and Traveller respondents to protect family members through not talking about

the deceased person, ignoring others' pain and simply 'getting on with it' may be detrimental to individual emotional resilience; as grief is internalised. Hence the desire to alleviate grief, and culturally accepted way of protecting family members from pain by avoiding the subject of death and loss is so strong that it seems to create personal vulnerability rather than increased emotional protection for some vulnerable individuals.

This protective attitude is summarised by this interview extract,

'If it's a member of your own family, your brother or sister, you can't show your feelings you can't because you are afraid to hurt them, you have to keep a brave face on it' Irish Traveller woman, aged 36, (Roger's unpublished data).

Conclusion.

The role that family and community play in supporting health and wellbeing is highlighted in Marmot's (2010) [23] discussion of social capital, where he suggests that close relationships between individuals promote resilience and provide barriers to exacerbated health risk. In contrast, I suggest however that a lack of inter-generational resilience and learnt responses to grief and bereavement as enacted in the current case, is likely to result in the high levels of grief related mental health problems experienced by Gypsies and Travellers.

In conclusion the challenges and complexities of Gypsy and Traveller culture outlined above, means that they live with high levels of risk and vulnerability when compared to majority cultures. Whilst, the strong family attachments that should provide the balance in their lives, and which in many ways help them to develop resilience to the hardships of life are important in supporting them through physical and practical struggles, resilience in the face of bereavement (something which is difficult for anyone to cope with) appears to be compromised by the overriding need to protect Gypsy and Traveller family members by asserting stoicism, and in doing so, risking ignoring the cost of individual emotional health and wellbeing with intergenerational impacts.

'Putting the last first'- how participatory action research can turn things around for Roma communities

Vajda V.

University of Sussex (UK)
Institute of Development Studies (UK)
V.Vajda@sussex.ac.uk

Abstract

In the academic field of Romani Studies and also from national and European governments and NGOs, there are calls for researchers and policy makers to engage more directly and meaningfully with Romani communities. There is the implicit hope that participation of Roma people in both research and policy setting on issues that affect their lives can overcome some of the major development challenges faced by Roma in Eastern Europe, specifically in terms of housing, education, employment and healthcare.

This paper agrees with the principle but argues that 'the devil is in the detail'. Far from being a quick fix, it argues, taking a participatory approach to working with communities where Roma people live needs to be based on a sound theoretical and methodological framework, and requires long term investment in allowing both Roma and non-Roma people to engage with and own research that they can then use to make changes in their communities.

The theoretical framework proposed here brings together philosophical hermeneutics, critical race theory and feminist thinking and applies it to contemporary thinking about Roma and non-Roma communities living in close proximity. Methodologically, the paper proposes, participatory action research is a logical choice that flows from this theoretical background, but also an ethically sounder approach than non-participatory methods, allowing communities to have power over research and its outcomes.

In practical terms, participatory action research has been shown to provide unique perspectives on the resilience and strategies for social change employed by communities that are not easily accessible to policy makers. Even more importantly, participatory action research has emerged as a key tool for emancipation and liberation of people living on the margins. This paper will provide examples of how participatory action research can contribute to Roma communities moving beyond mere survival and resilience to become agents of change.

Keywords: participation, racism, feminism, hermeneutics

Participatory approaches and Romani Studies

Romani Studies is by now an established field, with one of the oldest academic organization, the Gypsy Lore Society, established in 1888. Other organisations such as the Open Society Institute or the Central European University also regularly hold conferences and publish research about Roma people and communities. In this academic context, the question of who represents Roma views is at the forefront of research and policy making.

1.1 Who are the Roma?

'Roma' and 'Romani' (as opposed to Gypsy) are political terms that have a particular history attached to them, being first used by the "Komiteto Lumniako Romano organisers in 1971 of the First World Romani Congress [7]. But who are the Roma? It is a difficult question for a group of people whose very self-identification is problematic and can be imposed by outsiders [8]. Scholars such as Michael Stewart [31:12] argue that for many reasons Roma identity does not fit neatly into patterns of ethnicity as devised by nation states.

Much of the seminal work in Romani Studies has been anthropological in character [30], [27]. In response to this rich ethnography and taking issue with what is sometimes seen as its tendency to reify a certain

view of the 'true Gypsy', Romani Studies academics are increasingly calling for the field to move beyond this limited understanding of Romani identity [32].

Importantly and in spite of their differences, academics and policy makers agree that Romani people in Eastern and Central Europe are subjected to severe discrimination that is often but not always acknowledged and named as racism [18]; [23]; [6].

Again, Romani scholars such as Angela Kóczé [22] go deeper and further than non-Romani academics, linking 'Romani subalterity' to neo-colonialism and borrowing the term 'infra-humanity' from Paul Gilroy [14] to describe how Roma are invisible 'as humans within European discursive and social fabrics, from history books to everyday workplaces'.

However, while anti-Roma racism is openly acknowledged and discussed, strategies to overcome it are seen as highly problematic, with criticism levelled at all actors engaged in this effort, from NGOs such as the Open Society Institute [22], to national governments [6] and to the EU itself [34].

How this less rigid, more complex and more emancipatory story of Roma identity is to be told is perhaps one of the most salient questions in Romani Studies at the current moment.

1.2 Participatory approaches in Romani Studies

Following on from these arguments, a growing strand of Romani scholarship and activism today is grappling with the realisation that neither academics nor practitioners can easily understand or engage with Roma people from the point of view of external observers. The question of 'who speaks for the Roma?' in current political and academic debates crops up most insistently [24]. The question is tacit in the EU's call for 'dialogue with and participation of the Roma' [9] or in efforts by Romani activists of coming together to make their voices heard (such as in the Fourth International Conference of Roma Women, held in Helsinki between 16-17 September 2013).

The more difficult matter, particularly highlighted by [24], is that the opportunity and right to speak on behalf of Roma is so far limited to elite Roma individuals and a number of international and national organisations that are more or less in touch with the needs and interests of grassroots communities. However without hearing the voices of the grassroots, it is difficult to imagine Roma who are politically engaged and can speak for themselves with authority. To remedy this we need more 'participation of Romani people in research that focuses on them' [33].

It is this gap in participatory approaches to Romani Studies that the present paper aims to address. First, it looks to hermeneutics and critical race theory, as well as on contemporary thinking around identity to make the case for a deeper, historically rooted and politically engaged understanding of Roma identity as a precursor for participatory approaches to research.

Second, drawing on the considerable experience with participatory action research methodology in other settings the research sets out to give a flavour of how far it is possible to journey in the as yet little explored realms of dialogical inquiry with 'ordinary' Roma and non-Roma people in the role of researchers.

Hermeneutics and Romani Studies

Philosophical hermeneutics as an ontological discipline was developed to its fullest by Hans Georg Gadamer [13]. Gadamer's theory of hermeneutics points the way to a 'powerful ontological mode of being-in-the-world-with-others' and a way of understanding 'things' and people very different from ourselves [29].

Hermeneutic understanding has been described as a three-fold process: in order to understand a something, including people and their identity, one must be able to intellectually 'grasp' that thing [17: 36-45] one must be to operate with it, in the same way as an artisan operates with or wields the tools of her trade; and one must find a way to articulate it so that the thing becomes illuminated by language, a fundamental dimension of hermeneutics [17].

Importantly, in any act of understanding 'history is always at work'. Gadamer's concept of 'effective history' proposes the idea that we 'read' people in the same way as we read texts, bringing to the encounter all of our history, their history and the historical processes that have led to that encounter [10]. In hermeneutics, history both limits what can be understood and creates the conditions for testing that understanding.

Other corollaries of Gadamer's hermeneutics are [29]:

1. understanding is only possible from a certain historical vantage point and from within 'effective history', which then creates a horizon of meaning,
2. people seeking to come towards each other enter into a dialogue based on their historically constructed prejudices, and it is necessary to make these explicit to be able to progress in our understanding
3. a provocation arises in any encounter in which people are brought up against each other's prejudices and attempt to gain new meaning from each other
4. finally, this effort of understanding can lead to a fusion of horizons.

It is possible to apply hermeneutic thinking to research on identity (such as Roma identity) by designing an inquiry as a 'hermeneutic dialogue' between for example Roma and non-Roma people. However, this is not merely a matter of 'cultural exchange'. The effort of undoing a history of discrimination requires a 'confrontation and fusion of lifeworlds', it needs to go beyond superficial dialogue or positive discrimination to engage with effective history and the meanings, truths and relevance of that to people to are separated by the 'gulfs of effective history' [28]. Hermeneutics teaches that careful and thoughtful reflection on what does and doesn't make sense in any given situation is key to accurate understanding [35].

The work of critical race theorists such as Homi Bhabha [1:2] points to the the interstitial space where cultures are formed. Indeed, it is 'these 'in-between' spaces' that become 'the terrain for elaborating strategies of selfhood' and give rise to 'innovative sites of collaboration, and contestation' [1:2].

In practical terms, to gain understanding of what happens in the in-between space where Roma and non-Roma people meet, research approaches are needed that allow both 'sides' needs to go through a process of understanding their identity: theoretically by learning what their identities mean for them; practically by becoming able to operationalize those identities; and dialogically by learning to articulate Roma and non-Roma identity to oneself and to others. This is where participatory action research emerges as a crucial tool of inquiry.

The potential of participatory action research for Romani Studies

Participatory action research has deep and wide roots [3] in the field of liberation pedagogy. However, the meaning of participation itself has changed over the years from participation at the local level in rural contexts [4] to a more recent focus on participation connected to citizenship and structural change [26].

It is clearly difficult to create a situation in which participation actually gives real power to a community and there are many challenges and risks in promoting this approach. Big questions arise over who sets the agenda and whether research is truly participatory or just tokenistic. The critics of participation state that the approach has been high-jacked by an instrumentalist ethos that 'hides and at the same time perpetuates certain sets of power relations' [5:11]. However, even they recognize that participation is a valid concept when applied to political activism and challenges to oppression. Thus, it is important when setting into motion participatory processes, that the assumptions and beliefs of those who hold the power in the relationship are equally challenged and examined as the assumptions and beliefs of those who hold less power.

Any research happening with Roma will need to first openly acknowledge and describe the fact that it is situated in a historical of oppression [23]. Thus, building also on feminist thinking [12]; [21], the necessity emerges for those who hold the power in any given encounter to also critically examine their role in creating an unequal situation. In Romani Studies, it is important that research looks not just at the situation of the Roma but also at the way in which non-Roma have contributed to the status quo and how their identities have been shaped by that dynamic of oppression.

In this situation, action or even inaction by subordinated groups (such as the Roma) can be conceptualised as resistance, which 'redefines the causes and meaning of oppositional behaviour' by understanding it as a core element of political action [15]. Participatory action research can use these facts as opportunities, by helping to uncover existing oppressive structures, patterns of resistance and examine how this resistance engenders intentional political action, but may also contribute to it. Kemmis [20] shows how critical participatory action research in particular has the capacity to take 'resistance' further, in the sense that it can empower the oppressed to become 'critical' and reflect upon how their own ways of seeing the world, combined with the historically created social structures that surround them and the practices embraced by their group and others produce 'untoward effects'. Research thus becomes a tool for opening up communicative space, a 'process of facilitating public discourse in the public sphere' and of exploring a shared reality and praxis. In this way, research is ultimately aimed at emancipation; knowledge has the potential to become emancipatory and produce social change and action becomes an intrinsic and necessary companion to socially committed research. Embracing such a paradigm has a major influence on the methodology used, since it asks that the subject of the research has some control in how the research is conducted, with the researcher playing the role of advocate for the oppressed [23].

Beyond this, wider opportunities are also at stake when embracing a participation action research approach, all of which come with their own perils that the researcher has to skillfully navigate. One of these is a new way of giving rigour and validity to the research. Brydon-Miller [2:202] describes this as an extended, deeper and more complicated set of principles for research ethics, specific to action research and to settings where there are pre-existing close relationships between researchers and the local community [36].

For example, participatory action research demands that members of the community have a say in defining which issues are to be addressed by the research and thus can decide whether this is ultimately beneficial to their lives or not; it is possible to create a 'community review board' for the research, as a means of engaging Roma people with it while at the same time testing risks and benefits of it happening in their midst; and

community members can be asked to participate in decisions regarding 'the application of the research findings, and the generation, ownership, and dissemination of knowledge based on the research' [2].

Conclusion

In the context of Roma studies, participatory action research is particularly pertinent, given the centuries during which outsiders have spoken for and represented Roma people. In the UK, there has been work using participatory approaches with Gypsy, Roma and Traveller communities [16], but in Eastern Europe the approach is largely absent. The fact at present is that most of the research 'on' Roma people has not included them [33] and that this could be a reason for the identified lack of engagement of Roma communities with policies of integration proposed by national governments in Central and Eastern Europe [9].

By contrast, other marginalised groups have had opportunities to engage with and try out participatory approaches to finding their own solutions for many years and have been involved in finding out for themselves 'identifiable patterns which point to a way of providing assistance that supports the agency of those who have suffered the gravest forms of deprivation and prejudice' [26: 8].

The learning from many years of working with participatory approaches is that communities can and do engage with research but they do so gradually, and only when considerable resources and attention are focused on how research is conceptualised, carried out and disseminated, with 'mutual trust built up over the years' [26: 60].

Thus, without embracing participation, the picture painted by current research on Roma communities is incomplete and doesn't allow them to show themselves in the ways that they choose to do, while the voice of the outside researcher comes through loud and clear. But without a thorough theoretical and practical grounding in how participation can achieve its full potential, it can become another lost opportunity or antagonise the communities that it 'targets'.

This paper has sought to show that philosophical hermeneutics, critical race theory and feminism can provide such a theoretical basis for research that leads to a useful, productive and historically relevant dialogue between Roma and non-Roma communities. Using the utmost care and awareness of the complex relationships between both Roma and non-Roma research participants, it is possible to gradually bring them together into a research collective that works collaboratively over the long term. This carefully laid groundwork affords the possibility to overcome some of the most pressing political and social challenges that face Roma and non-Roma communities in Europe.

L'evaluation de la resilience de l'adolescent

Bekaert J.

