The Mourning and Resilience of People who have Suffered Significant Losses

Costin A.

alinatcostin@yahoo.com

Abstract

This paper makes an analysis of the mourning facilitated by a study that is in progress on the identification of differences in the resilience in people (Christians versus atheists) who have suffered significant losses. We have presented some impressions about how believers respond/ react to death. We found that exceeding the critical period is conditioned for Christians by their resilience which is based also on their beliefs regarding death.

Keywords: mourning, resilience, support forms

Introduction

Death is the most disconcerting, incomprehensible and in even in some way fascinating event, that a human being can live throughout his life. Anthropologists, philosophers, theologians and psychologists have approached death from different perspectives. The main crossing will remain an ongoing concern for people. Why? Because in one way or another we all face our own death. And this is not the most "feared" experience; to remain alive after the death of a loved one, this is truly a trauma or, even more than, it is the beginning of a new life, "I did not believe I would ever learn to die," said Eminescu. But this is exactly what we should do when we lose a loved one: learn to accept and above all to understand and to live without the person who has disappeared.

We approached this issue to highlight the need to understand death as a stage or a step in the process of adapting to a life without the person who died. Death itself is disturbing even for a person who assists from the outside and who is not emotionally involved. The event bears significant experiences, it raises questions, it calls for meditation and reflection, but the tumult of life or even the defence systems lay a blanket of forgetfulness after some time. It is not the same case for the person who has suffered the loss directly: one's spouse, one's parent, one's child, one's brother etc. And yet life continues, the person is forced to go on. Sometimes one cannot even conceive life after one's loss, yet we have witnessed the incredible recoveries of people who have experienced total collapse.

Aspects concerning resilience

"Resilience can be defined as one's capacity to cope with adversity and continue one's personal development" (Tomita, 2009). Resilience is a term used in psychology that characterizes the person who has the skills to effectively and relatively recover from failures or losses in a short period of time. Being resilient is a very valuable skill in our days, when the pressure we are exposed to, the speed with which we move, the uncertainty that we feel in all areas of life can lead to critical situations. There is no need to refer to an important loss (the death of someone close) to talk about resilience; the loss of one's home, one's job or simply to cope with life as it is right now, involves a process of resilience.

In popular language it is said that "what does not kill you makes you stronger"; this is exactly what Taylor [2] says, namely the fact that traumatic experiences can have a positive impact on the development of a person, and Tedeschi and Calhoun [3] detail the benefits of such experiences: to appreciate life more, to have closer relationships with others, spiritual flourishing, changing priorities and especially an increased personal power.

Methodology

This paper presents the partial results of a study which is ongoing and which aims to identify differences in people's resilience (Christians versus atheists) who have suffered significant losses. So far we

have conducted 50 interviews with people who have suffered significant losses; 12 of them have lost their children (four as a consequence of accidents). The study shows that each of the respondents feel a pressing need to understand "why" everything happened, especially in the case of accidents, where death was sudden and the event was of course unanticipated. In the first phase of our endeavour, the interviews were applied to individuals who attend Orthodox churches in Arad, followed by questioning other 50 people who consider themselves atheists. Both categories of respondents fall into different levels of education, age, residence. The variables which differentiate the reactions and manifestations of the respondents are: age, sex, time elapsed since death, their perception of death, the quality of the relationship with the deceased, the family of origin. Practically, this study aims to make a rapid radiography of the mechanisms by which faithful believer versus atheist people succeed in rehabilitating themselves emotionally after a loss.

I will hereby present an issue which distinguished itself in all the interviews, namely the respondents' urgent need to understand death itself, the significance and the meaning of the loss they have endured.

Which are the stages and mechanisms typical to the process of resilience in this case?

Losing an important person causes severe emotional distress accompanied by a tumult of feelings: the person agonizes, he/she becomes anxious, overwhelmed by feelings of loneliness and longing, abandonment and guilt. This pain affects the self-image of the person in question, who is lost in dreams and experiences suicidal thoughts. The whole being of the person who suffers the loss collapses; the universe that he/she had perceive in a particular way is reconfigured as frightening, while the prospect of life without the lost person is inexistent. But these are just some of the types of pain: stillness, storms of movements, illogical movements or dissociative experiences complete the picture of its manifestations [1]. What follows is the logical and natural manifestation of certain techniques of emotional adjustment and adaptation to the new situation.

I have studied the phase we experience when we undergo a trauma; if the traumatic event does not permit an adjustment, then we have to go through the following stages:

- The shock phase : it is the first phase, when we refuse to accept reality and all its related emotions: insensitivity, denial and depersonalization, selective forgetfulness;
- The action phase, or the awareness of the loss associated with states of anger, depression, guilt;
- Experiencing the loss/ mourning;
- Acceptance of the loss;
- The discharge phase: This necessarily involves the discussion of experienced events, the need for social and specialized support. This is the moment when the person actually returns to his/her life.

In an interview with Vasile Diana, a specialist is psycho-traumatology she said that "psychological injuries are part of our human nature, they are necessary to form our uniqueness and to enable us to evolve." The same author emphasizes the importance of The National Congress of Psycho-traumatology held last year, which aimed at stimulating precisely those areas that can improve psychological disruptive effects of trauma and which can lead to the healing of the human being. The congress slogan was: "Beyond Trauma: resources and opportunities".

Understanding death as a stage in the recovery of the person who suffered a significant loss

The recovery or mourning process itself usually takes, according to experts, one year or two, during which the person left behind tries to give new meanings to death. One needs to understand where his/her loved one went, why, how the split will be like, how long etc. Therefore, understanding death, respectively granting new meanings to the separation that can allow him/her to go on, is a highly important step in the recovery process. The belief that the suffering we are experiencing has meaning and that life itself, as well as death, have their meaning in God, offer a new perspective on life. It's amazing how people manage to rebuild their lives giving explanations and justifications of the tragic events of their lives: some turn to superstition, others abandon God, others take it as it is.

It seems that most people embrace the religious dimension by giving biblical explanations to death. Meeting again "sometime" with the lost person appears to be the only hope left for the survivor. As life seems pointless immediately after a loss, a feeling that continues for a year or two, the person needs to grant meanings to the event, trying to give a justification of death. An old curiosity I had about this topic was: how do people overcome moments of anguish after the death of someone who was very close (especially children, parents or siblings).

Some of the findings that have guided the people surveyed in accepting the deaths of his/her offspring or life partner were: "he/she had a great soul...God wanted him/her beside him", "Both children died...now they are together in heaven", "I cannot breathe because of the pain...the only thing that helps is knowing that God took him". It seems that the prospect of a meaningless death is hard to accept. Some people turn to God, while others tackle death objectively: "he didn't die because God wanted it...he died because he was very sick." The emotional support that those interviewed received was mainly provided by: a confessor, a psychologist and the family. There are slight differences between the number of people who sought the help of a priest (28), as opposed to the number of those who attended psychotherapy sessions according to their level of education (25). 14 people received both versions of support.

The search for connections between the traumatic event and family history is apparently an important dimension in the process of resilience:

- that the child's death had occurred due to a sin or a curse cast on the family a long time before;
- the spouse died because it is a third-generation family in which the young woman becomes a widow;
- the child's death is a punishment for the mother who had intervened in her present husband's marriage, determining his separation from his first wife and their child, whom she forbade him from meeting;
- God punished them by "taking" their child because the whole family (both parents, grandparents and relatives) were people "without God."

By recognizing the absolute power of God who made justice, even in this painful way, people seem to accept His decision by resigning gradually. Others think that the baby would not have deserved such a fate, as they all thoroughly respected all moral norms, but they accept that God's actions have meanings which cannot be understood by people.

An interesting aspect noted by several people interviewed was the importance of the requiem in the process of parting from the deceased. Commemorations are important forms of support for the survivors: they are occasions where they "can still do something" for the lost person; by carefully studying their perception of these commemorations we could see that they empower the survivors through they bare. In the Orthodox rite, nine days after death the soul of the deceased needs prayer and help from the living to continue its journey, prayer and almsgiving, which are realized in the service of the Divine Liturgy. This moment also has a psychological significance: by taking place very soon after the death, when the survivor still processes the experience of a close one's death, it is a new step in the awareness of the events that took place. Thus, the prayer is an instrument through which the man-God and the deceased are united. Prayer therefore becomes a task to the parent who has lost one's parental roles following the child's death; "he can still help the child, he can still provide the child with peace wherever he may be." On the same level we can also find the benefits/ handouts to the poor, which are designed to facilitate the journey of the deceased.

Psychologists use numerous methods to overcome grief, including:

- The evocation of pleasant events/ moments with the deceased through the use of symbols such as photographs, letters etc.;
- The termination of the relationship with the deceased by writing a letter which expresses all of one's emotions;
- Expressing feelings through drawing.

Only 14 of the respondents requested mourning therapy which they consider highly beneficial, stating that "I do not think I would have borne it without the support of a psychologist." Thus, the Christian perspective on death is the most "required" by the suffering person who remains after one has died. It is a typically human attitude, that of needing to be abandoned, to believe that someone powerful controls everything, who leaves nothing to chance and who has a plan for everyone. The fact that death is not a final separation but only a temporary separation seems to be the most effective theory for the Christian who has suffered a loss.

If we made a summary of the resilience of people who have lost someone close, we could point out the following attitudes/ beliefs that constitute forms of support to go on in life:

- Trust in God's will (death happened as a result of God's plan);
- Trust that the deceased is in a better place, that he/she is well, wherever he is;
- Trust in the fact that the prayers of the living help them;
- Hope that they will meet once again;
- The support of others;
- Responsibilities to other family members;
- Continuing life as a duty to God.

It should be noted that there are behaviours that indicate non-acceptance of death (more than 3 years after death) but which represent a way to continue the relationship with the deceased. Women become rather

depressed in these situations while men sink into labour until exhaustion or prefer oblivion by consuming alcohol.

Conclusions

The period of mourning is considered a major depressive episode in our lives. Depending on certain factors, mourning lasts from one year to three years according to specialists but loss impressions for life in some cases. The family support or even specialized support (psychological or religious) is very valuable to the person, giving desire and motivation to continue life after the loss of the loved ones. Understanding the meaning of death, the reasons the tragedy happened (such as the death of a child) are important moments in mourning. The need of those interviewed (to believe that separation is not final , that God had a specific plan and that He controls everything, etc) are Christian beliefs which works as a defense mechanism in situations that severely jeopardize the emotional balance. Overcoming this period of mourning varies from one person to another depending on its resiliency, on the context in which the event occurs, the quality of the relationship with the person who died, etc. At the same time, this experience gives the person the skills and abilities to adjust to critical situations and to overcome traumatic events.

Abstract

Resilience is a dynamic process that aims to overcome adversity through the development of positive qualities. Bipolar Disorder (BD) is an adverse experience, considered a serious mental illness (SMI) and characterized by cyclical and extreme moods fluctuations between mania/hypomania and depression. The objective of this study is to explore the phenomenon of resilience, its process and factors involved in adults recovered from BD.

This is a qualitative study using semi-structured interviews and focus groups with people recovered from BD belonging to the mental health network from the Basque Country (Spain), and clinical experts in the treatment of BD. All the content from the focus groups and interviews was transcribed and analyzed according to the conventional content analysis.

People recovered from BD affirmed having experienced a resilient process. It was described as progressive, dynamic and non-linear experience. During the resilient experience inner strength emerged, providing hope and confidence in getting better and displaying and developing interrelated internal and external qualities in order to overcome the BD. Some of the resilient qualities developed involved a self-analysis, being responsible for own mental health, searching for emotional, physical and social balance and wellness, self-reinvention or reorienting a personal life project, activating some positive personality characteristics (traits), employing conflict resolution ability, and finding external (formal and informal) support. Resilience arose after experiencing a life crisis (i.e. turning point) and the person was determined to overcome it.

People recovered from BD reported having experienced resilience. The resilient qualities found coincide with the traditional qualities of resilience, while others are specific to BD. It is recommended to continue the study of resilience in longitudinal studies to analyze whether resilience predicts recovery.

Keywords: Resilience process, Resilience factors, Mental Disorder, Bipolar Disorder, Qualitative study.

Introduction

The study of health is showing a shift from an epidemiological to a salutogenic approach, which aims to study phenomena that enable a satisfying and healthy life despite adverse life circumstances. Positive psychology asserts that the study of positive human traits enables understanding how to build qualities that not only help to resist and survive, but also to grow or thrive, to reduce, regulate and prevent mental illness as a side effect [1]. Some autobiographical reports show that although bipolar episodes are traumatic and disruptive, there is a possibility that people with Bipolar Disorder (BD) can experience wellness and manage their disease and live a fulfilling life, describing a variety of strategies to achieve it [2]. Nevertheless, the positive reports of living with BD remain largely absent in the current research literature, studying instead the high rates of suicide, substance abuse, criminal behavior and divorce.

BD is a mood disorder characterized by recurrent and cyclical periods of extreme moods, including depression –during which sadness, inhibition and ideas of death prevail- and mania –which is a phase of exaltation, euphoria and grandiosity- or hypomania [3]. BD is a chronic disease with periods of remission and relapse. Along the course of the disease, the patient may develop psychotic symptoms, rapid cycling, psychiatric and medical comorbidity, and cognitive and psychosocial impairment. Patients have a high risk of committing suicide.

This illness remains in the top ten causes of Years Lived with Disability (YLD) at global level, accounting for 2.5% of total global YLDs [4]. It is incorporated by the World Health Organization (WHO) as one of the six most debilitating conditions [5] and also classified among the Serious Mental Illness (SMI) [6]. According to the WHO World Mental Health Survey Initiative [7], the aggregate lifetime prevalences were 0.6% for bipolar type I disorder (BP-I), 0.4% for BP-II, 1.4% for subthreshold BP, and 2.4% for Bipolar Spectrum Disorder (BPS).

To be in line with the focus of current salutogenic approach and cover the lack of knowledge of positive qualities that contribute to recovery in this high health burden disease, the present study aims to study psychological resilience in BD.

According to several authors such as Grotberg [8] and Luthar, Cicchetti, & Becker [9], the resilient term must be understood as a universal and dynamic process in which both personal and interpersonal skills, as well as internal forces interact to allow positive adaptation despite adversity. Other authors argued that individual psychological variables are an essential part of resilience in terms of adverse circumstances [10]. Moreover, Richardson [11] and Grotberg [12], not only describe resilience as a disruptive and reintegrative process for accessing resilient qualities towards overcoming adversities, but also as a phenomenon that strengthens protective factors and drives to personal growth through adversity and disruptions.

There is evidence of the importance of resilience to overcome adverse events on somatic health and physical problems [13] as well as on mental ones [14]. Grotberg maintains that resilience is recognized as a contribution to the promotion and maintenance of mental health and quality of life [12]. For instance, a study found the presence of resilient qualities in a sample of eight participants in remission of various mental disorders, including BD [15]. Meanwhile, it has been shown that resilience could play an essential role in personal recovery and in improving psychosocial functioning and quality of life as well as in reducing symptoms in people with schizophrenia [16]. However, the review of the scientific literature by the major search engines (Web of knowledge, Ebscohost, Pubmed and Google Scholar), and the combination of keywords, "resilience" or "resilient "and "bipolar disorder" did not produce any results in reference to psychological resilience.

Therefore, the primary aim of the study was to explore from a qualitative perspective the resilience process phenomenon and the positive qualities or factors involved in it within a clinical adult sample of people recovered or functionally improved from BD. It is hypothesized that resilience is experienced by these individuals and it will be described as a multidimensional process. Also it is expected to find a number of resilient components similar to those studied in other diseases and adversities, and a few BD specific resilient components. Moreover, it is hypothesized that people affirmed having experienced a resilient process would also display high rates of posttraumatic growth and quality of life.

Methods

1.1 Design

This is a phenomenological qualitative study. Multiple triangulation technique was used: a) Methodological triangulation (semi-structured individual interviews and focus groups), b) Data triangulation (focus groups composed of both people recovered or functionally improved, as experts in the area), c) participants with BD also completed a battery of tests.

1.2 Participants

Participants came from various psychiatric services and Mental Health Centers of Basque Country (Spain): Mental Health Center Bombero Echaniz and Uribe-Kosta from Biscay, and Santiago Apostol Hospital from Álava.

The inclusion criteria for the individual interview and focus group patients were: (1) be functionally recovered or significantly improved from their BD diagnosis (BD type I, type II, and not Specified diagnosis were accepted). Additionally, a psychiatrist of each BD participant had completed the *"Clinical Global Impression Scale for Bipolar Disorder Modified (CGI-BP-M)"* [17]. To be eligible to participate, participants symptoms had to had been rated as "normal" and "mild" in severity. (2) Be between 18 and 65 years old. (3) Have appropriate levels of expression, understanding and insight to carry out the study. (4) Participate based on informed and voluntary consent. Patients who (1) did not meet the above criteria and (2) that also had other psychological, biological or physical conditions that would impede participation in the study were excluded.

The inclusion criteria for participating experts in the focus group were: (1) Possess more than two years of experience in treating patients with BD, and (2) agree to participate in an informed and voluntary way.

1.3 Procedure

The study satisfies ethical aspects of informed consent, voluntary participation, and confidentiality. Participants gave the informed consent to participate and they also allowed the interview to be taped in audio. Therefore, each interview and focus group was fully transcribed on paper.

Conventional content analysis [18] of each individualized interview and focus group was performed following steps proposed by Morse & Field [19] in order to identify most relevant topics, leading to the creation of a final model of resilience in BD.

The first draft model of resilience was obtained from the individualized interviews in which patients were asked about their resilient experience, and about qualities used during this process. Later, a patient focus group was carried out in order to discuss their resilient experience and validate the created first resilient model. This led to the creation of a second draft model of resilience, which was presented to six mental health professionals that participated in the expert focus group. They discussed and validated the second draft model of resilience from their objective view of the topic. Last, a final model of resilience in BD based both on users and on professionals views was created.

1.4 Instruments

Patients had to complete standardized questionnaires about their symptoms of BD "*Bipolar Spectrum Diagnostic Scale (BSDS) Spanish Version"* [20], general resilient level "*Spanish Version of the Resilience Scale 25 (RS-25)"* [21], posttraumatic growth "*Short Form of the Posttraumatic Growth Inventory (PTGI-SF) Spanish version"* [22], quality of life "*Brief Quality of Life in Bipolar Disorder (Brief QoL.BD) Spanish Version"* [23], and socio-demographical and clinical data. Additionally, an analogical visual scale (AVS) for recovery ranging from 0 "I have not experienced any recovery" to 100 "I am completely recovered" was administered.

Experts completed the "*CGI-BP-M"* [17] of their patients to report the severity of symptoms at present.

1.5 Statistical Analyses

Descriptive statistics and frequencies were performed, using the statistical package SPSS for Windows version 20.

Results

1.1 Quantitative Data

According to CGI-PB-M (Overall) and BSDS mean scores, participants showed no significant active BD symptoms (M = 1.60, *SD* = 0.83, within the range "Normal (1.00)" and "Minimal (2.00)"; M = 2.73, *SD* = 2.40, mean score was below the cut off value of 13 points necessary for screening BD). Furthermore, patients indicated to be highly recovered in the AVS for recovery (85.00, *SD* = 11.01).

Of the 15 patients enrolled (11 women , 4 men), nine of them from Santiago Apóstol Hospital, and six from Mental Health Center Bombero Echaniz and Uribe–Kosta, with a mean age of 42.87 years old (SD = 11.99), 7/15 were married, while most of the others were single (6/15) at the time of the interview or focus group. Although 8/15 patients had university degrees, and 4/15 worked in a job related to their university degrees, the majority of patients (11/15) were occupationally inactive at the time of the interviews were taped (mainly by occupational disabilities resulting from the BD).

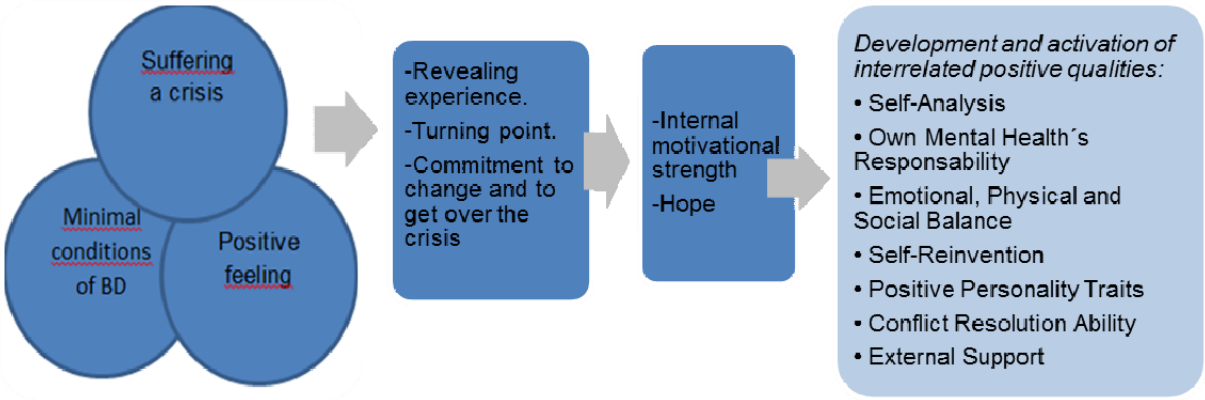
BD came out in early adulthood (M = 25.00 years old, SD = 9.71). All were receiving prescribed drug therapy (predominantly antipsychotics, mood stabilizers and anticonvulsants) and most had also received individual and/or group psychological therapy. Some participants indicated the presence of thyroid-related diseases as a side effect of the lithium carbonate.

Participants show medium-high levels of intrinsic factors in resilience, posttraumatic growth, and quality of life indicated by the mean scores of RS-25, PTGI–SF, and Brief QoL.BD (M = 137.80, SD = 16.97, range 25-175; M = 32.87, SD = 7.23, range: 0-50; M = 48.80, SD = 6.89, range: 12-60, correspondingly).

1.2 Qualitative Data

All patients affirmed having experienced a resilient process, which was described as a progressive, dynamic and non-linear process. The qualities or factors that contributed to the origin and function of resilience in BD are described in the diagram presented in Fig.1.

Fig. 1 Factors that contribute to the origin and functioning of Resilience in Bipolar Disorder Process



Participants agreed that resilience was originated within the context of having a minimal mental health condition. Being there they went through a bipolar crisis, and experienced positive flashbacks that made them feeling well. This situation worked as a revealing experience, which led them to a turning point. In this context, they referred feeling an enhanced commitment to change one's beliefs and attitudes and being determined to face the crisis. This generated an inner strength or motivation and increased hope and confidence in order to get over the adversity.

In this context, participants narrated the development and activation of various interrelated positive qualities which enabled them to overcome the BD:

1) Self-analysis: They agreed that self-knowledge about personal strengths, weaknesses, goals, values, and hobbies allowed them to redefine their identity and to differentiate themselves from the illness.
2) Being responsible for own mental health: They stressed the importance of knowing about the clinical features of BD, and trying to regulate it through the management of early warning signals and the adherence to psychopharmacological treatment. That gave them sense of empowerment above their lives. They also narrated the importance of dealing and re-establishing personal limits.
3) Searching for emotional, physical and social balance and wellness: Having a discipline and a healthy life-style, as well as having or searching for an interpersonal and occupational network in order to perceive emotional support. Participants agreed that enjoying relaxing and distracting activities were also necessary so that they could set aside their suffering.
4) Self-reinvention or reorienting a personal life project: These factors implied to undertake personalized goals that nurture one´s inner life. They also narrated the need for self-realization and personal growth, which it was also strengthened as a result of resilient process.
5) Activating some positive personality characteristics (traits) such a self-worth, courage, perseverance, humility, extroversion, optimism and sense of humor.
6) Employing present focused conflict resolution ability or being able to do an objective analysis of the problem and available resources. This allowed them to adapt their goals and to find out and get needed support to solve their problems. Creativity, assertiveness and social skills were also emphasized.
7) Finding external support both formal (psychopharmacological therapy) and informal (family, friends and colleagues).

Conclusions

The study provides evidence that resilient process is an experience in people recovered from BD. The resilient qualities found coincide with the traditional qualities of resilience [8, 9, 10] such as hope, optimism, creativity, dreams, self-control, and subjective wellness, while others are specific to BD, such as BD knowledge, redefinition of identity, and adherence to treatment. On the other hand, a few studies have explained a number of factors related to recovery from BD such as identity development, self-management, and development of social roles [2], when actually, they are resilient factors that lead to recovery. In addition, this study provides evidence that people recovered from BD and have gone across a resilience process, also show medium levels of quality of life and posttraumatic growth.

This study involved a small number of people. However, data saturation was obtained in individualized interviews and multiple triangulation was carried out, thus giving more validity to the results. An added limitation was that all patients with BD were recovered, so precautions should be taken when generalizing the results to people with active BD. However, as it is the first study in the area, people who more likely had

experienced resilience (ergo the recovered ones) had to be included in the study in order to ensure the exploration of the resilient phenomenon.

It is recommended to continue the study of resilience in longitudinal studies to analyze whether resilience predicts recovery. The severity of BD and the resulting socioeconomic and health burden [24] could be reduced through the development of specific resilience programs for people with BD that promote recovery.

Identifying Protective Factors in adults – a systematic review to inform Resilience-Building Programs

Höfler M.

Friedrich Schiller University Jena (Germany)
Institute of Education and Culture/ Chair of Adult Education
martha.hoefler@uni-jena.de

Abstract

Objective: This study aims to identify validated psychological protective factors that promote healthy mental development in adults confronted with life-risks. Background: Adult education aims to identify protective factors that build resilience with the goal of creating the foundation for resilience-building interventions. However, the expansion of empirical research on adult resilience has brought problems in terms of systematically comparing and combing heterogeneous studies. Factors that should be integrated into resilience-building measures must be validated by research which defines specific protective effects with regard to specific groups. Methodology: A systematic review on empirical studies was conducted across six databases. Inclusion criteria were relational resilience concept, stress-inducing risks, population aged 18 and older, psychological factor type, interactive protective effect, mental-health-related outcome, and, to make a qualitative pre-selection, a minimum two-fold confirmation of protective effects throughout longitudinal studies with no conflicting results. Results: The database search resulted in 664 studies; six studies matched all inclusion criteria. Validated factors were perception of personal control, responsibility, and socialization. Conclusion: The validated protective factors should be discussed in the context of mental-health-prevention programs targeting adults.

Keywords: resilience, adults, systematic review, protective factor, mental health, adult education.

Introduction

Resilience researchers suggest that future studies which aim to identify protective factors that are consistently associated with resilience are necessary for intervention research [1]. Adult education aims to identify factors that promote resilience, with the goal of developing resilience-promoting programs. However, the expansion of empirical research on adult resilience has brought problems of comparability between heterogeneous studies due to the lack of a consistent theoretical base which has made it difficult to combine results systematically. When a protective effect of a factor is validated in a specific study population, this does not mean that this factor is protective in another population and in the same way. Resilience research shows the interdependence between protective effects in terms of population characteristics, for example risk-type [2], risk-level [3], gender [4] and age [5], as well as in terms of the focused outcome-variable chosen by researchers to gather information on psychological functioning. If an individual shows competence in developmental tasks, it does not mean the individual has not, for instance, high levels of distress [6]. Furthermore, protective factors can be based on the observed resilience patterns of *recovery* and *sustainability* [7]. Research depicts the interdependence between protective factors in reference to these patterns [1]. Additionally, a factor may display a stronger compensation-effect – i.e. an effect that is independent of a risk assessment – as an interaction effect – i.e. an effect emerging from the interaction with special risks [1].

Since adult education cannot generalize on validated protective factors, program developers are facing the challenge of cautiously applying current research findings on confirmed protective factors to the target group, effect, and outcome according to their own interests. Systematic procedures that identify validated factors in their modes of action are required.

This study aims to systematically identify validated psychological protective factors in adults that promote healthy mental development despite life-risks. The focus lays on factors that could be integrated into stress prevention programs, as these programs provide a foundation for psychological functioning despite stress.

Methodology

A systematic review was conducted by following guidelines of manuals for systematic reviews and meta-analysis [8] [9].

1.1 Data Sources and Searches

A systematic search of six electronic databases (PubMed, PMC, PsycINFO, PsycNet; ERIC, FIS) was conducted for empirical primary studies measuring protective factors in adults and using quantitative design, published between 1970 and 2013 in English or German. Search terms included resilience [resilien*; risk* (AND) competen*], adulthood [adult*, late adolescen*, lifespan], protective factor [factor*, asset*, resource*] as well as the German variants.

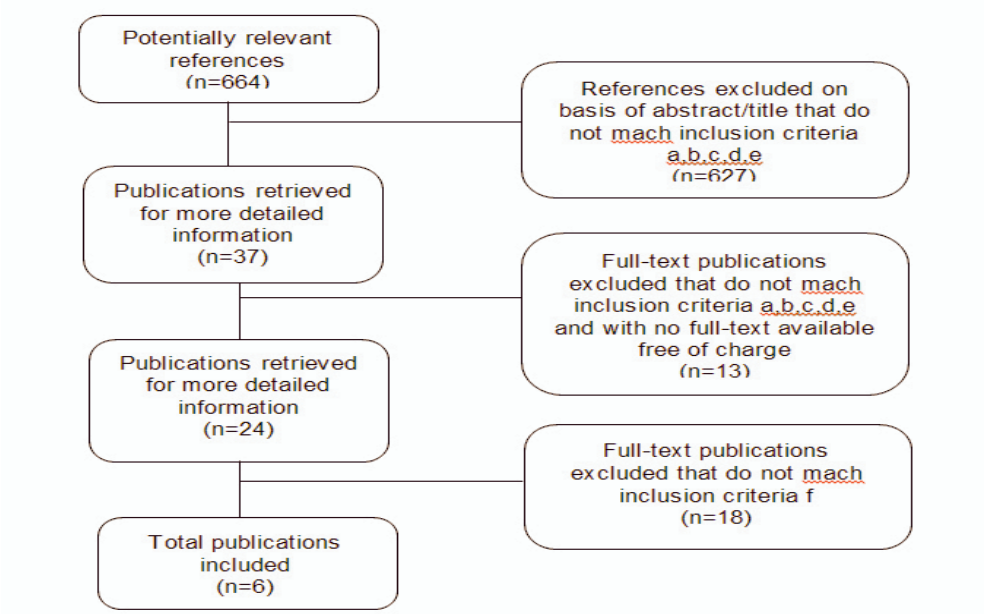
1.2 Study Selection

All article titles and abstracts (n= 664) were screened for inclusion. Inclusion criteria consisted of:

a) protective factor: psychological factors that are assumed to have a relational effect as consistent with research status quo; factors that interact with risk and buffer stress
b) population: adults aged 18 and older who had at least one stress-inducing risk
d) outcome: maintenance of mental functioning, measured only with indicators of psychopathology and/or wellbeing
c) study design: cohort studies, case-control studies and cross sectional studies that included a population size over 100
As the review searches purely for factors possibly seen as validated and relevant for discussion of resilience promotion; study result as well as validation of study result are also specified.
e) study result: protective factors show a significant positive relationship with outcome
f) validation of study result: a minimum two-fold confirmation of protective effects through prospective longitudinal studies measuring comparable constructs of a protective factor and no conflicting results in terms of a comparable construct within the studies

Figure 1 illustrates the study screening.

Figure 1: Flow diagram showing details of the studies included and excluded in the current review.



1.3 Quality Assessment

To analyze the quality of the selected studies, the review uses adapted criteria from NHS Centre for Reviews and Dissemination [10]. Of the nine criteria, two are left out because they refer to intervention studies. Criteria of internal validity (IV) were:

IV1: Adequate description of the study participants
IV2: Adequate measurement of the independent and dependent variables
IV3: Relevance of measures for answering the research question
IV4: Drop-out rate in studies following people over time introduced no bias
IV5: Study length that allow identification of changes in the outcome of interest
IV6: Similarity of groups being compared
IV7: Blind outcome assessment to exposure status

Although it is considered necessary, the generalization of the results assessed with reference to the individual research subject of a review is rarely specifically examined [8] [11]. It is crucial, particularly for intervention research, to know in which target population the validated factors have an effect. The review focuses on protective factors in populations aged 18 and older, which have at least one stress-inducing risk. Thus, it was important to assess, whether study results can be projected on this population, by assessing the following criteria of generalizability (G):

G1: Age the individual was when exposed to protective factor
G2: Gender
G3: Risk-type
G4: Risk-level
G5: Cultural background

Results

1.1 Included Studies

In total, three prospective longitudinal studies and three cross sectional studies were included. They validate the following protective factors: Perception of personal control, responsibility and socialization. Table 1 illustrates perception of personal control is confirmed by five studies; responsibility and socialization are both confirmed two-fold [4][12]. Comparability of the measured constructs was given.

Table 1: Studies which match all inclusion criteria ordered by validated factors.

Protective factor	Study	Study design
Perception of Personal Control	Fife et al. (2008)	Cohort study
	Werner & Smith (1992)	Cohort study
	Alim et al. (2008)	Cross sectional study
	Pitzer & Fingerman (2010)	Cross sectional study
	Lam & Grossman (1997)	Cross sectional study
Responsibility	Werner & Smith (2001)	Cohort study
	Werner & Smith (1992)	Cohort study
Socialization	Werner & Smith (2001)	Cohort study
	Werner & Smith (1992)	Cohort study

1.2 Results of Quality Assessment

All of the studies show high internal validity in population description as well as in choosing the measures that address the research question. For the three cross-sectional studies done by Alim and colleagues [1], Lam and Grossman [13], and Pitzer and Fingerman [5], the issue of drop-outs is not relevant. Furthermore, since there is only one measurement point, only correlative relationships are represented. However, as these studies, as well as by two longitudinal studies [4] [14], confirm personal control as a protective factor, a predictive effect on the outcome can be assumed. Although tested reliability and validity of outcome measurement instrument is not apparent in the Werner and Smith studies [4][12], these two studies are particularly characterized by a strong internal validity in terms of the other criteria. Both studies confirm many years of stable development of mental functioning in the face of risk effects. Personal control is confirmed to

predict fourteen years of stable psychological functioning [4] and responsibility and socialization fourteen and twenty-two years respectively [4][12]. Overall, none of the studies has such major shortcomings that it should be excluded from further discussion.

Table 2 illustrates the results on generalizability assessment.

Table 2: Study information ordered by validation of factors and criteria of generalizability.

Protective factor	Study	G1	G2	G3	G4	G5
Perception of Personal Control	Fife et al. (2008)	mean: 50.4 (range: not stated (n.s.); SD: 11.5)	m,f/m,f	Care for an ill family member during transplantation phase	1	Sample of mostly Caucasians; also African Americans, Hispanics, and Native Americans
	Werner & Smith (1992)	18	m,f/m,f	Range of critical life events, chronic disadvantages	4+	Residents of the Island of Kauai; inter alia, Phillipinos, Chinese, Japanese)
	Alim et al. (2008)	mean: 42,4 (range: n.s.; SD:14,9)	m,f/m,f	Traumatic event (Unspecified)	1+	Urban sample; African American Culture
	Pitzer & Fingerman (2010)	mean: 47 (range: 25-74; SD: n.s.)	m,f/m,f	Very severe physical abuse in childhood	1 dicho-tomous	n.s.
	Lam & Grossman (1997)	mean: 18.8 *(range: 17-46; SD:* 2.3)	f/f	Abuse in childhood	1 dicho-tomous	Students at a large Northeastern university; African Americans, Asian Americans, Hispanics, Caucasians; religion: inter alia Catholic, Jewish, Protestant
Sociali-zation and Respon-sibility	Werner & Smith (1992)	18	S: m,f/f R: m,f/f	Range of critical life events, chronic disadvantages	4+	Residents of the Island of Kauai (inter alia, Phillipinos; Chinese, Japanese)
	Werner & Smith (2001)	18	S: m,f/m,f R: m,f/f	Range of critical life events, chronic disadvantages	4+	Residents of the Island of Kauai (inter alia, Phillipinos; Chinese, Japanese)

While some studies [4][12][13] focus upon protective factors in young adults, the other studies include a wide range of adult ages. Most of the studies measure protective factors in both genders. Stress-inducing risks are very heterogeneous. From child abuse and its negative long-term consequences [5] to caring for a family member with a serious illness [14], as well as to a range of critical life events, for example a hurricane or growing up poverty stricken [12]. Risk levels differ among the referenced studies from one [14] to at least four and more risk factors [4].The level cannot be quantitatively detected in every case as risk measures sometimes use dichotomous assessments. There is very little comprehensive information about the cultural background of the study samples as most studies focus upon single aspects such as nationality or religion.

Discussion

1.1 Perception of Personal Control

The review results refer to a protective effect of personal control in young, middle-aged, and older adults. This is underlined by Pitzer and Fingerman [5] who control age in their wide-range age-sample and find no significant discrepancies. This review result somewhat contradicts Hay and Diehl [15] as they show that an internal locus of control is protective in all age-groups, but especially in young adults. Furthermore, personal control seems to be independent of gender. Due to the range of measured risk-types and levels, the studies rather suggest a broad-based protective effect against diverse stress-inducing chronic, or acute risks with short-and long-term effects acting on different risk levels. However, the generalizability of risk type in particular must be evaluated with caution since it is possible that there may be certain kinds of situations in which the individual has no control. A high perception of personal control can then cause more negative psychological effects [16].

When facing the cultural background, only few conclusions can be made about generalizability of the effects in terms of the entire adult population. Looking at the specified nationalities, the protection factor seems particularly validated in Americans [4][1][13]. As also other nationalities and living-worlds are assessed, personal control also portrays a rather generalizing effect when considering cultural background.

1.2 Responsibility and Socialization

The psychological constructs of responsibility and socialization are both validated two-fold by the same studies of Werner and Smith [4][12]. Since the studies confirm the protective factors solely in young adults, conclusions on protective effects cannot be extrapolated onto middle or older aged adults. The results of the studies suggest a stronger effect on women than on men, especially in terms of responsibility. Based on an developmental psychology-argument, the authors suggest that psychological protective factors are particularly significant for women in transitioning to adulthood [4].

The effect of responsibility and socialization is only validated in terms of high-risk individuals; assumptions of an equally protective effect on people facing lower risk levels cannot be made. As the Kauai Study focuses on a range of different risk factors, the interaction-effect seems to be given in adults facing multiple stress-inducing risks. However, the effect of responsibility and socialization in an environment other than that of the island remains unknown.

1.3 Excluded Studies

The excluded studies confirm a factors range from more general and often validated factors, such as emotional control [17][18], active coping [19], self-esteem [20], optimism [21][22], religiosity [23][24], or intelligence [25][18], as well as more specific factors such as Anglo-orientation [19] and self-compassion [26]. The relatively small number of six studies that met all inclusion criteria speaks for the problems identified in the current state of resilience research. Although there are many empirical studies investigating protective factors in adulthood, the studies are extremely heterogeneous, especially in the measured constructs of interest. This may result in a modest validation of a factor when the contingencies of the protective effect are kept to a minimum. While responsibility and socialization were not investigated by any other study within the 664 excluded studies, there is supporting evidence for the positive effect of personal control. However, in this cases a similar but not the same construct is measured [27][15][28] or the relation to solely health-based outcomes [29] is not given. Adult education cannot disregard these contingencies when aiming to identify validated factors for special target groups that make a specific promotion-outcome likely.

1.4 Limitations

Only one reviewer conducted the review. Another limitation is leaving out a view on generalizability of socio-economic status as well as a differentiation between well-being and psychopathology.

Conclusion and Future Directions

The review shows that adult related resilience research provides reasonable indications of personal control, responsibility, and socialization as being psychologically protective factors that buffer the negative effect of a variety of stress-inducing risks and predict the maintenance of mental health. It is relevant to discuss them in the context of prevention programs. However, all of the three factors need further conformance by empirical research. Further research should discuss the relatively but not absolutely stable personality factors in their plasticity through adult educational measures.

Abstract

Introduction. Resumption of the vocational activity is an important sector when considering the management of first-episode psychosis and the overall process of recovery. In clinical practice this goal is not always easily attainable.

Objectives. To assess the vocational status after the first-episode psychosis, along with the difficulties related to resuming professional activities and the potential clinical correlations that might have an impact on this issue.

Method. A total of 59 patients with a first-episode psychosis in 2012 were included in the study. We analyzed the demographic data (gender, education, type of work at their last job, working hours previous to the episode, financial satisfaction, own family existence, independence from parents), clinical data (age at onset, diagnostic according to the ICD 10). There was a follow-up at 12 months, which served to analyze the professional situation, as well as to test any potential reintegration difficulties.

Results. Job loss after a first-episode psychosis is a common occurrence. Resumption of the vocational activity and the related difficulties depend on: the type of diagnosis, presence of cognitive symptoms, the existence of psychotropic medication side effects, family induced stress, financial needs.

Conclusions. Vocational reinstatement after a first-episode psychosis is an important element that the clinician should consider during the overall process of recovery of patients with a first-episode psychosis. In addition to clinical monitoring and of medication side effects, counseling interventions for patients and their families are required, as well as interventions at the workplace.

Keywords: psychosis, vocational recovery, employers, counseling

Introduction

The first episode psychosis is an important event in a person's life because of the symptoms, the need for hospitalization but also the need for medical treatment. Thus, it represents a factor that influences many aspects of daily life including: employment and financial stability.

Furthermore, the onset of the disease is usually placed in the chrono-biological stage of young adult when a person is about to find a way of life and a professional trajectory. The disease affects on one hand the skills related to job performance, their competitive aspects, the capacity to cope with various stressors and on the other hand problems arise regarding saving self-esteem, worthlessness and stigma related to mental illness, situation that is extremely common [1]. One of the things that are now a harsh reality: in good economic times subjects with schizophrenia are the last to be employed and during the economic downturns they are the first to be fired [2].

Resumption of professional activity of a person who has experienced a psychotic disorder should be a priority in the process of recovery [3]. Resumption of professional activity is influenced by the patient's ability to negotiate, but also by the employer's acceptance [4].

Objectives

The study aims to assess the professional situation and the difficulties related to the resumption of professional activity after a first episode psychosis.

Method

The study sample consisted of 59 subjects who had a first episode of psychosis in 2012 and have been selected based on inclusion/exclusion, without using statistical methodology.

Inclusion criteria:

1. first episode of psychosis was in 2012 and required hospitalization in Timisoara Psychiatric Clinic
2. diagnosis established according to ICD-10 criteria
3. subjects are active outpatients of Timisoara Clinical Ambulatory
4.subjects agree to participate in the study

Exclusion criteria:

1. presence of personality disorders or mental retardation
2. presence of organic pathology or caused by substance abuse

The following parameters were analyzed at the onset:

- socio-demographic (gender, age at onset , educational level, family status , professional status)
- clinical (diagnosis at onset, duration of untreated psychosis)

After a year of evolution we found 25 subjects as active outpatients in clinical ambulatory and we assessed them on their current professional status and they also responded to a questionnaire regarding this issue. The questionnaire has been created by us and contained questions about: professional activity, financial satisfaction and factors correlated with professional integration difficulties. We mention that the questionnaire was applied to all the 25 subjects in order to assess their expectations from their professional activity.

Given the small number of subjects, a qualitative analysis of the data was performed.

Results

The sample we assessed in 2013 comprised only 25 subjects (42.3%). As regards the rest of the subjects from the initial sample, we couldn't find current information on them since they stopped presenting monthly in the clinical ambulatory.

Table 1. Socio-demographic and clinical data

	Subjects
Gender	
Male	32%
Female	68%
Average age at onset	37,5 years
Average education period	11,04 years
Family status	
Married	48%
Single	32%
Divorced	12%
Widow	8%
Duration of untreated psychosis	125 days
Clinical diagnosis at onset (ICD 10)	
F20	4%
F22	24%
F23	28%
F28	28%
F30	8%
F32	8%

F20-schizophrenia , F22- persistent delusional disorder, F23- acute and transient psychotic disorder, F28 other types of non-organic psychoses, F30 manic episode with psychotic symptoms, F32 depressive episode with psychotic symptoms

Current professional situation was analyzed after a year of evolution and compared with the one at onset and is presented in Figure 1.

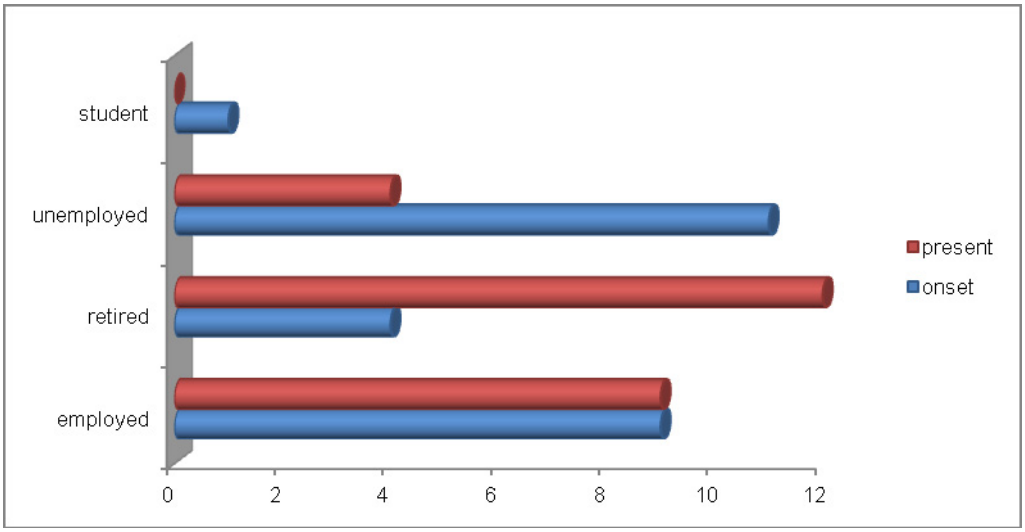

Figure 1. Professional situation present/onset

The questionnaire we applied contains more items and a part of the results we obtained are summarized in Table II.

Table 2. Questionnaire results

Questionnaire	Subjects (%)

Discussions

The term "recovery" should be understood as an active process in an ongoing dynamic that involves much more than simply "the return to the original state of normality". Illness should be understood also from a psychopathological perspective as an experienced life event, the important issue being the regain of the safety and control in the patient's personal life. Recovery means a life lived with purpose, meaning and even wealthy, along with the symptoms.

Recovery means gaining wisdom and the capacity to extract positive aspects even from the negative events. The issue is not between healthy or sick, but healthy and sick at the same time.

Job loss after a first episode psychosis is a common situation. Resumption of professional activity and the related difficulties depend on: the type of diagnosis, the presence of cognitive symptoms, coping difficulties, stigma, side effects of psychiatric medication, family pressure and financial needs.

Analyzing professional evolution a year after a first episode psychosis we observed the following dynamics:

- Of the 9 subjects who were employed only 6 have kept their workplace, 2 subjects retired due to mental illness and one of the subjects who had no job at onset is currently employed
- The number of retires subjects is higher at present since at onset the sample included 4 subjects that were already retired due to somatic illness to which, after an year, 6 other subjects retired due to mental illness were added;

- Of the 11 subjects that were unemployed at onset, only 4 of them remained unemployed, 6 retired and 1 is currently employed

It can be seen that most subjects who had a job were able to maintain it. This is favorable for the course of the disease because maintaining vocational functioning is one of the factors of protection.

The questionnaire was filled in by all of the subjects we have found as active outpatients after an year of evolution. The results show that the majority are satisfied with their current professional status even though they are retired on medical reasons which outlines the low expectations they have in relation to the professional activity. In terms of financial satisfaction, this is low even for those who work. To increase the professional level most subjects see healing as a possible solution and fewer subjects count on help from family or social programs.

After a first episode of psychosis in addition to clinical monitoring, counselling interventions for patients, families , and interventions at work are needed(negotiating with the employer, the identification of new professional skills , fight stigma). Professional functional outcome is as equally important as clinical symptomatic outcome. In the scientific literature the percentage of people that are unemployed after a first episode psychosis is 40-50%, but it can rise to 75%, which is actually a dramatic situation [5]. The status of being an employee is an important element in managing symptoms and preventing relapse and also is a factor of social validation and strengthening of self-esteem. In order to achieve a proper professional performance the following are need: a graded and flexible program, the acceptance of abilities and performances lower than professional requirements, the restructuring of everyday life, interpersonal empathy and acceptance, acceptance of limitations from the patients (including financial), new priorities for professional life (see focusing on well-being), training for employers to improve their visions of patients with first episode psychosis.

The limitations of this study are represented by the small number of subjects due to the restrictive inclusion criteria. It is necessary that the period for the inclusion in the study is longer, of approximately 3 years in order to increase the number of subjects.

Conclusions

- Professional functioning after a first episode psychosis is influenced by the disease but also by the functioning prior to the psychotic episode
- Decline in social functioning is common after an episode of psychosis
- Interventions for rehabilitation and for increasing resilience are needed for subjects with first episode psychosis
- Rehabilitation programs carried with employers and society are also important and needed.

Abstract

Protective factors involved in the resilience process are usually classified as individual, family-related and environmental. To our knowledge no publication refers to the protective property of inanimate objects. This research, conducted at the Reunion Island, on 120 university students, aims to answer the following three questions: (1) is the possession of amulet-like objects frequent in such a population? (2) What protect these objects? (3) From what are they protecting? The results show that 35 % of participants have an amulet-like object. Objects serve primarily to protect the holder from «malicious» persons, from what can motivate these persons or from means used by these people.

Keywords: Resilience, inanimate objects, protective factors, university students, Reunion Island

Introduction

Conçue actuellement comme un processus, la résilience se construit dans le cadre de l'interaction entre les facteurs de risque auxquels est exposée une personne et les facteurs de protection dont elle bénéficie [1-2]. Sur cette base, plusieurs propositions de modélisation du processus de résilience ont été avancées. Si au départ Garmezy, Masten et Tellegen [3] ont proposé trois modèles – compensation, défi et protection – d'autres modèles ont été décrits et testés par la suite [4, par exemple].

Les facteurs de risque et de protection impliqués dans le processus de résilience peuvent être individuels, familiaux et environnementaux [5]. À notre connaissance, aucune publication n'a été jusqu'à présent consacrée aux objets inanimés en tant que facteurs de protection pouvant participer au processus de résilience. Par contre, il existe depuis la première moitié du 20ème siècle de nombreux travaux ethnographiques, anthropologiques ou historiques concernant les amulettes, talismans ou porte-bonheurs [6-10, par exemple]. Quelques travaux, seulement, ont été réalisés dans une perspective clinique, les objets de type «amulette », y étant présentés comme des objets «de soutien» [11-12], des outils thérapeutiques [13-15] ou des «promoteurs» d'auto-efficacité et d'optimisme [16].

Des observations préalables [17] nous ont montré la présence relativement importante d'objets de protection, appelés *protéksyon*, *méday* ou *garanti* à l'Île de la Réunion. Nous avions alors observé plusieurs dispositifs thérapeutiques traditionnels au cours desquels des *garantis* étaient fabriqués et prescrits par des tradipraticiens. La présente communication vise à répondre, à partir des données recueillies sur une population d'étudiants d'université réunionnais, aux trois questions suivantes : (1) dans cette population, la possession de tels objets est-elle fréquente? (2) que protègent ces objets ? (3) de quoi protègent-ils? Elle constitue une partie d'un travail doctoral plus ample consacré aux objets comme facteurs de protection intervenant dans le processus de résilience.

Méthode

L'étude a été menée auprès de quatre groupes à effectifs égaux (N=30), composés d'étudiants d'université. Les groupes se différencient par le genre et les programmes universitaires dans lesquels les sujets sont inscrits : étudiantes en sciences humaines (groupe 1) et en sciences (groupe 2), étudiants en sciences humaines (groupe 3) et en sciences (groupe 4). Les participants sont âgés de 18 à 29 ans (moyenne de 21 ans et 4 mois; écart-type de 2,29). Les participants à l'étude ont répondu à un questionnaire qui leur a été proposé en français et en créole réunionnais. Les trois questions mentionnées ci-dessus faisaient partie de ce questionnaire.

Résultats

Les résultats obtenus montrent que 42 étudiants (soit 35 % des 120 participants à l'étude) possèdent un objet de protection. Ce pourcentage est inférieur à celui mis en évidence par Arakawa et Murukami [9] qui, dans une étude menée auprès d'étudiants japonais (75 hommes et 123 femmes), montraient que 60,6% d'entre eux étaient porteurs d'amulettes.

Sur l'ensemble de la population étudiée, le taux de possession d'objets de protection est moins élevé chez les hommes (30 %) que chez les femmes (40 %). L'influence du type d'études sur la possession n'est pas significative pour l'ensemble des étudiants. Cependant, pour les étudiants en sciences, le genre influence la possession de tels objets ($p = .046$), cinq hommes par rapport à douze femmes étudiant en sciences possèdent des objets protecteurs ; en sciences humaines la différence n'est pas significative. Nous notons que, chez les femmes, le cursus universitaire suivi n'a pas d'influence sur la fréquence de possession de ces objets : elles sont 12 sur 30 à en posséder aussi bien en sciences humaines qu'en sciences. Par contre, les hommes en sciences humaines possèdent plus d'objets de protection que ceux qui étudient en sciences (13/5).

Les participants à cette étude possédant de tels objets le font, en premier lieu, pour *se protéger eux-mêmes* ; ils sont 39 sur 42 (soit 92,8 %) à valider cette proposition. Ce constat nous indique un lien étroit entre le sujet et l'objet protecteur. En même temps, nous avons noté, pour cet aspect, l'absence de différence significative entre les groupes aussi bien en fonction du cursus suivi que du genre.

En deuxième lieu, le bénéficiaire de la protection est *l'habitat* (chez 40,4 8% des possesseurs d'objets). Il n'y a pas de différence significative entre les groupes par rapport au cursus suivi. Si 50% des hommes utilisent une protection pour leur domicile, les femmes ne sont que 33,33% à en utiliser. Le *véhicule* apparaît en troisième position avec 30,95 % des participants usant d'une amulette. Dans ce cas, il n'y a pas de différence significative ni en fonction du genre ni en fonction du cursus suivi. Notons, toutefois, que l'étude ne permet pas de connaître, parmi les participants, le nombre de ceux qui possèdent un véhicule. La *cour de la maison* est évoquée par 7,14 % des participants comme constituant la quatrième cible de la protection apportée par l'objet. Ces réponses concernent deux hommes – l'un en sciences, l'autre en sciences humaines – et une femme en sciences. La *famille* est également évoquée à 3 reprises, par des femmes uniquement : deux en sciences et une en sciences humaines. Par famille, il faut considérer uniquement les adultes de la famille puisqu'aucun participant n'a d'enfant. Notons, enfin, des réponses données seulement par un répondant : «les proches» (autres que la famille) sont évoqués par une étudiante en sciences humaines, «l'entourage» par un étudiant en sciences humaines et «un ami» par une étudiante en sciences.

Enfin, lorsque nous cherchons à identifier *contre quoi* les participants estiment avoir besoin de se protéger, nous constatons qu'il s'agit, en premier lieu (64,28% des réponses), *de personnes* «malintentionnées» (2 réponses), des «autres» (2), des «méchants» (1) de «mauvaises présences» (1), de *ce qui peut animer ces personnes*, comme la «jalousie» (2 réponses) et la «méchanceté» (1) ou enfin, des *moyens utilisés par ces personnes*, comme les «mauvais esprits» (5 réponses), les «mauvais regards» (4), les «mauvaises pensées» (3), le «mauvais œil» (2), les «mauvais sorts» (2), les «mauvais coups» (1), les «mauvaises intentions» (1).

La deuxième menace évoquée nécessitant une protection (correspondant à 35,71% des réponses) est *l'adversité* en général, plus précisément le «malheur» (4 réponses) et le «mal» (11). Les *accidents* viennent en troisième position (avec 11,9% des réponses, soit cinq étudiants).

Conclusion

Les résultats obtenus montrent qu'un peu plus d'un participant sur trois possède un objet de type «amulette».

L'influence du type d'études sur la possession n'est pas significative pour l'ensemble des étudiants. Cependant, pour les étudiants en sciences, le genre influence la possession de tels objets (cinq hommes/douze femmes étudiant en sciences possèdent des objets protecteurs) ; en sciences humaines, par contre, aucune différence n'est observée en relation avec le genre. Nous notons que chez les femmes le cursus universitaire suivi n'a pas d'influence sur la fréquence de possession de ces objets. Par contre, les hommes en sciences humaines possèdent plus d'objets de protection que ceux qui étudient en sciences.

Les objets servent en priorité à protéger le détenteur des «autres». Le volet suivant de cette recherche, actuellement en cours, concerne notamment les mécanismes par lesquels les différents objets exercent leur rôle de facteurs de protection.

Abstract

Self-transcendence is considered the landmark of spirituality in the structure of human personality. Self-transcendence can be defined as a high rank multifaceted descriptor, formed of the following inferior rank traits : Creative self-forgetful vs. Conscious individual experience, Transpersonal identification vs. Individual identification, Spiritual acceptance vs. Rational materialism.

Objectives: In an attempt to study the impact of personality factors on quality of life and personal resilience, personality resistence to stress and the role of personality dimensions in triggering suicidal behavior, we studied a lot of 131 patients diagnosed with personality disorder.

Results and discussion: By analyzing the correlations between the values obtained by the subjects in personality dimension tests and the scores they obtained on a scale of life quality – Multicultural Quality of Life Index (MCQL), we found significant correlations between the scores obtained for Self-transcendence and the scores for the quality of life.

Conclusion: Our study proved that patients with low self-transcendence scores manifest a decrease in quality of life, were less resilient and manifested a suicidal behavior.

Keywords: person, personality, self-transcendence, spirituality, quality of life, resilience .

Introduction

The concept of personality is an operational concept belonging to general psychology while the concept of person designates the unique human being, aware of himself/ herself as personal identity and existence in relation to the world. The concept of person is circumscribed to personality and has self-transcendence in its structure as central dimension. [1].

The analysis of self-transcendence as belonging to the person /human personality opens the door to self-knowledge in personology. At the same time Self-transcendence is considered the landmark of spirituality in the structure of human personality. Self-knowledge as a high moral duty was inaugurated in history by Socrates' "Daimonion" and seemed to end with Freud's "Unconscious". After Freud the concept of "self-knowledge" was not particularly addressed by psychologists/ psychiatrists and it became more of the psychotherapists' duty to invite their patients to self-discovery during the therapeutic process. [2].

Robert Cloninger is a particular researcher who stated that full assessment of the individual includes a moral and spiritual dimension involving deep self-knowledge, in the absence of which a person's subjective well-being is not possible.

Thus in Cloninger's vision self-transcendence is a character dimension, the 7-th personality dimension that can be evaluated using the Temperament and Character Inventory. Self-transcendence can be defined as a high rank multifaceted descriptor, formed of the following inferior rank traits: Creative self-bliss vs. Conscious individual experience, Transpersonal identification vs. Individual identification, Spiritual acceptance vs. Rational materialism . [3], [4], [5]

The presence of self-transcendence in personality

Self-transcendent people are often described as unpretentious, successful, patient , creative, unselfish, spiritualized . In eastern societies they are described as enlightened and wise, while in western societies the same traits are described as naive.

Those individuals seem to be able to tolerate ambiguity and uncertainty, they can enjoy most of their actions without feeling pushed to obtain results and without feeling the urge to control them.

In fact, many of these people feel that their spiritualization helped them understand the real purpose of life.

Self-transcendent people are perceived as humble, modest, accepting failure even after having done their best, satisfied with both failure and success. However, they may be criticized for what is considered in Western society as simplicity, magical thinking, subjective idealism that can interfere with the acquisition of wealth and material power. Self-transcendence has highly adaptive advantages when the individual is facing suffering and death, which are inevitable to appear in life with aging. Thus the spiritual dimension can be considered an important factor in personal resilience, since studies show that individuals with low scores presented a suicidal behavior. At present resiliency is considered the science of mastering life's greatest challenges. [3], [4], [5], [6].

Personology study

In an attempt to study the impact of personality factors on quality of life and personal resilience, personality resistence to stress and the role of personality dimensions in triggering suicidal behavior, we studied a lot of 131 patients diagnosed with personality disorder.

Sociodemographic characteristics of the study sample

A total of 131 patients with personality disorder, aged between 19 and 62 years (average = 34.13 years, standard deviation (SD) = 9.51) were included in the study.

Specific objective of the study

Evaluation of the relationships between the values obtained for personality dimensions and those for quality of life .

Research instruments

- Temperament and Character Inventory – TCI
- Multicultural Quality of Life Index - MQLI. [7].

Multicultural Quality of Life Index (MCQL)

Quality of life is defined as a subjective psychological dimension.

MCQL is an effective culturally adapted tool. It consists of 10 items, corresponding to some widely recognized dimensions of the quality of life concept.

The items include:

- psychological / emotional well-being ;
- independent occupational and interpersonal functioning ;
- emotional and community support ;
- personal and spiritual fulfillment ;
- overall perception of quality of life.

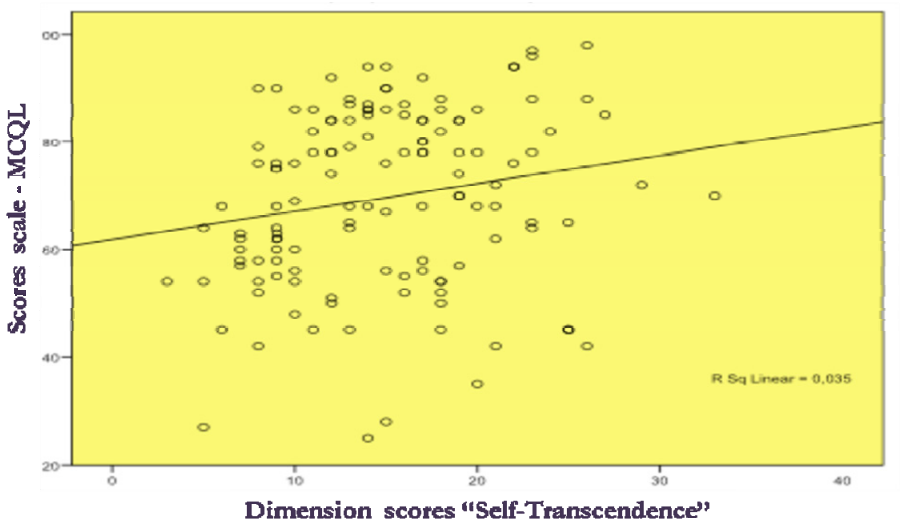
Each item is rated on a scale of 10 points, from poor to excellent. [7].

Results and discussion :

Significant correlations were found in the size of character Autotranscendenta the Multicultural Quality of Life Index .

Significant correlations were found between Self-transcendence and Multicultural Quality of Life Index.

Figure 1. The correlation between the scores obtained by the subjects at Self-transcendence and the scores on scale MCQL.



Thus according to that correlation analysis, 3.5% ($r^2 = 0.035$) of the variation in quality of life scale is due to the score variation on Self-transcendence dimension scale.

Our study proved that patients with low self-transcendence scores were less resilient and manifested a suicidal behavior with conotation of iresilient behavior.

Many people turn to religion or spirituality as a way to cope with personal adversity. [7].

Some find solace in formal religious services, while others seek inspiration and strength through private spiritual practices, only if they had the self- transcedence in medium through high scores and this personality dimension help them to connect to God or to find their place in the universe. [8].

Conclusions

1. Analysis of self-transcendence dimension as belonging to human personality opens the door to self-knowledge in personology.
2. Few researchers include nowadays the analysis of a person's spiritual dimensions when assessing his/her personality.
3. Human personality directly influences the scores on scales of quality of life, mainly by character dimensions.

Le symptome comme resilience

Robin D.

Equipe de recherche CRPC –CLCS [EA4050] France
daniele.robin@univ-brest.fr

Abstract

The concept of resilience is used to describe the process that, in the face of adversity, trauma or stress, individuals, families, groups of people are faring not have psychological problems and continue to live like before viewing better than before. The term resilience is often associated with the notion of material success, emotional or social which is to say, tends to designate a psycho-social fact. But it appears that resilience can take forms less positively connoted by the society. Thus certain subjects that are psychologically suffering try to improve their lives by creating a symptom that allows them to complain to others, to numerous requests to specialists or their relatives, to be heard and recognized in their singularity and gives them the feeling of existence. The symptom appears as an invention, a creation of the subject to overcome the anxieties and fears that arise whenever the unexpected and abroad occurs. Clinical psychologist or psychoanalyst allow him to be heard in the depths of his being without judgment and will allow him to be part of a process of re-subjectivation. Resilience could then designate by the effect of this intrapsychic work of the subject who can take place only from a meeting that Freud referred to as "transfer" and psychoanalytic work and would aim to create the conditions for resilience. From clinical cases this is the link between transfer and resilience that will be questioned.

Key words: transfer, unconscious, symptom, resilience

A la lecture des nombreux travaux et écrits concernant le concept de «résilience » et à partir de ma pratique en tant que psychologue clinicienne orientée par la psychanalyse il m'apparaît que cette notion pourrait s'appliquer à celle de « symptôme » dans son acception psychanalytique c'est-à-dire comme invention, création du sujet destinée à surmonter les angoisses et les peurs qui surgissent à chaque fois que survient de l'inattendu ou de l'étranger. Cette conception du symptôme comme une production, une substitution à un évènement appréhendé à l'origine comme inassimilable et comme tel refoulé, substitut à une satisfaction pulsionnelle qui n'a pas eu lieu, qui n'a pas pu se satisfaire, ayant le même statut que celui du rêve, du mot d'esprit et du lapsus, a été décrite par FREUD [1] comme formation de compromis, parole d'une vérité que FREUD reconnaîtra comme l'inconscient. LACAN après FREUD ira plus loin en décrivant le symptôme « structuré comme un langage » et non réduit au seul champ du symbolique mais en lien aussi avec l'imaginaire du corps et avec le réel en tant qu'impossible à dire [2]. Ainsi l'angoisse c'est ce qui pénètre du réel dans l'imaginaire c'est-à-dire dans le corps et se traduit par les manifestations physiques telles que le cœur qui bat la chamade, le ventre serré, les jambes qui flageolent…etc. Il ira jusqu'à montrer les effets de création du symptôme [3].

«La résilience n'est pas à rechercher seulement à l'intérieur de la personne, ni dans son entourage mais entre les deux parce qu'elle noue sans cesse un devenir intime avec le devenir social »[5]. Ainsi le symptôme, création originale d'un sujet lui permet-il de se plaindre à d'autres, d'attirer l'attention de son entourage sur lui, d'être reconnu dans sa singularité, d'être écouté, de se sentir exister et peut lui servir d'appui. C'est la rencontre avec un autre mis en position de savoir qui va rendre possible la transformation de la plainte en une demande qui, dans certains cas, va créer de la résilience. Le plus souvent cette rencontre se fait dans ce que FREUD a nommé le «transfert» dans la cure psychanalytique. Le transfert existe dans toute relation basée sur la parole dès lors qu'un savoir est prêté à quelqu'un et peut être défini comme un ensemble de projections, sentiments, pensées, affects, sur la personne « supposée savoir». Ce qui caractérise le transfert, répétition de prototypes infantiles vécus avec un sentiment d'actualité, c'est qu'il permet, par le jeu de la répétition, l'ouverture de l'inconscient. Il est donc la répétition dans le présent d'une relation imaginaire du passé marquée par la confiance et la sécurité. C'est la capacité de neutralité bienveillante du psychanalyste qui va créer l'ambiance nécessaire à son établissement. Carl ROGERS [4] parle de « l'attitude inconditionnelle bienveillante» de l'écoutant comme condition indispensable de la relation d'aide, qui va amener le demandeur d'aide à s'identifier à l'image qui lui est renvoyée pour se trouver aimable et digne d'intérêt. De ce fait il va commencer à croire en

lui et à faire confiance à ses pensées et ses affects. Aller parler à un analyste institue ce phénomène qui inclut le sujet et l'analyste, le transfert, qui place l'analyste en position de supposé savoir. Ce que pense trouver le névrosé en adressant sa plainte à un psychanalyste c'est l'interprétation de ses symptômes. Il lui suppose un tout savoir sur la cause de ses symptômes. Aller parler à un analyste institue ce phénomène qui inclut le sujet et l'analyste, le transfert qui place l'analyste en position de supposé savoir. Ce que pense trouver le névrosé en adressant sa plainte à un psychanalyste c'est l'interprétation de ses symptômes. Il lui suppose un tout savoir sur la cause de ses symptômes.

Boris CYRULNIK décrit trois facteurs déterminants dans la capacité de résilience à savoir la génétique, la stabilité affective des premiers mois et enfin l'école, la famille et la culture. De nombreux exemples cliniques montrent en effet qu'une relation de confiance est en effet plus difficile à instaurer lorsque l'un des partenaires dans la relation a connu une dé privation affective dans les premiers mois de sa vie qui ne lui a pas permis d'acquérir le sentiment de sécurité minimum à l'établissement d'une relation d'objet satisfaisante. Les enfants des rues en Roumanie et dans d'autres pays d'Amérique du sud, d'Afrique et d'Asie en sont le témoignage. Les familles dans lesquelles les liens avec l'extérieur sont très réduits voire inexistants laissent peu d'accès à leurs membres pour une rencontre susceptible de leur permettre de sortir des schémas répétitifs qui se transmettent de génération en génération. Un cas clinique va nous permettre d'apporter un éclairage sur ces assertions.

Edouard est un enfant de 9 ans suivi en thérapie depuis quelques mois par une collègue psychologue dans le cadre d'un service de consultation pédopsychiatrique. Il souffre depuis deux ans d'angoisses massives qui l'empêchent de dormir et de se concentrer à l'école. Des comportements bizarres à l'école ont été à l'origine des consultations. Après plusieurs séances au cours desquelles Edouard évoque une «grosse question dont la réponse est dans la famille» sa thérapeute décide de rencontrer les parents pour les adresser vers le centre de thérapie familiale où je travaille. C'est ainsi que je reçois Edouard, sa petite sœur âgée de 7 ans et les parents. Nous nous rencontrerons régulièrement pendant 4 ans.

Monsieur et madame se présentent d'emblée comme des parents très préoccupés par leur rôle de parents. Madame a arrêté de travailler à la naissance d'Edouard pour s'occuper des enfants. Monsieur a un métier qui lui permet d'avoir le même rythme que ses enfants scolarisés. A chaque période de vacances scolaires ils partent ensemble dans une autre région de France. Leur vie est organisée autour des enfants. La maison est conçue pour les enfants. Ils voient peu de monde. Madame s'occupe de sa mère, veuve et presqu'aveugle. Monsieur garde des liens avec sa mère assez âgée. Ils n'ont jamais confié leurs enfants à quiconque en dehors de l'école.

Edouard présente sa demande. Il a une grosse question dans la gorge (il montre l'emplacement de la question sur son corps) et il sait que la réponse est dans la famille. Ils sont tous d'accord pour aider Edouard. Pendant les premiers entretiens les histoires familiales de monsieur et madame sont déclinées ainsi que la naissance des enfants. Madame est la plus jeune d'une fratrie de deux enfants. Son frère est schizophrène et elle relate une enfance où elle avait le sentiment de ne pas exister à côté d'un frère qui faisait la fierté de sa mère et qui la remplissait, elle, d'effroi. A côté de son frère elle se sentait « pétrifiée » selon ses dires sous le regard de sa mère. Monsieur est fils unique. Sa mère, benjamine d'une fratrie de trois filles, s'est mariée à l'âge de 40 ans pour donner un héritier à la famille, les deux ainées n'ayant pas eu d'enfant. Dès la naissance de monsieur le père de celui-ci a été renvoyé et l'enfant a été élevé par sa grand- mère, sa mère et ses tantes. Il était l'héritier de la famille, l'objet cause du désir de sa mère, sa grand-mère et ses tantes. Il n'y avait pas de place pour le père. A la sixième séance Edouard parvient à verbaliser sa « question » : « Papa, maman est-ce que vous m'avez désiré?», soit la question de l'origine qui touchait au mythe et à l'idéal familial. Les enfants étaient nés du désir de leur mère. Monsieur, quant à lui, ne se sentait pas capable d'être père. Il s'efforçait d'être un père idéal c'est-à-dire un père sans manque pour ses enfants. C'est ce qu'Edouard avait besoin de questionner. Grâce à la relation transférentielle établie avec sa thérapeute il a pu dans le cadre de la thérapie avec sa famille décompléter l'image du père et se faire une place, ce qui lui a permis de réinvestir le travail en individuel avec sa thérapeute. Quant aux parents d'Edouard ils ont entrepris chacun un travail psychanalytique.