Hôpital Maritime de Zuydcoote boulevard Vancauwenbergue 59123 Zuydcoote (FRANCE)
jessica.bekaert@hotmail.fr

Abstract

In order to have a tool for measuring protective factors among adolescents, with a view to resilience research, we implemented the development and validation of an instrument (IFR-40 Bekaert et al. 2011). The IFR-40 was developed from a literature review identifying the set of protective factors reported in the papers. An exploratory factor analysis with oblique rotation allowed to highlight a three-dimensional structure (personal, familial and extrafamilial), composed of 40 items. A Likert five-point scale is used to determine the level of agreement of the adolescent with each statement (0: "Totally disagree" and 4 "Strongly agree").The positive correlations with measurement scale of the manifestations of psychological well-being of Massé et al. (1998) and the scale of life satisfaction by Diener et al. (1985) demonstrate the validity of the IFR-40. The results also demonstrate excellent internal consistency. regards the temporal stability of the instrument, it proves to be very satisfactory. These preliminary results need to be reinforced and updated through a confirmatory data analysis. In addition, the study of divergent validity is still necessary to complete the evaluation of the IFR-40. Thus, this writing presents data obtained from designed to assess the properties of the tool. The results suggest that the IFR-40 has psychometric properties and provides prompt and adequate evaluation of FP contributing to resilience among french adolescents.

Key words: Questionnaire, trauma, resilience, protective factors, youth

Introduction

Bien que certains adolescents soient exposés à un événement traumatique au cours de leur vie, les travaux épidémiologiques montrent que seulement certains d'entre eux manifestent un syndrôme de stress post-traumatique [1-2], suggérant que certains adolescents ne manifestent pas de pathologie ou d'altération du développement. On évoque alors le terme de « résilients » pour les désigner.
Le concept de résilience est multidimensionnel et dépend des caractéristiques intrinsèques et extrinsèques à l'individu. Lecomte (2002) a donné une définition assez consensuelle de la résilience, décrite comme « un processus dynamique consistant à bien se développer malgré des conditions de vie difficiles ou des événements traumatiques, basé sur l'interaction de potentialités internes à l'individu et de soutien environnementaux […]. » [3]. L'importance de la résilience a été mis en évidence dans la littérature du développement de l'enfant et de l'adolescent depuis plusieurs années, avec plus récemment des travaux se focalisant sur la prise en compte des critères internes et externes favorisant la résilience [4-5]. Ainsi, les études portant sur la résilience visent non seulement le repérage des facteurs de protection mis en jeu mais également la compréhension des différences intra et inter-individuelles. La résilience est souvent définie en fonction des facteurs de protection liés à l'individu lui-même et à son environnement. On parle alors de variables protectrices ayant trait au domaine personnel, familial et social conformément au modèle de Garmezy & Masten (1991) [6] pour désigner les facteurs concourant à la résilience [11-12]. La résilience a été prouvée comme étant quantifiable au travers d'échelles telles que le CD-RISC de Connor et Davidson (2003) [7], le RS de Wagnild et Young (1993) [8], l'ARS d'Oshio, Nakaya, Kaneko et Nagamine (2002) [9], la resiliency scale de Jew (1991) [10] ou encore le READ de Hjemdal, Friborg, Stiles, Martinussen et Rosenvinge (2006) [11]. On recense, ainsi, cinq instruments de mesure de la résilience chez les adolescents [12]. Cependant certains d'entre eux ont été conçus pour répondre uniquement à l'évaluation des variables individuelles (CD-RISC, RS, ARS) et ne prennent pas en compte les différents types de facteurs tels que définis par Garmezy et al. (1991) [6]. D'autres ne satisfont pas aux critères psychométriques nécessaires [13]. Bien que le READ se distingue des outils actuels puisqu'évaluant la cohésion familiale et les ressources sociales à l'instar des autres instruments, il présente de nombreuses limites [12]. Parmi celles-ci, citons que l'échelle a été testée uniquement sur des adolescents norvégiens avec une tranche d'âge restreinte aux 13-15 ans. Aucune analyse factorielle exploratoire n'a été conduite sur l'échantillon et l'analyse confirmatoire comptabilisait moins de six observations pour chacun des items, ce qui peut représenter une limite à la présente échelle [14]. Ahern, Ark et Byers (2008) rapportaient que des analyses supplémentaires ayant trait

aux qualités psychométriques de l'outil telles que la validité et la fiabilité s'avéraient nécessaires [15]. Une récente étude s'adressant non pas à des adolescents mais à de jeunes adultes norvégiens âgés de 18 à 20 ans n'a pas permis de mettre à jour la structure initiale de l'échelle. Il ressort de ces analyses une version modifiée du READ composée de 23 items. La fidélité test-retest de cette nouvelle version n'a pas fait l'objet d'une appréciation. Il est à noter également que la dimension nommée style structuré compte dorénavant trois items et que les auteurs envisagent d'y inclure des items supplémentaires en vue d'asseoir la consistance interne de l'échelle [14]. Malgré la prise en compte des dimensions sociales et familiales, certaines variables protectrices relevées au sein de la littérature n'apparaissent pas au sein de ces deux dimensions du READ. L'importance de la qualité relationnelle de l'adolescent avec ses parents, la disponibilité des parents, le sentiment de sécurité procuré par la relation ou le soutien social émanant des adultes extérieurs au cercle familial sont autant de facteurs de protection qui ne sont pas évalués par cet outil psychométrique. Nous avons, ainsi, souhaité développer un outil psychométrique permettant de palier aux différentes limites relevées dans l'évaluation de la résilience et intégrant, de fait, les différents domaines constitutifs de ce concept tout en satisfaisant aux critères psychométriques nécessaires.

Développement de l'échelle et analyses préliminaires

Cette étude décrit les étapes du développement de l'I.F.R-40 et évalue, auprès d'adolescents, la structure factorielle, la cohérence interne, la qualité de ses items et la validité convergente. On y présente également des données normatives (moyennes et écarts types), selon le sexe des participants de cet échantillon.

1.1 Méthode

1.1.1 Élaboration et sélection des items de l'instrument

Le développement de l'instrument a été effectué en plusieurs étapes, similaires à celles utilisées dans plusieurs autres échelles telles que le READ et l'ARS. Tout d'abord, les caractéristiques propres aux personnes résilientes relevées dans les nombreux travaux issus de la littérature ont permis de dégager un ensemble exhaustif de facteurs de protection et de générer des items permettant d'évaluer la résilience. Cette première étape a permis de créer 100 items évaluant les différents types de facteurs de protection (personnels, familiaux et extrafamiliaux) présents chez les individus résilients en référence au modèle de Garmezy et al. (1991) [6]. Certains items ont été, ainsi, générés afin d'évaluer les facteurs de protection personnels (e.g. « Je m'adapte facilement aux situations lorsque des changements arrivent. ») alors que d'autres ont été générés pour représenter les facteurs de protection familiaux (e.g. « L'un de mes parents est disponible quand j'en ai besoin. ») et les facteurs de protection extrafamiliaux (e.g. « Il y a quelqu'un avec qui je peux discuter de décisions importantes qui concernent ma vie. »). L'ensemble des items a par la suite été évalués par un comité de cliniciens et chercheurs spécialisés en clinique infanto-juvénile (clinique du traumatisme, développement de l'enfant) en fonction de sa correspondance sur chacun des trois facteurs (personnel, familial ou extrafamilial). 40 items ayant la meilleure validité ont été retenus et soumis à un échantillon de 20 participants afin de confirmer leur intelligibilité et ainsi, d'évaluer leur validité de contenu. Une échelle de format Likert en 5 points, similaire à celle utilisée dans plusieurs autres outils tels que le READ et le CD-RISC, a été retenue afin de répondre à chacun des items (de 0 : « Pas du tout d'accord » à 4 : « Tout à fait d'accord »). Ainsi, les scores obtenus sur l'échelle varient de 0 à 160.

1.1.2 Participants et procédures

L'I.F.R-40 a été administré à un échantillon de 299 adolescents volontaires issus de la population générale, similaire à celui utilisé dans d'autres échelles comme le CD-RISC [7]. L'échantillon était composé de 161 filles (âge moyen = 15,43 ; ET = 3,01) et de 130 garçons (âge moyen = 15,26 ; ET = 2,97). Huit personnes ont omis de mentionner leur sexe. L'âge des participants pour l'échantillon total varie entre 11 et 19 ans (âge moyen = 15,03 ; ET = 3,76). Il est à noter que les données concernant l'âge étaient manquantes pour 7 adolescents et pour 4 adolescents en ce qui concerne le niveau d'étude. Ceux-ci ont été recrutés auprès de divers collèges, lycées et universités. La passation des instruments a été effectuée pendant le temps de classe. Aucune compensation ou incitatif n'a été remis aux adolescents pour leur participation.

1.1.3 Instruments

Un questionnaire d'informations générales évaluant les caractéristiques personnelles des répondants, soit l'âge, le sexe et le cycle d'études a été administré avec l'I.F.R-40. La version française de l'I.F.R-40 a été développée pour évaluer les différents domaines constitutifs de la résilience. Plus précisément, ce questionnaire de 40 items explore les variables protectrices dont dispose l'adolescent au niveau personnel, familial et social.

Les questionnaires suivants ont également été administrés :

- L'échelle de satisfaction de la vie développée par Diener, Emmons, Larsen et Griffin (1985) [16], se compose de 5 items de type (« Je suis satisfait(e) de ma vie. ») qui incitent l'adolescent à porter une évaluation globale sur sa vie. Pour chaque énoncé, le répondant dispose d'une échelle de Likert en 7 points allant de 1 pour « fortement en désaccord » à 7 pour « fortement en accord ».
- L'échelle de mesure des manifestations du bien-être psychologique (EMMBEP) de Massé, Poulin, Dassa, Lambert, Bélair et Battaglini (1998) [17] mesure le niveau de santé psychologique à partir de la fréquence d'occurrence d'une liste de manifestations (1 : « jamais » ; 5 : « presque toujours »). Cet instrument repose sur 25 items mesurant l'estime de soi, l'équilibre, l'engagement social, la sociabilité, le contrôle de soi et le bonheur (exemple d'item : « J'étais bien dans ma peau, en paix avec moi-même. »).

Résultats

1.1 Structure factorielle de l'I.F.R-40

Compte tenu des limites citées au sein de la littérature à l'encontre de certains des outils mesurant la résilience, notamment celle ayant trait à l'analyse factorielle avec rotation orthogonale [18]**,** nous avons choisi de réaliser une analyse factorielle avec rotation oblique qui semblait plus en adéquation [18] puisque présupposant l'interrelation des dimensions de l'échelle. Ainsi, nous avons soumis l'ensemble des données à une analyse factorielle en composantes principales (ACP, avec le logiciel SPSS 17.0) avec rotation oblique dans laquelle nous avons demandé une solution en trois facteurs conformément au modèle de Garmezy et al. (1991) [6]. L'indice d'adéquation de l'échantillon à la factorisation est très satisfaisant (KMO = 0.890). Le test de sphéricité de Bartlett est significatif (p = .00). L'examen de la solution factorielle fait ressortir une structure en trois facteurs composée de 40 items. Les saturations factorielles sur chacun des items se situent entre 0.31 et 0.84 (Fig.1). Les trois facteurs dégagés expliquent 43,46% de la variance et s'élève respectivement pour chacune des échelles à 25,77%, 9,98% et 7,71%.

Le facteur 1 regroupe des items évaluant les facteurs de protection familiaux. Ce facteur comprend 14 items qui mesurent la dimension familiale, notamment les caractéristiques ayant trait aux parents, à la relation parent-adolescent et à l'ensemble de la famille nucléaire. Le facteur 2 composé de 14 items rassemble les items évaluant la dimension personnelle, plus spécifiquement les caractéristiques individuelles de l'adolescent (la croyance en soi et en ses capacités ; la confiance en soi ; le sentiment d'utilité ; l'adaptabilité ; l'autonomie ; la recherche d'informations et la capacité à découvrir un sens ; la capacité à planifier et à s'organiser dans la vie de tous les jours ; le sens du contrôle interne ; la capacité à résoudre les problèmes ; l'optimisme ; la détermination et la spiritualité) alors que le facteur 3 comprenant 12 items réfère à la dimension sociale et rassemble des items traduisant les contacts sociaux, le soutien provenant des pairs, d'une relation amoureuse, de professionnels, de personnes extérieures au cercle familial ou d'un groupe.

1.2 La fidélité : cohérence interne de l'I.F.R-40 et la qualité des items

Un coefficient alpha de Cronbach a ensuite été calculé à partir des résultats obtenus à chacun des items afin d'évaluer la cohérence interne du questionnaire et d'avoir un estimé de sa fidélité. Le coefficient obtenu pour l'ensemble des items s'élève à 0, 91 pour l'échantillon total. Les corrélations item-total (Fig.2) oscillent entre 0.21 (item 19) et 0.58 (item 8) et se situent au-dessus du seuil critique de 0.20 [19-20]. Seul l'item 22 présente une corrélation item-total inférieure à 0.20, cependant, le retrait de cet item n'augmente en rien la cohérence interne. Le coefficient alpha de Cronbach obtenu pour le facteur 1 est de 0.91, pour le facteur 2 de 0.88 et pour le facteur 3 de 0.77.

1.3 La validité convergente de l'I.F.R-40

Afin d'évaluer la validité convergente de l'I.F.R-40 une corrélation a été établie entre les résultats au questionnaire et ceux obtenus à l'échelle de mesure des manifestations du bien être psychologique. 15 participants parmi les 299 ont présenté des données manquantes à l'EMMBEP. Une autre corrélation a également été calculée entre l'I.F.R-40 et l'échelle de satisfaction de la vie afin d'obtenir des indices supplémentaires de la validité convergente de l'instrument. 14 adolescents parmi les 299 ont présenté des données manquantes sur l'échelle de satisfaction de la vie. Rappelons que dans certains études, des associations positives ont été trouvées entre la résilience et la bonne santé [8], le bien être [21] et la satisfaction de la vie [22] et des associations négatives entre la résilience et la dépression [8]. Une corrélation de 0,61 est observée entre l'I.F.R-40 et l'échelle de satisfaction de la vie et une corrélation de 0,72 a été obtenue entre l'I.F.R-40 et la mesure des manifestations du bien être psychologique. La figure 3 présente les corrélations obtenues entre les différentes mesures de l'étude.