Edouard était un enfant psychotique. Suite à ce travail il a pu suivre une scolarité normale jusqu'à l'obtention d'un BEP technique à l'âge de 18 ans. Il a son appartement et le même emploi depuis. La petite sœur, grâce à lui, a grandi sans problème. Elle est mariée et a deux enfants. Le symptôme d'Edouard, parce qu'il a rencontré le désir de sa psychothérapeute dans le transfert, a créé un processus de résilience qui a amené l'arrêt d'une répétition mortifère dans la famille, l'arrêt de ses angoisses destructrices et lui a permis de rebondir d'une position d'enfant porteur de symptôme et voué à devenir «fou» à celle d'un jeune homme qui a pris sa vie en mains. On peut parler de résilience puisqu'il y a bien eu reprise d'un bon développement après un traumatisme, sans retour à l'état initial, et que l'on peut repérer un processus naturel et interactif qui a dépendu autant de l'environnement que du sujet lui-même. Mais ce processus n'a pu se faire que parce qu'il y a eu rencontre à un moment donné, dans le transfert, avec le désir de sa psychothérapeute qui a accueilli sa demande et a été à l'origine de la démarche familiale.

C'est donc bien en tant qu'il y a une personne qui est là pour accueillir et entendre ce que dit le symptôme et ce que le sujet a à en dire, en lui permettant de trouver du sens et des signifiants, qu'il pourra y

avoir un effet de résilience pour le sujet. Ainsi en est-il pour Jean Valjean, le héros de Victor HUGO, dans son roman «Les misérables», après sa rencontre avec l'évêque qui lui fait confiance, le nourrit, lui fait des cadeaux et refuse de l'accuser pour le vol qu'il a commis. La rencontre de cette figure paternelle bienveillante va mettre un terme à sa vie de misérable et de voleur. Par identification à « son sauveur » il va transformer sa vie et devenir à son tour un homme bon et généreux. Son symptôme qui le fait se considérer comme un rebus, un moins que rien et à s'identifier à cette position de déchet, par le traitement qu'en fait l'homme d'église devient facteur de résilience.

On pourrait évoquer d'autres cas célèbres où la rencontre d'un signifiant à partir d'un processus d'identification à un autre a été facteur de résilience. La littérature nous donne de nombreux exemples de cas semblables. James JOYCE, l'écrivain anglais, à travers sa rencontre avec l'écriture parvient à se faire un nom là où rien n'avait eu valeur de nomination auparavant. Virginia WOOLF, célèbre auteure du début du 20ème siècle, dont l'œuvre est bâtie sur sa « bataille avec les mots contre une douleur d'existence » qui avait commencé très tôt dans sa vie. « La lecture de son œuvre révèle la tâche infernale à laquelle elle s'est livrée et les moyens qu'elle a trouvés pour se protéger de ce qu'elle nomme son « horreur ». La rencontre avec son mari fut à l'origine de sa production littéraire. Il sut la convaincre de ne pas cesser d'écrire et lui permis, de ce fait, « de se tenir dans le monde » assez longtemps avant que de se suicider. La liste est longue des romanciers et écrivaines, des artistes, des philosophes qui, à partir d'une rencontre avec un homme ou une femme qui a su se mettre à l'écoute de leur symptôme, ont réussi à se tenir dans le monde grâce à leur œuvre.

Abstract

Health and psychological well-being of educators now represent a concern of psychological research since the advent of a field of study based on stress and teacher burnout. However, out of a traditional approach that tilts towards the adoption of pathological models of work, the study of resilience rather allows for a positive perspective on mental health and its relationship to the work, including education. The fundamental plane of the definition of resilience, we adopt the dynamic person-environment [1], which establishes resilience as a provision to develop context model. We ask more specifically the role of psychological flexibility, a concept that takes shape in psychological theory and psychotherapeutic models. Empirically, this question of the relationship between flexibility and resilience was operationalized through research by electronic questionnaire conducted among schools staff, including 232 in Quebec. Although conceptual analysis may reveal a relationship between resilience and flexibility, this statistical exploration of the role of flexibility for psychological health as well as links between the two concepts seems first to have been conducted with a population non-clinical, in the context of their work. The results show that psychological flexibility may explain part of the resilience of these education professionals as well as several aspects of their health to the work place. These results seem particularly interesting to us on two levels, basic and applied, in that it help to understand a fundamental psychological mechanism of resilience and also help develop practical ways to stimulate its development.

Keywords: Resilience, Psychological flexibility, acceptance, emotions, health.

Problématique

1.1 La santé psychologique et la résilience des gestionnaires scolaires

Peut-être en raison des démonstrations de la complexification de la tâche des directions d'établissements scolaires, qui abondent depuis une vingtaine d'années, accompagnées par des indices que ces éducateurs travaillent souvent dans un environnement tumultueux, la recherche sur leur santé psychologique au travail est encore clairsemée, au détriment de celle qui porte sur leur détresse. Le choix d'une telle question relève clairement du paradigme de la résilience au travail. Ainsi vues, les questions du maintien du bien-être et de la santé au travail apparaissent d'autant plus critiques à examiner dans la conjoncture actuelle, où le recrutement et la progression en carrière de ces professionnels demeurent difficile [2]. L'une des raisons qui peut expliquer cette faille relève sans doute de l'envahissement du paradigme du stress dans le champ de la santé psychologique, et en particulier dans celui du travail des professionnels de l'éducation. Il est vrai que plusieurs études abordent indirectement leur santé psychologique à partir d'un point de vue négatif, montrant ainsi qu'ils vivent beaucoup de stress et se sentent souvent dépassés par les contraintes administratives, l'application des réformes et la gestion des conflits interpersonnels [3].

1.2 Les facteurs de la résilience éducationnelle

L'une des premières études qualitatives explorant leur travail d'un point de vue positif à partir de leur résilience suggérait que les directions d'écoles résilientes pourraient s'appuyer sur leurs compétences professionnelles devant l'adversité du travail en milieu défavorisé pour en tirer bénéfice pour eux-mêmes et leur communauté [4] .Dans une enquête menée par voie électronique auprès de directions d'écoles (N=627), Pepe [5] a trouvé une relation positive entre la résilience des directions et leur satisfaction au travail, de même qu'avec

leur engagement affectif au travail. Cette variable s'exprime par l'alignement du gestionnaire avec la mission et la vision de l'organisation, c'est-à-dire lorsqu'il s'identifie avec les valeurs et les buts de son institution. À elle seule, la variable de l'engagement affectif explique la variance dans la résilience observée chez ces directions d'écoles du primaire et du secondaire. Il nous apparaît dès lors pertinent de questionner les liens entre les variables affectives et la résilience.

En tout état de cause, la recherche sur cette fonction administrative semble indiquer que la résilience des gestionnaires scolaires engage bien plus que des compétences professionnelles et organisationnelles, mais émotionnelles aussi, surtout quand ils sont confrontés au stress chronique. De plus, exactement comme chez les enseignants [6], les émotions les plus fréquentes des gestionnaires scolaires sont de valence négative, notamment de colère, de frustration et d'anxiété [4]. En raison de la conception de leur rôle, qui doit les montrer en contrôle de leurs émotions, ils tentent alors de s'ajuster en inhibant leurs émotions négatives[7]. Or, on sait que la suppression des pensées et des émotions négatives produit un effet rebond, très nocif pour la santé [8]. En adoptant la perspective de la résilience et de la santé psychologique au travail, il importe donc de chercher des facteurs de protection plus efficaces que l'inhibition des émotions négatives, pour aider ces professionnels à développer leur résilience, de manière à maintenir leur santé psychologique et leur efficacité au travail.

Cadre théorique

Deux modèles théoriques servent à mettre en perspective notre problème de recherche, celui de la résilience établi comme un processus du développement adulte et celui de la flexibilité psychologique, issu de la théorie des cadres relationnels, une théorie du développement du langage et des cognitions appliquée à l'intervention.

1.1 Les dynamiques de la résilience dans le contexte du travail

Plus loin que ses pivots d'adversité et d'adaptation, le concept de résilience n'est certes pas facile à définir, sans doute parce qu'il recouvre plusieurs dimensions et qu'il résulte de divers processus qui se profilent distinctement selon la perspective théorique adoptée [9]). Dans le contexte de la résilience des adultes au travail, on convient généralement que les personnes résilientes sont moins stressées, plus efficaces et en meilleure santé, mais on s'interroge toujours sur les mécanismes responsables de ces adaptations positives à des situations de travail difficiles. On retrace plusieurs mécanismes selon les approches, mais le modèle le plus intégrateur insiste sur trois processus principaux: la récupération de la santé par la diminution des dommages, l'équilibration par la protection de la santé et l'amélioration des habiletés de vie saines et productives par la promotion de la santé [10]. On comprend que ces trois mécanismes s'échelonnent dans le temps, suivant la rencontre de stresseurs avec lesquels l'individu n'arrive pas à composer et qu'ils constituent en tout ou en partie, ce qu'il est convenu de nommer la résilience. Écartelées entre facteurs de risque et de protection, personnels et environnementaux, ces dynamiques qui sous-tendent la résilience mènent de plus à des hypothèses étiologiques variées, selon que l'on considère le phénomène sous l'angle des traits ou sous celui des processus développementaux et qu'on opérationnalise ses mécanismes davantage en termes de résistance aux obstacles, comme la dépression, l'anxiété, le stress, les émotions négatives, ou en termes de développement des forces. En ce qui concerne ces dernières, on reconnaît généralement six grandes catégories de facteurs de protection, qui sont celles de la satisfaction avec la vie, des relations interpersonnelles ou du soutien social, de l'auto-efficacité, de l'estime de soi, de la résolution de problèmes, des émotions positives et de l'optimisme [11].

En questionnant ainsi l'importance relative des liens entre la résilience et la résistance aux obstacles, le développement des forces et les variables de la personne dans l'explication de son développement, une récente méta-analyse [11] a permis d'ordonner statistiquement l'effet de ces trois grandes catégories de facteurs explicatifs de la résilience, en référence à un corpus de recherches regroupant 33 études et plus de 31,000 participants. En termes de prédiction statistique, les chercheurs concluent que la résilience est fortement redevable à l'impact de mécanismes de protection et des facteurs d'autoefficacité et d'émotions positives qui leur sont associés, qu'elle est modérément reliée aux mécanismes de résistance aux obstacles comme le stress et l'anxiété et faiblement redevable aux données démographiques de la personne, comme son âge et son genre. Dit autrement, la résilience se déploierait plus facilement grâce aux facteurs de protection personnels et environnementaux.

1.2 La flexibilité psychologique

Tenant compte de l'importance des facteurs de protection personnels, la synthèse de ces écrits peut nous aiguiller sur la voie de l'auto-contrôle ou de la régulation émotionnelle, ou inversement sur celle de l'acceptation des émotions et des contenus psychologiques négatifs. Dans le premier cas, on tentera de modifier les contenus de pensée et d'émotion alors que dans le second, on les observera sans tenter de les diminuer ou de les supprimer. L'acceptation diffère de l'inhibition et de l'autorégulation, en ce qu'elle amène l'individu à limiter

l'évitement des événements désagréables pour au contraire, s'y exposer davantage. Elle diffère de la résignation en ce qu'elle amène l'individu à pouvoir évaluer une situation comme négative, sans fonder ses agissements sur ce jugement.

L'acceptation sert à augmenter la flexibilité psychologique, qui peut se définir comme un changement radical de perspective sur ce que l'on fait, ce que l'on pense et ce que l'on ressent, dans un sens d'élargissement cognitif plutôt que de restriction cognitive [12]. Elle permet à un individu d'accepter la situation telle qu'elle est, ce qui présente l'avantage de tolérer l'anxiété associée, plutôt que de l'éviter. La flexibilité psychologique offre aussi de considérer des pistes d'action réalistes [13]. Un survivant des camps de concentration exprime magistralement ce que nous définissons comme la flexibilité psychologique. Rapportant un moment où il s'était surpris à être absorbé dans des préoccupations et des inquiétudes autour de ses conditions de vie quotidiennes dans le camp de concentration où il était retenu prisonnier, Frankl [14]) s'exprime ainsi:

«J'ai alors orienté mon flot de pensées vers un autre sujet. Soudainement, je me suis vu sur l'estrade d'une salle de conférences chaude et claire. Devant moi, était assis un auditoire attentif sur des fauteuils confortables. Je donnais un cours sur la psychologie des camps de concentration ! Tout ce qui m'oppressait à ce moment, devint une réalité objective vue et décrite par la science. Grâce à cette technique de pensée, j'ai réussi à m'élever au-dessus de la situation, des souffrances de cette journée et je les ai observées comme si elles étaient des souvenirs du passé.» trad.libre, p.82 (Frankl,1992).

Si en rapportant la citation, Pepe (2011) rattache la description de ce processus cognitif à la résilience dont a fait preuve Frankl, nous ajouterions que cet exemple décrit bien l'élargissement de l'expérience de la pensée et la flexibilité psychologique, en ce que le témoin démontre qu'il observe ses propres processus internes et qu'il a conscience que le contenu de sa pensée anxieuse ne reflète pas toute la réalité.

Le concept de flexibilité psychologique que nous utilisons ici vient de la théorie des cadres relationnels, qui postule que la rigidité ou l'inflexibilité psychologique est à la source de la majorité des problèmes psychologiques et qu'elle émerge des processus langagiers que l'humain utilise pour s'expliquer les événements contextuels [15]. En ce qui concerne l'intervention sur la santé psychologique au travail, la flexibilité psychologique se retrouve au centre du modèle d'acceptation et d'engagement (ACT) [16]. Dans le domaine de la résilience, une des toutes premières mentions de la flexibilité psychologique est retracée chez Block & Block [17], alors qu'on la retrouve mentionnée comme un facteur de protection personnel relié à la résilience des enseignants, chez des chercheurs contemporains [18] et qu'on y réfère comme un facteur de la santé [13].

1.3 Question de recherche

En nous situant au point de convergence d'une perspective positive de la santé psychologique et développementale de la résilience, notre question spécifique concerne les relations qui existent entre la flexibilité psychologique et la résilience au travail, en questionnant le rôle de l'acceptation des émotions et cognitions difficiles dans un contexte de gestion, qui valorise plutôt leur inhibition. Découlant du modèle théorique de la flexibilité psychologique, nous posons l'hypothèse que les directions qui acceptent leurs émotions et leur vécu difficiles seraient plus résilientes et éprouveraient davantage de bien-être au travail.

Méthodologie

1.1 Participants et questionnaires

À l'automne 2012, les directions d'établissement du primaire et du secondaire ont été invitées à participer à une étude sur leur santé psychologique au travail par une équipe de chercheurs canadiens. L'enquête visait à mieux cerner les facteurs organisationnels, psychosociaux et individuels qui affectent la santé psychologique et la performance au travail. L'invitation a été lancée via une plateforme internet dans deux provinces canadiennes dont nous rapportons ici une partie des résultats issus des directions d'écoles du Québec (N=232). Outre treize questions d'ordre sociodémographique, l'instrument de mesure est constitué de quatorze échelles et 232 items. Il couvre différentes dimensions du travail de direction d'une école et du bien-être au travail et leur est parvenu sous la forme d'un questionnaire électronique.

Parmi les domaines de la santé investigués pour cette enquête, la flexibilité psychologique est mesurée par un questionnaire conçu par Hayes et ses collègues [19] dont la version courte a été validée [16] sous le titre "Anxiety Acceptance Questionnaire" (AAQ-II), que nous avons traduit en français. Il comporte sept items formulés négativement, dont *«Mes inquiétudes peuvent m'empêcher de réussi* », que le sujets sont appelés à rapprocher de leur expérience vécue, selon une échelle Likert en 7 points (1 = jamais vrai à 7 = toujours vrai). L'analyse factorielle révèle un seul facteur, qui explique 68% de la variance et un alpha de Cronbach de 0.92.

La résilience est mesurée par l'échelle de résilience [20] .Elle comprend 23 items sur une échelle en 5 points (1 = presque jamais et 5 = presque toujours) dont «*Lorsque survient une grande difficulté, j'ai tendance à : chercher une solution pour y faire face*». L'alpha de Cronbach est de 0.86.

Le bien-être psychologique (BEP) est mesuré par l'échelle de bien-être au travail [21]. Elle comprend 25 items sur une échelle en 5 points (1 =presque jamais et 5 =presque toujours) dont «*J'ai un bon mora* ». L'alpha de Cronbach est de 0.85.

Tableau 1-Description des variables à l'étude

ÉCHELLE	MOYENNE	ÉCART-TYPE	N
Flexibilité psychologique (AAQ-II, 7 items)	2,14	1,05	232
Résilience (23 items)	3,95	0,57	232
Bien-être psychologiqueau travail (25 items)	3,79	,65	232

Résultats

Les résultats divulgués ici sont partiels et leur présentation se concentre sur les liens entre la flexibilité psychologique et les dimensions positives de la santé au travail. Au plan descriptif des données sociodémographiques tout d'abord, les analyses de test T ne révèlent pas de différence significative sur la flexibilité psychologique entre les hommes et les femmes, lesquelles sont au demeurant majoritaires dans cet échantillon. Aucune différence significative n'est décelée sur cette variable et la scolarité, la charge de travail, ni sur la charge familiale. Par contre, on relève une différence significative entre les directions (M=1,98 ET= .08) et les directions adjointes (M= 2,34 ET= 1,16), indiquant moins de flexibilité chez ces dernières (vu l'inversion des énoncés, plus le score est bas, plus la flexibilité est grande), avec un petit effet de taille, selon les standards proposés par Cohen [22].

La distribution des scores de l'AAQ-II établit la moyenne de flexibilité psychologique à 2,14, révélant qu'elle est assez élevée pour cet échantillon de directions d'établissement. Les corrélations de Pearson montrent que la flexibilité psychologique et la résilience sont corrélées (R^2= 0.71 p ≤,001), de même que la flexibilité psychologique et le bien-être psychologique au travail (R^2= 0,52 p ≤,001).

Après avoir constaté ces corrélations, des analyses de régression ont été conduites pour tenter de fournir une meilleure explication des liens et explorer le rôle de la flexibilité. Les analyses de régression simple montrent que la flexibilité psychologique, comme variable indépendante, explique une part des variances de plusieurs dimensions de la santé psychologique au travail: elle explique ainsi 24% de la variance du score de résilience F [1, 230]= 71,688, p < ,001) et 27% du score de BEP (F [1, 230]= 86.602, p < ,001). Elle explique encore 13% de l'adaptation au travail (F [1, 230]= 34.121, p < ,001),15% de l'harmonie au travail (F [1, 230]= 41.809, p < ,001), 19% de l'implication au travail (F [1, 230]= 55.443, p < ,001) et 29% de l'équilibre personnel au travail (F [1, 230]= 95,099 p < ,001). Par la suite, le rôle de médiation de la flexibilité psychologique a été estimé selon la procédure suggérée par Preacher & Hayes [23]. En explorant ces relations, on note que la FP exercerait un effet de médiation partielle entre la résilience et le BEP. Nous constatons aussi un effet de médiation de la FP dans la relation entre la justice organisationnelle et le BEP. La FP exerce encore un effet de médiation partielle dans la relation entre le climat organisationnel et le BEP, de même qu'entre les ressources organisationnelles et le BEP, et entre les demandes organisationnelles et le BEP.

Discussion

Dans l'avancement de l'étude des processus de la résilience, ces résultats indiquent que la flexibilité psychologique, par l'acceptation des émotions difficiles, éclaire d'une façon différente la résilience et le bien-être psychologique au travail, tout en permettant de concevoir des liens nouveaux que nous n'avions pas prévu au départ. Toutefois, la forte corrélation entre la résilience et la flexibilité psychologique impose une révision de la validité des deux construits, qui devrait permettre de vérifier qu'aucun recouvrement significatif n'explique cette relation. Sans doute importerait-il d'examiner l'instrumentation avant de pousser plus loin le questionnement sur des processus distincts.

Mais, vu ses liens convergents et de bonne ampleur avec plusieurs dimensions positives, on peut supposer que la flexibilité psychologique pourrait bien être en soi, un facteur de protection personnel. La promotion de la flexibilité psychologique, particulièrement dans ce type de travail, aiderait les gestionnaires à maintenir ou accentuer les dimensions de leur santé, plutôt qu'à inhiber toute forme d'expression négative. Sans confirmer l'hypothèse d'une médiation de la résilience par la flexibilité, ces résultats montrent assez clairement que les directions d'établissement qui acceptent leurs émotions et leur vécu difficiles sont aussi résilientes et lorsqu'elles sont flexibles, elles éprouvent du bien-être au travail. Ces relations empiriques viennent enrichir les concepts à l'étude, mais ne permettent pas d'établir qu'un processus les relie l'un à l'autre. Tout au plus, pouvons-nous indiquer que la présence de flexibilité psychologique, en termes de mesure fiable [16] montre des liens théoriques avec la santé psychologique, mais sans pour autant confirmer la nécessité d'en tenir compte comme une voie qui mène à la résilience. Plusieurs processus pouvant être en jeu dans la résilience, cette

conclusion n'invalide pas les interventions porteuses pour la santé psychologique, surtout lorsqu'elles révèlent des índices probants [12].

Bien qu'exploratoire, ce type d'analyse fine des processus de la résilience invite à accentuer les démarches d'explication des états positifs, en situation d'adversité [10]. De tels résultats permettent aussi de redéfinir la terminologie de la régulation des émotions négatives, souvent comprise en termes de diminution ou d'inhibition, en lui ajoutant l'acceptation, elle-même une notion encore peu connue. La capacité à observer pour ce qu'elles sont, ses émotions négatives comme une partie du vécu au travail pourrait permettre la récupération, l'équilibration, voire la promotion de solutions aux problèmes rencontrés, ce qui constitue la résilience. Surtout si la santé psychologique au travail des professionnels de l'éducation peut en être tributaire, on comprendra toute l'importance d'ajouter ce type de compétence émotionnelle à leur formation. On peut en effet supposer que l'amélioration des capacités fonctionnelles des gestionnaires est un critère important, lorsqu'il s'agit de dépasser les difficultés reliées au travail de gestion.

Ayant déjà constaté que les facteurs de risque et de protection se ressemblent, tant au plan personnel qu'environnemental pour les enseignants et les directions d'écoles[24], il restera à vérifier si les enseignants peuvent aussi bénéficier des mêmes facteurs de protection personnels que les directions, particulièrement sur leur flexibilité psychologique et leur acceptation des émotions difficiles.

Conclusion

Bien que comportant certaines limites méthodologiques, dont la passation par voie électronique qui rend impossible toute vérification de la qualité des réponses, cette recherche sur la santé psychologique au travail représente une certaine avancée sur le plan de l'explication des sources de la résilience. En considérant au rang des facteurs de protection, la flexibilité psychologique évaluée par l'acceptation des émotions difficiles, nos résultats apportent une validation supplémentaire du concept. En autant que l'on puisse mieux isoler son action au sein des processus, l'explication pourrait conduire à l'élaboration de stratégies d'intervention sur la résilience, et sur la résilience au travail.

Abstract

The present article was intended to outline the guidelines of a new resilience-oriented therapeutic model of intervention and to present preliminary data about its effectiveness on a sample of polyabusers undergoing residential treatment.

Resilience being a multidimensional process not easy to measure, in order to evaluate the effectiveness of our model we considered as indicators of resilience some of its outcomes that extant literature has described; in particular, we assessed, pre- and post-intervention, coping styles and perceived stress and psychological well-being, together with levels of anxiety and depression.

Student's t-test showed significant differences in all the scales, with the exceptions of the "humour" coping strategy and anxiety. The preliminary findings suggests that a targeted intervention shaped within the framework of a resilience-oriented model can facilitate the raising of resources that are useful to activate a resilient process.

Keywords: Resilience, Intervention Model, Substance Abuse, Stress, Coping

Introduction

Nowadays resilience must be considered as a major factor directing public health policy strategies aimed at promoting individual and collective functional responses to adversities. Recent advances in the study of resilience have considerably contributed to the knowledge of individual adjustment by focusing, among others, on the possibility to implement interventions aimed at activating a person's resilient resources. Contemporary research on resilience is focused on the investigation of factors leading to wellbeing [1] and also seeks to highlight the underlying social and psychological processes and practices through which resilience may be achieved [2], [3], [4].

Intervention, in the field of substance use disorder, based on a resilience framework still represent a partially unexplored domain, since much of the extant literature on resilience has dealt with children's and adolescents' development within unfavourable contexts [5] or with responses to trauma and loss in adulthood [6]; furthermore, to date research on resilience and substance use disorder has been focused on the development of children with at least an addicted parent, or on community-based prevention actions, while researching on the implementation of intervention programs for adult with substance abuse problems is still a challenge.

Resilience refers to a dynamic process by which an individual, a family, or a community system is able to adapt to and function well within a context characterized by significant adversity or risk [7], [8], [9]. Rather than as a trait, resilience should be construed as a set of processes that can be inferred when the individual or the system being considered shows competence in response to substantial risk exposure [8]. This ability can change over time and may be enhanced by protective factors related to the person and/or the environment [10].

The resilient process includes also the practices and strategies individuals resort to in order to mitigate the psychological distress related to the exposure to an adverse event. This evidence indicates that coping is a crucial construct for research on resilience that it is considered jointly a function of the stressful situation and the individual's resources [11].

Various studies investigating stress-and-coping interaction models have been focused on the moderating role of certain strategies useful to face hostile situations and have shown how an addictive behavior, such as the use of alcohol and drugs, can be utilized to reduce or counter the effects of stress [12], [13]. It seems therefore that a central aspect of the resilient process can be identified in the quality of the regulatory competence that an individual displays when facing daily stressors. To respond in an adaptive way to unfavorable events or

situations everyday life entails represents an essential prerequisite with reference to the ability to face major adverse events in a similarly adaptive way, by activating a resilient process [14].

The Resilience-Oriented Treatment Model

The intervention model we designed [15] stems from resilience concepts, some key assumptions of Milton Erickson's (1901-1980) intervention approach and from the evolutions of modern systemic theories on chaos [16], [17].

The intervention is articulated into four phases based upon three levels.

The four phases are: 1) entrance, including a watching period during which an observation of the patient is carried out together with a first assessment consisting of the administration of tests specifically designed for measuring resilience and the associated constructs, and of an investigation into the patient's life story with the collection of biographical information 2) treatment, carried out on three specific levels: vertical, horizontal and cross-domain 3) exit, with a re-assessment of resilience and finally 4) follow up, after 6 months and again after 1 year.

The core of the resilience-oriented intervention develops through three levels, vertical, horizontal and cross-domain.

1.1 Vertical Level Of Intervention

The *vertical intervention* addresses each single patient and thus it must be "tailored" to the individual on the basis of her/his story, taking into account peculiar risk and protective factors. With the patients' active participation a Resilient Therapeutic Program (from now on RTP) is planned: stress indicators related to the three areas – individual, familial and social – of resilience development are identified.

For each indicator a prescription is given with reference to a concrete, feasible and measurable objective, on the basis of the person's resilient characteristics (resources and protective factors) and of the analysis of the "attempted solutions", that is, the dysfunctional modalities used in the past when trying to overcome a given stressful situation. Prescriptions, designed *ad hoc* for the patient and by the patient, stimulate the activation of a small-steps resilient process: trying their hand at facing minor, but significant daily stressful situations, individuals are given the chance to develop skills by activating coping strategies related to salient risk factors in their treatment and life trajectories [18], [19].

Cognitive and behavioral responses to these stimuli can activate one or more "turning points" [20], [21] helping the individual restructure her/his experiences through new learning. The RTP is constantly monitored and supervised by mentor figures (social workers, psychologists etc.)

A roadmap is traced, that is a schedule by means of which patients actively commit themselves to organize their time (interviews with clinicians, participation in group activities, test completion etc.). The roadmap has the function to assign each patient the responsibility of her/his treatment course and, at the same time, to provide feedbacks stimulating self-regulation and self-reflexivity processes.

Another example of vertical intervention is the assignment of a care-manager (that is, a figure in charge of tutoring and monitoring activities) to each patient, in accordance with the crucial relevance of the relationship with at least one reference figure in the activation of a resilient process extant literature on resilience has emphasized. Therefore, the care-manager represents the mentor with whom the patient, by means of interviews on a weekly basis, can discuss about the various aspects of the course of her/his treatment.

1.2 Orizontal Level Of Intervention

The *horizontal intervention* refers to experiential moments involving patients in group activities, and is structured in a way that allows to work on the risk and protective factors characterizing the problematic situation shared by all group members, for example: addiction (tailoring on the category of users). The intervention is carried out within specific settings designed to facilitate and foster the activation of implicit associative processes between the risky situation (stressor) and specific protective factors related to the specialist activity being performed, in order to generate functional coping and regulation strategies. This kind of intervention helps participants to use social resources like the group and/or the activity conductor (with tutoring or mentoring functions), in addition to the resources the activity itself provides.

At the horizontal level, both a direct form of learning (achieved by doing) and an indirect one (through the observation of the other group members) are stimulated.

1.3 Cross Domain Level Of Intervention

The *cross-domain intervention* pertains to the context within which the model is applied. The physical and relational space the therapeutic program develops within must be structured and managed in a way that

allows it to become a "container" of resources. According to this perspective, the intervention is structured in order to provide a continuous and constant monitoring and supervision of the work carried out by educators, social workers and specialists.

Emphasis is put on the communication, support, coordination and reflection systems. The staff, activities, rules, values, team meetings, activity planning, physical environment, represent crucial context-related protective factors.

At this level the intervention targets the organizational system and consequently the workers who represent one of the key components of the work setting. Indeed, some actions (implemented both at the vertical and the horizontal level) are tailored to the workers' characteristics. In particular, actions of supervision and training specifically related to the theme of resilience. Furthermore, similarly to what has been established for patients who are required to complete the RTP, instruments were created for the assessment of the workers' and the whole structure resilient processes: the RWP (*Resilient Work Program)* and the RSP (*Resilient Structure Program*); their aim is to help workers identify individual, group, organizational and structural resources and protective factors, useful to cope with difficulties and work-related stressful conditions.

The groundbreaking and, in our view, particularly relevant element is the introduction of the *Online Diary*, an electronic tool accessible through an Internet connection, organized as an online forum. By this diary each worker can be updated in real time about the organizational decisions, the course of the collective activities, the patients' conditions. The diary also makes it possible to examine patients' tests and intervention programs and to check the course of each single activity every patient participates in. In general, the diary is associated to the acronym SIL, representing its three basic functions: Sharing, Informing, Learning.

The cross-domain level is, in our view, perhaps even more important than the other two; it does not involve directly the individuals undergoing the treatment, but it is based upon the idea that patients need to be supported by a resilient context and it is designed to allow the structuring of such a context. In a systemic perspective, resilience is a phenomenon strongly mediated by environmental factors, and consequently it is essential to build a resilient community context: the activation of a resilient process can be very difficult, if not impossible, if the context does not provide or facilitate the access to resilient resources.

Method

1.1 Hypotheses

We postulated that our resilience-oriented intervention model could be effective in triggering resilience in polyabusers. Resilience being a process, its assessment is not easy, unless we consider as indicators the outcomes of the process itself in terms of coping skills and stress perception.

Thus, to demonstrate the effectiveness of our model, we hypothesized that the treatment would a) have positive effects on participants' perception of their psychological condition, b) decrease their levels of perceived stress and c) elicit an improvement of the use of adaptive coping strategies.

1.2 Participants

Our sample includes 57 subjects (M=37; F=20), mean age 42.3 years (SD = 9.8), undergoing a residential treatment program in two therapeutic rehabilitation centers for polyabusers located in the Lombardy region (Italy). Both centers apply a resilience-oriented therapeutic intervention model and host individuals diagnosed with alcohol or substance abuse associated to poly-abuse of other psychotropic substances. The two centers differ in that one carries out a rehabilitation program that lasts two and a half months (P1), while the other's program (P2) takes 6 months to be carried out. Among the 57 subjects involved in our research, 37 participated in P1, the other 19 in P2.

1.3 Measures

Coping Strategies. The Italian validated version of the Coping Orientation to Problems Experiences (COPE – [30], [31], consisting of 60 items subdivided into 15 subscales. Respondents are asked to indicate to what extent they adopt the investigated coping strategies while experiencing stressful or difficult situations. Items are rated on a 4-point scale: I usually don't do this at all; I usually do this a little bit; I usually do this a medium amount; I usually do this a lot. The 15 subscales are: 1) active coping; 2) planning; 3) suppression of competing activities; 4) restraint coping; 5) seeking support for instrumental reasons; 6) seeking support for emotional reasons; 7) emotional venting; 8) positive reinterpretation and growth; 9) acceptance; 10) religion; 11) humour; 12) denial; 13) behavioral disengagement; 14) mental disengagement; 15) alcohol and substance use.

Psychological Condition: Cognitive Behavioural Assessment - Outcomes Evaluation (CBA-VE – [24], consisting of 80 items assessing the patients' psychological condition during the last 15 days. Answers are rated

on a 5-point scale: No at all / A little /A medium amount / A lot / Extremely. The test comprises five scales: 1) anxiety; 2) wellness; 3) perceived positive changing (i.e., being able to manage difficulties and to receive support from others); 4) depression; 5) psychological discomfort (i.e., the presence of serious symptoms and low impulse control).

Psychosomatic response to stress: the PHIT Subscale is part of the Italian validation of the Occupational Stress Inventory (OSI – [25]. It consists of 12 items rated on a 6-point scale: very often / often / sometimes / seldom / very seldom / never.

1.4 Procedure

Participants were recruited in two therapeutic rehabilitation centers for polyabusers located in the north of Italy. All the subjects were not intoxicates or in need of medical assistance at the time of the test administration.

The instruments described above were counterbalanced in an attempt to offset possible ordering effects and were administered to participants individually, during scheduled appointments in two different times: one week after the beginning of the residential treatment and one week before the release of the residential treatment. The pre and post-test screening battery were administered to participants by computer, under the supervision of a researcher, and it takes forty-five minutes to complete. Instructions on how to respond to items in each instrument were provided by professional clinical psychologist. Informed consent was obtained from all participants. This study was approved by the appropriate ethics review board prior to initiation.

1.5 Data analyses and results

To evaluate the effectiveness of the treatment a One-Sample Student t test was performed to compare scores at the beginning and at the end of treatment in the COPE, CBA-VE scales, and with reference to the dimension of psychosomatic stress as it can be measured by the subscale PHIT. Please note that the following findings refer to the global sample, because no statistically significant differences emerged between the two subsamples (participants in the P1 and P2 programs) and between gender.

Following the authors' scoring instructions, scores were calculated with reference to each subscale, by summing its items. Missing data were replaced by the means of the series. All scales had positively-oriented scores: high scores showed the presence of the measured dimension, while low ones indicated its absence.

Significant pre- and post-treatment differences were found with reference to all the analyzed scales, with the exception of the *humour*, *focus on and venting of emotions* and *turning to religion* ones. The table below (Fig. 1) shows the means referring to each scale.