1.4 La stabilité temporelle

L'évaluation de la validité temporelle de l'I.F.R-40 a été réalisée à l'aide de deux passations séparées par un intervalle temporel de 4 semaines. Des adolescents de niveau ont participé à cette étude (N = 73). L'échantillon est composé de 62 filles et 11 garçons, ayant une moyenne d'âge de 17.84 ans (ET=0.49). Tous les participants ont été informés de la double passation. Les moyennes obtenus à l'I.F.R-40 lors de la première et la deuxième complétion sont de 109.75 (ET = 20.18) et 112.21 (ET= 20.96) respectivement. Afin d'évaluer la stabilité temporelle des réponses à l'instrument, une corrélation pour échantillon appariés a été calculée entre les résultats à la première administration et les résultats à la deuxième administration. Les résultats obtenus indiquent un coefficient de constance tout à fait satisfaisant de 0.92 (p = 0.01).

Fig. 3 : Corrélations entre l'I.F.R-40 et les différentes mesures.

Mesures	I.F.R-40	EMMBEP	SATISF
I.F.R-40	1.00	.721*	.616*
EMMBEP		1.00	.660*
SATISF			1.00

Discussion

Cette première étude visait à évaluer les propriétés psychométriques de la version française de l'I.F.R-40 Les résultats obtenus attestent que ce nouvel outil évalue de façon adéquate et rigoureuse les différents facteurs constitutifs de la résilience. Par ailleurs, les résultats de l'analyse factorielle appuient une structure à trois dimensions et montrent que l'IF.R-40 corrèle fortement avec les variables pour lesquelles un lien fort a été observé dans la littérature. Ce dernier élément permet d'établir la validité convergente de l'outil. La consistance interne de chaque sous-échelle (alphas) ainsi que leur fidélité (passation test-retest) indiquent que l'outil présente également des qualités psychométriques satisfaisantes. Effectivement, le coefficient de stabilité temporelle lequel permet d'obtenir un indice de son utilité pour évaluer les changements en contexte d'intervention psychologique indique une bonne fidélité propre à l'ensemble de l'échelle. Il s'avère toutefois nécessaire d'envisager de futures analyses pour mettre à jour ces résultats au moyen d'une analyse factorielle confirmatoire. Bien que la population de validation (échantillon d'adolescents issus de la population générale) soit justifiée pour une première opération de validation, il semble utile de mettre à l'épreuve cet outil auprès de population d'adolescents ayant été confrontés à un traumatisme afin de compléter la validation de cet outil. Outre cet impératif de poursuivre et de finaliser la procédure de validation, ces recherches doivent également permettre d'étudier la validité divergente. A cet égard, des associations négatives étant relevées entre la dépression et la résilience [8], il s'avérerait judicieux d'envisager la complétion d'une échelle de dépression s'adressant aux adolescents telle que l'échelle composite de dépression (MDI-C) de Berndt et Kaiser (1999) [23] conjointement à l'I.F.R-40 dans le but d'asseoir la validité divergente. Ainsi, d'autres recherches visant à évaluer les propriétés psychométriques de l'I.F.R-40 demeurent nécessaires afin de confirmer les données obtenues et de maximiser la généralisation des propriétés de l'instrument. Les résultats préliminaires de cette recherche suggèrent, par conséquent, que cet instrument soit valide, fiable et puisse être utile aux professionnels de la santé, cliniciens et chercheurs, désirant procéder à l'évaluation des facteurs de protection chez les adolescents. L'I.F.R-40, dans cette perspective, offre l'opportunité de disposer d'un outil standardisé apte à distinguer de manière multidimensionnelle les adolescents au regard de leurs caractéristiques.

Conclusion

Les facteurs de protection jouent un rôle important dans le processus de résilience chez les individus ayant été confrontés à un traumatisme. Ils constituent, selon plusieurs chercheurs, des variables protectrices qui se déclinent selon trois grandes dimensions (personnelles, familiales et sociales) et qui permettent de moduler l'effet du traumatisme. A l'heure actuelle, seul le READ de Hjemdal, Friborg, Stiles, Martinussen et Rosenvinge (2006) [11] permettait d'évaluer ces dimensions avec plusieurs limites. Le but du présent article était de présenter les résultats visant à développer et valider un nouvel outil permettant de palier aux différentes limites énoncées. D'autres études demeurent toutefois nécessaires afin de compléter l'évaluation des propriétés psychométriques de l'I.F.R-40 telle que l'étude de la validité divergente. Il importe également de valider cet outil à l'aide d'une analyse confirmatoire. Des traductions, comme celle effectuée en langue anglaise pourront par ailleurs permettre d'augmenter l'accessibilité au questionnaire.

The management of resilience in organisations

Brate Adrian T.

Lucian Blaga University of Sibiu (ROMANIA)
adrian.brate@ulbsibiu.ro

Abstract

The awareness of the utility and training of approaches for diagnosing and management of resilience in organizations, at individual and group level, leads to organizational behavior efficiency, through the development of specific skills and abilities of employees and the involvement of specialists in prevention and intervention programs. This article aims to present current research and studies (from romanian organisational experience) on diagnosing and intervention strategies on resilience and its correlated factors in organizations, in order to provide resources for the development of management/ intervention programs and optimization at individual and organizational level.

Keywords: resilience, intervention strategies, individual and organisational level

Introduction

A step towards an adaptive approach to ensure an operational management during crises – based on building organizational resilience potential – requires the resources and the ability to measure and manage resilience in different occupational and organizational settings. *Resilience* is developed in the process of coping with day-to-day developmentally specific stressful social, occupational and organisational situations. The trait of *resilience* can be considered the outcome of an adaptation process and from a developmental perspective, the trait of *resilience* can be an outcome of integrating past positive and negative coping experiences into individuals *sense of self*; thus, it is possible that this trait influences individuals initial attitude toward stressful situations more than it influences their coping process [7]. The stability of *resilience* seems to be the key to explore the direction of influence between itself and stress: if *resilience* is stable, its stability resists the influence of stress on individuals (can be used to explain a negative *stress-resilience* correlation), on the other hand, if *resilience* is not stable, it can not resist the influence of stress on individuals (the appropriate explanation for a negative correlation between stress and resilience**)** [7]. A recent meta-analytic study [6] investigated the relationship between psychological *resilience* and its relevant variables: the results indicated that the largest effect on *resilience* was found to stem from the protective factors (life satisfaction, optimism, positive affect, self-efficacy, self-esteem, social support: positive association), a medium effect from risk factors (anxiety, depression, negative affect, perceived stress, PTSD: negative association) and the smallest effect from demographic factors (age, gender) [6].

Objective

The objective of this this article is to present current research and case studies (from romanian organisational experience) on diagnosing and intervention strategies on resilience and its correlated factors in organizations, in order to provide resources for the development of management/ intervention programs and optimization at individual and organizational level.

Organisational studies on resilience: examples of diagnosis and intervention strategies

The psychological effects of daily stress affects concentration, attention to detail, productivity and behavior [5], so developing resilience to create a healthy working environment reduces absenteeism, improve teamwork and increase team morale [11]. A resource for emotional resilience is optimism: increased employee optimism can lead to increased performance, which is a challenge for all managers. Developing an optimistic/ resilient organizational culture at work can increase the well being of employees and also to increase optimism and performance [8].

In the following, we will describe 2 examples (studies) from romanian organisational experience/ culture, of diagnosing and proposing/ implementing specific intervention strategies.

Example 1

A recent case study in an romanian organisation [12] has investigated the mechanisms that intervene in the relationship between *resilience, organization commitment* (attachment to the organization), *supervisory support and loneliness at the workplace* (LW) for the employees in a medical unit. After completing the instruments, the demographic questionnaire and the interview, that examined the relationship with the supervisory support, the objective was to identify whether resilience and organization commitment are predictors for *loneliness at workplace* (LW) and to examine differences in loneliness scores reported by employees who feel supported by their supervisors and those who do not feel supported. The *results* show that *resilience* and the attachment to the organization are predictors for loneliness at work, also the employees who receive good support of superiors have lower LW scores than those who lack the support offered by superiors. The findings have suggested specific strategies of the medical unit for improving organisational decisions and for the development of intervention.

The psychologist can build training programs for developing emotional resilience and health professionals in these programs to train nurses with seniority in the organization to support newcomers. If supported by experienced nurses, new employees can develop the necessary skills to identify negative triggers and stressful situations at work which causes distress and poor coping mechanisms. Newly employed nurses can develop their commitment to the organization and reduce the sense of isolation, can identify their own values and common and can learn to appreciate and work the other members of the team. New employees so supported can learn to appreciate and respect the needs and values of others, to form the necessary skills to communicate effectively with others, to improve their relationship with patients and colleagues, and to be more attentive to the work environment and decrease the number of 'incidents' [11], caused by stressfull events.

All major types of interventions were included (in accordance with [3]):

- stimulating and training social skills;
- providing social support;
- developing opportunities for social interaction;
- addressing maladaptive social cognition.

Specific strategies at group and individual level, for stimulating resilience in relationship with loneliness at work were also proposed for implementation:

- Colleagues who feel lonely can be helped if they are involved in discussions, ask whether information about a project, or are invited to a coffee break. It seems that coffee breaks and discussions taking place in the workplace can foster team unity and to grow return to work (according also to [13]);
- Managers should ensure that their teams and team members have corect and good interpersonal relationships with each other and that they are connected to each other (according also to [4]);
- The person who feels alone is hypervigilant to social threat, which exerts a strong influence on perception, cognition and behavior; in this context loneliness can be reduced by modifying/ eliminating incorrect cognitions and irrational or counterproductive perceptions, that favors predominantly focus attention on negative social issues, that occur in the environment (for ex . with rational- emotive techniques, according also to [3]);
- Training the support of superiors is a resource that can increase the feeling of attachment to the organization and reduces loneliness at work (LW);

In conclusion, (emotional) resilience, organizational commitment and support are resources that may decrease the risk of LW and help senior professional and new entrants employees to build a strong team and/ or reduce the feeling of loneliness felt engaging in a new job.

Example 2

Another recent case study [2] investigates the perception of resilience associated with occupational stress indicators, for romanian employees, from an administrative-public service institution: specific stressors, individual differences, coping strategies and specific effects, based on a comprehensive model for diagnosing occupational stress, at individual and organizational level. The participants have completed the Pressure Management Indicator and a biographical questionnaire. The results present and focus on significant associations between the dimension of *resilience* and specific indicators of social and professional pressure sources, of individual differences, of coping strategies and the measurable effects of occupational stress:

- *Resilience* is significantly positive corelated with specific effects of the occupational stress process, especially with state of mind and job satisfaction: the ability to 'bounce back' from setbacks or problems of the participants (employees) is more effective if it is associated with how satisfied they feel about their

state of mind, the satisfaction that they feel about the type of work they are involved, in terms of tasks and functions, but also about their organisation and commitement, of feeling calm, less tired.

- The analysis of the relationship between socio -professional pressure sources and resilience (as an effect variable to stress) reveals the folllowing significant associations: the higher pressures exprienced by the participants with workload, work- family balance and daily hassless is asociated with lower levels of **resilience**; a lower merit recognition is associated with a low level of job satisfaction with work, satisfaction , security and organizational commitment , mental state and **resilience**;
- The analysis of the relationships between individual differences and resilience show the following significant associations: Impatience is positively associated with **resilience,** that means that *the higher pace of life and the ability to cope with the need for urgency makes employees capable of 'bouncing back' from setbacks or problems*; Control and personal influence are positively associated with **resilience**: *higher levels of the ability to influence and control events (control) and to exercise discretion in the job (personal Influence) are associated to resilience resources*; regarding the relationship of coping strategies - effects of stress: as there is a greater *focus on the problem and a better* work- life balance*, the participants report higher levels of* ***optimism/ resilience*** ;

This results offer the diagnosis tool to the organization (management level and human resource department), from which to initiate an intervention programmme or specific intervention/ management strategies, for strengthening/ stimulating organisational decisions/ interventions/ changes, or eliminating/ lowering/ managing organisational stressors at group and individual level.

The management of resilience at individual and organisational level

Resilience is a key concept for these days of postmodern life and for the future. Regarding the process of maintaining well being and sanity for the person and the organisation, of adapting well in front of a threat, a difficult situation, a stressor, aggression, adversity, tragedy, trauma, disaster - resilience involves behaviours, cognitions, emotions, actions, strategies that can be learned and developed.

We consider that the main processes of managing resilience in organizations are :

- Prevention and control (monitoring) ;
- Diagnosis / auditing (specific tools) ;
- Intervention and management (programs and techniques at the individual and organizational).

A systemic comprehensive approach for the stimulation and intervention of resilient organizational strategies should include the following levels of management :

- Primary : identifying, eliminating or reducing / minimizing stress (stressors);
- Secondary: education and training of employees, by practicing strategies / techniques and stimulating resource management (the control of consequences / effects at the individual and organizational level);
- Tertiary : treating symptoms of employees who become victims of exposure to organizational stress or aggression (counseling, medical services).

Resources/ qualities for building resilience *at individual level* (psychological fitness) should include:

- The ability to make realistic plans and take stages to carry them out;
- Confidence in personal abilities and a positive self-view;
- Good communication skills and problem-solving abilities;
- Having caring and supportive relationships;
- Being able to control and manage emotions and impulses;

What can we say and learn about resourcefull characteristics and culture required to build a resilient organisation? We can reduce the impact of stressors on our working lives, by designing efficient and tested management strategies / standards/ procedures, to help ensure that organisations address key aspects of 'risk factors' (including demands, control, support, relationships, role, change), with a operational description of what should be happening in the organisation or 'states to be achieved', or regulation to be met. While these possible management standards provide a foundation for stress reduction, there are other *interventions* at *organizational level* (see also [1]), that should be considered, in order to increase resilience:

- Managing organisational climate and culture;
- Improving the perception of control over work / job;
- Managing the stress of job demands and shiftwork;
- Stress Control related to career management;
- Commitment to stress mangement and appropriate management style;
- Appropriate recruitement, selection and evaluation processes, based on efficient job analysis;

- Stress awareness and stress management training;
- Mediation and negotiation strategies.