COPE	Pre-treatment mean	Post-treatment mean	t	df	Sig.
mental disengagement	9.2	8.1	2.9	56	.005
focus on and venting of emotion	9.5	10.2	-1.9	56	.057
seeking social support for instrumental reasons	9.1	11.1	-5.1	56	.001
active coping	9.6	11.1	-4.5	56	.001
Denial	7	6.1	2,4	56	.020
Humour	7.3	7	.7	56	.506
turning to religion	7.4	8	1.7	56	.102
behavioural disengagement	7.2	9	3.8	56	.001
restraint coping	8.7	10.5	-3.7	56	.001
seeking social support for emotional reasons	8.7	10.2	-3.6	56	.001
alcohol-drug disengagement	11.1	5.9	7.9	56	.001
acceptance	9.2	10.9	-4.5	56	.001
suppression of competing activities	9	10.5	-3.9	56	.001
planning	10	12.4	-6.2	56	.001
positive reinterpretation and growth	10.6	12.7	-5	56	.001

CBA-VE					
anxiety	15.8	12.6	4.1	56	.001
wellness	42.4	48.3	-3.5	56	.001
perception of positive changing	24.9	26.9	-2.3	56	.011
depression	17.4	13.8	3.8	56	.001
psychological discomfort	44.4	35.7	3.5	56	.001
PHIT					
psychosomatic stress	26.4	21.1	3.4	56	.001

Figure 1. Shows the means referring to each scale, reporting pre- and post-treatment means, t values, degrees of freedom and significance.

With reference to the adopted coping strategies, results showed an improvement, with an increase of scores between the beginning and the end of treatment, an increase that was statistically significant in relation to adaptive strategies as *seeking social support for instrumental reasons, active coping, restraint coping, seeking social support for emotional reasons, acceptance, suppression of competing activities, planning, positive reinterpretation and growth.*

Pre- and post- treatment difference in the *humour* and *turning to religion* strategies was not significant; pre- and post- treatment difference in the *focus on and venting of emotions* strategy was near significant.

As for maladaptive strategies like *denial, behavioral disengagement, mental disengagement* and *alcohol-drug disengagement*, post-treatment scores were significantly lower, thus indicating the participants' tendency to use these strategies less.

Results in the CBA – VE scales (referring to the subjects' perception of their psychological condition) showed a positive trend in the measures of *wellness* and *perception of positive changing*; as for scores in the *depression* and *psychological discomfort* and *anxiety* scales, significant decreases between the beginning and the end of treatment were shown.

Finally, levels of psychosomatic stress, measured with the subscale PHIT, were found to have significantly decreased at the end of treatment.

Discussion

The aim of the present work was the preliminary assessment of the effectiveness of a new resilience-oriented intervention model on a sample of polyabusers undergoing residential treatment.

Extant literature on the possible measures to take in order to activate a resilient process present inconsistent evidence. Resilience is construed as an abstract concept and a process whose indicators can be assessed only through the evaluation of its outcomes, in terms of adaptive coping strategies that are useful to manage stressors. Therefore, on the basis of the landmark studies on the issue [26], [27], [28], [7], we chose to take into consideration hypotheses related to the decrease of stress levels, the increase of perceived well-being, and to the adoption of functional strategies for coping with stressful conditions and difficulties, in order to evaluate the treatment we proposed.

The findings we presented allow us to consider the resilience-oriented model, whose guidelines were described in detail, as a valid instrument for the residential treatment of patients with alcohol and substance abuse problems. In fact, our hypotheses were confirmed, thus giving positive indications on the model effectiveness, at least in relation to the investigated aspects.

Despite its encouraging preliminary findings, this work has some limitations that are worth noting. First, it does not demonstrate that a subject can become resilient, but it only suggests that a targeted intervention shaped within the framework of a resilience-oriented model can facilitate the raising of resources that are useful to activate a resilient process. Furthermore, the small sample cannot give guarantees about the model effectiveness, and the lack of a follow-up assessment makes it impossible, to date, to provide any evidence of the stability of the triggered changes over time.

Abstract

Introduction. Cases of cancer have increased greatly over the last decades. Over the same period, medical progress in the field of oncology (including developments in surgical interventions, chemotherapy and radiotherapy) has led to an increase in the survival rates of people diagnosed with cancer. In light of this, there is growing interest in the concept of resilience and understanding which factors enable individuals to enjoy a good quality of life in spite of a diagnosis of cancer.

Objectives. To identify the coping mechanisms of individuals diagnosed with cancer compared with non-clinical subjects.

Method**.** Nineteen individuals diagnosed with cancer who were receiving chemotherapy were recruited to the study. For comparison, a control group of non-clinical participants were also recruited. Participants were included into the study according to particular inclusion / exclusion criteria. The evaluation was conducted during 2013 and consisted of the analysis of the following parameters: socio-demographic data (gender, age, level of education- demographic questionnaire), clinical data (diagnosis according to the ICD 10, level of functioning as assessed by GAF scale), and coping mechanisms (COPE scale).

Results. The group of individuals diagnosed with cancer demonstrated coping mechanisms that were characterised by an emphasis on social support (religiosity, social and emotional support), whereas the control group had coping mechanisms that focused on emotions.

Conclusions. There are differences in coping mechanisms between subjects with cancer compared to the non-clinical group. It may be that coping mechanisms can be optimized through psychotherapy interventions to increase resilience of individuals diagnosed with cancer.

Keywords. resilience, coping mechanisms, oncological pathology

Introduction

Oncological pathology falls into the chronic diseases category affecting the overall functioning and quality of life of patients, both through the clinical symptoms and by the therapeutic scheme to be followed. The presence of oncological illnesses causes a change in a person's life by bringing on an intense state of anxiety induced by the negative situation, but also the need for adjustment. Adaptation is reached through the process of coping, which can be defined as the cognitive and behavioral effort to reduce, control or tolerate the internal or external demands that are required to overcome the situation [1].

The available literature [2] describes several ways of coping:

- The process of coping centered on the issue that includes an active approach, planning, suppression of competing activities
- The coping mechanism centered on emotions that includes: positive interpretation, abstention, acceptance, the religious approach
- The coping centered on social support: the use of instrumental social support, the use of emotional social support, expressing the emotions
- The coping focused on avoiding problems: denial, mental disengagement, behavioral disengagement

As is the case in general medicine, the scope of oncology is to ensure that a person who has a diagnosis of cancer should be able to still develop well, to continue, as much as possible, with their future projects, and to ensure that they have an ability of resilience. Coping mechanisms are part of resilience, along with other factors, such as high intellectual endowment, the capacity for autonomy and adaptation, empathy, appropriate humor etc.

The purpose of this study was to identify the coping mechanisms of some subjects with an oncological pathology compared with those of subjects without a pathology.

Method

In this study we comparatively analyzed two groups: group A (n = 19) consisting of subjects with an oncological pathology and a group B (n = 19) with persons without a cancer pathology. Subjects in group A were introduced in the study on the basis of inclusion / exclusion criteria that included: a clinical diagnostic of cancer (according to the ICD 10), currently treated with chemotherapy, the absence of an organic cerebral pathology, and the subjects' consent for participation in the study. Group B was a control group formed in accordance to the demographics of group A.

Data were obtained through: direct interviews with the subjects, medical records and discussions with the attending oncologist for each of the cases. We analyzed the following parameters:

- Socio-demographic: current age, gender, origin, instructional level, family status
- Clinical: oncology clinical diagnosis, duration of evolution of the pathology, family history of cancer
- Coping mechanisms: COPE scale - which is a self-assessment tool that comprises of 60 items. This scale examines the 15 coping strategies, with each strategy being assessed by 4 items. The answer for each item is made on a Likert scale from 1 to 4, with 1 meaning 'I do not do this' and 4 meaning 'I often do this' [2].

Results

Socio-demographic data are presented in table 1.

Table 1 Socio-demographic data group A

	Sample A , N = 19 subjects
Gender	
Men	68,4 %
Women	31,6 %

Evaluation of cancer history showed that this was present in 37% of subjects, and the average duration of evolution was 4.42 years (maximum 16 years - minimum 1 year). The clinical diagnosis of the subjects in group A is shown in Fig 1.

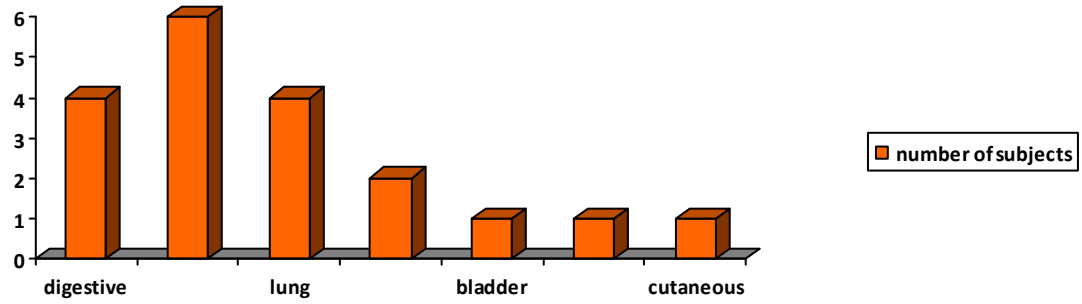

Fig.1 Clinical diagnosis group A

The COPE questionnaire results were analyzed in comparison with those of a group of subjects without a cancer pathology, and are shown in Fig 2.

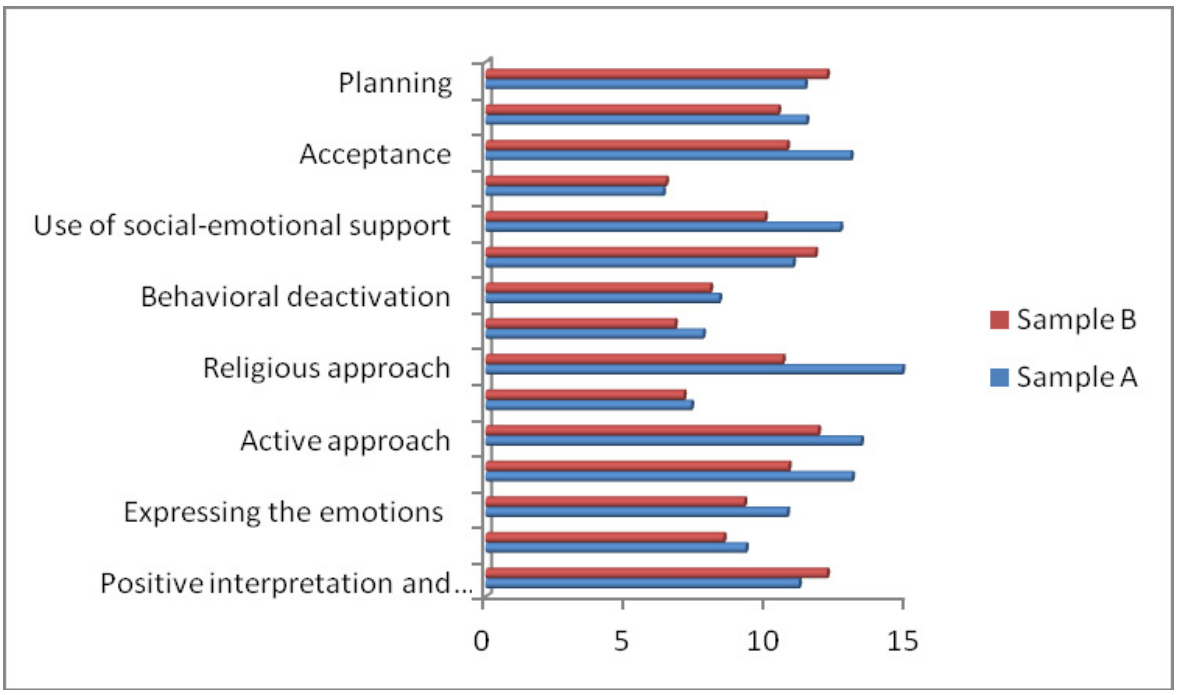

Fig.2 COPE questionnaire sample A/ sample B

Discussions

The socio-demographic data in this study have no epidemiological value, because of the reduced number of subjects, as well as their inclusion having been done without a statistical methodology. The group was comprised of several types of subjects, i.e. with different oncological pathologies, with different staging, with different duration of evolution and treatments. We might say that the group is quite varied.

The COPE questionnaire assesses 15 categories of coping: positive interpretation and growth, mental disengagement, focus on expressing emotions, the use of instrumental social support, active approach, denial, religious approach, humor, behavioral disengagement, abstinence, use of emotional social support, substance use, acceptance, suppression of competing activities and planning. The comparative analysis of these mechanisms showed no statistically significant differences in any of these areas, except for the religious coping, meaning that this mechanism is more developed in individuals with a cancer pathology.

By analyzing religious coping we can say that it consists of two components: the cognitive one (the subject perceives the neoplastic disease as part of God's plan) and the behavioral component (the subject is praying or attending religious services). In literature there are several studies on subjects with oncological pathologies, with most being performed on patients with the same type of cancer. The most frequently analyzed

pathologies are: breast, head, throat, skin, and gastrointestinal. Fewer studies are composed of patients with various types of neoplastic pathology.

In general, research focuses on the relationship between religious coping and maintaining a state of well-being, of increasing the quality of life and possibly enhancing the survival period. Religious coping may be associated with disease stage, the type of treatment received, usually being more developed in cases with high malignancy or those who have to undergo more complex surgical interventions [3][4].

This study only managed to perform a cross analysis of coping mechanisms and their comparison with those of a group of subjects without a pathology. We would have expected to find other coping mechanisms to be developed in people with an oncological pathology, such as: active approach, the use of instrumental social support, and acceptance, besides the religious coping mechanism. The role of this type of coping can be varied, i.e. it can give meaning to a negative event, it can provide a sense of control in a difficult situation, it can offer a support group conducted by people who do not suffer from this serious health problem. Through all of this, in reality, religious coping has a positive role in the life of a person suffering with cancer, but it might also have a negative role, when considering the refusal of treatment, with the patient is certain of the idea that God would solve them all.

Another possible explanation for the development of religious coping is the age of the subjects that can be seen as more advanced (average age - 60.8 years) and, therefore, it generally appears as a return to the religious aspect of life, with the perspective of death also occuring in a greater percentage for some of these subjects.

Conclusions

Subjects with an oncological pathology have a more developed religious coping than those without. It may be that coping mechanisms can be optimized through psychotherapy interventions to increase resilience of individuals diagnosed with cancer.

Abstract

Many adolescents with type 1 diabetes have difficult time adjusting to their treatment. Increasingly, researchers have focused on the factors that influence resilience in coping to this chronic disease. Social cognitive theory suggests that dealing with a chronic disease requires a strong sense of self efficacy in the face of personal, social and, environmental barriers.

We aim to document the association between coping strategies and metabolic control in relation to eating pattern among adolescents with type 1 diabetes as indicator of resilience. More specifically, we focus on the association between self efficacy and compensatory behavior, as coping strategies, and their effects on metabolic control.

Based on the results, suggestions for designing intervention to increase metabolic control and resilience in coping with the challenges of the disease for adolescents with type 1 diabetes will be made.

Key words: diabetes, adolescents, resilience, coping style

Introduction

One well-known fact about living with diabetes is the requirement to establish optimal blood glucose levels and to maintain the individual's quality of life for as long as possible. This requirement proves difficult to keep, especially during adolescence. Many adolescents with type 1 diabetes (T1D) have difficult time adjusting to their treatment, which can have a negative impact on their health [1].

Investigating the literature, resilience is related to metabolic control and it is defined in terms of resources that may be protective to those facing the stressors associated with living with diabetes [2]. Although there is a large amount of data investigating the relationship between coping styles and diabetic outcomes [3], there are few studies that explore the relationship between resilience, coping styles and metabolic control. Lately, researchers have focused on understanding how maladaptive coping styles, as compensatory behavior and low self efficacy, relate to eating pattern in order to shed a light on poor metabolic control in adolescents with T1D [4].

We aim to document in the literature the association between coping strategies and metabolic control in relation to eating pattern among adolescents with type 1 diabetes as indicator of resilience. More specifically, we focus on the association between self efficacy and compensatory behavior, as coping strategies, and their effects on metabolic control.

The relationship between resilience, coping styles and metabolic control

Resilience is a psychosocial construct referring to an individual's capacity to maintain psychological and physical well-being in the face of adversity [2]. Although this concept has been investigated in children and adolescents [5], little is known about resilience in children and adolescents living with diabetes. One explanation for this lack of research is that there is no universal agreement on what constitutes resilience. On the other hand, in the literature, there is not a clear distinction between predictor and outcome in terms of resilience [6].

Reviewing the literature, resilience resources appear to predict metabolic control and also to buffer self care behaviors. Those with lower levels of resilience resulted in fewer self-care behaviors when faced with rising distress [7]. Another study shows that low resilience is associated with poor quality of life and poor glycemic control [7]. Specifically, those with low resilience showed deteriorating A1C levels and self-care behaviors in

the face of stress, while those with high resilience did not. The follow up study showed that maladaptive coping is an important mechanism of this association [8].

Understanding the role and impact of personal resilience may be an important way to improve outcomes among youth with T1D. Specifically, the literature suggests that promoting resilience helps improve coping which thereby may enable better health outcomes [7]. Therefore, understanding the coping styles used by adolescents with T1D can shed a light on ways to improve metabolic control.

On one hand, there is a large amount of studies investigating coping styles in adolescents with T1D and on the other hand, there are few studies that show the relationship between resilience and coping styles. There are two approaches used in the literature: problem or emotion focused coping [9] and primary, secondary and disengagement coping [3] . Coping styles refer to strategies that people use to cope across wide range of stressors [9]. It has been suggested that problem-focused coping is associated with better adjustment to diabetes [6]. On the other hand, avoidance coping and venting emotions have been found to predict poor illness-specific self-care behavior but were unrelated to metabolic control [10]. These evidence are also supported in a study [11] showing that greater use of active coping was related to better metabolic control. Authors highlight the fact that adolescents might "choose" a particular coping style in response to poorly controlled diabetes, meaning that beliefs about control play an important role in determining the degree to which a person feels threatened or challenged in stressful encounter [9]. Mental disengagement and aggressive coping might thus serve as adaptive mechanisms.

Another approach used in the literature shows that is important to consider developmental stage when assessing coping strategies in adolescents [3]. In recent lights, emotion and problem focused coping are considered broad categories of coping, neither exclusive nor exhaustive [12]. For example, a coping strategy such as forming a plan may help to solve a problem and also help to relieve negative emotions. Revisiting this evidence, there is a clear shift into a new model of assessing coping strategies in adolescent with T1D. Authors of this new conceptualization recognize the role of development proposing three coping strategies [3] . Primary control engagement coping strategies are defined as coping attempts directed towards influencing objective events/ conditions or directly regulating one's emotions. Secondary control engagement coping strategies are defined as efforts to fit with or adapt to the environment. Disengagement coping strategies are defined as responses that are oriented away from the stressor or one's responses to it [13] .

One study investigated coping in relation to resilience in adolescents with T1D using a developmentally sensitive measure of coping [2]. The results indicated that adolescents that were more likely to use secondary control coping strategies, such as acceptance and distraction, had higher quality of life and metabolic control. Regarding the use of primary control coping strategies, such as problem solving and emotional expression, it was associated with positive outcomes of resilience, including metabolic control. Disengagement coping strategies, such as avoidance and denial, were associated with lower levels of resilience and poorer metabolic control [2].

Another line of research shows the relationship between coping strategies, compensatory behavior and metabolic control. Specifically, the most investigated relationships are between treatment related factors and poor metabolic control and, to a lesser extent, on psychosocial factors underlying maladaptive coping styles. The risk of disordered eating behavior is considered to be higher in type 1 diabetic adolescents than in general population due to combined factors related to diabetes and its treatment [14]. Because the diabetes regime often requires the restriction of food, adolescents are more prone to activate compensatory behaviors, in terms of splitting insulin doses, insulin omission, restricting food intake in order to reduce weight. These are considered maladaptive coping styles which have a negative effect on metabolic control. Poorer adherence to diabetes care is related to self efficacy- the degree to which adolescents with T1D feel confidence in their ability to follow their diabetic regime [15]. Among youth with diabetes, lower self efficacy was related to poorer metabolic control [4].

Conclusions

The purpose of this paper was to document the relationship between resilience, coping styles and metabolic control in adolescents with T1D. Revisting the literature, we aimed to integrate both classical and recent studies attempting to highlight different coping styles in relation with metabolic control. Two general types of approaches have been analyzed: problem-focused and emotion-focused coping [9] and primary engagement, secondary engagement, and/or disengagement coping strategies [3]. Studies suggest that primary and secondary control coping strategies are associated with better metabolic control [2]. Lately, researchers have focused on understanding how maladaptive coping styles, as compensatory behavior and low self efficacy, relate to eating pattern in order to shed a light on poor metabolic control in adolescents with T1D.

Health promotion interventions should be designed to help adolescents to better integrate the challenges of the illness into routine outpatient care. Management of maladaptive coping styles should address cognitive behavioral modification, social problem solving, coping skills training. Adopting more constructive self care

behavior and coping mechanisms will form healthy life routines in order to optimize metabolic control and quality of life.

Resilience et coping chez les adolescentes agressees sexuellement

Dubuc L.

Université du Québec à Trois-Rivières (Canada)
ldubuc.psy@gmail.com

Abstract

Scientific research on sexual abuse in childhood has experienced long-term growth show great variation. The fact that as high as half proportion of sexually abused children show no symptoms turned out one of the most stable [1] data. Adaptation or coping strategies [2] and resilience (complex process of adapting flexibly to trauma or stress [3]) have been proposed as factors that may explain the variability or absence of symptoms in some victims sexual abuse. The objective of this research is to attempt to clarify the variables that promote good adaptation of adolescent victims of sexual assault. Participants (19 sexually abused adolescent aged 13-18 years) were recruited through announcements. The instruments used were: the French translation of the Brief COPE [4] and the Questionnaire Resilience by Wagnild & Young [5]. The evaluation of symptoms of post-traumatic stress disorder was made using the criteria of PTSD [6]. We will present the results to both questionnaires based on the determined diagnosis for each participant.

Key-words: resilience, sexual abuse, adolescent

Instruments

1.1 Defense Style Questionnaire (DSQ).

Les mécanismes de défense ont été identifiés à l'aide de la traduction en langue française de la forme à 40 items du *DSQ* [7]. Cet instrument explore 20 mécanismes de défense (deux items par défense) regroupés en trois facteurs : matures, névrotiques et immatures. Le mode de cotation est de 9 degrés (échelle Likert) allant de pas du tout d'accord jusqu'à tout à fait d'accord. Trois études ont étudié la validité de façade. Dans la première étude [8], un accord a été observé pour 74 % des items mais les auteurs n'ont pas donné les précisions. Les auteurs de la deuxième étude [9] indiquent que quelques items n'ont pas fait l'objet d'un consensus parfait. Cependant, l'attribution de tels items à une défense particulière a été faite sur d'autres critères évaluant la validité de construit et la validité critériée. Enfin, dans la troisième étude [10] ont réalisé la première étude publiée de validité de façade. La validité de façade excellente. Ce questionnaire a été le plus utilisé dans les études empiriques.

1.2 L'Échelle de résilience de Wagnild & Young [7]

Les réponses aux items se situent entre 1 (accord) et 7 (désaccord). On demande au participant de lire l'énoncé et de marquer le chiffre qui correspond le mieux à ce qu'il pense de lui. Un score global est calculé et deux autres scores pour les dimensions «comportements» et «acceptation de la vie». Plusieurs études de petites envergures effectuées au début des années 90, mais en 1993, l'Échelle de résilience a été testée sur une population de 810 adultes d'âge moyen et d'âge plus avancé dont 48 % étaient des hommes. Les mesures de validation incluaient la dépression, la morale et la satisfaction. La validité de contenu (0,62) et la fidélité (0,91) ont démontré des scores acceptables comme les études précédentes. Le coefficient alpha de Cronbach s'est situé à 0,82. L'analyse factorielle a indiqué deux facteurs principaux, qui ont été nommés «l'acceptation de soi et de la vie».

1.3 Brief COPE.

Le questionnaire utilisé dans cette recherche est la traduction française du *Brief COPE* [11] Cet instrument est une version abrégée de l'*Inventaire COPE* [4]. Il comprend 14 échelles évaluant toutes des dimensions distinctes du coping. Chacune de ces échelles comprend 2 items (28 items au total). Le choix des réponses proposées est : «pas du tout», «de temps en temps», «souvent» et «toujours» et leur score respectif s'établit de 1 à 4. La traduction a été faite en France et validée sur cette population [7]. Deux études ont été

effectuées pour la validation. Cet outil présente de bonnes qualités psychométriques dans sa version situationnelle. Sa structure factorielle est congruente avec celle attendue. Quant à la validité externe, l'étude des relations entre perceptions du contrôle de la situation et de l'évolution de celle-ci, et stratégies mises en place montre que la perception d'un faible contrôle est associée à des stratégies décrites comme dysfonctionnelles, alors que la perception d'un contrôle important ou d'une évolution favorable est associée à des stratégies décrites comme fonctionnelles.

Résultats

Dix-neuf adolescentes âgées entre 12 ans et 18 ans, ont participé à notre recherche. L'âge moyen était de 189 mois (15 ans et 10 mois; ÉT = 20,58). Les âges des participantes étaient répartis entre 152 mois (12 ans et 8 mois) et 214 mois (17 ans et 10 mois). Le niveau socioéconomique de la famille de six participantes était faible, pour douze autres, il était moyen et une seule vivait dans une famille de niveau socioéconomique élevé. Quatre participantes ont vécu dans un environnement familial de négligence. Douze adolescentes ont rapporté la présence de maladie mentale du côté familial maternelle et paternel. Tous les abuseurs sexuels étaient des hommes, le plus jeune avait 13 ans et le plus âgé avait 60 ans (M = 34,11; ÉT = 16,12). Onze jeunes ont été victimes d'un ASE intrafamilial (père, beau-père, frère, demi-frère ou cousin), huit ont vécu un ASE extrafamilial. Une seule adolescente a connu les deux situations, intrafamiliale et extrafamiliale, soit le père, le cousin et trois hommes connus de la famille. Sept participantes ont rapporté entre un et trois épisodes (M = 1,8) et le plus long intervalle entre deux épisodes était deux ans et le plus court six mois. Les autres participantes (12) ont été victimes d'AS sur une base continue. La plus courte période rapportée est six mois et la plus longue est 8 ans. La plus longue période d'AS sans arrêt a été révélée par une participante qui a été victime pendant huit ans d'attouchements et d'exhibitionnisme de la part de son beau-père. L'âge de survenue de la première agression est répartie entre trois ans et 16 ans (M =10,16; ÉT = 4,21). Seize adolescentes ont rapporté des attouchements, quatre la pénétration, quatre le viol, quatre d'entre elles ont signalé la présence de violence physique, trois de pornographie, une de l'utilisation d'internet, deux d'exhibitionnisme et enfin deux avec menace de mort, de tuer la famille, etc. La comparaison entre les statuts «avec diagnostic» et «sans diagnostic» et l'âge de survenue n'est pas significative au test de Mann-Withney ($\chi 2$ =.318).

Échelle de résilience. Les scores globaux varient de 25 à 175. Les scores obtenus dans notre cohorte se situent entre 59 et 156 (M = 127,16; ÉT = 25,02), à la dimension «compétence» ils se répartissent entre 35 et 112 (M = 91,8; ÉT = 19,08) et à la dimension «acceptation de la vie» ils sont entre 18 et 46 (M = 35,2; ÉT = 8,7). Dans une recherche précédente auprès d'étudiants québécois, la moyenne du score global obtenu était de 135,88 (É.T.= 18; la dispersion allait de 135 à 176). Les résultats ont aussi démontré que sept items n'avaient pas reçu la cotation 1 («totalement en désaccord»; items 2, 4, 9 10, 17 et 24) deux items avaient été cotés de 3 à 7 (items 15, 16) et un item de 4 à 7 (item 23).

Brief COPE. Les résultats obtenus dans l'évaluation du coping montrent que les adolescentes utilisent en moyenne huit types de stratégies (M=8,4) pour faire face au traumatisme de l'ASE. La stratégie la plus utilisée est la *distraction* (84 %) et celle la moins utilisée est la *religion* (16 %). D'autres stratégies sont régulièrement utilisées par les participantes : l'*acceptation* et le *soutien instrumental* (79 %), le *coping actif*, *l'expression des sentiments* et le *déni* (74 %), le *soutien émotionnel*, le *blâme* et le *désengagement* (68 %). Dans sa recherche prédisant l'expérience de stress chez les adolescentes, Michelle Dumont [12] a rapporté que les adolescentes se sentent davantage menacées par le stress chronique que les adolescents et elles utilisent plus souvent des stratégies adaptatives cognitives ou de recherche de soutien social. Ses résultats indiquent aussi que l'*évitement* prédit la fréquence et la sévérité du stress à l'adolescence.

Résilience et coping. En ce qui a trait à la résilience et le coping, les résultats nous révèlent que les quatre adolescentes ayant obtenu les scores de résilience les plus élevés (145 et plus), utilisent (toujours ou de temps en temps) en moyenne huit stratégies de coping. Parmi celles-ci, deux participantes avec des scores de résilience homologues (152) et manifestant des symptômes post-traumatiques sans toutefois répondre à tous les critères *ÉSPT*, utilisent sept stratégies de coping (m=7) alors que les deux autres avec des scores de résilience de 156 et 146 et diagnostiquées *ÉSPT*, ont recours en moyenne à huit stratégies différentes (m=8,3). Par ailleurs, l'*expression des sentiments* est corrélée positivement et significativement avec la dimension acceptation de la résilience (corrélation r de Pearson = .52 p=,022). Nous observons de plus, trois tendances : le blâme est relié négativement à la dimension acceptation (corrélation de Pearson = -4,25 p=,070), la distraction associée positivement au score global de résilience (corrélation r de Pearson = .43 p=,06) et à la dimension compétence (corrélation r de Pearson = .46 p=,047). En présence d'un plus grand nombre de participants, ces corrélations auraient été significatives.

Discussion et conclusion

Les résultats de cette étude permettent de constater que les variables reliées directement à l'AS (âge de survenue, type d'AS, lien avec l'agresseur et durée de l'AS) ne sont pas associées significativement au statut «sans diagnostic *ÉSPT*» et «avec diagnostic *ÉSPT*». Trickett et ses collaborateurs [12] rapportent que même si les variables reliées à l'AS ont reçu une attention considérable dans les écrits scientifiques depuis les années '80, les résultats variaient toujours d'une recherche à l'autre. De plus, les auteurs ont suggéré que les différences dans la nature et la sévérité de l'AS provoqueraient différents degrés de traumatismes qui en retour auraient une incidence sur la variabilité des séquelles [13].

Les résultats de notre étude montrent cependant des corrélations entre la résilience et les stratégies de coping qui, selon Lazarus & Folkman [2], sont d'importants modulateurs des conséquences liées à des évènements stressants. Nous avons observé chez les adolescentes résilientes que *l'expression des sentiments* est positivement associée à la dimension de la résilience «acceptation de la vie». Ainsi, le fait de pouvoir exprimer ses sentiments favorise leur adaptation en les aidant à accepter, à faire du sens avec le traumatisme de l'AS. Pour Lengua et Long [14], la catharsis et le fait de ressentir des émotions douloureuses peuvent être néfastes si l'acquisition d'habiletés pour les gérer ne se fait pas simultanément ou préalablement. En fait, le coping «*expression des sentiments*» est considéré comme étant souvent peu fonctionnel, car il est associé avec une détresse émotionnelle chez la personne qui ne parvient pas à évacuer ses sentiments. Il est souvent réalisé au détriment d'un effort pour un coping plus actif. Cependant, il peut être transitoirement fonctionnel, par exemple, pendant la phase de deuil [11]. Il est donc fort possible que pour les adolescentes de l'étude *l'expression des émotions* soit utilisée au début de leur adaptation à la situation traumatisante. Cependant, la seule stratégie de coping actif qui s'est avérée avoir une tendance significative avec le score global de la résilience et la dimension «compétence» est la *distraction* classée parmi le coping actif et efficace parce qu'il impliquait un engagement avec une pensée ou une activité sans relation avec le stresseur et qui avait comme but de diminuer l'intensité des émotions [15]. À la décharge de ces chercheurs ci-haut mentionnés, il n'en demeure pas moins que *l'expression des sentiments* entrave le coping actif.

Une autre stratégie d'adaptation qui a démontrée une tendance significative avec la dimension «acceptation de la vie» est le *blâme*. Ces deux variables sont corrélées négativement, le fait de se blâmer nuit à l'adaptation des adolescentes. Les adolescentes qui acceptent davantage avoir été victime d'AS se perçoivent plus résilientes. Cependant, se blâmer par rapport aux AS peut être une réaction normale momentanément dans un contexte abusif. Feiring & Cleland [16] ont démontré que les enfants avaient une tendance décroissante à se blâmer et à attribuer le blâme à l'abuseur au fil du temps. De plus, le fait que nous ayons utilisé un questionnaire peut avoir une incidence sur les résultats tel que l'a démontré cet auteur : les enfants semblent s'attribuer plus de blâme quand ils répondent aux questionnaires que lorsqu'ils sont en entrevues cliniques. Et enfin, dans notre étude, les attributions de blâme à l'abuseur n'ont pas été significativement associées aux symptômes, corroborant ainsi les résultats de leur recherche.

Abstract

Numerous studies deal with the explanatory factors and the resources needed for survival and maintaining the psychological health after political repression or collective violence. They are concerned with coping strategies, attachment, as well as historical and social determinants of the development of protective factors [1], [2], or how the effects of repression are moderated by the political involvement and beliefs [3], [4]. In a group of 45 former political prisoners (mean age = 80.5 years) we aimed to reveal the coping styles and the key elements of their survival during political repression (1948-1989).

The coping strategies developed by participants were evaluated using the Brief COPE inventory [5], while the biographical interview aimed to find the significant elements related with the survival during repression.

Participant's scores to the Brief COPE scales show a significant presence of active coping and seeking instrumental support dimensions, suggesting their usefulness when confronting difficulties after release (insertion in a changed social environment, finding a job, etc.). Thematic analysis of the narratives identifies a number of key elements in dealing with adversity: beliefs, social or political concerns, perception of social changes after release, the presence of challenges, social activism, professional achievement.Moreover, the flexibility in the choice and the ability to use different strategies appears to be an adaptive aspect in dealing with stressful situations and lived problematic experiences.

Keywords: Coping, surviving strategies, adversity, repression, political prisoners.

Introduction

The consequences of collective or political violence has been for decades studied, with an emphasis on negative symptoms such as chronic depression, anxiety, sleep disturbances, nightmares and psychosomatic disorders. More recently, the data regarding the explanatory factors for the resources needed for survival and maintaining the psychological health have increased considerably. Among them, we found the studies on Kurdish political prisoners from Turkey [3], [4], considering the effects of repression and the role of the political involvement and beliefs. Also, other authors [6],[7] studied a certain capacity to overcome the difficulties and trauma following Nazi concentration camps, capacity named sense of coherence. Further studies conducted by a group of Finnish researchers [1], [2], on former Palestinian political prisoners gave a good comprehension on how people survive after political repression or collective violence. The later studies are concerned with coping strategies, attachment, sense of coherence and post-traumatic growth.

Another concept to consider in the study of reactions on a adversity context is resilience, which generally refers to one's ability to "cope well with adversity" and "persevere and adapt when things go awry. Resilience helps people deal with stress and adversity... and reach out to new opportunities"[8]. Considering the political repression in the communism regime from Romania, the survivors of the imprisonment and persecutions made a large inventory of the threats, difficulties and traumatic events lived during that era [9], [10], [11].

Still, the development of strategies to cope with the adversive events are not sufficiently clarified. Thereby, the present study intends to unreveal the coping strategies developed by participants and to find significant elements related with the survival during repression.

Methods

Participants are 45 former political prisoners (M = 80.58, SD = 5.03), mostly men (39 from 45), structure representative for the population of former political prisoners, according to historical data. They were subject to imprisonment and to persecution during the political repression during the communism regime (between 1948 and 1964). Data were collected in familiar locations, in 2008-2009.

51.1% of participants graduated high school, while 35.6% completed university studies. About 20% (9 individuals) were arrested during their studies; 6 of them fulfilled their studies after imprisonment.

Using a mixed design - quantitative and qualitative, we evaluated the presence of the coping strategies as described by Carver (1997) and searched for significant elements related to the survival during their lifelong experiences. The instruments were an in-depth (biographical) interview and the BriefCOPE inventory [5]. BriefCOPE is an abbreviated version of the COPE inventory [12], perfected to evaluate the coping strategies developed by individuals in stressful situations.

This inventory contains 14 subscales of 2 items (outlined in table nr. 1), with a Cronbach alpha coefficient of validity between 0.50 and 0.90. Brief COPE questionnaire is especially useful when time constraints are significant, or when participants have difficulty in concentrating for a long time. Data from the questionnaire were analyzed using SPSS 14.0, being treated in a descriptive manner.

The content analysis sought to identify themes in the subjects' narratives; the selected themes had to hold a significant part in the participants' personal history, and a satisfactory representation of the whole group.

Results

1.1 *Descriptives of Brief Cope scores*

The data presented in the table 1 indicate that the most frequent coping strategies are the active coping, followed by seeking instrumental support and religion. Scores reported by subjects in the active coping (range 4-8, M= 5.6) suggest that each of our subjects used at least a few times this strategy. Regarding the use of instrumental support, the mean scores suggest the habit of most participant to frequently appeal to this strategy in a number of problematic life situations.

Among the less frequent chosen ways of coping reported we noted the use of drugs or alcohol strategy, with scores not higher than 3 for a subject, meaning that for maximum one question of the two items indicating this dimension the answer was "sometimes". Further, we found low than average scores on dimensions like humor (M = 3.07), self -blame (M = 3.4) and denial (M = 3.64). Scores variability shows that subjects did not report the maximum possible scores on these scales, indicating a low presence of humor coping strategies, denial and self-blame for the whole group.

Table. nr. 1. Descriptives of scores reported on coping dimensions (N = 45, two items scale, range from 2 to 8)

	Coping strategies	Statistics of scores			
		min	max	Mean	SD
1.	Active coping	4	8	5.60	1.03
2.	Planning	3	7	4.82	1.11
3.	Positive reframing	2	7	4.04	1.10
4.	Acceptance	2	8	4.53	1.50
5.	Humor	2	5	3.07	.75
6.	Religion	3	8	5.00	1.34
7.	Use of emotional support	2	8	4.82	1.26
8.	Use of instrumental support	2	7	5.33	1.16
9.	Self-distraction	2	7	4.93	1.03
10.	Denial	2	7	3.64	1.09
11.	Venting	2	7	4.47	1.23
12.	Substance use	2	3	2.33	.47
13.	Behavioral disengagement	2	6	4.00	1.06
14.	Self-blame	2	6	3.40	.93

1.2 *Cathegories and themes related with adversity conditions (biographical data)*

Personal beliefs. A significant number of subjects (51.1%) refer to their beliefs as relevant in the period prior to arrest; during imprisonment the proportion decreases to 33.3% of the total group, proportion which

remains relatively constant in subsequent periods, with a slight recovery after 1989 (fall of the communist regime).

Political interest. A similar trend seems to be followed: a relative decrease of this interest in the period after the liberation could be related to the impossibility to activate or to discuss matters of this kind with the close ones.

Expectation of the arrest: Two thirds of the participants in our study were expecting to be arrested, which could indicate us that they were considering the deployment of socio-political events, and they were aware of being under their incidence.

Confronting the social and political changes. The confrontation with the environmental changes seems to occur even before incarceration, period during which the Communist party has already gained influence over all the social or decisional segments. Most assessments assert the difficulties to support changes occurring during arrest and imprisonment, when it was a direct confrontation with the repressive and coercive environment, the individual having to live in a way totally different from the known one.

Persecutions are appreciated as significant in the period of imprisonment and after the liberation. During imprisonment, the references include: confinement, lack of privacy, disregard for any personal rights, etc. Considering the post-release period, the persecutions include administrative barriers when applying for a job, police citation; the subjects assess the persecutions as difficult to avoid. The possibilities for avoidance were related to the nature of the profession, to the security staff from the administrative region, and the personal capacity to anticipate the actions of the repressive actions.

Solicitations (challenges, demands) from the environment and the assessment of life situations suggest a considerable variability and the absence of a typical pattern for the adversity situations encountered (historical data assert that the repression was not organized in a unitary way).

The positive or negative *assessment of life situations* seems to be related to the resources available at the time of liberation, but also to the duration of incarceration. As major sources of support are mentioned: the profession, the family, the people encountered, and also a certain way of approaching the situations they were confronted with. The same issues are often the source of the most important difficulties during their lives, when the expected support does not become a resource.

Discussion

The results show a significant presence of types of active coping and seeking instrumental support, potentially explained by the specificity of this type of coping, and the social political context necessary after release. Having faced numerous restrictions to further studies or employment, often facing persecution against them or family of origin, former political prisoners had to adapt to the new administrative system. They endeavored substantially to continue their education, facing numerous bureaucratic barriers. Moreover, job search involved in some cases a waiting period of several months or years, during which they needed the support of relatives or acquaintances and in most cases certain administrative "juggling" to avoid rejection as "undesirable". All these challenges may require as strategies an active coping or seeking instrumental support, in order to overcome the mentioned difficulties.

Among the possible explanations for the extremely low use of substances as a way to cope with difficult situations we can first think to our group characteristics: surviving after many years of adversity, this may be a vital selected population, including the avoidance of health risk factors. We also had to consider the impossibility to buy drugs or alcohol during detention; further, demands and difficulties after release (graduation issue, employment or job maintenance, sometimes persecutions) did not allow the recourse to this means of mitigation of negative psychological states. In very few cases, the use of drugs was mentioned sporadically, mainly because it did not bring any relief to their psychological condition.

The affirmation of personal beliefs and the relevance for the individual don't seem to be affected by repression in the long term; a similar tendency seems to be followed by political interest stated by subjects, when a relative decrease of interest after release may be related to the inability to activate or to discuss this kind of matters with the closest people.

Considering the competence to deal with a changed environment, the narrative suggests that a longer imprisonment leads to the development and the constant affirmation of distinct coping strategies; as a consequence, more years of prison demanded the use of these strategies, making the subject more prepared for the adversive environment encountered after release.

Concepts like coping and resilience provide some support for this assertion. Thus, every change generates a certain amount of stress, or at least a request to which the body reacts; an eventual success in adaptation will result in a higher capacity to cope with stress [13]. On the other hand, it is described as resilience the characteristic of a person who lived or is living events of traumatic nature or chronic adversity, and proves good adjustment as a result of an interactive process between the individual, the family and its environment [14].

Conclusion

Among the dimensions of coping, the most commonly reported are active coping, seeking instrumental support and religion. As mentioned, these strategies may be required by the characteristics of difficulties and adversity lived during or after imprisonment. On the other hand, the most underrepresented coping strategies are the use of substances, humor, self-blame, and denial.

Data from narratives suggest that own values and beliefs were important milestones in the decision-making in critical situations or experiences. Moreover, the conditions of adversity and organized repression seem to reinforce the subject's own beliefs and judgments of a particular fact or event.

In a broader acception, the last decades of research show that we can learn to be more resilient by changing how we think about challenges and adversities [8], [15], [16].

Abstract

Based on the integrative psychology and multifactorial health model of Bruchon Schweitzer (2002), an empirical study was conducted among parents of Belgian children with autism spectrum disorders. During the diagnostic process and throughout the education of their child, parents are faced with situations of stress and burdened parenting threatening family well-being. Several questionnaires were completed online or in paper form by the parents in this case: the Appraisal of Life Event Scale [9] assessing perceived stress, Perceived Control Scale (adapted from Cancer Locus of Control Scale, Cousson-Gélie, 1997), Perceived Social Support Questionnaire [5], the adaptation of the Ways of Coping Checklist Revisited, [6] to assess coping strategies, focusing on the problem, on the emotions or seeking social support and the Scale of Quality of Life for parents of children with ASD [8].An analysis of their perceived stress, their control, the type of social support and coping strategies, allows us to understand their perception of subjective quality of life and their psychological needs and family support.

Key-words: coping, autism, quality of life

Introduction

Notre étude se penche sur la qualité de vie et les processus d'adaptation de parents belges ayant un enfant présentant par un trouble du spectre de l'autisme (TSA) et sur les facteurs de risque et de protection en jeu. Des études ont montré que les parents d'enfants TSA sont plus sujets à la *dépression,* au *stress* à différents moments de la vie de leur enfant, vu la confrontation à de multiples problèmes au quotidien et pour son éducation. Ceux-ci sont difficiles à gérer et induisent un *sentiment de perte de contrôle*. Les parents utilisent des *stratégies de coping* pour faire face à ce stress. Le *soutien social* de l'entourage et des professionnels peut contribuer à leur qualité de vie (QV). Celle-ci peut être influencée par des facteurs individuels et environnementaux. La littérature s'est développée ces dernières années à ce sujet alors que les parents expriment depuis longtemps leur souffrance liée au handicap de leur enfant [1], [2]. Cette étude se base sur le modèle intégratif et multifactoriel de Bruchon-Schweitzer [3], développé en psychologie de la santé, fondé sur une conception transactionnelle du stress de Lazarus et Folkman [4]; stress qui peut provenir de causes individuelles, familiales ou sociales (Fig. 1). Ce modèle intègre trois types de variables:

(1) *les prédicteurs* comprenant les *antécédents* avant le stresseur (dont les caractéristiques des individus) *et les déclencheurs* de l'apparition du stress;
(2) *les processus transactionnels* ou stratégies cognitives, émotionnelles et comportementales de la personne pour faire face à la situation stressante comportant: (a) l'évaluation primaire du stress, (b) l'évaluation secondaire des ressources personnelles (ou contrôle perçu) et des ressources sociales (ou soutien perçu) ainsi que (c) les stratégies de *coping*;
(3) l*es issues adaptatives* se reflétant par l'état somatique et émotionnel de la personne ou sa QV.

Les processus transactionnels jouent un rôle modérateur ou médiateur sur les relations entre *les prédicteurs* et les *issues adaptatives.*

Concernant le *contrôle perçu*, dans ce cadre, nous distinguons la perception de contrôle sur le trouble, sur l'évolution de développement de l'enfant et les croyances irrationnelles à propos du trouble. Le *soutien social perçu* concerne le sentiment de la personne d'être aidée, protégée et valorisée par son entourage, ou pas [5]. La personne est invitée à estimer la disponibilité du soutien social par le nombre de personnes sur qui elle peut compter ainsi qu'à apprécier le degré de satisfaction à propos du soutien. Ils se différencient en «soutien émotionnel» par le réconfort, l'expression d'affects positifs à son égard; en «soutien informatif» par l'apport de

connaissances face à un problème; en «soutien d'estime» par la rassurance quant à ses compétences lors de doute; et en «soutien matériel et financier» [5]. Lorsque la personne met en œuvre des stratégies de *coping, elle exerce des «efforts cognitifs et comportementaux, constamment changeants, destinés à gérer les existences externes et/ou internes spécifiques qui sont perçues comme menaçant ou débordant les ressources d'une personne»* [4]). Celles-ci sont déterminées par les caractéristiques du contexte et peuvent changer dans le temps [3]. On distingue le coping «centré sur le problème» par la recherche de ressources diverses dont l'information, le soutien, «centré sur l'émotion» par l'expression et la régulation des émotions engendrées par la situation, et induisant le déni ou l'évitement; et enfin «la recherche de soutien social» [6], [7].

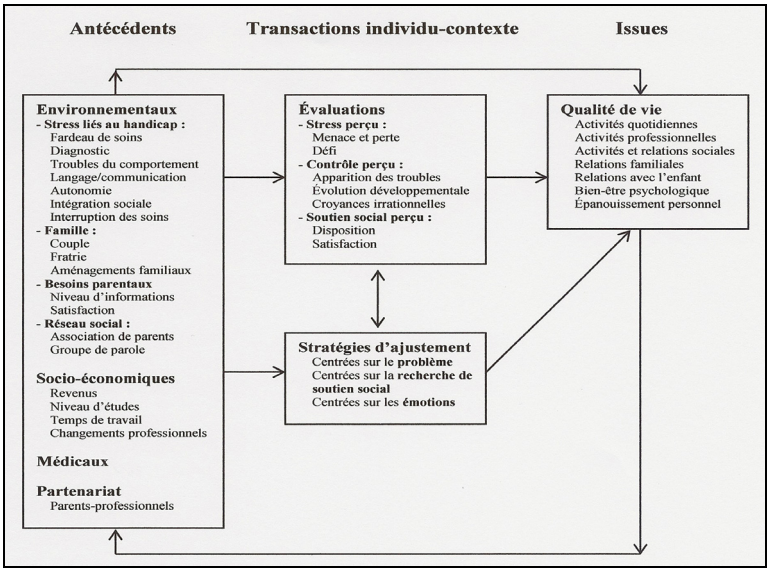

Fig. 1. Modèle intégratif et multifactoriel adapté à la situation des parents d'un enfant TSA [8]

L'étude vise à examiner les questions suivantes. *Quels sont les facteurs individuels et environnementaux qui font varier la perception du stress, du contrôle, du soutien, des stratégies de coping et de la qualité de vie des parents ayant un enfant TSA? La qualité de vie des parents ayant un enfant TSA varie-t-elle en fonction de leurs perceptions du stress, du contrôle, du soutien social et de leurs stratégies de coping?»*

Méthode

1.1 Participants

31 parents (27 mères, 4 pères) âgés de 28 à 55 ans (M = 41 ; ET = 6.5) ont participé à l'étude. Leurs enfants TSA (25 garçons, 6 filles) sont âgés entre 35 et 261 mois (M = 125 ; ET = 63).

1.2 Instruments

Une *estimation des besoins* de soutien psychologique et de conseils, d'aides concrètes et de partage d'expériences ou collaboration (max = 66) est obtenue par une échelle de 22 items. Une *estimation de satisfaction* concernant l'annonce du diagnostic, les prises en charge, le suivi médical et thérapeutique après l'annonce, la scolarité de l'enfant, le partage des tâches au sein du couple, l'aide apportée par les associations et les relations avec les professionnels est obtenue au moyen d'une échelle de 14 items (max = 30).

L'échelle *ALES* (*Appraisal of Life Event Scale* [9]) mesure le stress perçu selon que l'expérience est perçue comme une menace, une perte (max = 50) ou comme un défi (max = 30).

Le *CLCS* (adaptation de la *Cancer Locus of Control* [10]) évalue degré de contrôle perçu des parents concernant l'apparition du TSA, l'évolution du développement de l'enfant et les croyances irrationnelles.

Le *QSSP* (*Questionnaire de Soutien Social Perçu* [5]) évalue le soutien social perçu en différenciant les soutiens émotionnel, informatif, d'estime, matériel et financier.

La *WCC-R* (*Adaptation du Ways of Coping Checklist Revisited* [6]) mesure les stratégies de coping des parents «centré sur le problème», «centré sur l'émotion » et « la recherche de soutien social».

Une échelle de qualité de vie [7] évalue les conséquences du TSA dans 7 domaines : activités et relations quotidiennes, professionnelles, sociales, familiales et de couple, relations avec l'enfant TSA, bien-être, épanouissement personnel.

1.3 Procédure

Le recrutement s'est réalisé par une information et un appel aux parents par l'intermédiaire de la présidence de l'Association de Parents pour l'Epanouissement des Personnes avec Autisme, par affichage dans des services spécialisés assurant des suivis d'enfants TSA, par un stand d'information à des journées d'études ainsi que par une demande postée sur Facebook «Autisme TED Belgique: groupe d'entraide». Une fiche signalétique relative aux informations sociodémographiques et d'anamnèse et les cinq questionnaires ont été intégrés en un dossier, envoyé sous format papier ou rendu accessible en Limesurvey, à l'intention des parents ayant donné leur consentement.

Résultats

1.4 Processus

Le tableau 1 présente les statistiques descriptives des processus étudiés. Le score de satisfaction globale (relative aux informations sur le TSA, à l'évolution de l'enfant, à l'intervention, à l'écoute, l'aide et aux relations avec les professionnels) ainsi que le score en besoins varient beaucoup selon les parents.

Tableau 1. Moyennes, écart-type, min, max des scores aux échelles

		M	ET	Min	Max
Besoins (max = 66)		28.5	14.5	7	61
Satisfaction (max = 30)		17	6	0	28
Perception du TSA (%)					
	menace/perte	53.6	20.5	22	100
	défi	47.9	27.1	0	100
Contrôle (%)					
	apparition TSA	8.9	13.7	0	53.3
	évolution TSA	76.15	18.6	38	100
	croyances irrationnelles	11.41	20.1	0	77.8
Soutien					
Nombre de personnes	émotionnel	5	3.8	0	15
	informatif	4	4	0	13
	estime	10	6	0	28
	matériel et financier	1.7	2.5	0	10
(%)	Satisfaction	26.1	7.9	0	36
Coping (%)					
	problème	68	19.2	26	100
	émotions	47	22.1	7.4	81.5
	recherche soutien social	64.7	24.8	0	100
Impact TSA sur qualité de vie (%)					
	Globale	51.7	12.6	23.6	85.5
	Quotidien	63.7	17.1	27.8	92.6
	Profession	49.3	33.8	0	100
	Social	52.6	18.5	6.7	85
	Famille-couple	54.7	13.1	30	91.7
	Relations-enfant TSA	40.1	22.3	0	76.2
	Bien-être	50.9	19.2	9.8	98.5
	Epanouissement	31.6	23.1	0	100

Des comparaisons par *t* pairés de Student et des analyses de variance des moyennes des sous-scores relevant des cinq échelles mettent en évidence certaines différences significatives. Préalablement, les sous-scores à ces échelles ont été transformés en pourcentage. Concernant le stress perçu, le TSA n'est pas plus perçu comme une menace, une perte que comme un défi. Concernant le contrôle perçu, la perception de contrôle est plus élevée pour l'évolution du développement de l'enfant que pour l'apparition du TSA et les croyances irrationnelles. Concernant la perception du soutien, le nombre de personnes disponibles varie beaucoup selon le type de soutien et les parents : c'est le soutien d'estime qui est le plus présent. La satisfaction du soutien varie très fort selon les parents. Concernant le coping, la stratégie de coping centrée sur les émotions est moins mobilisée que les stratégies de coping centré sur le problème et de recherche de soutien social.

Quant à la QV des parents, elle varie significativement selon les domaines. La QV des activités quotidiennes est plus atteinte que celle relative aux activités professionnelles, aux relations sociales, aux relations familiales et de couple, au bien-être et à l'épanouissement personnel. La QV des relations sociales est

plus touchée que celle relative à l'épanouissement personnel. La QV des relations familiales et de couple est plus affectée que celle relative aux relations avec l'enfant, et à l'épanouissement personnel. La QV relative au bien-être est plus atteinte que celle relative aux relations avec l'enfant TSA et à l'épanouissement personnel. Bref, l'épanouissement personnel semble être le domaine le moins affecté par la présence du TSA de l'enfant.

1.5 Variation des processus en fonction des caractéristiques de l'enfant

Des analyses de variance ont mis en évidence que la QV en relations familiales varie en fonction de l'autonomie de l'enfant; la QV en activités quotidiennes varie en fonction de la communication de l'enfant, de son usage d'un système alternatif de communication ainsi que de sa pratique de loisirs ; la QV en épanouissement personnel varie en fonction de la pratique de loisirs.

Le soutien matériel et financier varie en fonction de la propreté de l'enfant le jour et la nuit. La propreté la nuit fait aussi varier le score de besoins, le score de satisfaction et le TSA perçu comme une menace ou perte. Le coping centré sur le problème varie selon la présence de troubles associés.

1.6 Variation des processus en fonction des caractéristiques des parents

La répartition des tâches fait varier le score de satisfaction, le coping centré sur les émotions, la QV globale, en activités quotidiennes et en relations sociales. Les revenus font varier le score en besoins, le soutien matériel et financier, la satisfaction du soutien, le coping centré sur le problème, la QV globale, en activités quotidiennes et en relations sociales. Le fait de considérer leurs revenus comme suffisants fait varier le score en besoins et le score de satisfaction, la QV globale et en bien-être. Le temps de travail fait varier la QV en activités professionnelles. Les changements professionnels font varier le contrôle perçu sur l'évolution de l'enfant TSA, la QV en activités professionnelles. Le fait d'être membre d'associations de parents fait varier la perception de contrôle sur l'évolution de l'enfant TSA, la QV en activités professionnelles, en relations familiales et de couple.

1.7 Variation des processus selon la procédure diagnostique et le parcours de l'enfant

La personne ou l'équipe qui établit le diagnostic fait varier la perception de contrôle sur l'évolution de l'enfant TSA. Le fait d'avoir des doutes fait varier le coping par recherche de soutien social. Le fait d'avoir son mot à dire lors de l'intervention précoce fait varier le score en satisfaction, la perception du TSA comme une menace ou perte, la QV en activités quotidiennes et en bien-être. Le fait d'avoir son mot à dire pour la scolarisation de l'enfant fait varier le score en satisfaction, le coping centré sur les émotions, la QV globale, en activités quotidiennes et en relations sociales. Le fait de considérer la scolarité adaptée à leur enfant fait varier le score de satisfaction, les soutiens d'estime et informatif.

1.8 Liens prédictifs des processus sur la qualité de vie

Des analyses en régression montrent des liens prédictifs suivants.

L'âge de la première intervention et la perception de contrôle sous forme de croyances irrationnelles expliquent 57% de la variance du soutien d'estime. L'âge de la première intervention et la perception de contrôle sur l'évolution de l'enfant explique 54% de la variance du soutien informatif. Le temps de scolarisation de l'enfant explique 19% de la variance du soutien émotionnel. Le score de besoins, la perception du contrôle sur l'évolution de l'enfant et le temps de scolarisation explique 62% du coping centré sur le problème. Le soutien émotionnel explique 24% du coping centré sur les émotions. La perception de contrôle sur l'évolution de l'enfant explique 40% de la variance du coping centré sur la recherche de soutien social.

Le score en besoins explique 33% de la variance de la QV globale. Par domaine, la QV par domaine est prédite par des variables plus spécifiques. Le score en besoins, la perception du contrôle sous forme de croyances irrationnelles et de fréquence de scolarisation explique 78% de la variance de la QV des activités quotidiennes. Le coping centré sur le problème explique 19% de la variance de la QV des activités professionnelles. Le score en besoins explique 28% de la variance de la QV des relations sociales. La perception du contrôle sur l'évolution de l'enfant, l'âge des parents et le temps de scolarisation explique 51% de la variance de la QV des relations familiales et de couple. La fréquence de scolarisation explique 33% de la variance de la QV des relations avec l'enfant TSA. Le score en besoins, la perception du TSA de l'enfant comme une menace ou perte explique 70% de la variance de la QV en bien-être. Le coping centré sur le problème, l'âge de l'enfant et la perception du TSA de l'enfant comme une menace ou perte explique 76% de la variance de la QV en épanouissement personnel.

Pour conclure, les professionnels doivent considérer les besoins, le parcours d'intervention et de scolarisation, pour soutenir la perception de contrôle sur l'évolution de l'enfant, le coping centré sur le problème et la qualité de vie des parents dans plusieurs domaines.

Critical discourses on resilience: Exploring alternatives strategies used by young people at-risk

Abstract

The concept of resilience is often situated in a dominant discourse that reflects medical and developmentalist epistemology, in Western models, with the ideology of white people, and middle class hegemonic norms. Behavior that falls outside of the "normal", or what is "socially acceptable", is associated with riskiness and tacitly if not explicitly labeled as pathological, and then, not resilient. However, the context of social injustice of many young people at-risk can have drastic effects on them. When we offer institutions such as schools that do not understand their needs, they may refuse our services and some of them may engage in anti-social activities, since they are looking for personal validation, pathways to recognize themselves, and places and organizations that contribute to the building of their social identity. This paper analyses how the denial of support and resources for the wellbeing of young people can lead them to situations that are socially unacceptable, such as sexual exploitation and drug trafficking. The main argument is that these activities, in the absence of conventional mechanisms, may bring some benefit to the subjects. Benefits may be in material conditions, though strongly marked by issues of social inequality; or subjective, in gaining relationships with people outside the normative places and institutions for young people. Unconventional circumstances produce unconventional attitudes that are expressed in alternative forms of resilience.

Keywords: resilience, adolescents, sexual exploitation, drug trafficking

Epistemological issues on resilience theory

Although there are different assumptions about the concept of resilience and its implications in the human development, the main concern is to understand what makes people deal with hard situations and still show personal positivity even when the circumstances are unfavorable. Based on this understanding, the proposal of this paper is to problematize aspects involved in resilience processes for adolescents involved in drug trafficking and sexual exploitation

In general, resilience has been conceptualized as psychological capacity to deal with positively problematic situations, including social issues (poverty, natural disasters, lack of resources) and concerning to subjectiveness (trauma, history of violence, disabilities, etc.). Bolzam & Gale [1] describe the studies on resilience in recent decades and show us "four waves" of investigation, which can be understood as explanatory models that supported the researches. Such movements reveal theoretical propositions ranging from more static positions, once resilience is conceived as a personality trait, and therefore hereditarily assigned as a mark of the individual, even speeches that overvalue social issues such as producing resilience.

We stand opposed to theoretical perspectives that claim that resilience is related exclusively to biological attributes. We define emphatically that resilience is a social construction process. It means that the offering of protective and useful resources can contribute to minimize the negative effects of challenging contexts. Thus, our proposal is to discuss the social aspects that collaborate in the social construction of resilience, once we understand that the required resources for the subjective strengthening are extracted from the context, including interpersonal relationships, social programs, public policy and culture itself.

The approach of Canadian researcher Michael Ungar inspires us. He emphasizes in his work the role of community and cultural issues to show how children and adolescents at-risk navigate through pathways into resilience. It changes the focus on the individual and allows us to create a systematic evaluation about the role of the society in promoting resilience [2] [3] [4].

Unfortunately, resilience as an academic concept is most often located at a dominant discourse. The knowledge in the medical field, as well as in the psychology or even social work, defines arbitrarily what it means to be "good enough", therefore, "resilient". Wherefore, resilience has being grounded in dominant models

of human development and centred within “right patterns” linked to dominant culture: Western models, ideology of white people and in the middle class.

Challenging the notion of patterns of resilience

Based on that, the behavior expected for young people are also assigned in terms of social expectations. The behavior that falls outside of the “normal”, or what is “socially acceptable”, is associate to a risk behavior and probably labeled as pathologic, and then, not resilient. Bottrell [5) says in her work that “resilience and psychopathology are dichotomized responses to risks to development defined by normative criteria, which minimize the significance of cultural diversity and social positioning”.

It makes sense when you listen to marginalized people telling about their own experiences. A study conducted by Fefferman [6] with young boys involved in drug trafficking in favelas at Sao Paulo (Brazil) challenges our notion of resilience. Some of the participants reported during the interviews positive aspects for their development through the engagement in those activities, especially associated with obtaining financial resources, actions of the drug dealers in the communities, and social status gained.

Similarly, Davidson and Taylor [7] point out that the classification of the involvement of children and adolescents in the sexual market as "violence, forced labor or slavery, and the emphasis on the inability of children to choose prostitution " limited the discussions to immediacy and impoverished analyses. The authors claim that some adolescents engage themselves to prostitution because the places where they live and grow up do not offer satisfactory opportunities to develop, or when they can not find work or even to escape of forms of violence experienced within their home.

Of course we are not defending the involvement of adolescents in the drug trafficking or in the sexual trade. But their speeches are showing us that we are failing in somewhere or somehow as a society which it should be responsible for offering opportunities for their development. When they do not find pathways to resilience in the conventional mechanisms, they need to search it in alternative places. Unfortunately, for some of them, the only possibilitie is through the engagement in anti-social activities.

The context of social injustice of many young people at-risk can have drastic effects on them. When we offer services that do not understand their needs, they will refuse our services and some individuals will engage in anti-social activities, because they are looking for validation, a way to recognize themselves, and places and institutions that contribute for the building of their social identity.

The lack of meaning in educational programs, as well as the inefficiency of youth services is often replaced by a sense of belonging that was found only by engaging in anti-social activities, and sometimes within groups of people that share similar histories. The meeting with people in the same conditions may be advantageous to create meaningful relationships, even when it requires to take on the stigma of "misfits". Thus, based on Kaplan’s work: “From the subjective point of view, the individual may be manifesting resilience, while from the social point of view the individual may be manifesting vulnerability” [8].

The denial of support and resources for the wellness of young people can lead them to situations that is socially unacceptable, as the cases of sexual exploitation and drug trafficking. Furthermore, it is true that some of these activities in the absence of conventional mechanisms may bring some benefit to the subject, whether in the material conditions, strongly marked by issues of social inequality, or subjective, once the inefficiency of relationships with other people and services lead to unconventional attitudes.

This theme can evoke polemical debates, especially regarding to theoretical models grounded on traditionalist mental health approach and human development within a conservative perspective. For us, it is also quite challenging to find plausible justifications to support our arguments. It is not comfortable to recognize that the involvement in illegal or criminal activities can be configured as paths of personal empowerment. But we have to denounce that public policies, including the Federal interventions, as well as academic studies, neglect the understanding of children and young people on their trajectories of involvement in illegal activities [9] [10]. When we start to listen to them, we will find that their personal stories of engagement in crime or illicit activities may differ from the understanding of scientific rhetoric.

Armstrong [11]suggests that researches conducted with young people involved in crime are based on statistics correlations which ignore the reality of these groups, since the criminological perspective disregards completely the perspective of young people themselves, as well as other variables that support the annulment of comprehension of risk factors as a social construction. Other studies on the subject, despite being based in different theoretical and methodological propositions, reveal the complexity of the social contexts where young people were inserted in the illicit drug trade [12] [13].

Through all this inhumane process of marginalization and the evident lack of opportunities, some adolescents need to adopt unconventional strategies of personal recognition which can help them to replace unachievable expectations within a system that label them as "youth in trouble". Even when they recognize the implications of dealing drugs, such as the risk of death experienced daily, some of them “choose” to be part of the trade, hoping to improve their lives or at least overcome the miserable conditions experienced before.

The same arguments can be used to explain some cases involving adolescents and young people in sexual exploitation trade. A study conducted by Rubenson, Hanh, Höjer & Johansson [14] aimed to understand the perspective of Vietnamese adolescents involved in sexual exploitation, emphasizing themes regarding how they live and the strategies to deal with challenges in their lives. The first core discussed by researchers refers to poverty, which implies a precarious repertoire of opportunities for social participation. Unexpectedly, another group presented that sexual activities contribute to make their dreams come true. And only a small group see themselves as victimized, and in these cases the adolescents demonstrated other vulnerabilities (financial debt, oppressive relationships and addict behavior). These findings also dialogue with the surveys conducted in the Brazilian context by Libório [15] [16].

In a society that overestimate the consumption, producing the need to access manufactured products, it is understandable that adolescents and young people desire to be part of this, once they have been highly encouraged to become costumers in the capitalist society. As they are prevented to participate in conventional ways (accumulating capital enough through work), some of them go to alternative strategies. Drug trafficking and sexual exploitation, highly profitable activities for their realities, become attractive for this segment.

Brief considerations

The main argument is that anti-social activities, in the absence of conventional mechanisms, may bring some benefit to the subjects [17] [18] [19]. Benefits may be in material conditions, strongly marked by issues of social inequality, or subjective, in gaining relationships with people outside the normative places and institutions for young people. Unconventional circumstances produce unconventional attitudes that are expressed in alternative forms of resilience.

Our intention is not to validate the drug trafficking and sexual exploitation of children and adolescents in the contemporaneity. But it is necessary to admit that the social model, marked by inequalities and oppressive realities, lead some young people to alternative ways to build their resilience processes. Thus, we need to eliminate moralist speeches, as well as recognize that the precariousness of resources, inefficiency and lack of social policies, often lead children and adolescents to situations socially undesirable, but these were the only possibilities to generate the sense of wellbeing, belonging and self-esteem, and it supplies something that was not found in settings such as family, school, community, church, and certainly in public policy in general.

Exposure to adverse childhood experiences and health problems in adulthood: the role of family related protective factors

Baban A., Cosma A., Balazsi R.

Babes Bolyai University, Cluj Napoca, Romania
adrianababan@psychology.ro

Abstract

The exposure to adverse experiences (ACEs) during the first 18 years of life can have long negative term effects on people's mental and somatic health. ACEs include verbal, physical, or sexual abuse, as well as family dysfunction (e.g., an incarcerated, mentally ill, or substance-abusing family member; domestic violence; divorce or parental separation). Using a CDC-WHO methodology (the Adverse Childhood Experiences Study), the present study aims to investigate the relationship between ACE and mental and somatic health problems in young adults. Secondly, we investigated the role of family related protective factors (e.g. there was someone in your family to take care of you, to make you feel important or loved) in the relationship between the exposure to adverse childhood experiences and health problems. Our sample consisted from 2088 Romanian university students. The results indicate that as the exposure to ACEs categories increases, the odds for experiencing mental health and somatic health problems also increase. The presence of positive related family factors did not change the association between exposure to ACE and health outcomes. Several recommendations for future research are presented.

Keywords: adverse childhood experiences, mental health problems, somatic health problems, family protective factors.

Introduction

During their development, in their first 18 years of life, children can be exposed to an increased number of adverse experiences and situations. These experiences vary from child abuse and maltreatment (physical and psychological abuse and/or neglect) to a large number of family dysfunctional situations (mother's abuse; alcohol, illicit drug consumption by one of the family members; mental illness of one of the family members) [1]. Researchers, practitioners, educators, policy makers, NGOs, and other community members offer a constant attention towards this issue [2].

1.1 Exposure to adverse experiences during childhood

Being exposed to abuse and neglect throughout childhood can have for a person immediate and long term negative consequences [3, 4]. Using a retrospective research methodology, a number of studies (ACE studies) had investigated the prevalence of exposure to adverse childhood experiences (ACE) and its relationship with health outcomes in adulthood [3, 5, 6, 7]. A consistent number of studies indicated that certain abuse categories (physical abuse and neglect, psychological abuse and neglect, sexual abuse) co-occur throughout childhood with several categories of family and household dysfunctions (from domestic violence and substance abuse by a family member, to criminal behavior or mental illness of a family member). These categories have been labeled ACE categories in the studies which adopted the same methodology. According to these studies, as the child is exposed to a higher number of ACE categories, risk for developing health problems such as: chronic obstructive pulmonary disease (COPD), ischemic heart disease (IHD), or liver disease increases also [3]. Moreover, experiencing adversity during childhood has been linked to a higher risk for developing mental health problems in adulthood, such as: depression [7], suicidal ideations and suicidal attempts [5].

According to a WHO international report, in a Romanian university sample, the exposure to adverse experience during childhood has high prevalence among young adults. Specifically, the most prevalent ACE categories to which the participants were exposed are: physical abuse (26.9%); psychological neglect (26.3%); psychological abuse (23.6%); alcohol misuse by a family member/FM (21.6%); mother treated violently (16.5%) and physical neglect (16.5%). Female participants were exposed more often to psychological neglect, sexual

abuse, alcohol misuse by family member, mental illness of one family member, and domestic violence; on the other hand, male participants experienced more often physical abuse and physical neglect [9].

Similarly, other studies which have used other research methodologies evidence that an increased exposure to childhood adversity has a corresponding increased levels of conduct/antisocial personality disorder, violent and property crimes, alcohol and drug dependence. Moreover, the exposure to a higher number of adversities (more than 6) during childhood increased the risks for externalizing and internalizing problems later in adolescence and young adulthood [10].

Despite all the evidence previously presented, the relationship between exposure to adverse experiences during childhood and negative outcomes later on in life it is not a deterministic one. There are plenty of evidence which indicate that even children who had lived in extremely adverse conditions had not develop adjustment and health problems later on in life [11, 12].

1.2 Resilience and child maltreatment

Resilience is viewed as the dynamic developmental process which facilitates the attainment of positive adaptation within the context of significant adversity [13]. The two main critical conditions required to conceptualize resilient development as exposure to severe adversity, threat or trauma and the manifestation of positive adaptation despite experiencing those adversities [13, 14].