Murphy [9] consider three elements as necessary interventions at the organizational level to be successful:

- employee involvement;
- the commitment of managers;
- supportive organizational culture.

If these items listed above are missing, the best intervention project will be doomed to failure. In the future, studies should incorporate these elements into the design of organizational level stress interventions.

A meta-analysis [10] on the effectiveness of organizational stress management interventions in the work environment revealed that the type of intervention (cognitive-behavioral, relaxation, organizational, multimodal or alternative) has a moderating role; in addition, cognitive -behavioral programs are most effective, if accompanied by other components of additional treatment, relaxation-type interventions were most commonly used and the organizational studies continues to be rare (studies on organizational type interventions reflects the fact that such interventions are complex and difficult to assess and design, than individual stress management programs).

Future research and intervention programs are needed, for testing efficient strategies and obtaining significant data on stimulating resilience resources at organisational level.

The perception of resilience and indicators of occupational stress

Brate Adrian T.

Lucian Blaga University of Sibiu (ROMANIA)
adrian.brate@ulbsibiu.ro

Abstract

The study investigates the perception of resilience associated with occupational stress indicators, for romanian employees, from an administrative-public service institution: specific stressors, individual differences, coping strategies and specific effects, based on a comprehensive model for diagnosing occupational stress, at individual and organizational level. The participants have completed the Pressure Management Indicator (PMI, [7]; IMP-RO, [1]) and a biographical questionnaire. The results present and focus on significant associations between the dimension of resilience and specific indicators of social and professional pressure sources, of individual differences, of coping strategies and the measurable effects of occupational stress. The implications of the study are discussed and future research directions on resilience in organisations are proposed.

Keywords: resilience, occupational stress, sources of socioprofessional pressures, individual differences, coping strategies, effects of occupational stress.

Introduction

Resilience at individual or organizational level is demonstrated after an event or crisis has occurred. The concept of organizational resilience has been studied in and applied to a number of different organizational settings, including the health system, business and industry.

In organizational theory, *resilience* is often defined in terms of the the ability of the organization or the person to simply 'bounce back' [7] from a distinctive event that creates vulnerability and requires a response [4]. It was also described as the ability to 'absorb' strain or change with a minimum of disruption [6] or, as the capacity to cope with unanticipated dangers after they have become manifest [5], which operationalise resilience into a reaction to a crisis situation. Some authors define resilience in terms of building it by maximizing the capacity of the organization to adapt to complex situations, identifying potential risks and taking proactive steps, to ensure that an organization thrives in the face of adversity and can cope/ manage (with) specific occupational/ organizational pressures [5].

The impact of specific stressors (of different intensity, frequency or type) and the perception of the these effects to occupational stress is moderated or mediated by *individual differences* (personality dimensions, emotions and coping strategies), which could be also crucial in developing, applying or improving stress management and intervention strategies [2].

Objective

The *objective* of this study is to identify significant interactions of the measured variables of resilience (operationalised as an effect to occupational stress) and specific individual differences, coping strategies, stressors (socioprofessional pressures) and effects. Using a comprehensive model of diagnosis and management of occupational/ organizational stress ([1], [2]), this paper presents a part of the results of the larger study on diagnosing and intervention in occupational stress for Romanian employees, from different socioprofessional categories.

Method / Procedure

1.1 Participants

The participants were 311 employees from an romanian organization with administrative and services activities. We have selected the following demographic characteristics, derived from a comprehensive biographic data inventory:

- Age m = 37.29 years, std. dev. = 10.44, min = 18 years - max = 59 years
- N1m = 148 male subjects (47.6%);
- N1f = 163 female subjects (52.4%);
- Experience in organization: M = 10.11 years, std. dev. = 8.70;
- 32.8% report a major event in the last three months;
- 12.9% say they have suffered or are suffering from a major illness in the last three months;
- 75.6% report that their health is good at the moment;
- 28.3% say that they are subject to socio-professional pressures;
- 27% do not practice physical exercise;
- 44.1% smoked on average 11.08 cigarettes / day (females 8.8 and males 13.25);
- 31.2% consumed alcohol on average 18.02 units / week (women 7.71, men 28,33);
- On a performance selfevaluation scale from 0-100: m = 81.74, std. dev. 12.54;

1.2 The Instrument

The Pressure Management Indicator (PMI [7], translated and adapted for Romanian subjects by the autor: PMI-RO [1] is a 120 item self-report questionnaire developed from the Occupational Stress Indicator (OSI). The instrument contains a biographic questionnaire and provides an integrated multidimensional diagnosis of the major dimensions of occupational stress, witch measure the stressors' level, coping strategies, individual differences and stress effects.

1.3 Procedure

The Romanian version of the *Pressure Management Indicator* was distributed to several participants (for diagnosing stress in romanian organisations, as part of a larger study), from which a sample of N=311 employees, from an organization with administrative and services activities was selected for this study. At the time of completition, participants were informed about the objectives of the study and give their consent to participate to the study. The data were computed with specific statistical programs.

1.4 Variables Description

The amount of pressure a person feels as a result of (Less/More pressure) - independent/ predictor variables (Low Score/High Score):

- *Workload* (PW): operationalised by the amount or difficulty of work they have to deal with;
- *Relationships* (PR): How well they get on with the people around them, particularly those at work;
- *Recognition* (PC): The extent to which people feel they need to have their achievements recognized
- *Organisational Climate* (PO)*:* The 'feel' or 'atmosphere' within the place of work;
- *Personal Responsibility* (PP): Taking responsibility for their actions and decisions;
- *Managerial Role* (PM)*:* Being responsible for managing and supervising other people;
- *Home / Work Balance* (PH): 'Switching off' from the pressure of work when at home, and vice versa;
- *Daily Hassles* (PD): The day-to-day irritants and aggravations in the workplace;

Individual differences and coping strategies - mediator variables (Low Score/High Score):

- *Drive* (TD)**:** The desire to succeed and achieve results (Less/More drive);
- *Impatience* (TI): A person's pace of life and ability to cope with their need for urgency (More patient);
- *Control* (LC): How much you feel able to influence and control events (Not much/More influence and control);
- *Personal Influence* (LI)*:* The extent to which someone is able to exercise discretion in their job (Not much/More influence and discretion);
- *Problem Focus* (CO)*:* The extent to which people plan ahead and manage their time to deal with problems (Less/More use of problem focusing);
- *Life / Work Balance* (CD)*:* The extent to which a person is able to separate home from work and not let things get to them (Less/More use of life work balance);

- *Social Support* (SS)*:* The help people get by discussing problems or situations with other people (Less/More use of social support);

Effects of organisational stress - dependent/ criteria variables (Low Score/High Score):

- *Job satisfaction* (JI), operationalised by how satisfied someone feels about the type of work they are involved in, in terms of tasks and functions (Little/A lot of satisfaction from the job);
- *Organisational Satisfaction* (JO)*:* How satisfied someone feels about the way an organisation is structured and the way it works (Little/A lot of satisfaction from the organisation);
- *Organisational Security* (OS)*:* How secure someone feels about the stability of their organisation and level of job security (Very insecure/secure);
- *Organisational Commitment* (OC)*:* How committed a person is to their organisation and the extent to which they feel that work improves the quality of their life (Not/Very committed to the organisation);
- *State of Mind* (MA)*:* How satisfied an individual feels about their state of mind (Feels anxious/ content);
- ***Resilience*** (MR)***:*** The ability to 'bounce back' from setbacks or problems (Poor/Good at 'bouncing back');
- *Confidence Level* (MW)*:* The extent to which someone feels settled or worried (Feels worried/ settled);
- *Physical Symptoms* (PA)*:* How calm a person feels in terms of physical tension or other uncomfortable sensations (Some feeling of physical discomfort/ Feels calm);
- *Energy Level* (PE)*:* The amount of energy and vitality someone has before they feel tired and worn out (Less energy and feels more tired/ More energy and feels less tired);

Results

If we analyse the intercorrelations between the criterion variables (dependent), represented by the effects of stress, shown in „Table 1", it can be seen that most of them are significantly positively associated with each other. *Resilience* is significantly positive corelated with the effects variables of stress, especially with state of mind and job satisfaction, with the exceptions: organisational security and confidence level. In other words, the ability to 'bounce back' from setbacks or problems of the participants (employees) is more effective if it is associated with how satisfied they feel about theyr state of mind, the satisfaction that they feel about the type of work they are involved, in terms of tasks and functions, about theyr organisation and commitement, of feeling calm, less tired.

Table 1. Intercorelations between the variables that measure the effects of occupational stress

Subscale EFFECTS	1	2	3	4	5	6	7	8	9
1. Job satisfaction	1								
2. Organisational Satisfaction	.62**	1							
3. Organisational Security	.28**	.28**	1						
4. Organisational Commitment	.63**	.44**	.19**	1					
5. State of Mind	.26**	.22**	.23**	.18**	1				
6. **Resilience**	**.30****	**.17****	**.03**	**.18****	**.36****	1			
7. Confidence Level	.03	.008	.22**	-.07	.45**	**.05**	1		
8. Physical Symptoms	.07	.04	.16**	.11*	.31**	**.20****	.19**	1	
9. Energy Level	.30**	.15**	.27**	.27**	.45**	**.28****	.27**	.52**	1

*Legend: * Corelation is significant p<.05 ; ** Corelation is significant p<.01*

The analysis of the relationship between socio -professional pressure sources and effects for the N = 311 participants (**„**Table 2**"**) reveals that there is generally a negative significant relationship, between the stressor and effect variables. We will focus only on the significant associations of resilience:

- The higher level of workload exprienced by the participants is associated with lower energy level , mental status , organizational security , job satisfaction , organizational commitment and **resilience** ;
- The higher pressures caused by work- family balance and daily hassless is asociated with lower levels of the organizational security , mental status , **resilience** and energy levels , in addition, increased work-family balance influences the higher satisfaction level with the organization , and a low level of daily harassment is associated with higher levels of job satisfaction and confidence , lack of negative physical symptoms;
- A lower merit recognition is associated with a low level of job satisfaction with work, satisfaction , security and organizational commitment , mental state and **resilience**;

Table 2. The Intercorelations Between the Stressors and the Outcome Variables Scales

Stressors Variables Subscales / Outcome Variables Subscales	Workload (PW)	Relationships (PR)	Recognition (PC)	Organisational Climate (PO)	Personal Responsibility (PR)	Managerial Role (PM)	Home - Work Balance (PH)	Daily Hassles (PD)
Job satisfaction (JI)	-.11*		-.18*	-.14*				-.14*
Organisational satisfation (JO)	-.14*	-.21**	-.26**	-.15**		-.15**	-.12*	
Organisational security (OS)	-.20**	-.18**	-.23**	-.34**	-.23**	-.18**	-.20**	-.23**
Organisational commitment (OC)	-.13*		-.12*					
State of mind (MA)	-.24**		-.17**	-.20**		-.12*	-.25**	-.25**
Resilience (MR)	**-.14***		**-.13***				**-.16****	**-.17****
Confidence level (MW)						-.19**		-.12*
Physical symptoms (PA)								-.18**
Energy levels (PE)	-.30**			-.17**	-.19**	-.17**	-.17**	-.20**

*Legend: * Corelation is significant p<.05 ; ** Corelation is significant p<.01*

The analysis of the relationships between individual differences and effects variables, especially resilience („Table 3") show the following significant associations:

- Impatience is negatively associated with organizational satisfaction, energy levels and positively with **resilience,** that means that *the higher pace of life and the ability to cope with the need for urgency makes employees capable of 'bouncing back' from setbacks or problems*;
- Control is positively associated with most of the effects of pressure -professional sources , while personal influence is positively associated with job satisfaction, organizational security and commitment, mental health and **resilience**: *higher levels of the ability to influence and control events (control) and to exercise discretion in their job (personal Influence) are associated to resilience resources*;
- Regarding the relationship of stress management strategies - effects of stress: as there is a greater *focus on the problem, the participants report higher levels of job and organisational satisfaction, organizational commitment, mental health and* ***optimism / resilience*** ; also work- life balance is positively associated with **resilience**, with psychological and physical comfort;

Table 3. The Intercorelations Between the Individual Differences and the Outcome Variables Scales

Subscale Individual Differences / Outcome Variables Subscales	Drive (Type A)	Impatience	Control	Personal Influence	Problem Focus	Life / Work Balance	Social Support
Job satisfaction (JI)			.27**	.34**	.21**		
Organisational satisfation (JO)		-.16**	.29**	.27**	.20**		.14*
Organisational security (OS)			.36**	.24**			
Organisational commitment (OC)				.37**	.27**

*Legend: * Corelation is significant p<.05 ; ** Corelation is significant p<.01*

Conclusion

The results led us to the conclusion that the stressors variables have generally a negative impact on the outcome variables (effects) and that specific individual differences and coping strategies are significantly

associated with resilience, for the romanian participants. This study, conducted on Romanian employees led us to results, that are similar mostly and in accordance with findings and research tendencies on stress and resilience in organisations ([3], [5], [7]).

As implications and applications of the study, the findings offer a starting diagnosis base for the specific organisational audit process, for developing intervention programs, at individual and organisational level and for stimulating/ managing resilience resources. Future research should focus on organisational and individual predictors of resilience and the moderating/ mediating role of resilience in the stress process.

Abstract

Hypothesis: High scores obtained applying psychological test and scales for family functioning are statistically significant for the risk / protection and resilience in the development of psychopathological conditions in children and adolescents.

Material and method : psychological tests and scales for family functioning and psychopathological conditions were applied to indoor patients of Child and Adolescent Psychiatric Compartment of Psychiatry Hospital Titan « Constantin Gorgos » and to a control group of scholars assumed from families with normal functioning.

Used scales were: Kid- SCID, Raven, ASEBA, SDQ, FAD, ADHD –RS, M_CHAT.

Inclusion criteria:

- indoor patients - complete battery of tests and scales for diagnosis and family functioning; psychological assessment; normal cognitive development
- control group – the same battery of tests and scales were applied

Results:

The retrospective study of observational charts of referrals from the 1st of February 2012 –the 15th of December 2013 grouped the patients into demographical variables; the same criteria were used for the control group. The tests results were statistical interpreted.

Highly significant scores were obtained in ASEBA scales applied to parents and adolescents.

Conclusions:

Dysfunctional family environment with a lack of encouragement and support as parental style, disorganized attachment, unclear familial roles and high emotional expression offer the frame for developing psychopathological conditions in children and adolescent and do not offer the resilience needed for an adequate psycho-social-emotional development.

Further studies are necessary for a better correlation between psychopathology and familial variables.

Keywords: resilience, family functioning, psychopathological disorders, children, CBSL, YSR, FAD

Family functioning as resilience factor

Resilience, as a psychological term refers to a special bio-psycho-social process permitting individuals, families and groups to pass over difficult, traumatic events without psychopathological issues and to live like before the stressful event.

As a universal process, resilience is not a characteristic only of the most powerful individual, and this process could not be understood without social interactions, without mentors, tutors and social networking.(5)

Despite the lack of a unique definition, there is an agreement: resilience is a characteristic for a person living a chronically adverse event, even traumatic and adapting well after it and this adapting process is interconnected– person-family-environment.(4)

As a complex process, resilience is conditioned by the interpersonal interaction models. M. Rutter has given the following considerations about the resilience as a process:

- As in all psychiatric developments, multiple factors are implicated in resilience – risk and protection factors with cumulative effect. The effect of one factor is wicker than the cumulative effect of multiple risk factors.

- The way children react in chronically adverse situations is different, this being a vulnerability model to respond to variable risk factors. This vulnerability model is related to genetic factors, individual characteristics, environment, but also past individual experience. Individual differences come from the different position and role of children in family dynamics.
- Family factors – chronically conflicts and tension – have different effects on children living in the same family. The factors stressing on one child could be more important than those stressing the whole family. When home environment is lacking confidence, cooperation, children tend to look for support outside the family.
- Chain reactions influence the duration of adversity effects. Early stress and adverse events could cause by such reactions psychopathological effects.
- Decreasing negative chain reactions and increasing positive ones could cause a decrease of adversity span.
- New events and situations could determine breakdowns in these circuits of adverse events and more, in psychopathological developments.
- Positive events don't have much protective effect, but they could be useful for neutralizing risk factors. Risk and protective factors could be found in family, in peer groups and in community.
- Cognitive and affective assessment of the living trauma – offering a sense – is the core of resilience.(7)

Mrazek &Mrazek (1987) proposed the cognitive evaluation theory as resilience development – the individual ability to analyze and to give a meaning to adverse situation accordingly to his own conceptualizing system. (5)

These authors established a list of abilities and characteristics of resilient persons:

- Rapid stress reaction
- Early maturity of the child
- Ability to stay away from intense affects
- Seeking information (environmental risks)
- Ability to develop connections and to use them in crisis
- Positive projective anticipation (ability to see in the future his own life without actual difficulties)
- Decision making ability even when implying risks
- Conviction to be loved and to deserve to be loved
- Positive reevaluation of the harmful event (the traumatic event becomes more acceptable)
- Ability to identify oneself with some aspects related to aggressor competences
- Selflessness
- Optimism and hope

Accordingly to this theoretical concept, resilience is a dynamic process thus the individual is using a sum of convictions in order to develop and use competences for adapting more efficient to stress situations.

For children and adolescents living traumatic events the resilience development as a dynamic process is closely related to family functioning. Rutter stated affective and secure relations as core protective factor in resilience process. (7)

Social responsiveness and positive affective response from family members, availability to participate and cope, engagement and good humor, solving problems skills, assuming responsibility could stand for assessing potential resilience.

We focused on the positive effect of familial environment named familial coherence and on the negative effect on resilience of somatic and psychiatric disorders of the parents, divorce and death of one parents.

It is well known that family atmosphere will generate later adapting skills for children and adolescents. Observing the parents' roles and the way they are solving problems, children will manage to develop their own ways to cope in different situations.

When living in calm, supporting, encouraging atmosphere, with parents that praise child's creativity and initiative when exploring environment, a child will grow knowing that he/she is capable and has courage to confront various events. The connections developed during this independent exploration will stand for future net support. More than this, on these connections and observations, the child will build his own values and its orientation.

Different authors studying resilience in various scales focus on three important categories of protective factors: positive traits and individual resources, coherent, supportive and stable familial environment and social network increasing individual adaptative efforts.

Family coherence and family functioning as protective factors in resilience development were mentioned in following features: problem solving, communication, assigning roles, affective responsiveness and involvement, behavioral control.

Problem solving assesses the family ability to solve problems and maintain family functioning.

Communication assesses whether the verbal message exchanged between family members is clear and direct.

Assigning roles means that the family is organized in order to insure provision of resources, nurture and support for personal development and, in the same time, whether the roles are carried out responsibly.

Affective responsiveness and involvement assess the degree in which family members express appropriate affect, are interested and take value in other members' concern.

Behavioral control assesses the way in which the family standards of behavioral are maintained within the family system. (6)

Somatic and psychiatric disorders- risk factors in family functioning

When focusing on risk factors we look for somatic and psychiatric disorders of the parents, divorce and death of a parent as negative factors, one by one, or by accumulation in resilience process. The impact of a disorder is closely related to the degree of impairment.

A disorder could appear suddenly or insidiously; could affect parts of the body, seen or unseen, or the entire organism; could determine fatigue, pain, lose weight, failure in job functioning; could have a lethal evolution or not and thus necessitate hospitalization – frequently or on long term; a disorder will necessitate treatment, any treatment has secondary effects and could stigmatize the person.

The individual response to a disorder is related to age, gender, personality, previous health state, tolerance to suffering and relation with religious convictions. Mirroring these, other family members –especially children will develop special skills to adapt using the parent's model.

The sick parent could refuse to cooperate, feel anxiety or be compliant to the treatment, be defiant, aggressive, look for secondary benefits, regress to a infantile behavior and isolate in social environment.

From the parent's affective behavior, mood, cognitions, body image and motivation, a sum of abilities will develop in children that have to cope with this adverse event – having a chronically sick parent.

Protective factors for this situation could be noticed – good nurture and good physical shape of the child, high self esteem, low alcohol and cigarettes consume, responsibility, good judgment, good understanding for abstract concepts (illness, suffering, cause-effect relations), secure attachment, solid information about the disorder, good management of previous difficulties and the ability to pass over them, the feeling of control and spiritual convictions, in school - good peer and teachers relation, the presence of grandparents, social active networking for support and encouragement, adequate internet using- social network, serious information about the disease, normal intellectual status of the parents, good financial outcome of the family, ability of the parent to encourage children. (5)

From the risk factors we mention: low self esteem, victimization, anxious attachment, low suffering tolerance, feelings of unfairness, discrimination, pressure from the school, lack of understanding from the networking – peers and teachers, limited social interests, for this, adolescence time being by itself a risk factor; from the parent – pressure, lack of understanding, low economical status, low intellectual status of the parent, high expectations from the child, tension in couple relationship,

The situation to have a close relative with a mental illness is common, considering the large family, too. One study of the European Union mentions that three million children have a parent with a diagnosed mental disorder. (5)

Living and developing with this condition could rise the question of how important is the negative outcome for these children, even if children and adolescent with one parent with a diagnosed psychiatric disorder are not always in the direct concern of social services.

Very often, children learn to raise silence over the parent's diagnosis, knowing the stigma and having few persons and friends to talk to about their concern about the parent. Silence is good for not being judged, but also strengthens the loneliness and social isolation.

We consider that genetic vulnerability when having a parent with a mental disorder should be taken into account for the children.

We should mention also, as risk factors for developing resilience, for children: helplessness as they could not always understand the parent's symptoms, guilt, fear and separation anxiety when the parent goes to the hospital, disorientation. Some children act as an adult – parentification of the child – and thus they suffer and live away from their childhood. (5)

Concerning the adult's point of view, a parent with a mental disorder is not always able to develop a secure attachment, by having an impulsive way to behave, going often to the hospital and thus modifying the way to communicate and support the child in his particular and special needs: an anxious attachment and sometimes a disorganized one, lack of emotional reciprocity, a negative emotional tone, disruptive mood, poor educational abilities, especially when it's hard for the parent to understand the developmental stages of the child and not being able to respond in a adequate way to the child's needs.

All these various factors have different consequences: neglect, abuse, psychiatric disorders development in children and from these depression, conduct disorders, attention deficit, mood disorders and academic delay are more common.

Not all the children living with a mental ill parent will develop ineffective adjust abilities. Rutter introduces the "rule of thirds" – one third developed psychiatric disorders stabile in time, another third developed a temporarily disorder and the other third never developed a psychiatric disorder. This means that some protective factors play an important role in becoming resilient: a good friend or a supportive adult away from the family, a secure attachment with an adult with good mental status, having information about the psychiatric disorder.

Divorce

The specific situation of our society, with more separation and divorces, raised the question about the welfare of children after the parents' separation. Many studies and analysis state that most of the children from divorced families have no problems.

The parental conflict is for sure an important stress factor. This conflict could start long before the divorce and persist after.

Sometimes, after the divorce the child is standing between the parents in their conflict – this having an important risk outcome for an emotional impairment of the child. The conflictual relation of the divorced parents with various subjects – visiting hours, financial resources, child's residence – creates a low parental ability to emotionally respond to child's needs. Thus, children of a divorced parent could develop externalization disorders – ADHD, conduct disorder, oppositional defiant disorder, but also adapting problems seen in academicals difficulties, problems in school with peers, low scholar results, spending more time with TV and computer playing, low motivation for homework. Poor parental control could be a risk factor for all these. (5)

It's important to mention that divorce do not condemn child to suffer. There are studies that mention that children of divorced parents are resilient. The protective factors could be: financial support from the parent that is not living with the child, low parental conflict after the divorce, living with the most emotional competent parent, family coherence – emotional support, worm as family atmosphere, adequate parental control by both parents, a structured and persistent educational model in both families, mostly when children live with both parents, support and attention in school and from other significant adults – in extended family or in religious community. In accessible connectivity, children will develop resources for their needs.

Death of one parent

Death of one parent is one of the most important stress factors for children and adolescents. It is not only the loss of the caregiver, traumatic by itself, but the consequent changes in the child's life – changes for a long time, implying school, friends, home and changes that could contribute to psychiatric disorders development – social withdrawal, depression, conduct disorders. (5)

There are in this particular situation protective and risk factors for child's resilience.

The death of one parent will bring a diminished financial outcome for the family and this stresses all, the living parent could not be able to offer the necessary worm and emotional implication, because of the mourning or a developing psychiatric disorder. The child instead has his own difficulties – inhibited affect expression, low self esteem, his poor capacity to explain the event, sometimes considering his fault the death of the parent, psychiatric disorders of the child.

There are still resilient children, and for those the protective factors could be: the warmth brought by the living parent, adequate parental control, adequate emotional reciprocity of the parent, good coping from the child by efficient effort to adapt to daily stress, good evaluation of the negative event, supportive social network from family, friends, spirituality.(5)

Child and adolescent resilience in special condition – small research

1.1 Hypothesis

High scores obtained applying psychological test and scales for family functioning are clinically and statistically significant for the risk / protection and resilience in the development of psychopathological conditions in children and adolescents.

1.2 Material and method

Psychological tests and scales for family functioning and psychopathological conditions diagnosis were applied to indoor patients of Child and Adolescent Psychiatric Compartment of Psychiatry Hospital Titan « Constantin Gorgos » and to a control group of scholars assumed from families with normal functioning.

Used scales and questioners were: Kid- SCID, Raven, ASEBA, SDQ, FAD, ADHD –RS, M_CHAT.

We used the following inclusion criteria:

- indoor patients - complete battery of tests, questioners and scales for diagnosis and family functioning; psychological assessment; normal cognitive development
- control group – the same battery of tests and scales were applied

1.3 Results

The retrospective study of observational charts of referrals from the 1st of February 2012 –the 15th of December 2013 grouped the patients into demographical variables; the same criteria were used for the control group. The tests results were statistical interpreted.

Highly significant scores were obtained in ASEBA scales applied to parents and adolescents.

	Somatic diseases debilitating	24	22	24,62
	Mental illness	36	41	41,12
	Suicide at 1st degree relatives	25	8	2,9
Economic situation	Poverty	17	12	9
	Middle income	62	65	31
	High income	21	23	18

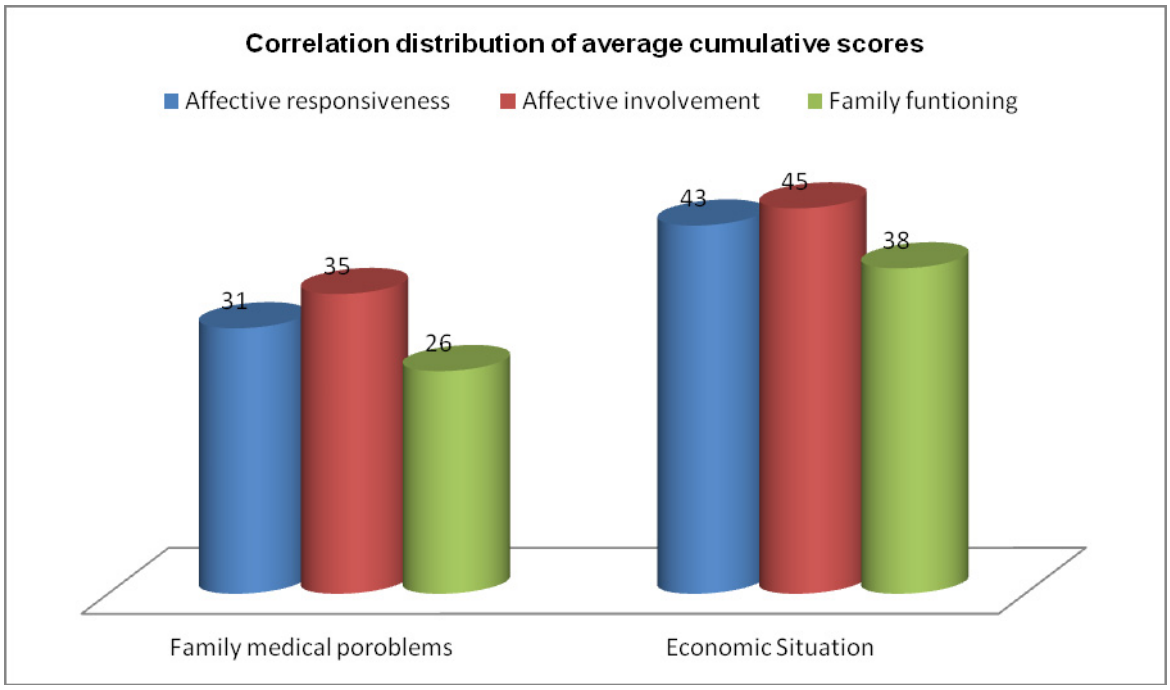

Fig. 6

Note: Correlations distribution of average cumulative scores report highlight the functionality of the family according to resilience factors, clinical range fits between 0-50.