Experiencing abuse and neglect while growing up can have a negative impact upon the physical, social, psychological development. Nonetheless, not all individuals who experienced those negative life situations end up by having an impaired development. Cicchetti and Rogosch [15] identified that ego-control and ego-resilience (as personality characteristics), and positive self-esteem act as factors which foster resilient development in disadvantaged maltreated children. In addition, the use of functional emotional regulation strategies has been identified as predictors for resilience. The same authors indicated that EEG asymmetry and cortisol levels are related with resilience in maltreated children (physically abused children with higher levels of morning cortisol displayed higher resilient functioning) [14, 15]. Moreover, resilient functioning for abused children has been associated with the availability of emotional support at the time of the abuse [16] and with the ability to form, maintain and benefit from good inter-personal relationships [17]. The extent of recalled parental care and support, and the quality of adolescent peer relationships have been reported to be protective factors in a longitudinal study for children exposed to child abuse [18].

The present study has two main objectives. First, we investigate the relationship between exposure to adverse childhood experiences and health problems in young adults; secondly, we assessed the role of family related protective factors in the relationship between the exposure to adverse childhood experiences and health problems.

Methodology

1.3 Participants

In the present study were included 2088 participants (64.3% were female and 35.7% were male). We selected a representative sample for Romanian university students. The mean age of respondents was 24.51 years old (SD=± 7.09).

1.4 Instruments

The Adverse Childhood Experiences (ACE) questionnaires were used for this study. These questionnaires were developed by the Center for Disease Control and Prevention (Atlanta) in 1997, (www.cdc.gov/nccdphp/ace) and include *Family Health Questionnaire* and *Physical Health Appraisal Questionnaire*, both with separate versions for men and women. For the purpose of this study, the following dimensions were included: exposure to adverse childhood experiences, family protective factors, mental and somatic health problems.

1.4.1 Exposure to Adverse Childhood Experiences

Exposure to child maltreatment (physical abuse and neglect, psychological abuse and neglect, sexual abuse) and *household dysfunctions* (alcohol abuse, mental illness in the family, mother treated violently, parental divorce, family member incarcerated) was measured. A composite score (ACE score) was computed to form an indicator of exposure to adverse childhood experiences by adding individual items score, the score ranging from 0 up to 11 (0 means that the absence of any of adverse experience) (3, 7).

1.4.2 Positive Family Related Context

Positive family related context (PFRC) was measured using 7 items: *there was someone in your family: who took care of you; took you to the doctor; who loved you; who helped you feel important*; *your family members felt close to each other, your family members took care one of other; your family was a source of strength and support*. In order to verify the single-dimensionality of the scale, we used a confirmatory factorial analysis, and the computed fit indices supported the existence of a single factor. A composite score was computed by summing the score to each of the seven items, the score ranged from 5 to 35.

1.4.3 Mental and Somatic Health problems

Mental health problems score was generated by adding the score of two items: "have you had depression" and "have you had sleep problems". *Somatic health problems* score was computed by adding the score of the following items: constipation, high blood pressure, back pains, headaches, and problems with urinary tract.

1.5 Data analysis

For the purposes of the study we used univariate and bivariate descriptive statistics. In order to verify the hypothesis of our study, we tested a path analysis model. All the statistical procedures and analysis were done by using SPSS-IBM 20.

Results

About one third of the participants (35.5%) haven't been exposed to any ACE category. More than 64% of participants have been exposed to at least one ACE category (64.4% of males and 65.5% of females). One ACE category was experienced by 25.9% of females and 19.8% of males. The experience of any two categories of ACEs occurring together was common for 25.9% of males and 19.8% of females. Any three categories of ACEs were experienced by 9.3% of males and 9.5% of females. Four or more ACEs categories were experienced by 15.2% of males and 20.1% of females.

The odds of having most of these health problems were higher as the number of ACEs increased. The odd ratio for having depression was 1.9 times more likely as the person was exposed to one ACE category, and it increased to 6.33 times as the number of ACEs reached four and more (OR=6.33, 95% CI=6.64-8.65). The chance of having sleep problems was 1.62 more likely (OR=1.62, 95% CI=1.25-2.11) when the person was exposed to one ACE category, and it increased to 3.32 times more likely if the person was experienced four or more ACE categories (OR=3.32, 95% CI=2.53-4.35).

In the case of somatic health problems, the chance of experiencing constipation was 1.46 (OR=1.46, 95% CI=1.08-1.97) more likely if the person was exposed to one ACE category, and the chance increased to 1.65 (OR=1.65, 95% CI=1.22-2.24) as the person was exposed to four or more ACE categories. The chance of experiencing back pains was 1.52 (OR=1.52, 95% CI=1.18-2.09) more likely if the person was exposed to one ACE category, and the chance increased to 2 (OR=2, 95% CI=1.54-2.62) as the person was exposed to four or more ACE categories. Experiencing headaches was 1.41 more likely (OR=1.41, 95% CI=1.08-1.85) if the person was exposed to one ACE category, and it increased to 1.82 (OR=1.82, 95% CI=1.38-2.4). Reporting having problems with urinary tract was 1.86 more likely (OR=1.86, 95% CI=1.22-2.83) for the persons exposed to one ACE category, and the likelihood increased to 2.55 (OR=2.55, 95% CI=1.77-3.7) when the person was exposed to four or more ACE categories.

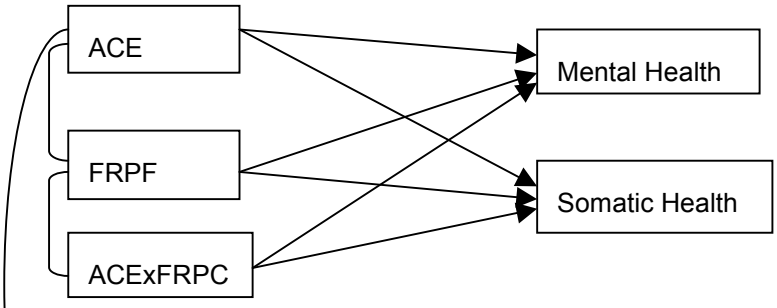

Fig. 1. Proposed Path Model

In order to verify our hypothesis, we specified a path analytic model using ACE, PFRC and ACExPFRC as exogenous variable (predictors) and mental and somatic health as endogenous variable (criteria). The resulted model was just identified as a consequence no global model fit was computed. Path indicators are presented in Table 1 (unstandardized coefficients).

Table 1 Path indicators for the proposed model

	Estimate	S.E.	C.R.	P
Mental Health <--- ACE	-.212	.020	-10.749	***
Somatic Health <--- ACE	.218	.032	6.867	***
Mental Health <--- PFRC	.033	.022	1.475	.140
Somatic Health <--- PFRC	-.033	.036	-.906	.365
Mental Health <--- Moderation	-.002	.018	-.117	.907
Somatic Health <--- Moderation	-.001	.029	-.034	.973

An increase with one unit of the ACE scores is significantly associated with a -.212 decrease of the scores of mental health (p>.001). Also, an increase with one unit of the ACE scores is significantly associated with a .218 increase of the scores of somatic health (p>.001). We indentified no significant associations between PFRC and somatic and mental health. Moreover, the interaction of ACE and PFRC did not moderate the relationship between exposure to ACE and health outcomes.

Conclusions

This study evidenced the relationship between exposure to adverse experiences during childhood and health outcomes. As a person was exposed to more ACE categories the chances of having poor health outcomes increased. These results come in line with recent literature [3, 7, 8]. The strongest indentified associations were between being exposed to ACE and mental health problems in young adulthood, especially experiencing depression.

For the present study, we conceptualize that a resilient development will characterize individuals who have been exposed to ACE, but had low scores for mental and somatic health outcomes. That fact that we identified no moderation effect between being exposed to ACE and health outcomes in adulthood could be attributable due to measurement issues. All measures indicating childhood abuse history, family interaction history and health outcomes were done by self report, and in the same session. Moreover, we might have not identified this effect because our sample was formed by young adults, who due to their age have lower chance of experiencing serious health problems.

This study brings some insight regarding the prevalence and the effects of experiencing adversities during childhood on several health outcomes during adulthood. In addition, future studies should employ more precise and valid measures when evaluating health problems in adulthood in order to have a more clear understanding about the possible resilient outcomes. Also, other inter-personal (parental attachment style, relationships with peers) or intra-personal factors (self-esteem, self-regulation, attributional style) should be tested as possible moderators in the aforementioned relationship.

Bullying victimization in childhood: which factors act as buffer for health problems in adulthood?

Abstract

Bullying behaviors among children are a worldwide problem and their effects, especially for victims, can be long lasting throughout adulthood. The present data was collected for the Adverse Childhood Experiences Study (N= 2088 Romanian university students). By using a retrospective approach, the first aim of this study was to identify the prevalence of bullying victimization for Romanian university students. The second aim was to assess the role of positive related family context in the relationship between the being bullied during the first 18 years of life and health problems during adulthood (mental and somatic health). Our results indicate the existence of a high history of bullying victimization for the Romanian university students. The exposure to positive related family context was a moderator in the relationship between bullying victimization and somatic health problems. Several research directions are proposed.

Keywords: bullying victimization, mental health problems, somatic health problems, family protective factors.

Introduction

Bullying behaviors are a particular type of aggressive behavior, which can be defined as any acts intended to inflict injury and discomfort upon another individual [1, 2]. There are several criteria used by specialists to distinguish bullying behaviors from other types of aggressive behavior: intentionality, repetitiveness and the imbalance of power [2]. Bullying involves also some specific roles: bully, victim, bully-victim (or reactive victims), and by-standers [1, 3].

1.1 Bullying victimization: prevalence and consequences

According to recent international epidemiologic studies, bullying behaviors have high prevalence worldwide, with estimates ranging from 8.6% to 45.2% among boys, and from 4.8% to 35.8% among girls [4]. At European level, the school children from Baltic countries reported higher rates of bullying and victimization, whereas northern European countries reported the lowest [4,5]. Among Romanian school aged children, bullying behaviors have a high prevalence. More specifically, 25.7% of 11 years old boys, 35.3% of 13 years old boys and 30.4% of years old boys have been experiencing victimization at least 2-3 times per month. Following a similar trend, 17.2% of 11 years old girls, 26.1% of 13 years old girls and 18.9% of 15 years old girls have experienced victimization for more than two-three times in the last month [6]. The authors identified a significant difference among the two genders, with boys reporting the engagement in these type of behaviors significantly more often. These findings come in line with research literature which emphasize that boys report higher rates of involvement in bullying [2,4]. Also, it appears that for Romanian school children, having a low social economical status has been associated with higher rates of bullying victimization for both genders [7]. Romanian school aged children, reported higher percentage for bullying other and being bullied compared to the HBSC average [6].

The negative effects of bullying involvement upon children's health are very well documented. Bullies tend to report a higher level of externalizing problems; victims tend to report more internalizing symptoms, and bully/victims tend to report both a higher level of externalizing and internalizing symptoms compared to other two groups [8]. Moreover, bullied children have significantly higher levels of anxious and depressive symptoms compared to bullies or non-involved peers [8, 9,10]. In the debate if depressive symptoms act as predisposing factors for bullying victimization, or it is a consequence of it, several studies indicate that internalizing symptoms seem to increase as a consequence of bullying victimization [10, 11]. In a longitudinal study, children who were bullied had significantly higher chances for developing new psychosomatic and psychosocial

problems compared with non-involved peers. Also, children with depressive and anxieties symptoms had significantly higher chance of being bullied 6 months later [12].

1.2 Resilience and bullying victimization

Resilience it is present when an individual manifest positive development despite of experiencing several significant adversities [13]. Positive relationships within family are one important aspect that has been related with resilient development for children [14,15]. According to this research, the experience of positive relationships with family diminishes the negative impact of adversity to which children had experienced [15]. One study which conceptualized the existence of resilient functioning for bullied children through the low depression scores indicate that being male, having high self-esteem, having low levels of conflict with parents and no victimization from siblings were characteristics associated with resilience [16]. Moreover, other longitudinal studies indicate that for children who experience bullying victimization characteristics such as: maternal warmth, sibling warmth and a positive atmosphere at home were associated with fewer emotional and behavioral problems [17].

The present study had two main objectives. First, we investigated the prevalence of being bullied while growing up for the young adults. Secondly, we assessed the role of positive related family context in the relationship between the being bullied during the first 18 years of life and health problems.

Methodology

1.3 Participants

Present study included 2088 participants (64.3% were female and 35.7% were male). We selected a representative sample for Romanian university students. The mean age of respondents was 24.51 years old (SD=± 7.09).

1.4 Instruments

The Adverse Childhood Experiences (ACE) questionnaires were used for this study. These questionnaires were developed by the Center for Disease Control and Prevention (Atlanta) in 1997, (www.cdc.gov/nccdphp/ace) and include *Family Health Questionnaire* and *Physical Health Appraisal Questionnaire*, both with separate versions for men and women. For the purpose of this study, the following dimensions were included: exposure to adverse childhood experiences, positive family related context, mental and somatic health problems.

1.4.1 Bullying Victimization

Questions about bullying experiences were preceded by the following introduction: *Here are some questions about bullying experience. We say a student is BEING BULLIED when another student, or a group of students, say or do nasty and unpleasant things to him or her. It is also bullying when a student is teased repeatedly in a way he or she doesn't like. But it is NOT BULLYING when two students of about the same strength quarrel or fight*. Being bullied was assessed by one question that respondents had to report the frequency with which they were bullied in school and away from school in the last 2 months. Response categories were: "I refuse to answer", "I haven't . . . ," "once," "a few times", and "several times" We included in our analysis all answer which indicated a frequency of at least "once". Also, participants were asked to indicate the type of bullying to which they have been subjected to.

1.4.2 Positive Family Related Context

Positive family related context (PFRC) was measured using 7 items: *there was someone in your family: who took care of you; took you to the doctor; who loved you; who helped you feel important*; *your family members felt close to each other, your family members took care one of other; your family was a source of strength and support*. In order to verify the single-dimensionality of the scale, we used a confirmatory factorial analysis, and the computed fit indices supported the existence of a single factor. A composite score was computed by summing the score to each of the seven items, the final score ranged from 5 to 35.

1.4.3 Mental and Somatic Health problems

Mental health problems score was generated by adding the score of two items: "have you had depression" and "have you had sleep problems". A composite score was computed by summing the score to each of the seven items, the final score ranged from 0 to 2.

Somatic health problems score was computed by adding the score of the following items: constipation, high blood pressure, back pains, headaches, and problems with urinary tract. A composite score was computed by summing the score to each of the seven items, the final score ranged from 0 to 5.

1.5 Data analysis

For the purposes of the study we used univariate and bivariate descriptive statistics. In order to verify the hypothesis of our study, we tested a path analysis model. All the statistical procedures and analysis were done by using SPSS-IBM 20.

Results

Overall, 39.2% of participants reported they have been bullied during their childhood (first 18 years of life). We identified a significant gender difference ($p<0.05$), male participants reporting that they were bullied more frequently than female participants (46.3% of males vs. 35.5% of females). The most frequent victimization categories to which participants have been exposed to were: situations when other persons made fun because of the way they looked (28.7% of females vs. 7.8% of males), situations in which they were left out of activities on purpose (18.1% of males and 20.7% of females) or situations in which they were made fun of by the use of sexual jokes (13.8% of males and 11.6% of females). Female participants reported significantly more often than male participants that they have been made fun of because of the way they looked.

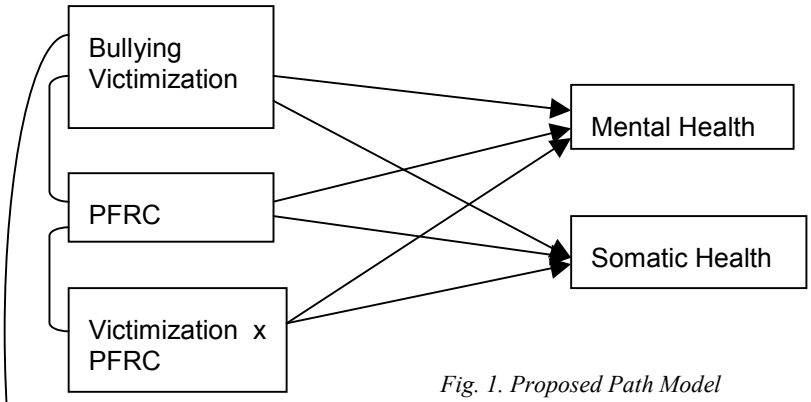

Fig. 1. Proposed Path Model

In order to verify our hypothesis, we specified a path analytic model using bullying victimization, PFRC and Bullying VictimizationxPFRC as exogenous variable (predictors) and mental and somatic health as endogenous variable (criteria). The resulted model was just identified, as a consequence no global model fit was computed. Path indicators are presented in Table 1 (unstandardized coefficients).

Table 1 Path indicators for the proposed model

			Estimate	S.E.	C.R.	P
Mental Health	<---	Bullying Victimization	.175	.017	9.992	***
Somatic Health	<---	Bullying Victimization	-.104	.028	-3.692	***
Mental Health	<---	PFRC	.095	.018	5.402	***
Somatic Health	<---	PFRC	-.108	.029	-3.786	***
Somatic Health	<---	Bullying Victimization x PFRC	-.069	.027	2.603	.009
Mental Health	<---	Bullying Victimization x PFRC	-.029	.016	-1.788	.074

An increase with one unit of the bullying victimization scores was significantly associated with a .175 increase of the scores of mental health ($p>.001$). Also, an increase with one unit of the bullying victimization scores is significantly associated with a -.104 decrease of the scores of somatic health ($p>.001$). We indentified a significant association between PFRC and somatic and mental health. Specifically, an increase with one unit for

the PFRC scores was associated with a .095 increase for mental health scores (p>.001). An increase with one unit for the PFRC scores was associated with a .095 decrease for somatic health scores (p>.001). Moreover, the interaction of bullying victimization and PFRC did moderate only the relationship between exposure to bullying victimization and somatic health scores.

Conclusions

This study brings new information upon the prevalence of retrospective bullying victimization for the Romanian university students' population and the role played by a positive family related context in the relationship between victimization and health outcomes. Bullying victimization experienced during the first 18 years of life by the young Romanian adults has a high prevalence. The prevalence is higher than the one previously identified in a Romanian school aged sample [6]. This difference could be attributable to the measurement scale. In the present study, participants were asked to recall how often they have been victimized in bullying episodes in their first 18 years of life, whereas the other study had a stricter time frame: only the incidents that have occurred in the last two weeks.

Being bullied during childhood has been associated with an increase in mental health problems in young adulthood. This finding comes in line with previous findings which emphasize the long term effects of bullying victimization [18]. Moreover, the fact that we identified a negative relationship between being bullied and somatic health problems (an increase of bullying victimization was associated with a decrease of somatic health problems) could be due to the fact that our sample was formed by young adults who do not have yet seriously medical conditions.

One important aspect revealed by the present research is that for children who were bullied, the experience of positive related family context decreased the score for somatic health problems. Thus, in the context of having someone in their family who fostered positive interaction and care, the reported somatic health problems for bullied children were lower. The trend is similar for the mental health problems, but the association was not statistically significant. Future studies should focus on analyzing the role of positive family related factors in the interplay between different types bullying victimization (social bullying, physical bullying, cyberbullying) and health outcomes.

Abstract

Introduction: We approach an integrated research-action model of the interactions between the psychosis of the parent, parenting, family relations, the child's development, risk and resilience factors.

Objectives: Identifying the resilience factors, the research of the interaction between the risk and resilience mechanisms, predicting or not the development of psychopathology in children of psychotic parents, the dynamic evaluation of the resilience.

Methods: The longitudinal study was conducted in the period 2003-2013 on a group of 75 children with a schizophrenic parent and 70 children with a parent with bipolar disorder. We applied the scales: CBCL, Vth Axis ICD 10 , PANSS and CD-RISC (Connor-Davidson Resilience Scale).

Through PANSS for the psychotic parents, we correlated the scores for specific items with those obtained by the children through CD-RISC. Through MANOVA and the Pearson test we correlated the dependent variables with the predictive influence factors.

Results The high PANSS scores for specific items were correlated negatively with the resilience scores of the children with psychotic parents. The maximum frequency of positive codifications on the Vth Axis, found for: rejection behavior from one parent (76, 4%), family disharmony (73, 52%), distorted family communication (70, 58%), was significantly correlated ($p<0.001$) with low scores of the child's resilience for personal competency, negative effects tolerance, safe interpersonal relations, high performance.

Conclusions: The social, family support and social connectedness proved to be relevant variables. Resilience can be modified and improved through targeted interventions, so that the understanding of the resilience process and of the concurrent factors is needed.

Keywords: Resilience, research-action, parenting

Introduction

Research in the frame of developmental psychopathology, which is focused on children exposed to high-risk family environments, identified children having parents with severe psychopathology, who develop maladjustment or symptomatology or who adapted well despite the challenges posed to their adjustment [1, 2, 3]. Children of parents with schizophrenia/affective disorders who avoided a psychopathologic outcome through developing a healthy pattern are considered to be more resilient [4, 5, 1]. The "high risk" design of choosing children, offspring of psychotic parents who developed and who didn't express psychopathology, encourages the examination of gene-environment, risk and protective factors interactions [6, 7]. Developmental psychopathology and well-being are a function of the interplay of bio-psychosocial risks and resilience factors in children and their supportive environments [8]. Previous research showed the multiplicative effects of cumulative and interactive risks on child adjustments and on the expression of psychopathology [9].

Recent studies converge on the idea that high risk children may acquire cognitive vulnerability by receiving direct inferential feed-back from significant others or as result of negative parenting practice. Prevention interventions should target at-risk populations because the goal is to prevent a high risk person from developing psychopathology [10].

Objectives

Our aims were: the quantification of the resilience mechanisms in high risk children; to assess how multiple risk factors during different developmental periods work together and express psychopathology or provide the offspring of a psychotic parent, the opportunity to be resilient; the identification of protective factors in the subgroups that were less prone to develop psychopathology despite exposure to risk; the evaluation of resilience in different timepoints in order to assess the efficacy of targeted interventions. We also targeted the prospective identification of children with a high probability to develop a mental illness in order to prevent through improving the resilience mechanisms or to apply a proper intervention.

Methodology

Our prospective research was performed in the University Hospital of Psychiatry for Children and Adolescents, Timisoara, in the period from 2003-2013, on high risk children, with ages between 10-19 years, who were offspring of psychotic parents:75 children with a parent suffering of schizophrenia and 70 children of parents with bipolar disorder [10]. We identified help-seeking families, with one psychotic parent, having children, who needed care in our clinic in that period [11]. We signed the informed consent with the parents and the assent to participate with the children. From the 75 high risk children, being offspring of parents with schizophrenia, 55 developed psychopathology and 20 were without. From the 70 high risk children of parents with bipolar disorder: 40 children were with psychopathology and 30 without. The children without psychopathology in both groups, were siblings of those who developed psychopatholgy, living in the same environment.

We applied the standardized research instruments: PANSS-Positive and Negative Syndrome Scale was applied on the psychotic parents; CBCL and the Fifth Axis ICD 10 were applied on all the parents in the study groups; CD-RISC-Connor-Davidson Resilience Scale on the two groups of children; CD-RISC consists of 25-items that measure the ability to cope with stress and adversity. It was designed to quantify self-reports of resilience and to measure response to treatment in a clinical population. Each item is rated on a 5-point scale (0-4), higher scores reflecting greater resilience. The items reflect several aspects of resilience that include: a sense of personal competence, tolerance of negative affect, positive acceptance of change, trust in one's instincts, sense of social support, spiritual faith, and an action-oriented approach to problem solving [12, 2]. Through PANSS, we evaluated the positive, negative and general symptoms of the psychotic parents and we correlated the scores for specific items with those obtained by the children through CD-RISC for the resilience. Through the CBCL, we evaluated some symptomatic categories referring to behavioral and social competence problems of the children, perceived by their parents. Through the Fifth Axis we evaluated the abnormal psycho-social conditions. The categories included in this axis, have been chosen, knowing the fact that they can represent significant risk factors [10]. We applied the scales in different time-points in order to evaluate and quantify the efficacy of proper interventions through the resilience scores.

We used: descriptive statistics-average, standard deviation, absolute and relative frequencies, parametric statistical tests-simple ANOVA and simple factorial ANOVA; the Pearson correlation test to check for the presence of statistically significant correlations between the CD-RISC-CBCL results, the CD-RISC-Fifth Axis results and the PANSS-CD-RISC results; We applied the qui square analysis to evaluate if the variation of the resilience scores from CD-RISC, was statistically significant in different timepoints. We had the support of SPSS and MedCalc statistics. We evaluated the differences between the children with and without psychopathology in both groups concerning their own mechanisms of resilience or their risk factors.

Results

The most frequent diagnostic categories of the offspring with psychopathology are illustrated in **Fig.1-** HR SZ-high risk children with schizophrenic parents and HR BPD-high risk children of parents with bipolar disorder:

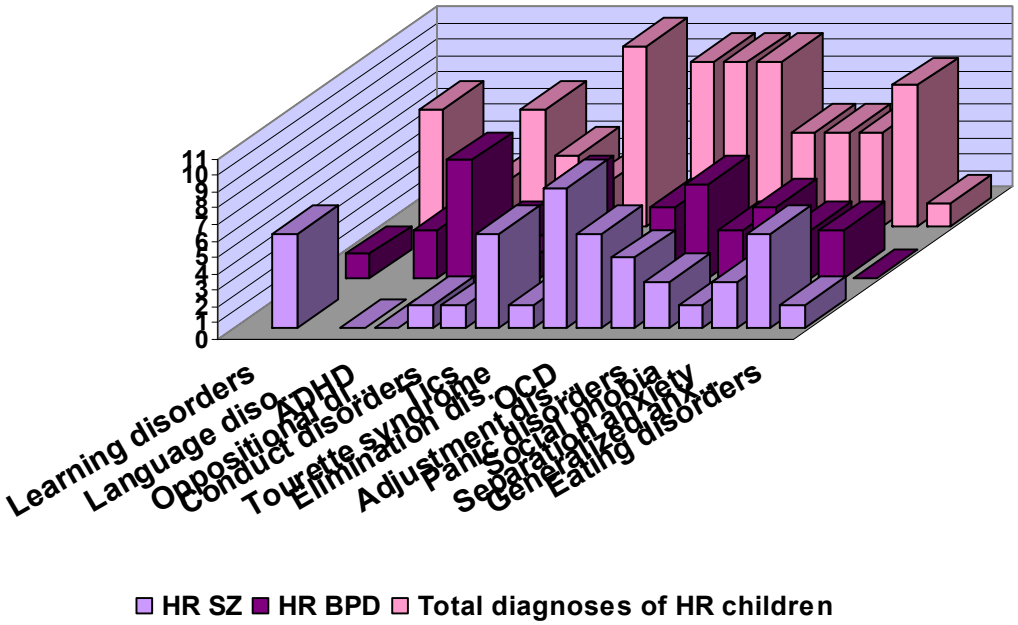

Fig. 1 Diagnoses of the high risk children

Concerning the diagnoses of the high risk children we found the lowest CD-RISC scores of resilience for the offspring with generalized anxiety disorders, OCD-Obsessive-compulsive disorder and ADHD, as a marker of low self-efficacy and low self-esteem.

1.1 The CD-RISC, CBCL, DSM IV Fifth Axis, PANSS scores and the Correlations Analysis

Through the CD-RISC application, we noticed in both groups of children who developed psychopathology, low resilience scores in the main domains, coded through the key factors: strong sense of self-efficacy, tenacity, emotional and cognitive control under pressure, adaptability, control and meaning. The lowest resilience scores were registered for the children of parents with schizophrenia with one exception concerning the domain-aspects of persistence/tenacity, where the offspring of depressive parents had the lowest resilience score. The mean total CD-RISC score for the high risk children who developed psychopathology was 45.5 (standard deviation-sd=8.7) for the offspring of schizophrenic parents and 52.8 (sd =9.4) for the offspring of bipolar parents [12].

Fig. 2 illustrates the mean scores in CD-RISC on the 5 domains coded through the 25 items of the scale for: HRPBPD-high risk children of parents with bipolar disorder, HRPSZ-high risk children of parents with schizophrenia, T2HRPBPD-timepoint2 scores - children of parents with bipolar disorder, T2HRPSZ-timepoint2 scores - high risk children of parents with schizophrenia and for the offspring, who didn't develop any psychopathology.

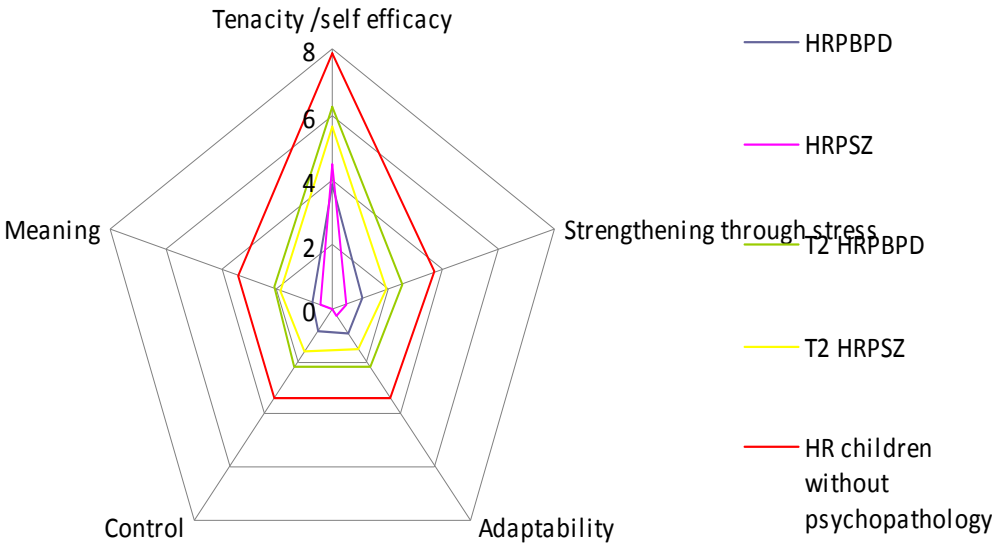

Fig. 2 Mean scores in CD-RISC on the 5 domains in timepoint1 and 2

We evaluated the CD-RISC scores of the high risk children with psychopathology for timepoint1 and after applying proper intervention strategies in timepoint2. We noticed higher mean total resilience scores (improved from 45.5 to 58.2 for the offspring of schizophrenic parents and from 52.8 to 69.7 for HRPBPD) and on the 5 key domains, reflecting greater resilience in both studied groups after the individualized interventions. We noticed that the children without psychopathology in both groups had generally higher mean scores for resilience in CD-RISC, as well as concerning the 5 key factors: tenacity/ self-efficacy, strengthening through stress, adaptability, control and meaning. Their mean total resilience scores in timepoint1 were 70.6 for HRPSZ and 74.3 for HRPBPD (sd=10.4) and their highest mean scores found were for tenacity/self-efficacy. In their case, targeted intervention has not been applied and in timepoint2 we found for HRPSZ-25% and for HRPBPD-30% developed psychopathology and their mean total resilience scores were 57.3.-HRPSZ and 60.1-HRPBPD.

Through the CBCL, we found in both offspring groups, who developed psychopathology lower median total competencies scores, high, clinically significant externalizing scores, the high risk children of schizophrenic parents being most affected. These values in high risk children prove the fact that a high percentage of children with psychotic parents show a dysfunctional social functioning. High risk children in both groups, showed high scores for depression, hyperactivity and aggressiveness.The siblings who didn't develop psychopathology had higher median total competencies scores and their CBCL externalizing and internalizing scores were in non-clinical range. They were very close to the healthy parent, finding a meaning even in the disturbed family system.Therefore the availability of a stable attachment person was crucial.Their age was higher than the age of their siblings with psychopathology, when their parents developed psychosis. We found high statistically significant correlations (Spearman's p =0.012) between the CBCL externalizing, total, competencies scores of the children in both groups and the resilience scores on CD-RISC.

Fig. 3 represents, through the dispersion diagram, the negative correlation between the Externalizing scores of the children in both high risk groups through CBCL and the resilience scores through the CD-RISC. So that, high Externalizing scores of the high risk children predicted low CD-RISC resilience scores.

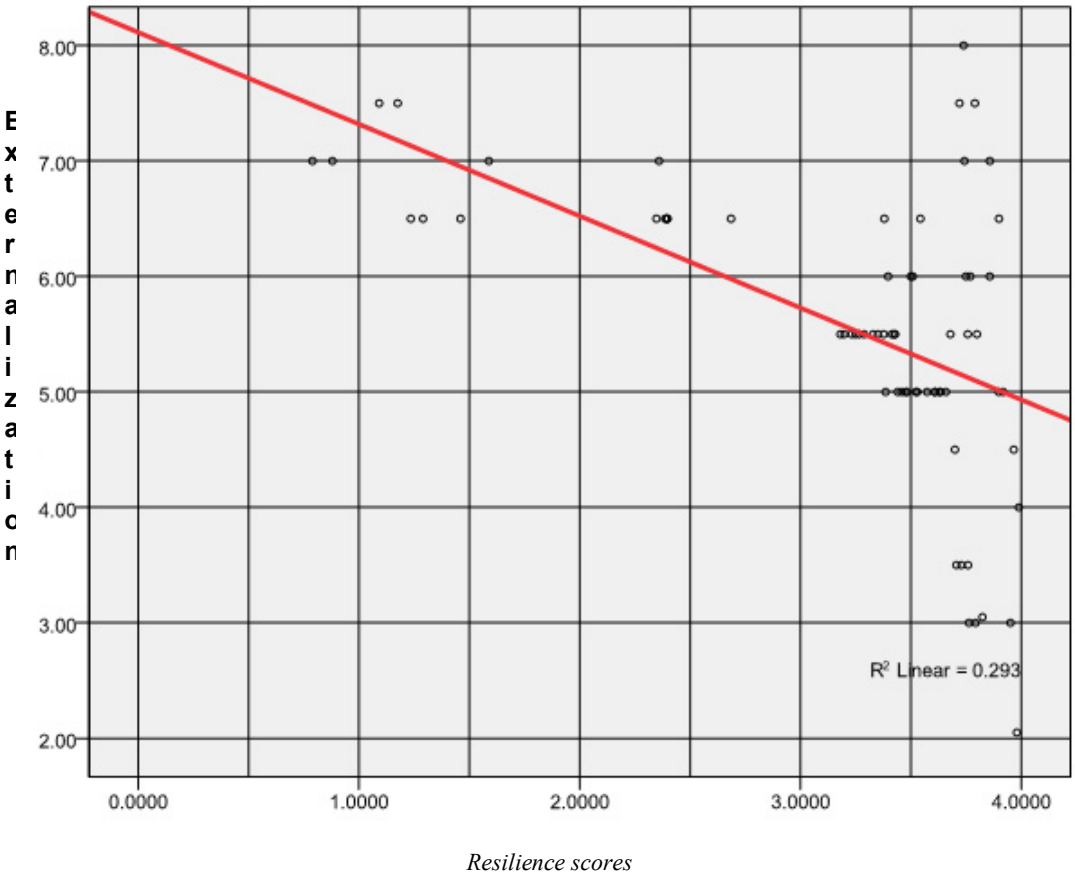

Fig. 3 The Negative Correlation between Externalization(CBCL) and Resilence scores(CD-RISC)

In the cases of children without psychopathology from both high risk groups, the more the child exhibited overall competence and skills through the CBCL, the less likely it was that the child showed externalizing behavior problems and his scores for resilience in CD-RISC were higher.

The Pearson correlations between the high PANSS scores of the parents and low resilience scores were statistically significant, especially in the case of psychotic mothers and concerning the negative symptoms of the schizophrenic mother and the resilience scores of the offspring ($p<0,001$).

The maximum frequency of positive codifications on the Fifth Axis in both study groups of high risk children of schizophrenic and bipolar parents, was significantly correlated ($p<0.001$) with low scores of the child's resilience for personal competency, negative effects tolerance, safe interpersonal relations, adaptability. We found through the Pearson correlations between CD-RISC - Fifth Axis, high negative correlations, meaning that higher scores for the abnormal family relations and distorted communication predicted low resilience scores.

Conclusions

Resilience is modifiable and can improve after targeted interventions. The presence of seemingly healthy adaptation of high risk children at one developmental stage may change in time, positive adaptation never being permanent, so they need early intervention and support, too.