Conclusions

Dysfunctional family environment with a lack of encouragement and support as parental style, disorganized attachment, unclear familial roles and high emotional expression offer the frame for developing psychopathological conditions in children and adolescent and do not offer the resilience needed for an adequate psycho-social-emotional development.

Abstract

The psychiatric disorder of the parent is considered a risk factor for the offspring. Under what circumstances can these persons develop resilience? The study explores the experiences of 13 persons having a parent diagnosed with a psychiatric illness. It aims to highlight the resilient processes, but also the difficulties and costs of resilience, by means of in-depth interviews. The data was analysed using qualitative methods. Common themes emerged from the autobiographical narratives of the subjects. The presence of significant persons and relationships, the ability of analyzing and reframing negative events, individual qualities of the person, positive parenting styles were identified as contributors to the development of resilience. The research in this domain can have theoretical and practical implications for intervention and prevention in mental health.

Keywords: resilience, parental psychiatric disorder, offspring, qualitative research

Background

Resilience is not a linear, constant process, nor a single quality of a person. It is a dynamic process, influenced by the interactions between the individual and his environment [1],[2],[3]. This makes it difficult to study the resilience, especially when analyzing it from the life-cycle perspective. Besides the normal vulnerable moments which characterize different phases of a person's development, the presence of a psychiatric disorder in the family is and additional stressor. The parental illness is considered a risk factor for the child [4],[5], which in some cases increases his vulnerability. However, in others cases, it can lead to the development of resilience, having a "steeling" effect [6].

Considering the complexity of these processes, qualitative research in the domain of resilience gives the opportunity to deeply explore and understand various phenomena, to conceptualize the psychiatric cases from different points of view and to develop strategies for intervention and prevention [7], [8].

Objectives

The study aims to explore the experience of having a parent with a psychiatric disorder through the autobiographical narrations of the subjects. It focuses on the development of resilience, but also on the difficulties and costs of this process.

Materials and Methods

1.1 Participants

We selected a purposive sample of 30 subjects who have one parent diagnosed with a psychiatric disorder, either admitted in the Psychiatric Clinic in Timisoara or from the outpatient centres. The inclusion criteria for the participation in the study were: the subject's age at the onset of their parent's disorder under 16, their current age over 18 and an evolution of the parent's disorder of at least 5 years. The subjects and their

parents were informed about the purpose of the research. Out of 30 subjects, 13 gave their consent to participate in the study and an individual meeting with each of them was scheduled.

1.2 Instruments

The following instruments were used: a sheet with socio-demographical and clinical data of the subjects and parents (Table 1), audio-taped interviews with the subjects and the EMBU scale for the assessment of the parenting style.

Table 1. Data of the subjects

Mean age of subjects (years)	**29**	
Mean age of parents (years)	55	
Age of subjects at the onset of parental disorder (years)	0-3 4-11 12-16	5 4 4
Gender of the subjects	Male 2	Female 11
Gender of the parent	Male 2	Female 2
Education	Highschool University	6 7
Professional status	Employed Studying	10 3
Marital Status	Married Stable relationship Single	4 7 2
Siblings	Yes No	5 8
Diagnosis of the parent according to ICD-10 criteria.	Schizophrenia Schizo-affective Disorder Persistent Delusional Disorder Recurrent Depressive Disorder	7 1 4 1

The interview consisted in open questions which included a short history of the parent's disorder as it is remembered by the offspring, a short family history and questions about the impact of the disorder on the child's life, the difficult moments, the changes in their families, the ways in which they dealt with them, their resources. The interview was designed by the first author, based on the research literature. It was reviewed by the other authors, until a consensus was reached. The order of the questions was sometimes changed during the interviews, certain questions were discussed in greater detail, according to the course of the interview and the subject's interest in the topic and additional questions were included if necessary. The interviews were conducted by the first author. The verbal consent for the recording of the interviews was obtained. The average duration of the interviews was 1 hour.

The interviews were transcribed and analyzed separately by the authors. Data was analyzed during data collection and also after finishing all the interviews. Categories and themes were identified and context analyzed.

The EMBU (My Memories of Upbringing) scale [9] measures the memories of parental rearing behaviour, for mothers and fathers separately. It consists in 81 items in 15 subscales rated on a 4-point Likert-type scale. It evaluates the following parenting styles: abusive, depriving, punitive, shaming, rejecting, overprotective, overinvolved, tolerant, affectionate, performance-oriented, guilt-engendering, stimulating, favoured siblings, and favoured subject.

Results

All the participants in the study are employed or still in the educational system. 10 subjects have their own family or a stable relationship.

Most of them consider themselves satisfied with their lives and believe that they succeeded in taking the best out of a difficult situation and that they became more capable of dealing with other stressful life events.

Every participant had an unique experience of the situation we studied. In each case, multiple risk and protective factors were involved. Despite the numerous differences, common themes were identified in their narratives, based on which resilient processes could be explored.

The subjects' perception of the disorder was influenced by their age at the onset of the parent's illness. More than half of the subjects were very young at that point of time. Still, they can recall moments or periods of

time connected to the parent's symptoms (fights, violence, unusual behaviours, mood changes, affective inversion towards them) and events related to the disorder (the admissions in the hospital, the parent leaving home, the behaviours of the other family members). The emotional reactions regarding those situations were mostly characterized by confusion ("I could not understand what was happening"), fear, ignorance or difficulty in accepting that it is a disorder ("It was a kind of ignorance of the situation. I did not want to believe she is sick. It was easier this way, as a child"). In most of the cases, the child received no explanation or very few information about the disorder. The moment they realized that their parent had a psychiatric disorder was placed by the subjects somewhere between 12 and 15 years of age. It was also considered the moment that changed the way they conceptualized the situation. This age also corresponds to the adolescence phase, which is characterized by an increase in the autonomy and independence of the person, by a development of the cognitive functions and by higher emotional and communicational needs. 7 out of 13 subjects reported that they would have wanted to communicate more with their parent during that period. Other feelings related to the disorder during time were shame and guilt. Almost all of the subjects reported the fear of the possibility of inheriting the disorder.

Making a difference between the person and the disorder was a common way of perceiving the situation ("My mom was doing all those things because she was ill. But, in fact, she is a very good and caring person"). The perception of the disorder and the impact on the child were also influenced by the diagnosis, duration of the illness, the severity of the symptoms and the manifestation of the disorder between the episodes.

The current perception of the parent's illness, as adults, is a consequence of the ability of the person to accept and integrate the experience in his own life. In the majority of the cases, we consider that the subjects were able to do this and the others are working and trying to achieve this purpose.

7 of the subjects come from organized families, the other parent being a significant support of the family. In 2 cases, the family environment was characterized by verbal and physical abuse (by the father), in 3 families, the subject did not have a relationship with the father after the parents' divorce and 3 subjects maintain a relationship with the parent who left home after divorce, but without him being a real support.

Most of the subjects reported family changes due to the disorder. Only 3 of them did not consider that there were any changes when asked directly. However, during the interview, different aspects related to this theme emerged.

For some of the subjects, the parent's disorder was the normal reference system, because they did not know their parent in a different way. Thus, they experienced fewer changes in their families and relationships.

Some changes can be considered as directly related to the presence of the disorder, others need to be placed in a larger context and in relation to other events as well. The most common aspects reported by the subjects were parentification and the redistribution of various responsibilities in the family. They felt responsible for protecting the parent, they had to do chores in the house or became a balance factor in the family. The exceptions were the cases in which the father was the patient or where other family members took the role of the parent when needed (for example, grandparents). Responsibility at a young age was sometimes seen as overwhelming. Still, almost all the subjects believe that this also made them more mature, independent and strong.

Most of the subjects recall a good relationship with the parent in the childhood. We also observed a tendency to ambivalent feelings towards the parent during time or an idealization of the parental figure.

8 subjects reported no change or a positive one in the relationship with their parent (a closer relationship, more support) and the others think that the change was in a negative way (more conflicts, distance, loss of trust).

The most common parenting styles, explored by the EMBU scale, were: affectionate, overinvolved, stimulating and performance-oriented. 11 out of 13 subjects had the highest 3 scores in these domains for both parents. In only 2 cases there were major differences between the parenting styles of the two parents. These parenting styles can be analysed from different perspectives. The subject's perception of positive parenting can be viewed as contributors to resilience. On the other side, they could be related to the need for idealization the parent in some of the cases. The overinvolved parenting style can be a compensatory mechanism used by the parent.

All the subjects mentioned the importance of significant persons in their lives: the other parent, grandparents, siblings, other relatives, husband/wife, children, friends or teachers. They describe them as strong, supportive, trustful persons. Some of the subjects felt a real support in their parent as well, despite the disorder.

By analysing the long-time experience of the subjects, we tried to identify the phases of the process they followed. The first phase can be characterized by denial, anger, shock or confusion. In a second phase, the subjects started to understand and accept the situation. An important phase is the one of reframing the negative events and giving significance to the situation, in order to finally succeed to integrate the experience, regain balance and work towards personal growth. These phases were not clearly delimitated, nor were they exactly the same in all the cases, but the main themes can provide a framework to a better understanding of the resilient processes.

The common individual features described by the offspring as being helpful in difficult situations were: optimism, humour, positive thinking, ambition, patience, empathy, sociability, ability to analyze things, involvement in activities.

These themes could not be interpreted separate from the larger context, all of them being strongly interconnected.

Discussions

We can consider that the participants in the study somehow self-selected themselves. The fact that they accepted to talk about their experience can be considered part of the process of resilience. It is a proof of acceptance and integration of the experience in their lives or at least a step forward in this direction. Even if it was not an easy task, the participants were able to discuss openly about the themes related to their parents' disorder and almost all of them said that it was not the first time to think about them. As expected, their perception of the situation changed over time during a long process characterized by mixed positive and negative feelings.

Many of the participants related that they succeeded to integrate the experience and feel satisfied with their lives. Still, the whole process was a long, difficult one. The past and present relationships with significant persons were considered as highly relevant for their success. These persons are called tutors of resilience [10]. On the contrary, very few received professional support. This fact makes us approach the situation from the perspective of assisted resilience [11] and highlight the need for early assistance of the children having a parent with a psychiatric disorder. Further research in this field should also rely on this important aspect.

The ability of a person to develop resilient mechanisms is also related to the attachment style [12], [13]. Persons with a secure attachment are more likely to pass through the phases we described earlier and become resilient. An avoidant attachment style could lead to the blockage of the person in the denial phase, an ambivalent or anxious attachment could lead to persistent feelings of anger and fear. Hence, the assessment of the attachment style in the study of resilience can provide a better understanding of the subject's experience and can be a resource for an effective intervention.

The use of interviews as assessment instruments gave the subjects the opportunity to narrate the stories of their experience in a different framework. They reconstructed their memories in an organized way, they could make better sense of some events. From this point of view, the discussion was therapeutic [14],. Most of them considered it helpful. The evaluation of the interview's impact on the subjects might be useful for future research.

Being a qualitative research, the findings cannot be generalized. Still, they are in accordance with the literature in the field [15], [16]. [17].

The study is part of a larger project. Therefore, further research in this field will be conducted, including larger samples of participants (with the inclusion of other family members as well) and additional methodology (focus-groups).

Conclusions

Having a parent with a psychiatric disorder is a challenge for the child. The development of resilience is a complex, ongoing process. The study of the relationships between the various internal and external factors that can influence this process is a difficult, yet very important task for theory and practice. It can provide a different perspective of the psychiatric cases and can have essential implications in the development of psycho-educational and preventive programs in mental health.

Psycho-social cognition of elders' quality of life and assisted resilience measures

Rascanu R., Rugescu Ana-Maria M., Macovei Melania M.

University of Bucharest, Faculty of Psychology and Social Sciences;

Abstract

Even if old age is generally considered an age stage and not a disease, objectifying the inter-individual differences represents, especially for the 3rd age a well acknowledged reality.

We tried to identify the necessary measures for assisted resilience intervention (direct or indirect), in order to observe the differences in recognizing the quality of life, by evaluating the cognitive impairment, of self-esteem and of the influence of the background of the individuals. We studied two groups of old people, both sexes, aged between 65 and 85 years (M=76.4; SD=20.41) from Bucharest (33 individuals) and Galati County). The instruments we used were: Rosenberg Scale, MMSE and ICVPA. For the original instrument ICVPA alpha Cronback the results were .82.

Confirmation of our hypotheses was supported by the correlation analysis. Significant associations were registered between the self-esteem scores and cognitive impairment ($r=.57$; $p<.05$; $r=.64$; $p<.05$; $r=.59$; $p<.05$).

Our results, though they could not be extrapolated, showed a significant relation between the presence of cognitive impairment, low self-esteem and, per total, the quality of life being considered poor – for the investigated participants.

The changes specific for old age needed some experiments with new models of group adherence, of special measures to solve problems, measures that were previously unsupported. The volunteers and the psychologists from different centers offered psychological counseling, thus stimulating some conjoint domestic activities, all included in the program "Grand-parents' Club" (GERON). It was a perfect opportunity to observe the increase in sociability and a more flexible communication of the elders.

Keywords: old age, resilience factors, prayers, painting classes

Introduction

The concept of resilience found its place with great difficulty, among the numerous psychological and medical studies and approaches on human traumas, violence, stress, aging associated with dysfunctions and diseases, as it has been approached in a completely different way and it has been classified and introduced in the field of our existence often as a result of individual or group sufferings.

In the civil life, be it at an early stage or in old age, either inside the familial background - only formally harmonious, in fact undermined by stressing emotions, conflicts, deviations – or in the military area, that is the core itself of rigid rules and hierarchy that has to be observed, discipline and frequent tense situations, violent psycho-physical experiences, waivers, dangers, etc., resilience found a place that is not only empirical but mainly scientific. While in the families with minors we could find problems and compensated approaches for resilience, we could also accept the idea that for old age we need resilience measures for old people who can and sometimes must be helped actively "to age in a decent manner".

Even if the necessary resilience measures in everyday life are studied and accepted nowadays, for individuals, as well as for groups of people, we cannot overlook the efforts made by Aaron Antonovsky (1987)[1], who tried to come up with a scientific approach of the factors and components of resilience, in the context of his theory of health and illness, which he named „the salutogenesis model", still considered more comprehensive than the one offered by OMS [2]. The author, by identifying the elements of one's style life, concentrates the content of the concept by giving the first place to „the sense of coherence" or to the generalized resources of resilience [3].

In the light of a systemic approach, Serban Ionescu [3] addresses the process of resilience as a social pattern, where we find different internal or external situations that shape the individual, as well as a person weakened due to various reasons, on an evolutionary scale, from birth to death.

The result of an interactive process between the individual and his family and the environment, resilience is specific for a person who experienced or experiences a traumatic or chronic event and who proves to be well adjusted, according to his/her age and the socio-cultural context [3].

Ionescu Serban [3] segmented resilience into natural and assisted resilience, and he decodes the latter as being achieved together with the specialists in mental health who help the subject – and in the end the subject can knowingly decide how to act. Transiting psychological orientations and currents, the same Serban Ionescu opens a psycho-analytic Pandora box, by insisting on the need for the specialists' interventions in critical situations (in fact, it means training the subject for diagnose) but without keeping the neutral position, by becoming relatively objective, especially towards the persons who are more or less unable to judge, to reason, due to certain distress (including a moral distress).

Objectives and hypotheses

The objectives and hypotheses of our study, in full agreement with the results of the studies and researches coordinated by Serban Ionescu [3], led us not only to a professional effort to understand and acknowledge the problems of old people in two different parts of our country, but also to a reorganization of the empirical-theoretical apparatus for interventions in such cases. Therefore, fully understanding that our subjects need to accept their conditions of life, that they should be encouraged, guided, in order to learn how to forgive and in order to be able to accept that they had made mistakes in their lives, we created the experimental design by adding some elements that would help us monitor (in a 6 to 12 months period) the elders ability to manage with efficiency some life situations. By means of a set of activities created in a differentiated way and applied to the subjects of the 2 groups we studied, we tried and hope to have succeeded to observe the personality traits described as specific to the resilient subject, in the literature on the matter.

Methodology

We studied two groups of old people, both genders, aged between 65 and 85 years (M=76.4; SD=20.41) from Bucharest - 33 individuals - and Galati County). The instruments we used were: Rosenberg Scale, MMSE and ICVPA. For the original instrument ICVPA alpha Cronback the results were .82. Confirmation of our hypotheses was supported by the correlation analysis. Significant associations were registered between the self-esteem scores and cognitive impairment ($r=.57$; $p<.05$; $r=.64$; $p<.05$; $r=.59$; $p<.05$).

Our subjects participated to expositions, conferences, excursions, dance evenings and our team (doctors, psychologists, medical assistant, social assistant) could observe directly and indirectly (mainly after 3-4 weeks of activities conducted in common) some elements of optimism, acceptance of their situation described as "wellbeing", as compared to the situation of their friends who did not take part in group activities, as well as a desire to socially help their colleagues in difficult situations.

This fact supports the idea that our efforts helped the preservation of the internal positive structure of our subjects, as well as their lasting strength to transform the losses (moral, emotional, material) into some objectives to be approached together with the therapists, therefore benefiting from the experience of our specialists, in order to overcome the inevitable moments of crisis, by validating their own feelings and emotions.

Besides the result of our research on the level of clinical psychology and the notes from the social background, presented from the statistically-mathematical point of view, we studied some elements of assisted resilience in the two areas: Bucharest, GERON Center and Galati.

By considering assisted resilience as a complex way of evaluating and predicting the ability to adjustment for normal circumstances, as well as for adverse situations, we created a differentiated program, personalized at the same time, for our subjects. Therefore, even if the results cannot be generalized or extrapolated for a large population – for the whole country or even for all old people in the two areas we conducted our research (urban/rural) – these results refer to a type of action that truly helped the participants to acquire some more flexible communication and interrelations skills. We made some lists of topics for conferences, with the help of several specialists, including important names in medicine, psychology, sociology (mainly in Bucharest).

Previous discussions with the 15-20 subjects who took part constantly to the activities helped us to give shape to our plans. The subjects stated that they were interested in group socialization – to integrate and learn how to manage the stress determined by "making two ends meet" and living another day. We consider that the conferences (around 15 for each urban/rural center) influenced their abilities to perceive the alter-ego, opened new perspectives of self-appreciation and appreciation of their group colleagues, the personal acceptance of their "wellbeing".

Topics like "life and stress", "acceptance of our age and inherent dysfunctions", "dangers of smoking and alcohol addiction", "the refuge in disease – a solution for the elder?", were followed by discussions with people working in the centers and the speakers who answered the participants' questions.

Also following the suggestions of our respondents we organized some paintings exhibitions – since some of our participants wanted to try "this superior modality of relaxation" – and they were encouraged by arts specialists as well as by psychologists. Their statements were: "I am greatly satisfied", "I am glad I tried, regardless of the results", "even if my paintings have no true artistic value, at least they represent me", etc.

Our frequent discussions with the respondents before and after the group event (conferences, painting classes, etc.) revealed their need to listen to good music "since they were young" and even to dance. Therefore, we organized 4 such meetings, when we selected the music they decided upon, and the conference hall was transformed, for 90 minutes, into a "dance floor".

They started to trust us more and more, and they expressed the desire to take part in prayers, at church and to visit some monasteries. It was exemplary the openness of the priests from Biserica tuturor sfintilor romani, in Bucharest, Salaj Street, who showed exemplary empathy and tolerance in communication with our subjects all the time, as well as during the great Orthodox celebrations (Easter, Rusaliile, Sfanta Maria, Christmas).

Our sponsors also made possible 2 trips (one day each) to Cernica Monastery (near Bucharest) and Sfintii Arhangheli METOC Monastery (Galati).

The most frequent events consisting of a program previously announced were the ones proposed by our respondents, who wanted to have their birth days or name days celebrated with the group of colleagues – and we supported them both morally and materially.

Even if such events cannot be truly statistically processed, the qualitative presentation remains a proof of the need for assisted resilience for the elders, and we noted many differences on multiple levels: urban/rural, the socio-professional level, social status, as well as those generated by the way they managed traumas, their past, revenge, dissatisfactions, loss of family, etc.

Results

Resilience, be it a complex process or personality trait, with numerous sub-structures and emotional and cognitive-volitional elements in an adverse situation [4], has become not only an object of study for different socio-humane disciplines but also a type of social strategy generically necessary for any human being who wants to expand the adjustment abilities, regardless of the age, gender, culture, traumas, etc.

Old people, more than other categories of subjects, tend to re-live the previous traumas, to contemplate their negative emotions, sometimes even the positive ones. For these reasons we created a program of cooperation in our center – to be learned and used by them at home, implying an active participation in different daily activities, with the support of their relatives or their friends. They learned, during their meetings with the psychologist and the social assistant, a set of beliefs (religious beliefs) that induced positive thinking, a more realistic model of approaching the daily problems, actions that have a tendency to become group activities, in order to help them face their fears, inside an efficient social network.

Abstract

The present paper briefly analyses the way, during the communist dictatorship, some of the political prisoners became resilient through the Christian religion. They discovered and developed specific resilient features, used strategies similar to those of the orthodox monks and managed to confront the extreme adversity they experienced. The result was an important improvement of their personality.

The natural resilient prisoners assisted other prisoners to become resilient.

Severely deprived of elementary needs (Maslow's Pyramid), they managed to fulfill other important needs (social communion, knowledge and in particular, spiritual needs).

Keywords: resilience, Christian faith, communist prisons

The Martyrs of the communist prisons

"They believed that the soul can be destroyed by destroying the body, because they were materialistic. They believed that the soul, tortured beyond human limits of endurance, would be destroyed and they could do whatever they wish with it. But it's not like that. If a stick is broken it's hard to mend it. But the soul, if it's "broken", I tell you it will renew. The soul puts out buds in the same way a tree or a branch you've broken does. Bit by bit we've rebuilt ourselves. And without any doubt, we got better afterwards." [1]

The aim of this paper is to briefly analyse what happened inside the communist prisons in Romania, how some of the prisoners managed to discover and to develop resilient features on their own by means of the Christian religion. They used strategies to confront the atrocious adversity they had experienced. As many of them confessed afterwards, the result of this experience was an improvement of their personality.

The communist dictatorship was based on materialism and atheism. They tried to replace the spiritual values of the society with materialistic ones; they wanted to build a man without God - a "new man".

Most of the political prisoners were punished for their Christian beliefs and their liberty of conscience.

"What was our purpose in prison, what was the goal of our fight? It was not political, it was the moral goal. We were full of idealistic dreams, knights of the Christian cross, exponents of honour and dignity; we were confronting in fact the whole world. We identified communism with antichrist and denied any pact with him" [2].

Some of those prisoners became resilient through culture, but most of them (especially the educated ones - teachers, priests) became resilient trough the Christian religion. They discovered or deepened their Christian faith in detention and found it as a new way of life, deep and full of meaning. These resilient prisoners helped many of their companions (simple, uneducated people, who suffered in the same way) to became resilient.

We can say it was a paradoxical phenomenon. On one hand the torturers did "re-educate" some of the prisoners to become torturers themselves (victims turned into aggressors) and on the other hand the natural resilient prisoners assisted others to become resilient (assisted resilience).

" They (Valeriu Gafencu and Costache Oprisan) did this miracle inside the cell, they changed our heart (…) they turned our heart from revenge or even hate, towards God and love; and all these changes worked in our heart, and our body changed itself through the prayers they did, or the gifts they spread around them. And that's how we managed to survive. In all other cells people died because they had mentally disabled among them as well." [2].

In this situation we can make the difference between the mere resistance to trauma and resilience, the last implying inner metamorphosis (improvement of the personality).

They are probably natural resilience models, witnesses of their own complex process of neo-development with profound spiritual values in which the second itinerary gives way to new liberating and germinating perspectives [3].

"It's like my mind cleared up. I perceive the beauty of Christianity with all intensity (…) I'm so enthusiastic, it's a moment of true spiritual rebirth (…) On the frontispiece of this prison cell should lay in letters of fire " in this tomb a man is born". I never had before such a moment of inner growth, I feel profoundly another man, changed." [4]

Paradoxically, although these prisoners were deprived of the elementary needs of Maslow's Pyramid (physiological needs, security needs), they were able to reach unexpected profoundness in other levels. Needs of social communion were met by improving their capacity of loving the people next to them with such intensity they even sacrificed their personal needs for them. Needs of belonging and recognition, needs of knowledge (they shared within the group cultural and theological knowledge), aesthetical needs (through Christian poetry) were also met - but they especially excelled in the last level of Maslow's Pyramid - the spiritual one. At this stage the person realizes its own place and meaning in the world and can give a supreme goal of his own existence. Therefore the person is no more bound by the limits of material existence, but feels free in spirit and closer to God [1].

Some of the prisoners had characteristic features "upright soul, intelligent, honest, faithful, with a great capacity of loving" (Costica Dumitrescu – who became monk after his release from prison), "a great capacity of loving, emotionally balanced, discreet" (Marin Naidim) [1]. They applied specific strategies – turned the adverse prison conditions into optimal conditions for spiritual accomplishment resembling the monks isolated in their monastic cells. They also discovered techniques mentioned by the Orthodox Saints such as: the fight with the negative thoughts (avoiding to transform these thoughts into passions and negative acts), the continuous prayers, the communion with other prisoners. The result was improving themselves through resilience.

"Incarceration creates special conditions for the prisoner. The prison cell becomes a monastic cell inducing prayer, the lack of food is an occasion of asceticism, isolation and giving away the goods of life – occasion of living in simplicity and chastity (monastic values), the unknown – occasion of confidence in God's will and care (…). Who didn't understand this divine intention was mentally tortured by thoughts about confinement, hunger and terror, anxious about the family situation. Who understood this gained great spiritual gifts." [5]

Father Gh. Calciu- Dumitreasa (former prisoner who emigrated in USA) confessed about the fulfilment of the needs of social communion by means of the Christian love. He said about Valeriu Gafencu (named "The Saint of the prison"): " The people (prisoners) received from him a message of love and prayer, without the need for him to theorize (…) his mere presence and appearance brought peace into the soul and heart and gave birth to devotement towards him" [6].

Therefore, these people had and continued to develop many of the traits and abilities that define a resilient person - through the Christian religion, as authors like Rutter and Mrazek and Mrazek describe in their works [3]:

- **Positive re-evaluation of painful events** by rethinking them as a reason chosen by God for them to affirm their Christian faith. The model was Christ himself who suffered on Earth.
  "When I left prison, I dedicated all my suffering to God (Priest Vasile Patrascu)." [7]
  Mother Mina says [8]: "There weren't days of pain and darkness only. There were days of spiritual joy in being close to God. In those moments we knew God was with us."
- **The ability and will to create and make use of support relations** with those having either the same or a different religion, a community based on Christian love and human solidarity. These people were taking part together, though sometimes isolated in separate cells, in religious services (transmitted through Morse code), they were confessing to a priest (also a prisoner) by Morse code and were celebrating together in an extraordinary spiritual fellowship the great Christian feasts (Christmas and Easter).
  "Because we were not understood, we loved each other, in the meaning of a real Heaven. Thus the sufferance didn't matter anymore; it was like a soothing plaster. You could perceive the results of suffering […] we were all having the same secret ideal that would keep us together (Father Arsenie Papacioc)." [7]
- **Altruism** as far as personal sacrifice for the other suffering people by giving their own food and even drugs. Relevant examples of such people are Mircea Vulcanescu, Valeriu Gafencu, Nicolae Steinhardt, Costache Oprisan and others.
- **The capability of making decisions** by affirming their religion in spite of risk of torture.
  "Not only I was refusing their "reeducation", but I was also facing them. This represented an assumed risk in order to maintain my inner balance. They have tried many ways to persuade me to give up, but God gave me strength so I succeeded in finishing what I had decided (Mother Mina)" [7].
  There was also the example of Dumitru Balasa, an orthodox priest, imprisoned in Balta Brailei, who was called by the authorities in front of 2600 people, in order to declare that he was ready to give up being religious. He was meant to be a" model of re-education". Instead of satisfying the communists, he proved

an enormous courage by preaching in front of all those people, knowing he could be shot in any moment. He said it was the most beautiful sermon in all his life, finished by a moving collective prayer of 2600 people.