The quantification of resilience remained a significant predictor of outcome, proving to be a target for early detection and prevention of psychopathology.

Concerning, the risk/protective factors, non-shared environmental influences are important for age-specific behavioral problems, in our case the age of the sibling at the onset of the parent's psychosis was crucial.

The abnormal psychosocial conditions for the children are higher in the families with a schizophrenic parent, especially the mother, this fact becoming a burden for the psychological development and the prognosis.

Discussions

The fact that the resilience of the high risk children improved in time after targeted interventions, gives hope that the outcome and the onset of psychopathology can be influenced.

Our research-action model of systemic, family-centered evaluation and intervention, proved to be a succesful way to enhance the empowerment, the positive aspects of individual and family functioning even under high risk conditions. Through the whole research, the needs of the parents as well as of the children, were approached concomitantly creating an interface between the mental health services for children with those of the adult services [10, 11].

Our study of resilience, including children with and without psychopathology, assessing genetic and environmental factors, is likely to lead to improvements in the ability to design effective interventions [6]. The vulnerable child has some characteristics, which put him in a risk position. If proper intervention strategies are applied, the vulnerability can be balanced through protective factors. So that we have to work on the rehabilitation of the child and of the parental capacities. Through the resources and quantification of resilience, we achieved new perspectives of implementing a complex and individualized model of interventional strategies.

Explanatory variables of resilience in latin american youngsters

Omar A.

National Council of Scientific and Technical Research (CONICET) and National University of Rosario (ARGENTINA)
agraomar@yahoo.com

Abstract

This study tested an explanatory model of resilience in youth and adolescents. All variables introduced in the model were rooted in published theoretical and/or empirical evidence. Because of the nature of the variables included (optimism, sense of humor, personal values, positive emotions, well-being, positive coping, emotional intelligence), the model meets the guidelines of Positive Psychology. The model was tested with a sample of 1478 students (450 Argentines, 493 Brazilians, and 535 Mexicans). Stepwise regression analyses showed that all the variables considered explained significant amounts of the total variance of resilience, although subjective well-being and optimism emerged as the strongest predictors. Mediated regression analyses indicated that horizontal collectivism moderates the relationship between positive coping and resilience. These results suggest that collectivist orientation, characterized by a sense of equality (i.e., by the active rejection of any socially constructed hierarchy), is the primary mediator between the young, the demands of the environment, their resources to cope with stress, and their level of resilience. The current predictive and moderating model can be useful to build knowledge about resilience among Latin Americans youngsters. To conclude, we discuss the strengths and limitations of the empirical verification performed.

Keywords: Explanatory model, empirical verification, Latin American youngsters, positive emotions, well-being, optimism, positive coping, emotional intelligence, values.

Introduction

There is growing support that resilience is influenced by protective factors, both personal and environmental. Although many of these factors have been identified, little is known about the way they contribute to the development of resilience among adolescents and young people. So much so that several scholars [1], [2] have called for research that expands beyond the simple examination of the direct effects of protective factors, to explore how resilience interacts with either individual differences (e.g. demographics, personality) or contextual factors (e.g. values). Hence the importance of developing models that attempts to reproduce the dynamics of the interrelationships between predictive or moderator variables and a subsequent dependent variable (resilience). Moreover, a better understanding of these aspects would help identify the interplay between the variables involved, and would promote the implementation of programs to develop and/or enhance the resilience of youth and adolescents at risk.

The aim of this study was to verify the conceptual model of resilience in adolescents and young people, developed by Omar et al. [3]. The model has its basis in evidence published so the inclusion of each variable, far from reflecting subjective speculation, is rooted in both theoretical and empirical reasons. Because of the nature of the variables considered (optimism, sense of humor, positive emotions, subjective well-being, positive coping, emotional intelligence), the model meets the guidelines of Positive Psychology. The model also includes personal values, since we postulate that cultural variables act as differentiating factors of resilient behavior. Because we studied values as mediators between resilience and positive aspects that contribute to its emergence and development, the verification of the model required the examination of samples of youth and adolescents from different cultural contexts. This cross-cultural perspective allowed us not only to analyze the variability in the emergence of resilient behaviors in each cultural group, but also to compare the results across groups in order to detect commonalities and/or differences.

1.1 Theoretical development and hypotheses

Recent studies have shown positive relationships between resilience, confidence to face difficulties, and perceived social support [4], as well as between resilience, positive emotionality, and expectation-achievement

congruence [5]. As these variables constitute different facets of subjective well-being, we predicted *hypothesis 1: subjective well-being will be positively related to resilience in adolescents and young adults.*

It has been reported that positive attributions made by optimists impact favorably on their immune system, and increase their well-being and resilience [6]. It has also been demonstrated that people who come out strengthened from crucial events are those with greater emotional stability and with an optimistic perspective of life [7]. Based on such evidence, we postulated *hypothesis 2: optimism will be positively linked to resilience in adolescents and young adults.*

Nielsen and Hansson [8] have pointed out that sense of humor of adolescents contributes to increasing satisfaction with their achievements, which could lead to the development of resilience. Meanwhile, other authors [9] have shown that humor is directly associated with the ability to cope with difficulties, which could also impact positively on resilience. In view of these findings, we proposed *hypothesis 3: sense of humor will be positively related to resilience in adolescents and young adults.*

The most recent empirical evidence [10] relates emotional intelligence to higher levels of life satisfaction, quality of social relations, maintenance of good health, and less somatic symptoms in stressful situations. A growing number of studies [2] link the emotional intelligence of young people and adolescents with better indices of social adaptation, and better stress management in the presence of social and academic pressures. In light of such evidence, we postulated *hypothesis 4: emotional intelligence will be positively related to resilience in adolescents and young adults.*

Other scientific findings show that resilient individuals tend to use active strategies to cope with stress [11], [12]. In this regard, it has been reported that strategies such as seeking social support and active problem solving play an important role in the process of resilience. In this line of studies, Alumran and Punamaki [6] reported significant relationships between resilience and coping focused on the task among Arabs teenagers, while Omar et al. [13] informed positive associations between resilience and strategies of active problem solving and seeking social support, among Mexican, Argentinean, and Brazilian youth and teenagers. Although a substantial body of studies shows clear relationships between resilience and positive coping strategies, it could be assumed that socialization processes play a role in such relationships. In this regard, the most current research attempt to explain whether cultural variables act as differentiating factors of resilient behavior. Values that characterize a society (especially individualism and collectivism) appear among the most frequently studied cultural variables. Utsey et al. [14] argued that collectivism contributes to subjective well-being, while individualism hinders the use of positive coping, decreasing resilient behavior. Wilson et al. [15] reported that collectivists, because of their greater need for affiliation, opt for seeking social support as a coping strategy to deal with stress. These observations are consistent with those of Pinkerton and Dolan [16], who showed that members of collectivist cultures generally have family and friends as sources of social support. It seems that these links with the primary group may have a buffering effect on the anxiety and stress provoked by postmodern hostile environments, and that perceived social support may play a crucial role in successfully coping with stress [12], thus contributing to building resilience. From such evidences, we predicted *hypothesis 5: collectivist orientation will mediate the relationship between the use of positive coping strategies and resilience among adolescents and young adults.*

Method

1.2 Participants

We worked with a sample of 1512 adolescents and young adults who attended public and private schools and universities in Argentina (n = 484), Brazil (n = 363), and Mexico (n = 665), 876 of whom were women. The age of participants ranged between 16 and 26 years (mean = 19.61; standard deviation = 2.49).

1.3 Instruments

Subjects were invited to answer a booklet prepared in its official language (Spanish for Argentineans and Mexicans, and Portuguese for Brazilians), which was designed to explore the following variables:

Resilience. It was measured using the cross-cultural adaptation [17] of the Resilience Scale designed by Wagnild and Young [18], which consists of 12 items ($\alpha = .85$) with a 5-point Likert format.

Positive coping with stress. This variable was measured using the subscales of Problem-focused strategies, and Adaptive and seeking social support strategies, from the Adolescents' Scale of Coping with Stress developed Frydenberg and Lewis [19], previously adapted for their use in the current study. The score for positive coping ($\alpha = .80$) was represented by the mean of the two subscales. Higher means indicate more positive coping.

Sense of humor. It was assessed by means of the cross-cultural adaptation [17] of the subscale Generation and Social Uses of Humor (α = .92), from the Multidimensional Sense of Humor Scale designed by Thorson and Powell [20]. The subscales consists of 5 items with a 5-point Likert format.

Emotional Intelligence. It was measured through the cross-cultural adaptation [17] of the subscales of Evaluation, expression and regulation of emotion, and Uses of emotion, from the Emotional Intelligence Scale developed by Schutte et al. [21]. Each subscale consists of 11 items with a 5-point Likert format. The total score of emotional intelligence (α = .86) was represented by the mean of the scores on the two subscales.

Optimism. It was examined with the homonymous subscale of the cross-cultural adaptation [17] of the Optimism-Pessimism Scale published by Dember et al. [22]. Optimism subscale consists of 8 items (α = .94) with a 5-point Likert format.

Subjective well-being. It was measured using the cross-cultural adaptation [23] of the homonymous scale developed by Nacpal and Shell [24], which consists of 21 items (α = .81) with a 5-point Likert format.

Personal values. These were assessed with the cross-cultural adaptation [17] of the subscales of Horizontal Collectivism (α = .80) and Vertical Collectivism (α = .87) from the Values Scale developed by Singelis, Triandis, Bhawuk, and Gelfand [25]. Each subscale consists of 8 items with a Likert 5-point format.

1.4 Procedure

Participants were contacted during school hours in their classrooms. After informing them of the objectives of the research, they were invited to participate in the study. Only subjects who voluntarily agreed to participate took part in the research. They all signed an informed consent protocol and/or had the written consent of their parents, depending on their age. Anonymity and confidentiality of the information provided was guaranteed.

1.5 Data analysis

First, descriptive indices (means and standard deviations) for each measured variable were calculated considering country of origin of the subjects. Then, with the purpose of comparing means across the three nationalities considered, analyses of variance (ANOVA) were calculated. Since these analyses yielded no statistically significant differences, the total sample was considered as a single group. Next, in order to determine the contribution of each variable to the variance of resilience, a stepwise regression analysis was calculated. Finally, with the aim of understanding the role of personal values (HC: Horizontal Collectivism, and VC: Vertical Collectivism) in the relationship between resilience and coping, mediated regression analyses were calculated. In each of these analyses, positive coping was entered as the independent variable, and resilience as the dependent variable. We used the process developed by Baron and Kenny [26] to determine the mediation effect.

Results

Stepwise regression analysis was used to test hypotheses 1-4, entering psychosocial variables as predictors, and resilience as the dependent variable. In step 1, the variable well-being contributed significantly to the regression equation, accounting for about 19% (ΔR^2 = .189) of the variance in resilience. In step 2, optimism contributed with 9.8% to the total variance (287-189 = .098), whereas sense of humor, incorporated in step 3, contributed with an additional 2.8% (.315 - 287 = 028). Finally, emotional intelligence, incorporated in step 4, contributed with a reduced 1.3% to the total variance (328 - 315 = .013). Taken together, the predictor variables accounted for 32.8% (18.9% + 9.8 + 2.8% + 1.3% = 32.8%) of the total variance, and values (and signs) of the standardized beta coefficients (β) indicated that although all emerged as explanatory variables, well-being and optimism were the constructs that better explained resilience. Such results gave full support for hypotheses 1-4, which postulated the predictive role of subjective well-being, optimism, humor, and emotional intelligence on resilience.

Next, and in order to test hypothesis 5 which predicted the mediating role of collectivism in the relationship between resilience and positive coping, two separate mediated regression analyses were calculated (one for HC and another for VC). In each of these analyses positive coping was entered as the independent variable, resilience as the dependent variable, and collectivist orientations (HC and VC) as the mediating variables. The results gave partial support for hypothesis 5, since only horizontal collectivism orientation emerged as a mediator in the relationship between positive coping and resilience.

Conclusions

From the verification carried out on large samples of young Argentinean, Brazilian, and Mexican adolescents, information is now available about the predictive role of some human strengths and positive qualities (subjective well-being, sense of humor, optimism, and emotional intelligence), as well as about the mediating role of horizontal collectivism in the relationship between positive coping and resilience. Variables that showed a greater explanatory power were the perception of subjective well-being and optimism, while sense of humor and emotional intelligence made a smaller contribution. Such findings are in line with those previously reported by other researchers who have worked with samples from other countries. Regarding the role of subjective well-being, it has been reported that most of the dimensions of this construct (such as achievement of personal goals, confidence in facing difficulties, and the experience of positive emotions) have a positive impact on the development of resilience [5], [15], [27]. As far as optimism is concerned, it has been repeatedly informed [28] that it may act as an important source of resilience among both children and adults.

With respect to the limited predictive ability of sense of humor, one might assume that because they are adolescents and young people, they still have not learned to use humor to cope with difficulties and to overcome adversity. In this sense, although researchers agree on the benefits of humor to overcome adversity, they also agree on the need and importance of implementing programs to increase it as an effective mechanism to enhance control of stressors, problem solving, social skills, and interpersonal relationships [9]. Such interventions may contribute to developing mechanisms through which the use of humor may positively influence overall health.

As for emotional intelligence, the reduced predictive ability of this variable could be attributed to the selection of the subscales used in this study to measure this construct (Evaluation, expression and regulation of emotion, and Uses of emotion). This limitation coincides with that reported by Zeidner et al. [10], who pointed out that not all of the multiple facets of emotional intelligence are equally important for the development of resilience, since only positive beliefs about one's own social skills in interpersonal relationships may play the role of a protective factor.

Regarding the impact of personal values on the relationship between resilience and positive coping, the results indicate that horizontal collectivism mediates the relationship between these two variables. To properly interpret this finding, it is worth considering, at least, two crucial aspects. First, we must not lose sight of the fact that since psychology has begun to recognize the contribution of culture to mental health, different models have been proposed with the intention of explaining how cultural variables impact on the healthy functioning of people. In this regard, for example, Utsey and his colleagues [14] explain that collectivist cultures emphasize interrelationships and the connection with extended family and, precisely, these are the components that make up their coping strategies. Such observations are consistent with those of Pinkerton and Dolan [16], who showed that members of collectivist cultures generally have family, friends and neighbors as sources of social support. The perception of this type of social support not only plays a crucial role in successfully coping with stress, but also contributes to well-being and resilience. Second, we must not overlook that the horizontal and vertical attributes are proper to the power distance dimension, associated with the degree to which members of a society accept an unequal distribution of power, prestige, and wealth. When Triandis and his colleagues [25] enriched the axiological typology proposed by Hofstede [29], combining the dimensions of individualism and collectivism with the attributes of horizontal and vertical, they gave rise to the constructs of vertical individualism and vertical collectivism (if the emphasis is on differences in status and hierarchies) and horizontal individualism and horizontal collectivism (if the emphasis is on equality in status). The results obtained in this study indicate that collectivist orientation (characterized by perceiving oneself similar to other members of the group, especially in social status and position) would influence the relationship between resilience and the specific use of positive coping strategies among adolescents. So it could be concluded that the orientation to collectivism, imbued with the sense of equality, would be a mediating factor between the adolescents, the demands of the environment, their resources to deal with such demands, and the development of resilience.

Like all empirical research, the present is characterized by certain strengths and limitations. Among the latter, we should point out the composition of the sample under study. The convenience sampling method would limit the generalization of the results to the whole population of Argentinean, Brazilian, and Mexican youth and adolescents. Another limitation of the study would be linked to the self-report nature of the instruments we used for data collection, which could have generated both biases resulting from common method variance [30], as well as a greater tendency toward social desirability. For this reason, it would be desirable that future explorations incorporate one of the many reliable and available social desirability scales, as well as other data collection techniques, such as observations, interviews, focus groups, or similar. In this sense, our proposal would be to address the problem from a real methodological triangulation, avoiding paradigmatic subordinations.

With regard to the strengths of the current study, it is noteworthy that it represents a significant contribution to understanding the relationship between resilience and some psychosocial variables, highlighting the impact of cultural values. In this sense, it would be particularly desirable that both schools and government agencies contribute to raising awareness about the predictive role of human capabilities and strengths, as well as about the moderating role of personal values on the development of resilience in youth and adolescents. These

suggestions are aimed at implementing new explorations with samples from different cultures, which might also include other constructs potentially linked with resilience, as well as some of the protective factors, at either the institutional, familiar, communal and/or social level. Furthermore, it would be interesting not only to consider other countries as a way to build a truly representative body of knowledge of the Latin American reality, but also to incorporate contrasting samples in terms of their basic cultural values, in order to gather more evidence about how the cultural context may contribute to resilience by promoting healthy adaptation.

Qu'est-ce qu'a a dire la resilience au sujet du bullying (l'intimidation)

Sánchez J.

Psychologue du Decanatura de Estudiantes, Universidad de los Andes (LA COLOMBIE)
js81103@gmail.com

Abstract

This work is a theoretical and practical contribution for applying the concept of resilience in the therapy of children involved in bullying, and which are "victims" of it.

From the concept of "shame" developed by Boris Cyrulnik [1], the text shows how the child who commits violence, feels ashamed of himself and fear that the other knows and makes public its weakness, deviates the others regard and make a falsehood of its apparent strength. Thus, the attacker is presented as strong in his attack on the child, perceived as weak. In turn, the child who is identified as a victim is a child by excess protection or failure to act, which has not developed an ability to deal with confrontation. For out of the problem it seeks the support of third (of others), which confirms its weakness. The purpose of this therapeutic work share the importance of strengthening each child protagonists of this story, for they get to change the feeling of shame related to a relationship and allow their work with his weaknesses.

That's when the bullying is understood how a situation that can be used as a pretext for a new representation of oneself.

Key words: Bullying (bullying), Resilience, Shame, re-signification, complexity

Penser au travail avec et sur le Bullying fait revenir dans la mémoire une série d'images et de conversations avec enfants et adultes ayant été soit victimes, soit victimaires de harcèlement. Dans ces images, on trouve des enfants ayant été intimidés, des enfants ayant suivi une thérapie parce qu'ils intimidaient leurs camarades et étaient difficiles à mener, des adultes qui ont eu des difficultés causées par le harcèlement qu'ils avaient subi pendant leur enfance; mais, curieusement, on ne trouve aucun adulte qui eut été harceleur et qui ait discuté ce sujet en thérapie. Alors, il est inévitable de se demander, où sont les adultes qui ont harcelé pendant leur enfance? Ont-ils subi une transformation qui leur a permis de s'intégrer tranquillement à la vie?

Les contes de fées ont marqué notre façon de voir le monde, divisant celui-ci en «bons» et «mauvais».Cette vision simplifie les histoires de vie –naturellement plus «complexes» (concept largement développé par Morin) – négligeant la multiplicité de récits qui se récréent dans l'interaction avec les autres, et ainsi limite les thérapeutes au moment de faire une intervention. La plupart du temps, lorsqu'on parle du Bullying, on a l'habitude de faire une lecture antagoniste. Dans cette lecture on assume qu'il y existe un individu «bon» et un autre «mauvais», autrement dit, une victime et un victimaire. Ce dernier, dans le meilleur des cas, est excusé parce qu'on suppose que l'enfant qui manifeste ce type de comportement a été ou est victime de agression –ce qui le pousse à agresser et profiter des autres.

Pour rendre compte de l'énoncé on discutera deux histoires. Celles-ci illustrent plus clairement le travail clinique réalisé afin de donner une réponse à cette problématique. On appellera Juana le personnage principal de notre première histoire. Il s'agit d'une petite fille de dix ans qui arrive accompagnée par sa mère en thérapie parce qu'elle se sent incapable de contrôler la situation de harcèlement qu'elle subit au lycée. Pour la deuxième, on nommera le protagoniste Pedro, un enfant d'environ 12 ans qui continuellement harcèle ses compagnons. (Les noms utilisés ne correspondent pas à ceux des enfants avec lesquels on a travaillé.) Le thérapeute commence à travailler avec lui à cause de certains problèmes qu'il a dû assumer dans sa vie et à cause de son comportement agressif. Pedro habite dans une institution, avalée par l'État colombien, qui s'occupe du soin d'enfants ayant vécu une situation d'irrégularité dans leur milieu familial. Il doit demeurer dans cette institution jusqu'à qu'une décision soit prévue au sujet de sa résidence et ainsi garantir sa place dans un foyer en sécurité.

Le réseau social qui existe autour de ces personnages est généralement mis en mouvement chaque fois que l'un d'eux agit, ainsi une synergie face à la situation est générée. Quand un sub-système est activé, un

système relationnel est à son tour mis en mouvement: celui-ci s'autorégule avec le seul but de maintenir un patron (phénomène démontré par Bateson). Et ceci peut aggraver le problème.

Mais, que comprenons-nous par *bullying* ou «matoneo» (mot utilisé en Colombie, construit avec le verbe «tuer»)? Il s'agit d'une agression systématique et répétée qui est exercée par une ou plusieurs personnes contre un tiers [2] dans laquelle il y a une volonté manifeste de nuire l'autre avec des comportements de provocation directe ou indirecte, propre à une relation asymétrique [3].

Pendant l'entretien le thérapeute perçoit que Juana est une petite fille renfermée qui a du mal à parler de ses émotions, penche son corps et fuit le contact visuel. Lorsqu'on lui pose une question, elle cherche le regard de sa mère en attendant qu'elle réponde à sa place. Sa mère parle angoissée de la situation qui se présente dans le lycée de sa petite fille: Juana lui a confié que ses camarades l'intimident et la harcèlent. Les enfants profitent des compétences académiques de Juana et la forcent à faire les devoirs pour eux. En plus, ils l'insultent quand elle marche dans les couloirs du lycée, lui donnent des surnoms, la frappent et cachent son sac-à-dos ainsi que d'autres objets personnels.

Lorsque le praticien enquête sur les solutions prises jusqu'à présent pour résoudre la situation, c'est-à-dire les Solutions Tentatives, outil précieux fourni par la Thérapie Stratégique [4] la petite indique que sa mère lui avait conseillé de ne pas faire attention aux insultes; néanmoins, son conseil avait été peu efficace. Elles ont donc décidé de contacter les professeurs du lycée. Ceux-ci ont, à leur tour, parlé avec diligence aux enfants qui harcelaient Juana. Les enseignants ont expliqué aux élèves les effets que leurs comportements pouvaient avoir sur une fille comme Juana et ils leur ont clarifié que, dans le cas où le harcèlement continuait, ils devraient subir les conséquences de leurs actes.

Néanmoins, en absence des professeurs, les enfants ont continué avec l'intimidation. De plus, ils ont menacé les autres élèves de la classe: s'ils refusaient de poursuivre les moqueries ils deviendraient similaires à Juana, c'est-à-dire, «rares», «nuls» et «ennuyeux». Ainsi, Juana a été rapidement isolée du groupe. Quand elle rentrait à la maison, sa mère, avec l'espoir de la faire sentir protégée, lui posait des questions sur sa journée scolaire. Initialement, Juana lui racontait en détail les évènements de la journée. Cependant, peu à peu, elle a commencé à taire ce qui se passait à l'école et limitait ses réponses à de simples monosyllabes. Néanmoins, prise par le désespoir, elle éclatait en larmes et admettait que la situation empirait.

En ce qui concerne Pedro, il s'agit d'un enfant qui parle très peu de ses émotions, qui a du mal à fixer le regard et qui penche son corps lorsqu'il doit parler au sujet de ses difficultés. En présence d'adultes, il fait de son mieux pour devenir invisible. Ce comportement disparaît lorsqu'il harcèle un autre enfant. Au contraire, Pedro est perçu par ses pairs comme un enfant sûr de lui. Cette situation conduit certains enfants à obéir à ses incitations d'intimidation d'un autre enfant de l'Institution. Ces enfants reproduisent les insultes, injures, moqueries et autres agressions. Le harcèlement psychologique dégénère parfois en violence physique. Quant au reste du groupe, face au harcèlement il préfère garder le silence. Dans le cas de Pedro, l'agression se présente même en présence de ses responsables. Il perd régulièrement le contrôle de soi et commence à briser certains objets de l'Institution. Les mêmes solutions que pour le cas de Juana ont été mises en place (Solutions Tentatives): les enseignants ont parlé avec lui dans le but de le ramener à la raison et il a été puni avec l'élimination de certains privilèges. Parallèlement à cela, on a conseillé à l'enfant harcelé d'éviter de réagir face aux provocations de Pedro et de signaler les abus aux adultes.

Ces solutions ne sont que temporelles, et l'intimidation ne cesse pas de manière définitive. Au contraire, Pedro obéit de moins en moins, son comportement est encore pire face aux personnes qu'il ne perçoit pas comme figures représentatives de l'Institution. D'ailleurs, cela conduit à demander le soutien de l'Avocat de Famille (avocat chargé de travailler avec le cas d'enfants en situation de danger). L'Avocat de Famille, une autre autorité, parle avec l'enfant et tente de le transformer. Ainsi le nombre d'agents augmente.

Pourrait-il y avoir quelque chose en commun entre les deux personnages? La difficulté pour faire face à un problème: les deux enfants sentent qu'ils ne possèdent pas la force nécessaire ni les moyens suffisants pour s'en sortir. Cette situation se produit à cause d'une protection excessive ou de l'absence d'un environnement protecteur. Ceci, les a empêchés de développer les outils pour affronter une situation où leur confiance en eux est menacée. Évidemment, cette faiblesse n'accompagne pas les enfants dans tous les domaines de leur vie. Par exemple, Juana est très bonne académiquement et ne présente aucun problème pour assumer les défis des travaux scolaires. Pedro est habile dans les activités où sa motricité est mise en jeu –tel que grimper, jouer au football, etc.

Il est évident que les deux enfants éprouvent un sentiment de pénible humiliation. La *honte* les conduit à taire ce qu'ils considèrent une imperfection, signale Cyrulnik: «Puisque le silence établit une fonction défensive, la révélation du secret met en danger celui qui parle»[1]. Les deux enfants évitent le regard de l'Autre parce qu'ils craignent que leurs faiblesses soient mises en évidence. Cyrulnik d´un manière savante explique: une personne qui a honte est susceptible de penser «Je ne supporte pas de voir que vous me voyez dans cet état. Votre regard me transperce jusqu´à mon intime médiocrité» [1]. Ainsi, l'enfant sent que le regard d'autrui fait sa faiblesse visible. Ce regard devient par conséquent un fardeau.

L'enfant objet de harcèlement parle des agressions aux adultes seulement quand il est désespéré. Ce désespoir surgit à cause de l'isolement qu'il subit au lycée: il est humilié constamment face à ces camarades–sa faiblesse est continuellement rappelée– et donc ceux-ci commencent à l'écarter. De plus, souvent l'enfant ne trouve pas comment sortir de cette situation, alors, la *honte* augmente. Celui qui pratique le *bullying* détecte habilement la faiblesse de l'autre: il peut identifier le point de vulnérabilité de l'enfant qu'il harcèle, celle si coïncide avec le éloignement du groupe. Autrement dit, le harceleur annule socialement sa victime. On peut alors affirmer que le mot utilisé en Colombie et en Argentine pour signaler ce type de comportement illustre bien son objectif: «Matoneo», c'est-à-dire, tuer l'autre symboliquement.

L'enfant agressé se trouve face à un paradoxe lorsqu'un adulte, ou même un de ses pairs, prend en charge la situation: lorsqu'il reçoit du soutien (comme substitution) il est convaincu de son incapacité, il ne peut pas s'en sortir par ses propres moyens. Donc, la sensation d'inutilité est accentuée par rapport à la relation avec l'Autre. Par conséquent, lorsque l'enfant agresseur est renvoyé du lycée, celui qui a été harcelé est sensible de penser: «Que va-t-il arriver lorsqu'un autre enfant identifie ma faiblesse?».

D'un autre côté, le harceleur cache de son mieux son point de vulnérabilité en agressant l'Autre. Il dirige le regard envers l'Autre pour éviter que sa propre faiblesse soit évidente. Ce comportement le situe dans un paradoxe relationnel. Il s'identifie comme une personne fragile. S'il avoue la *honte*, les autres ne le respecteront plus et il deviendra la nouvelle cible du *bullying*. Mais, s'il ne parle pas de ce qu'il perçoit comme son point d'inflexion, celui-ci ne changera jamais de forme –puisqu'il refuse de nommer sa faiblesse il ne pourra pas réparer cette représentation négative de lui-même. Et donc, sociabiliser devient impossible. Ainsi, l'enfant ne se sent jamais satisfait dans la relation qu'il entretient avec les autres.

Tous deux vivront comme Sanson, avec la crainte de que quelqu'un coupe leurs cheveux. Si la vie ne conduit pas ces deux personnages à trouver un évènement ou une conversation qui leur permette de reconstruire leur faiblesse, il faut se demander, comment peuvent-ils porter leurs cheveux. Surtout l'enfant qui a exercé le *bullying*; généralement il est moins en mesure de partager sa faiblesse avec un autre parce qu'il est perçu comme un individu fort.

Le système relationnel doit éviter de faire partie du problème en protégeant celui qui est harcelé: en bloquant l'agresseur grâce à des argumentations et punitions dans le but de l'obliger à avoir un comportement adéquat ou le renvoyer du lycée.

Deux messages superposés existent lorsqu'on offre de l'aide [5]. Le premier: «ce qui arrive est injuste, je t'apprécie et donc je te soutiens et je ne permets pas que ceci se reproduise ». Ce premier message ne posse aucun problème puisqu'il fait sentir l'enfant estimé. Le deuxième sème le doute: «tu n'es pas capable de sortir du problème par tes propres moyens, tu as besoin de moi». Avec ce message, l'insécurité de l'enfant est augmentée puisqu'il se sent encore plus incapable de ce qu'il ne l'était avant d'être protégé. La seule possibilité de transformation qui peut se produire chez un enfant agressé serait de créer des stratégies qui augmenteraient progressivement sa confiance et ainsi sa capacité à se défendre. À son tour, la seule possibilité de transformer l'agresseur est qu'il comprenne qu'il peut entretenir une relation avec les autres sans être menacé et qu'il puisse parler de sa «faiblesse».

Il est inévitable sentir qu'il y a des points de faiblesse dans la vie. La reconnaissance et l'exploration de ces points nous permettent d'enrichir la vision de soi-même. Le problème s'origine quand ces «faiblesses» ne peuvent être re-signifiées.

Ici on propose de travailler avec pour logique, la résilience. Selon ce concept, la difficulté et le traumatisme –lorsque re-signifiées– permettent à la personne de se fortifier. Toutefois, sous la définition stricte de la résilience, il est nécessaire de partir d'un traumatisme qui permettra para la suite d'en parler.

La plupart des situations de bullying génèrent chez les personnes harcelées des traumatismes. Dans le cas de l'agresseur, la situation traumatique se présenta peut-être antérieurement ou peut se produire comme résultat d'interventions réalisées par le système relationnel.

Une des interventions proposées fait appel à la logique thérapeutique développée par Giorgio Nardone [5]. D'après celle-ci, la solution doit maintenir la même structure que le problème. Le professeur ou adulte en charge doit remercier l'agresseur pour le sacrifice qu'il est en train de faire en s'exposant à l'humiliation et au pointage puisque le seul but de son harcèlement est de forcer le regard des adultes envers un enfant qui a besoin de soutient. On pourrait, à son tour, ordonner à Juana (comme fait en thérapie brève) d'aller chez l'enfant qui l'agresse et remercier ses agressions et autres injures puisque chaque fois qu'il l'insulte cela l'aide à devenir encore plus forte –elle lui demanderait alors de continuer avec les insultes-. De cette façon, on parvient à faire rentrer l'enfant agresseur dans un paradoxe relationnel où le harcèlement perd son sens.

La thérapie «Narrative» développée par White [6] est une autre possibilité. Celle-ci propose réaliser une déconstruction du récit dominant à travers le dialogue. Dans le cas de Juana, le récit dominant raconte une histoire où il y a une fille faible et un garçon fort, définitions d'une caractéristique identitaire. Il est conseillé de chercher, en sortant d'une vision saturée du problème, à créer une narrative où ces structures soient mises en question et ainsi ouvrir les possibilités d'une lecture différente et d'actions de transformation. L'externalisation

du problème est un outil thérapeutique clé dans la thérapie narrative. L'externalisation permet à l'enfant de différencier le problème de son identité, de devenir un agent actif et ainsi, de s'en libérer du problème.

Dans les thérapies avec des enfants comme Juana –enfants qui s'identifient comme des êtres "faibles"– il est important que la faiblesse soit extériorisée dans une conversation pour pouvoir la différencier de l'identité même. Il est nécessaire de poser des questions comme: «Quand est-ce que la faiblesse te rattrape?»; "Es-tu capable de vaincre cette faiblesse?»; "Que font les adultes lorsque la faiblesse te rattrape?»; «Comment sera le jour où la faiblesse ne parviendra pas à t'affecter?»; entre autre. Postérieurement, le thérapeute doit fournir des stratégies créatives où le patient fait partie du processus de planification: la victime peut alors se transformer en acteur actif, en proposant des solutions au conflit et, ainsi, gagner la lutte contre la faiblesse.

Dans le cas de Pedro on peut utiliser la même ressource: externaliser la difficulté. Par exemple, demander: «Quand est-tu influencé par *l'agresseur féroce*, celui qui te fait dire ces choses aux autres enfants?»; «Que se passe-t-il avec les adultes quand *l'agresseur féroce* t'oblige à acculer un enfant dans l'institution?»; «Comment, d'après toi, pourrait être le jour où tu réussiras à vaincre *l'agresseur féroce*?». Ceci n'étant que quelques exemples de questions pouvant le mener à se détacher du problème.

Il est nécessaire de connaître en profondeur ces deux thérapies pour pouvoir les mettre en place de façon adéquate. Le principal dans les deux thérapies est que la *honte* de la victime et du victimaire soit modifiée dans la relation avec l'Autre.

Quand la résilience est activée, le cerveau se transforme, fait qu'on ne peut pas ignorer. Ces changements sont semblables à ceux produits par nos actions face à n'importe quelle situation ou lorsque on fuit pour ne pas affronter un évènement de notre vie. Accompagner l'enfant qui agresse et l'enfant agressé dans la réparation de la *honte* est fondamental. Kevin Ochsner et ses collègues de l'Université de Columbia [7] affirment qu'une transformation se produit dans le cerveau au niveau du cortex préfrontal lorsqu'on parvient à faire une réinterprétation d'une situation considérée comme négative précédemment –cet organe nous permet de planifier, adresser et inhiber certains comportements. De même, l'activité de l'amygdale –centre qui opère quand on a peur– diminue.

Dans ce sens, une situation de Bullying peut être vue comme une opportunité pour qu'un enfant, un adolescent, un jeune adulte puisse développer la gestion de ses émotions au niveau neurologique et ainsi, avoir plus d'outils pour faire face aux difficultés qu'il trouvera tout au long de la vie.

Abstract

Cumulative risk is one important threat to positive development in adolescence. This study aims to contribute to a further understanding of the cumulative risk effect on different outcomes and how protective factors can moderate its impact.

The sample included 2840 adolescents, 46% boys, mean age 14 years old, in the 6th, 8th and 10th grades of the public school system from Portugal. Data collection was held within the Health Behaviour in School-aged Children (HBSC) survey. For the purpose of this specific study, the questionnaire included questions concerning socio-demographic and behavioural risks, health related quality of life, psychological symptoms, academic achievement, substance use, and environmental and internal resilience assets.

Results showed three different risk effects: a cumulative effect, as referred by Rutter (1979), for substance use, where the significant impact of risk is possible to observe only in the presence of four or more risk factors; a linear effect for academic achievement, where it is possible to verify that each risk factor contributes to a significant decrease in academic achievement; and an effect, between the above mentioned cumulative and linear effects, for health related quality of life and psychological symptoms, where there is a significant increase of psychological symptoms, or decrease of health related quality of life, only in the presence of three risk factors, that is accentuated again in the presence of four or more risk factors. In this context, and for the different outcomes, moderator effects of environmental and internal resilience assets are also explored and discussed.