- **The belief that they are loved and chosen by God**
  "You realize that Jesus took a bit of His own sufferance and gave it to you. That means your own cross, not letting him carry it anymore on his back, but let you to carry it instead. Therefore you become happy that you are the son of God. (Aspazia Otel-Petrescu)" [9]
- **The capability to keep distance from strong negative feelings** ("the fear existed in the hearts of those who were guarding us", said one of the martyrs who finally became a priest [7]) and the capability to set instead an extraordinary love for their fellow men. All these martyrs shared the same special feeling of forgiveness, the capability of having no resentment against those who caused them so much sufferance". The sufferance has to be transformed by means of acceptance. You have to find a reason for it and then you are saved, because you have accepted. From that moment the sufferance becomes a joy, it becomes an honour." [9]
  Father Calciu Dumitreasa said about Costache Oprisan that he „never complained he was ill, never accused anyone for being tortured. He had forgiven everyone and he was always telling us about forgiveness and love".
  "The treasure of soul and mind is to love for being able to forgive", said priest Vasile Patrascu.
- **Positive anticipation of the future** (the soul redemption signifying the final aim of any Christian person).
  "We were ready to lose a deceptive life in order to find the real one, that was the meaning of defeating death through death" (Priest Dumitru Staniloaie) [1]

After liberation, the Christian surviving martyrs of communist prisons gave new dimensions to their own existence, became improved persons; they adjusted themselves to living in society often by choosing other professions than the prior ones; many of them became priests, some of them built their own families, but all of them kept all the great values that would define their new personalities: **faith**, **forgiveness** and **love**.

Conclusions

Studying the confessions of the Christian martyrs of the communist prisons we concluded that they experienced a process of resilience.

They used and developed resilient abilities to confront the adversity.

The means by which they succeeded to become resilient and to assist their companions was the practice of the Christian religion.

We noticed that in their case the deprivation of basic needs leaded to fulfilment of the superior, spiritual needs. They transformed, like the monks, the terms of deprivation in optimal conditions for spiritual perfection.

Researching resilience: the need for networked methods

Abstract

This paper stands from the idea that resilience might be better understood by using Social Network Analysis (SNA). This theoretical and methodological approach allows us to see how individual actors are connected with one another, and to explore different representations of their social worlds and get narratives about it.

Both "resilience" and "networks" have been extensively used in a wide range of disciplines. However, the term "network resilience" has been paradoxically coined in the field of computer engineering as an ability to tolerate (resist and autonomically recover from) sever impacts on the network. In this paper we advocate for the use of this concept in education, taking into account that just how at risk a child really is, cannot be easily discerned without understanding him/her in context. We want to demonstrate social network approach value to deeply analyse young people's contexts and their motivation to seek well-being. It is at this intersection (individual motivation and environment) where youth hidden resilience lies [1]. To do so, we direct our attention to some points which may help us to examine how resilient youth might be upon the analysis of their networks: this is how networks function and how the loss of ties may negatively impact resilience development. Finally, we discuss some strategies to improve network resilience and, as a consequence, decrease vulnerability.

Keywords: Resilience, social network analysis, network resilience, vulnerability

What about resilience and networks?

Briefly, the concept of resilience has been understood and interpreted through different theoretical frameworks: some more focused on a personal or individual level, and others on a social level, with intermediate positions in between. Consequently, there are definitions of resilience as an individual skill or ability based on a set of personal characteristics [2] [3] [4]; others which explain resilience as a result [5] [6] [7] and others that envisions resilience as a force that intertwines individual and contextual characteristics from the beginning to the end of the process [8] [9] [10] [1].

In this continuum of viewpoints, we might find Vanistendael [4] who distinguished two components in resilience: on the one hand, the resistance against destruction such as the ability to protect the integrity itself under pressure (somehow being resistant); and, on the other hand, the ability to form a positive vital behaviour despite facing harsh circumstances.

Meanwhile, other authors have defined resilience taking the expected result as a centre of their explanation. This is the case of Garmezy [5] which describes this phenomenon as the power to recover or the ability to return back to the patterns of adaptation which characterized the individual before the stressful period had taken place. Similarly, in the field of physical sciences and engineering, resilience has also been understood as the ability for an entity to tolerate, resist and autonomically recover from severe impacts.

However, although the origins of resilience date back to the 50s and there are plenty of studies across fields which centre their main attention to resilience, this construct has remained conceptually fuzzy with little consistency in how the term is operationalized [11] [3], both cited in [12]).

From our point of view, resilience is much more than returning to the previous state. Actually, in social sciences seems rather difficult that an individual can have the capacity to face and overcome a situation without being both him/her and the situation transformed. Just as the individual is not alone in society, the context plays a key role, and even more on youth when relationships hold a special place.

The relationships we develop, when linked with others, form social networks which are undoubtedly present in everyday life. People are connected to others, and the networks in which they are embedded can help them achieve what they could not accomplish in isolation. That is the reason why networks cause a powerful

effect on individuals' behaviours and outcomes, and the reason why in this paper, far from justifying the complexity of resilience process, we attempt to demonstrate the value of the social network approach to deeply analyse young people's contexts and their motivation to seek well-being.

A network point of view on resilience may help us move away from an attributive approach to take into consideration the structures and functionality of the links (i.e. more emotional support received) that persons establish with others, groups, associations, etc. [12]. Our connections affect every aspect of our daily lives; they are always there, exerting both subtle and dramatic influence over our choices, attitudes, actions, desires or thoughts, among others. And, what is more important, our connections do not end with the people we know [13].

Examining resilience thorough SNA

Ironically, we can't study resilience without studying risk [14]. Then, as studying resilience requires that the researcher assesses the level of risk posed to the person, methods such as social network analysis (SNA) can easily contribute to get a real photograph of their networks so as to evaluate their exposure to vulnerability, because sometimes the way we think and talk about who we know does not accurately reflect the social context.

Through life, one is always susceptible to random failures; network composition is indeed unstable since many people enter and leave the network. The following are the personal networks of two women –mother (Fig. 2) and daughter (Fig. 1)– which we will use as examples to explain the convenience of using SNA. Data has been collected using the free software EgoNet.

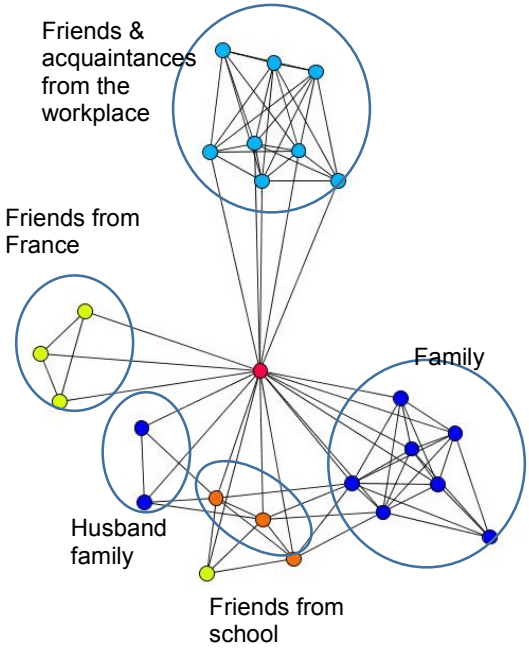

Figure 1. *Personal network of a 33-year-old woman*

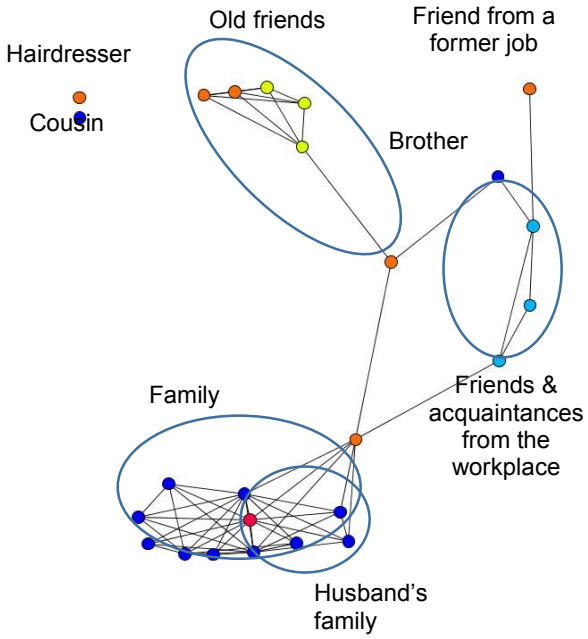

Figure 2. *Personal network of a 55-year-old woman*

The way one uses the visualization will be guided by the research question or one's interest. If one is interested in examining social support, the interpretation approach of the graph will be different than if one is interested in how people use their personal network to recover from a critical incident such as an abuse, racism, violence, poverty, etc.

If a link fails it will also disconnect network nodes. This might be easily seen in Fig. 2. In this sense, each node has a role: some are peripheral and, if lost, the impact to the network is not significant. Others, however, are central and the connections to other nodes depend heavily on them. See what happens if hypothetically, the 55-year-old woman had lost two nodes (Fig. 3). The same might have occurred to her daughter's personal network.

In the field of engineering, the loss of nodes implies that the network itself is not robust enough because its redundancy is weak. Redundancy refers to the amount of wasted space used to transmit certain data. In other words, the network has many nodes which are not connected to all others, so the paths to exchange information, support, etc. are lengthened. Everything depends on what happens when a node fails. It could be that just a node fails, but all the other nodes are unaffected or it can have a cascading effect and provoke the opposite effect.

Therefore, networks are vulnerable. Here we have referred to one kind of loss, which is node percolation, but one might have lost edges as well, so nodes losing the ability to communicate with one another (edge percolation). In one case or another, it is advisable to think of the changes in path lengths, because specific information, or supports might be located in only few nodes.

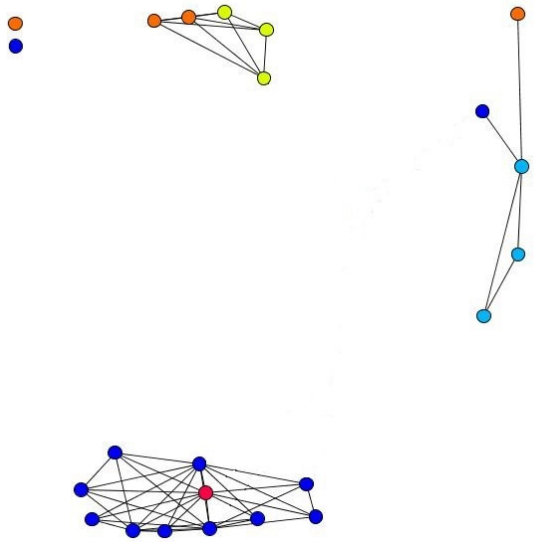

Figure 3. *Impact of the loss of two nodes*

It is also useful to notice that new vertices can attach to any of the old ones, but the higher the degree of an old node, the higher the probability of attracting a new one. Occasionally, less connected nodes will receive new links, but most of the time hubs will be much more attractive [15].

Up to this point, we have referred to the power of visualisation in SNA using a couple of examples. There are plenty of other analyses that might be done in order to understand how networks function (in this sense, see [16] [17]).

However, the network visualization also allows the conversion of quantitative and qualitative information, thus it is possible to show the structural features of social networks to informants and to gather qualitative information or narratives through an informal interview (Fig. 4). The type of information we collect from the visualisation will also depend on the researcher's focus. (For a detailed description of the use of interviews in SNA using a specific software such as EgoNet see [19].)

Research phases	**Data Analysis**
Data Collection	Visual typologies (graphs)
	Narratives

Figure 4. *SNA as a mixed method*

This appears to be especially significant, since the study of resilience is increasingly moving beyond the study of individuals to consider individuals in interaction with their environments and the adaptive qualities of both [14] [18]. And SNA is both a theoretical and methodological approach which allows us to do so.

Strategies to improve network resilience

Through this paper, we have seen that SNA is an effective method to visualize people's connections and explore relational dynamics. And in regards to resilience, networks may help us identify risks, challenges, but also potentialities. What follows are some strategies that can be used to increase resilience.

Firstly, networks might help us adventure risky situations and, as a consequence, reduce the impact of them on a child or teenager. If we realize that there are some components in his/her network that might lead to problems, we can design interventions which create opportunities. Sometimes gang behaviours, far from being bad, are resolving some tensions teenagers live which might be caused by marginalization process [20]. Networks give clear clues about how powerless or isolated a person might be.

Secondly, examining networks not only opens the possibility of studying strengths from the environment, but also the possibility to carefully analyse abilities and individual attributes, so it is an opportunity to address capacity rather than risk. The exploration of personal stories through network visualisations might be considered as a rich source of identifying and building positive aspects of the self that in turn might become central to overcome vulnerability.

Thirdly, although we have focused on the benefits of networks, and contexts, social networks can have a negative impact in people's life. People's contexts have the capacity to help the individual overcome an adversity, but at the same time are responsible for breakdowns and disorders. SNA can help us diagnose non-beneficial environments. As a response to this situation, we suggest that it is necessary to help the individual to build new relationships (add new nodes) and design interventions to cultivate support systems. Moreover, it is also necessary to help people cope with their struggles with adversity.

Finally, they might be seen as an opportunity to link personal characteristics and the environments in which people live. Improving compatibility between individual and environmental factors can shape resilience.