Keywords: Adolescence, risk effects, protective moderator effects, health related outcomes

Introduction

It is commonly recognized that family poverty and stress, exposure to family or community violence, maltreatment, divorce, poor schools, school disengagement, and lack of local resources constitutes a severe environmental hazard to children's adaptive and healthy development [1]. Several studies refer that children living in these contextual conditions are at greater risk for developing externalizing and internalizing problems [2, 3, 4, 5], such as substance use, psychopathology across the life span [3, 6, 7], poor quality of life [8, 9], and poor academic achievement [1].

Research has shown that generally, in adverse circumstances, risks tend to accumulate [10]. Moreover, in a cumulative risk context, there appears to be a consistent and strong negative relationship between the number of risk factors that children are exposed and their adaptive functioning [11, 12]. Cumulative risk can act through different mechanisms: the presence of multiple risk factors; multiple occurrences of the same risk factor; or the accumulating effects of ongoing adversity [13].Different effects had been reported for cumulative risk. Some studies refer an additive effect [7], or a linear effect, where each risk factor has a significant impact on the outcome, namely some studies found this effect on academic performance [1]. Other studies point to another kind effect, an exponential effect, generally known as cumulative risk, where the combination of four risk factors quadruplicates the likelihood of maladjustment, comparatively with the combination of three risk factors [14]. This hypothesis, emphasizes to a large extent the quantitative aspects of risk as the crucial question comparatively to the qualitative aspects of risk [15, 16].

Those findings point to the conclusion that when children experience significant dysfunction at home and at community environments, their risk for maladjustment and poor health outcomes becomes substantially higher. That comes in line with research showing that if children are faced with continuing and severe assaults from external environmental risks, they cannot sustain a resilient adaptation over time [17].

However, it is essential to highlight that these risks interact with adolescents internal and environmental (family, friends, teachers) assets and in some case this can revert the negative effects of risk factors [18, 19]. Some of these assets and effects are going to be under analysis in this study. This study aims at:

(1) Verifying the relationship between cumulative risk and different health outcomes (substance use, psychological symptoms, health related quality of life,) and academic achievement;
(2) Verifying if internal resilience assets (social and emotional competences) and environmental assets (family social capital, friends' social capital) are moderators of the relationship between cumulative risk and the different outcomes.

Method

1.1 Sample

The sample included 2840 adolescents, 46% boys, aged from 11 to 18 years old (M=13,95; SD=1,80). Data collection was held within the Health Behaviour in School-aged Children (HBSC) survey [20, 21].The study provides nationally representative data of Portuguese adolescents, from 139 Portuguese public schools using cluster sampling with class as the basic sampling unit (28.2% were attending the 6th grade, 31.4% the 8th grade and 40.3% the 10th grade).

1.2 The survey

The main HBSC survey included questions on different aspects of adolescent behaviour and life style [more details about the survey variables can be found in Matos, et al. (2012)]. For the purpose of this specific study, the following variables were used for different purposes:

- Cumulative risk index – father and mother employment, family structure, school satisfaction, skipping classes, and bullied at school;
- Outcomes variables - school achievement, psychological symptoms (3 items), health related quality of life (10 items), substance use (tobacco, alcohol and cannabis – 3 items);
- Moderator variables: Internal resilience assets scale (18 items), family social capital (4 items), friends and other relevant social capital (8 items), teachers relationship (3 items).

1.3 Procedure

Data were collected through anonymous self-completion questionnaires administered in the classroom by teachers [details about the survey procedures can be found in Roberts, Tynjälä, Currie, & King [22]. During the data collection procedure, a letter was sent to all the selected schools with the questionnaires and the information about procedures. The questionnaire took about 60 to 90 minutes to respond. The study had the approval of a Scientific Committee, the National Ethics Committee and the National Commission for Data Protection and followed strictly all the guidelines for human rights protection.

1.4 Analysis

SPSS Statistics 21 was used in data analysis. To obtain the cumulative risk index, each of the six variables were categorized into two categories (0=father/mother have a job, nuclear family, like school, doesn't skip classes, not victim of bullying; 1=father/mother doesn't have a job, single parent or reconstructed family, doesn't like school, skipping classes, victim of bullying). The six dichotomous variables were summed to obtain a score from zero to six. The outcome variables, namely substance use related variables, health related quality of life items, and psychological symptoms variables, were submitted to an *optimal scaling* procedure [see Simões, Batista-Foguet, Matos, & Calmeiro [23], for more details].The object scores were saved to obtain these three outcome factors. For the academic achievement the variable Z score was used. For the moderator variables, reliability analysis were conducted with the items of each moderator under study (internal assets α=.93; family social capital α=.92; friends and other relevant social capital α=.91; teachers relationship α=.64). After the reliability analysis, the items of each scale were summed to obtain the summative scales score. For the moderation analyses, the summative scales scores were categorized in two categories (1=low/medium scores; 2=high scores). In the analyses of variance, when homogeneity of variance wasn't verified, robust tests of equality of means (Brown-Forsythe) were used.

Results

Table 1 presents descriptive statistics for the cumulative risk index, outcomes and moderator variables. Since the last two categories of cumulative risk index had a small number of cases, they were aggregated to the fourth category.

Table1. Frequencies and percentages of cumulative risk index, mean values, standard deviations, maximum and minimum values of outcomes and moderator variables

Variable/Factor								
Cumulative Risk Index		**0**	**1**	**2**	**3**	**4**	**5**	**6**
%		13,7	21,1	31,1	22,3	9,0	2,5	0,3
Outcome variables/factor		**Min.**		**Max.**		**Mean**		**SD**
Substance use		-.37		9,84		0.00		1,00
Psychological symptoms		-.78		3.11		0.00		1,00
Health related quality of life		-.2.56		1,51		0.00		1,00
Academic achievement		-.2.03		2.04		0.00		1,00
Moderator variables								
Internal assets	Low/Medium	54.03		8.71		18		63
	High	76.14		7.33		64		90
Family social capital	Low/Medium	18.85		4.92		4		24
	High	27.21		1.06		25		28
Friends social capital	Low/Medium	38.64		9.80		8		48
	High	53.77		2.38		49		56
Teachers relationship	Low/Medium	5.07		1.03		3		6
	High	8.57		.50		7		9

1.5 Relationship between cumulative risk and different health outcomes (substance use, psychological symptoms, health related quality of life) and academic achievement

Four one-way ANOVA were carried out to analyse the relations between cumulative risk and health related outcomes and academic achievement. The variance analyses reveals a significant effect for cumulative risk on all the outcomes under study (substance use: $F4, 2652=12.37$, $p<.001$; psychological symptoms: $F4, 2652=14.74$, $p<.001$; health related quality of life: $F4, 2652=18.92$, $p<.001$; academic achievement: $F4, 2652=46.91$, $p<.001$). Despite reaching statistical significance, the effect size, calculated using eta squared, was small for the majority of the outcomes (.02 for substance use and psychological symptoms and .03 for health related quality of life). Only for academic achievement a medium effect size was verified (.07). Post-hoc comparisons using the Scheffe test (for academic achievement) or Dunnett T3 (for health related outcomes) indicated the present of different types of effects. For substance use, a cumulative effect was verified, as previously described, which means that only in the presence of four or more risk factors the levels of substance increase significantly. No differences were found between previous levels of risk (0 to 3). For academic achievement a linear effect was verified, after the first risk factor (no differences were found between no risk factors and one risk factor) where is possible to verify that each risk factor contributes to a significant decrease in academic achievement. For health related quality of life and psychological symptoms an effect between the above mentioned cumulative and the linear effects was verified, where there is a significant increase of psychological symptoms, or decrease of health related quality of life, only in the presence of three risk factors, that is accentuated again in the presence of four or more risk factors.

1.6 Internal and environmental resilience assets as moderators of the relationship between cumulative risk and health and academic outcomes

Since it was verified a significant relation between cumulative risk and health and academic outcomes, four sets two-way ANOVA's (one for each outcome) were carried out in order to see whether internal resilience assets (IA) and environmental assets (family social capital–FamSC, friends and other relevant-FriSC, teachers relationship-TR) can mitigate the effect of cumulative risk (CR) over the outcomes under study. The results are presented in Table 2.

Table 2. Two-way Anova: main effects and interactions of internal and environmental assets, and cumulative risk, and effects size (η^2) for the four outcomes

	Substance Use	Psychological Symptoms	Health Related Quality of Life	School Achievement

As shown in Table 2, only one significant interaction, between cumulative risk behaviour, and family social capital, for school achievement was significant, although with a very small effect size. Nevertheless, significant main effects of cumulative risk (as mentioned in the previous analysis, with medium effect size for school achievement) and internal and environmental assets were obtained. Internal assets present a significant main effect on school achievement, which means that independently of the cumulative risk, adolescents that have higher internal assets present a better school achievement. For the environmental assets, it was possible to verify that family social capital, and teachers' relationship have a significant and positive effect on every outcomes (adolescents with higher levels on family social capital and teachers relationship present lower levels of substance use and psychological symptoms, and higher levels of health related quality of life and school achievement). The same occurs with friends' social capital, except for school achievement, where friends' social capital didn't show a significant effect. Again, for these main effects, the effect sizes were, generally, small. A medium effect size was found for the family social capital on health related quality of life.

Conclusions

Cumulative risk presents an important threat to adolescent well-being and positive development. Our results support the theoretical framework stressing the impact of cumulative risk. We found that there is a significant impact of risk in all of the four outcomes under study (substance use, psychological symptoms, health related quality of life, and school achievement). This impact is higher on school achievement, as revealed by a medium effect size. For these results it may contribute the fact that in the composition of the cumulative risk index, three of the variables are school related variables (school satisfaction, skipping classes and bullied at school). Notably cumulative risk acts differently according to the outcome under analysis. For substance use, a cumulative effect was verified. This finding is similar to the one described by Rutter [14] and verified in other studies [15, 16], since the effect of risk is significantly higher in the group that refers four or more risks, comparatively to the groups that have fewer than four risks. Thus it appears that the risk only acts promoting a significant increase in substance use when it becomes accumulated. For school achievement another kind of effect was verified, a linear or addictive effect as mentioned by other authors [1], was verified after a non-significant impact of the first risk factor, where each risk factor contributes significantly for a progressive decrease in academic achievement. For psychological symptoms and health related quality of life, again a different effect was verified, which can be described as being between the previous mentioned effects. For these outcomes, we found that the first two risk factors don't present a significant impact, but that happens with the third risk factor and again with fourth risk factor.

The search for moderators of these cumulative risks had only revealed a small but significant effect of family social capital on school achievement. All the other internal and environmental assets analysed only appeared as protective factors. Family social capital and teacher's relationship present a significant protective effect for all outcomes under consideration, since adolescents that present higher levels of these assets present lower levels of involvement in substance use and psychological symptoms, as well as a better health related quality of life and higher school achievement. Internal assets present a protective effect only for school achievement and friends and other relevant for all outcomes, except for school achievement.

The findings should be interpreted within the limitations of this study, namely the cross-sectional design and potential errors or bias. Notwithstanding this limitation may have been overcome since our study used a large sample of adolescents with sampling procedures that ensured a nationally representative sample. Finally the procedures to define the cumulative risk variable were created considering similar weight of each item, and it may be the case that each item score has varying levels of weight for the cumulative risk.

Nevertheless, our results point towards two important directions in adolescent resilience: (1) the reduction of risk exposure and its effects, since cumulative risk impact significantly, and negatively, on health and academic outcomes; (2) the importance of internal and external resilience assets promotion, since they act as protective factors for positive outcomes. A special attention to the role of families should be taken in consideration, as well as embrace them as crucial partners for resilience promotion interventions, as it already is advocated in some of these programs [24].

Break rules behavior problems of children in long term foster care: a profile using the child behavior checklist 6-18

Birneanu A.

West University of Timisoara, Faculty of Sociology and Psychology
andreeabirneanu@yahoo.com.

Abstract

Many international studies describe the psychosocial functioning of children in foster care using the Child Behaviour Checklist (CBCL). Although children in foster care have been reported to show high rates of behavior and emotional problems (Bolger & Patterson 2001; Cicchetti & Barnett 1991; Fanshel & Shinn 1978; Kaufman & Cicchetti 1989; Dubowitz et al.,1994 ; Toth & Cicchetti et. al. 2000; Pecora et al., 2000), in our country we found little research on this topic. This article report findings on intake CBCL scores for a group of 92 Romanian children, 6 to18 years old served in long term foster care by 52 foster parents. The findings of this article show that children and youth in foster care experience high rates of break rules behavior problems and olso the implications for future research using Child Behavior Cheklist are discussed.

Keywords: foster children, behavior problems, break rules behaviors, CBCL.

Introduction

The best interest of a child at the beginning of his life, is to have a family able to satisfy the most needs for a healthy development, a family able to love and respect him. Children placement in foster families was designed as a temporary protective measure, to prepare the child reintegration in the biological family or to find an adoptive family. With a growing number of children living in family foster care, it is important to use standardized measures for studying behavioral and emotional problems of these children and youth. The foster care system was created to offer a normal family environment for normal children. Unfortunately, research proves that those children placed in foster care system „are not normal,, in the sense that they present serious emotional and behavior problems. Under these circumstances it is desired that the foster care families to offer the child a healthy environment, so that he/she acquires new skills, modifies the nagative aspects and increase their resilience prompting factors [1]. Children and adolescents living in foster care have often experienced adversities such as physical abuse, neglet, sexual abuse, parental psychopatology and family breakdown [2]. A large body of international previous studies have reports high rates of emotional and behaviour problems (mental health problems) among children in welfare systems [3,4,5,6]. Antisocial behavior appears to be a developmental trait that begin in early life and often continues into adolescence and adulthood. Aggressive behaviour measured from ages 6 to 13 consistently predicts later violence among males. Delinquency is a natural outcome of an emotionally deprived life.The approach of delinquency must always be governed by an attempt to understand the frustrations, the deprivations that have led the child to a particular expression of his unhappiness [7]. In social work practice it is not easy to find foster parents who will live with troubled children, one foster parent will be able to accept one form of delinquent behavior and another will be more comfortable with another variety. In general, studies show that during adolescence or adulthood, children who have experienced foster care are at increased risk for substance abuse [8], depression [9], anxiety [10], delinquency [11], school failure [12], incarceration [11]. To be effective, the community reinsertion of delinquent child must be done by a network of state institutions and non-governmental organizations which have as a primary or secondary target group the child [13] .

Methods

The sample was performed according to the eligible population of foster children and adolescents at the beging of September 2010 in Timiș and Arad country, Romania. The sampling frame included 52 foster parents and 92 children aged 6-18 years residing in foster care. To ensure that caregivers were sufficiently familiar with

children they care, we required that children had lives with their caregivers for at least three months. Data collection took place between Octomber 2011 and November 2011 and all the children and substitutive parents were evaluated at the foster parents residence, both in urban (n=14) and rural area (n=78). For the purposes of access of these foster families, collaboration agreements have been closed with DGASPC from the Arad and Timis countries.

Measures

The Child Behavior Checklist (CBCL) is a 113-item questionnaire which is completed by parent or foster parents in order to reflect their view of the child s behavior at the time of administration or within the previous 6 months [14]. It provides a Total Problems score, two broadband scales (Internalizing, Externalizing) and the following dimensions: Withdrawn Behaviour, Somatic Complaints, Anxiety/Depresses Behavior, Break rules Behavior, Aggressive Behavior, Social Problems, Thought Problems and Attention Problems. Foster parents rate each item from 0 (never true), 1 (sometimes true) to 2 (often or always true) for the chid. In this article we focus only on Break rules behaviour scale. Break rules behaviours represent Externalizing behaviours (publicly observable) and the children and youth tend to underestimate their misbehaviour and adults are generally considered the optimal informants on this scales.

Results

Child Behaviour Checklist scale VII examines foster parent perspective on behavior problems such as misbehavior, aggression, violence, interpersonal hostility, disturbing others behaviors and delinquency. This scale measures the overall well-established symptoms within antisocial problems, that are not necessarily characterize the pathological condition, but can express a certain pathogenic path. From this scale perspective, at the level of the total sample of children and adolescents in foster care, foster parents report symptoms whith a particulary high frequencies at the following items: 63. Prefer the company of older children (68.5%); 43. Lying, cheating (66.3%); 28. Violating rules (63.1%) and 26. Do not feel guilty (59.8%). Generally, present symptoms in the scale are influenced by age of children at the evaluation moment and another important fact is that with age these antisocial symptoms changes direction. Many researchers have noted the continuity in antisocial behaviour from early aggression to violent crime, more likely, the delinquent behavior among children and youth evolves from simple to complex and from minor to severe as the child develops in age and in negative social experiences [15, 16]. Most longitudinal studies show a negative trend in the incidence of aggressive behaviour with adolescence, so some forms of antisocial behaviour o occurring at different ages (theft, vandalism) appear to adolescence while other forms are decreasing with age (interpersonal aggression). Due to the principle that the Covert Pathway begin with child aggression such as annoying and bullying others as the first step, followed by physical fighting, and then violent crime.The Covert Pathway begins with minor covert behaviours such as shoplifting and lying and than progressed to property damage such as vandalism and fire setting. Some families produce children characterized by two problems [17]. They have antisocial symptoms and they are socially unskilled [18]. Olso the association between antisocial children, school failure and rejection by the normal peers group is well documented [19]. All these behaviours predisposes children to poor outcomes and to a life dependent on social services. Based on what is known about the attachment of abused, abandoned and neglected children, foster children have most probably an insecure attachment towards their biological parents [20, 21, 22].

Table 1. CBCL, Scale VII: Break-rules behavior symptoms – overall situation in percent

item	never true	sometimes true	always true
2. Drinks alcohol without parents' approval	96,7%	1,1%	2,2%
26. Do not feel guilty	40,2%	47,8%	12,0%
28. Violating rules	37,0%	62,0%	1,1%
39. Hangs around with others who who get in trouble	89,1%	9,8%	1,1%
43. Lying, cheating	33,7%	57,6%	8,7%
63. Prefer the company of older children	31,5%	45,7%	22,8%
67. Runs away from home	93,5%	5,4%	1,1%
72. Sets fires	91,3%	7,6%	1,1%
73. Sexual problems	98,9%	1,1%	,0%
81. Steals at home	90,2%	9,8%	,0%
82. Steals outside the home	94,6%	5,4%	,0%
90. Swearing or obscene language	73,9%	22,8%	3,3%
96. Thinks about sex to much	96,7%	3,3%	,0%
99. Smokes, chews, or sniffs tobacco	98,9%	1,1%	,0%
101 Truancy, skips school	94,6%	5,4%	,0%
105 Uses drugs for nonmedical purposes (don't include alcohol or tobacco)	100,0%	,0%	,0%
106 Vandalism	96,7%	3,3%	,0%

Statistical analysis result using Chi2 test antd t test did not identified any statistically significant association coefficients according to gender variable. As the values are above the threshold of $p<.05$ will not confirm the hypothesis that gender influences the incidence of child antisocial behavior in the items above. Overall, the gender variable does not induce significant statistical differences, althrouhg boys recorded higher antisocial behaviour problems than girls.

Table 2. CBCL VII mean according to gender variable

Mean CBCL	General mean	Boys mean	Girls mean
CBCL VII Break-rules behavior problems	3.93	4.06	3.80

Conclusions

The results of this study are consistent with those of prior studies that found higher levels of antisocial behavior problems, as manifeste in high CBCL scores. Because parent-child interaction is central in the etiology of antisocial behaviour the substitute care which they receive may have significant results (positive or negative) on their ability of adjustement and becoming resilient. Thus, after leaving the child protection system, many foster children become a social and economic burden for the community. The fact that children in foster care present a wide range of antisocial beahaviours is not surprising considering the relatively small number of protective factors and the large number of risk factors. To support this statement a large body of evidence suggests that broken homes, abusive parents, early childhood violence, physically abuse and neglet precedes a greater degree of delinquency in later life [23]. In conclusion, foster children demonstrate behavioral problems, as a result of the disturbed parent-child relationships. In dealing with troubled children, the foster parents must be especially careful to let the child know she feels that there are reasons behind his behaviour and that she is concerned in helping him to get at them. Children in foster care are clearly in nedd of follow-up assessment and counselling services. There is a need for more research on effects of foster placement, more longitudinal studies in which children are assessed as they enter the child welfare system and followed through their time in care and after they leaving care.

Abstract

This research is contextualized in the foster care system, focusing on the area of adolescent relationships and in the support that the figure of a natural mentor offers. Dealing with the situation generated by the childhood vulnerability constitutes a challenge for these adolescents (Grotberg, 2003) and in this way, some specific needs in interpersonal (Amorós & Fuertes, 2000; Fuentes et. al, 2013; Cyrulnik, 2005) and emotional areas (Barudy, 2005) have been identified. From the resilience paradigm, what is consistently found is the presence of significant persons as an essential element to make the process of resilience of maltreated children possible (Lecomte & Manciaux, 2003; Cyrulnik, 2002, 2005), the stage of adolescence being a special fertile period for its promotion.

The purpose of this communication is to show the adolescent's perspectives and perceptions of people who have been significant for them during their stay in a protection resource. A descriptive-comprehensive methodology is used, proposing 17 interviews as strategy to gather information which has been analysed on qualitative software Atlas-ti v.6.0.

Our findings show the value of the mentor, as well as some salient qualities of the relationships and many different benefits from these meaningful connections. As a salient issue, the importance of people from the informal network is highlighted. It evidences the importance of being connected with a key person for the development of the resilience process in youth (Barudy, 2005; Gilligan, 2009; Vanisteandel, 2003), this supportive figure becoming a mentor (Burguet & Forés, 2012).

Keywords: Foster care system, resilience, support relationship, mentoring.

Introduction

Our investigation is into part of the field of child protection, focusing on adolescents who as a consequence of a situation of vulnerability have had to leave the family nucleus and go and live in foster care. This and the later adaption to the protection measure is a significant moment of special adversity [1], to which we must add the necessities existing before they found themselves in a situation of vulnerability or defencelessness.

Looking at it from this perspective, several authors coincide in pointing out the specific interpersonal necessities of the adolescents taken into care [2] [3] [4] [5] [6] [7], and those necessities in the relationship and emotional area [3] [8]. In this sense it is manifest that for the adolescents there is a great need for a connection with figures who can meet these necessities and offer supportive elements that help them develop and add to their welfare.

It is at this point that the concept of resilience appears as an opening into the future, making possible a hopeful outcome for these young people. Although it is a concept that has diverse definitions, we shall take the definition accepted by the authors of reference, such as Manciaux, Vanisteandel, Lecomte and Cyrulnik [9], because they include the two elements common to any definition and their contributions in the field of resilience given to children in protection: "resilience is the capacity of a person or a group to develop healthily, to continue with a project for the future despite destabilising events, difficult decisions in life and sometime serious traumas". On the paradigm of resilience, there is great consensus that one of the most vital elements for the development of resilience processes is coming into contact with meaningful and affectionate people [4]; [10],

[7]; [11]; [1]; [9]. In particular, Lecomte and Manciaux [12) affirm that "the principal factor for an abused child's resilience and the growth thereof, is the presence of an affectionate person [...] with whom they have an intense link [...], who gives the sensation they accept and love them." The psychological development after the trauma is related, as Cyrulnik [7] says, with the possibility of finding an affective and social context, mentors of resilience, that is to say, people with whom they are able to feel loved unconditionally, to grow and to overcome the situation. Therefore, to achieve an integral development and to make possible resilience, it is vital there are significant people with whom the young people can establish a positive affective bond [7]. They become mentors of resilience [13]. After what we have set out, it is clear it is relevant to respond to the child's necessities at an emotional and relational level, and as well as to provide support figures capable of encouraging this resilience development in young people.

The objective of this paper is focused on making known the perceptions of the young people fostered and how they feel towards to these people who have been significant for the time during which they have been in the protection system. The paper analyzes the establishment of certain interpersonal relationships that have helped the young people to face this process and how they have done so. In this way, we have gone into the contributions and fundamental elements that sustain these types of relationships. Then we look at the role young people give to these people with whom they maintain the relationship or connection.

Methodology

To fully achieve the objective the descriptive-comprehensive method is used. It aims to explain the significance of the phenomena studied [14] with the intention of understanding and gaining insight into the experience of the participants, as they themselves feel it.

It is worth pointing out the added value represented in gathering together and listening to the voices of the adolescents. By doing so we encourage their right to participate in those questions which are directly their own, and affect them [15]; [6]. In this way we are working from a perspective close to the new policies and regulation on child protection, in which the child's rights to participate in research and practice are recognised.

To clearly achieve this proposal seventeen semi-structured interviews with adolescents were carried out. All of them had gone through or suffered a process of family break up and being taken into care in a residential centre of in a foster family. The interviews were transcribed literally in a text processor so the data could be processed and analyzed using a qualitative analysis methodology. To reduce the amount of the data and information a system of categories was created following an inductive strategy, reinforced afterwards by contrasting it and complementing it with the most relevant aspects indicated in the literature. The result was a system of fourteen codes. In the final stage, to carry out a codifying process we used the Atlas-ti, v.6.0 software, which facilitated the good organization and information processing analysis.

Results

In first place, the results showed that the adolescents are capable of identifying certain interpersonal relationships as sources of support. These help them to take on a situation in which they were in the protection system for a period.

We can observe that these relations may be constituted with figures who are either part of the formal network -we are referring to professionals who count on formal resources, for example, teams from the protection system, teachers, etc.- or informal network -people from their natural surroundings, such as friends, relatives, and "non-kin"-. The most mentioned figures from the formal network has been the educator and from their natural circle their parents and siblings.

From this perspective, there stand out a series of elements with common characteristics in the significant relations, both with people from the formal network and informal network. Firstly we can see the essential elements that frame the significant interpersonal relations are trust, support and emotional aid.

*"**What is it that has most helped you?** That they gave me a lot of trust"*

"[...] first you should speak with your parents, because family support is very important."

Secondly, we observe how this trust is generally accompanied by the sensation the young people have understanding with the other person, that there is a link, a feeling and an empathy which makes this relation special. We can also see that this type of relation is framed in a context of listening, comprehension and respect.

"Yes, this person helped me a lot, because they spoke to me, it let me vent my feelings, because I got to feel at ease with her too."

Another question is that they are relations based on esteem and affection. The affectionate context is fundamental and the security they have that the other person is accessible, there for them in the future. In addition the image the significant figure transmits back to them has an important positive effect or repercussion on the young people's self value: they can feel valued people.

"[...] your mother, well your parents, what they should do is spoil you."

"He's a boy that if I would have problems now with drugs or anything, the first person who I fall back on, together with my mother, would be him."

With regards to what the relationship contributes, what the benefits have been for the adolescents, we have been able to identify three large areas. First, the relationship gives a reference to the emotional support, referring above all to providing affective company.

"They always told us they were there for anything, to talk or anything else, and if anything happened to us we could talk to them, that they'd help us a lot."

Secondly, there is the supply of information with respect to the process, what we have called informational support. And the third is the instrumental support, based on the contribution of tangible aspects and infrastructure.

"Eva helped us a lot […] she went along telling us how we had to do things, what was positive for us, what was negative..."

Finally, we want to highlight the vital role of the significant figures during this process. As the evidence makes clear, the adolescences recognise their value and transparency, perceiving them as a value key for their development.

"[...] s*tart over your life again from zero, they give you the opportunity to come through this and from zero, you believe you are being reborn, because if you let them help, they'll help you."*

Discussion and conclusions

In the light of the results, it is evident that adolescents can identify the characteristics and contributions from these significant relationships, highlighting the emotional support as a key element that helps them in their process of taking on and facing up to this situation of protection and the child's projection into the future. The elements that define these types of relations coincide with those described in other investigations and research - among them Ahrens et al. [16]; Barudy & Dantagan [4]; Gilligan [17]; Greeson & Bowen [18]; Osterling & Hines [11] & Triseliotis, Borland, Hill & Lambert [19]. The confidence and support (emotional, informational and instrumental) provided by these figures are vital. Another question is that it has been seen that as the adolescents value these relations as empathetic, in which they feel respected, listened to and understood. These results match up with the previous literature. As a third key element, esteem and affect have been identified, coinciding with the results of Greeson and Bowen [18], which point in the same direction of love, care and nurture. Another contribution that stands out is the fact that the adolescents feel valued and respected, coinciding with Munson et al. [20]; Greeson and Bowen [18] and Triseliotis et al. [19], in contrast to what they feel in other relationships.

Evidence is provided that the emotional support and the interpersonal links are the vital elements that truly mark the difference and mean the relationship begins to be of aid in the process of resilience building. We also point out the diversity of roles and figures that appear as sources of support, figures that belong to the formal network and others from the informal network can be there. The figure who stands out in the formal network is the social educator, coinciding precisely in the fundaments of their accompanying methodology and type of educational relationship, with the characteristics we have mentioned before.

The fact of contemplating figures from the informal network is revealing, as there are few investigations focusing their attention on the contributions these figures can offer in the providing of support in this context. The figures from the nuclear family are highlighted: parents and siblings. It is paradoxical as even being removed from their parents because they did not comply with parental functions, in many cases they continue to be a source of support. Nevertheless, on occasions there seems to be an idealisation of the symbolic role the family represents as the description they make of the support provided is much more diffuse and imprecise compared with the support from the formal network. In the case of brothers and sisters it is different as all the support comes together with the following effect: on one hand the siblings are there and will always be there, standing by the person as a source of help and on the other hand, they make them feel near to the biological family. Coinciding with Fuentes et al. [5] and Gilligan [17], emphasis is made of the relevance and necessity of going in deep to the role that these figures, who are relatives, could have.

In conclusion, this study provides evidence which enables us to see the importance certain people have for adolescents: they consider them significant figures in their process of coming to terms with, facing up to the situation of foster care and their projection for the future. In accordance with Ahrens et al. [16], Barudy [3], Gilligan [17] and Vanisteandel [21], it is a key piece for their development in this process of resilience. Barudy [3] indicates that a policy of protection based on the child's necessities or rights has to strengthen the link between the child and the significant figures who offer relationships of care, affection, education and support. Having seen the importance of the relations of support in the development of the resilience and personal welfare for the child, the challenge is to put forward proposals that promote these types of relationships, just as Cyrulnik [10] affirms, "these children need to find adults with sufficient talent to be able to give them a hand up, despite the difficulties they have in establishing affective links". These figures can become mentors of resilience [13].

A final point: the necessity exists to continue to look into these significant figures and their role as mentors in resilience is highlighted [4] [10] [7]; [12], and the special importance the availability, or being there, of these figures in this stage of adolescence [7].

Abstract

One of the main requests professionals make is for new tools connecting theory and practice, while facilitating their complex work with vulnerable families. Within P.I.P.P.I. (Intervention Program for Prevention of Institutionalization), particular focus is placed on tools supporting the intervention process within a participatory and transformative evaluation perspective where the link between assessment, planning, intervention and evaluation is key.

RPM-Android app is a novel tablet application that aims at providing integrated support for all the parties involved in the intervention process. To professionals, the app currently:

- allows for an easy document practice with the support of assessment, (micro)planning, evaluation, and a log of meetings with families;
- provides retrieval and storage of information from/to the centralized data management tool RPMonline, while on the field.

To children and parents, the app:

- fosters the "story telling" process within a resilience-based approach;
- allows children to be actively involved in the assessment by making them interact directly with the tablet at an appropriate level of complexity;
- offers the possibility of sharing with parents information about the intervention process in an easily understandable way, thus making the parents more involved and thinning the relational barrier with the professionals.

RPM-Android provides a streamlined, intuitive human-machine interface that leverages on hardware facilities in tablets such as the touch screen, the camera, the on-board accelerometer.

From a technical standpoint, RPM-Android – and RPMonline as well – are based on the Italian adaptation of the triangular model of the British Common Assessment Framework. RPM-Android builds on the Android software platform, which ensures the app can be widely adopted at low cost.

The paper will present the app, how it works and its first use with children and families by a group of professionals within P.I.P.P.I..

Keywords: vulnerable families, family participation, resilience based tool, tablet app.

P.I.P.P.I.: Framework and tools

P.I.P.P.I. (Intervention Program for Prevention of Institutionalization) [1] is a research-training-intervention program developed as an intensive care program for vulnerable families, funded by the Italian Ministry of Welfare (2011-2012 1st implementation; 2013-2014 2nd implementation in 10 cities; 2014-2015 3th implementation in 50 cities). It is developed from 2 main goals of European Community that aim at decreasing the number of children that live out-of-home and improving the effectiveness of child placement and Child Protection Services. Hence, P.I.P.P.I. aims at preventing child placement by balancing risk and protective factors, and focuses on supporting parenting through multi-professional and resilient-based-intervention.

P.I.P.P.I. is designed as research-training-intervention program whose ultimate aim is to codify, test, evaluate an intensive approach, structured and flexible at the same time, for the family's care process, able to decrease children's risk of placement and/or to promote family reunification.

The theoretical framework underpinning P.I.P.P.I. is the bio-ecology of human development [2,3], with its awareness that, to promote child wellness, it is necessary to work with all the people involved within the child's world.

P.I.P.P.I. firstly expected to involve parents and children in care planning and intervention, knowing that the best predictor of success is the engagement of families [4]. It's key to really involve family and to listen to them, to listen to what they want and to be aware of not blaming them.

In order to support child wellbeing and parenting, different levels of interventions are used according to the needs and situation of each family:

- intervention of social services (meetings with case manager and social worker);
- home care intervention;
- parents' group;
- support family, that is a family that supports the target family;
- participation of school.

The different types of intervention attempt to supervise the various levels of the ecosystem and they have been required to work together in a sole care plan, shared with the participation of parents and children. For this reason the practitioners working with a family are members of a multidisciplinary team and are required to work together within a unique care plan in which everyone (parents, children and practitioners) give his/her contribution to the improvement of the situation according to his/her resources and role.

1.1 Subjects and methods

P.I.P.P.I. is the result of a collaboration between the Ministry of Welfare, the Laboratory of Research and Intervention in Family Education (LabRIEF, University of Padova), care and protection services, schools and local health authorities of 10 Italian cities (Bari, Bologna, Florence, Genoa, Milan, Naples, Palermo, Reggio Calabria, Turin, Venice) that joined the program for the first 2 implementations (2010-2012, 2013-2014) involving more than 350 children 0-11 years old and 260 families.

The method used in P.I.P.P.I. is based on the principles of participatory research, that aims to co-create knowledge starting from comparison of different actors' points of view. Negotiation is key [5]: through negotiation it is possible to discuss practice, rules, routines, etc. The final goal is to change and to improve practice [6].

1.2 RPMonline

RPMonline in Italian stands for "Assessment, Planning and Monitoring", and it is an online tool designed and developed at the University of Padova in a joint work between the FISPPA Department, the CSIA (Elisabetta Piva and Anna Maria Fornea of the Information Technology Center of the University of Padua), that can be used by practitioners and families to make the care plan for each child. RPMonline is based on Multidimensional Model of the Child's World that consists in the Italian translation and adaptation of the triangle of the Assessment Framework [7]. It aims to represent all the systems that compose the child's life, as shown in the Bronfenbrenner theory.

RPMonline is meant to foster all the process of the care plan (assessing risk and protective factors, planning and evaluating intervention) and aims at empowering the participation of all the actors involved in the intervention (firstly children and parents, and then practitioners, teachers, etc.) giving them voice, collecting their point of view and using their resources [8].

The sides of the Triangle refer to Child's Needs, Parenting Capacity and Environmental Factors that includes respectively 7, 5, and 5 dimensions that are provided with a space for assessment (child/family/community's need or resources, that is the initial situation) in order to record the multidimensional narrative about the child and family's situation.

Where a change, improvement and/or empowerment is expected, each dimension provides a section for care plan where children, family and professionals are asked to write goals, actions, responsibilities, time, monitoring, and verification.

A quantitative scale with 6 levels, from serious problem to evident strength, provides a synthesis in each dimension, in order to outline changes of families. Alongside the triangle, the quantitative scale creates a Child's World Questionnnaire (CWQ) that can be used for evaluating with the family or for a wider evaluation (city or nation-based).

All the information recorded in RPMonline can be automatically retrieved through a Pdf report of:

- Assessment (text and quantitative levels)
- Micro-planning
- Planning Memo for family

- Radar Graph of the WCQ

From practitioner perspective, it is an online instrument to promote cooperation:

- each child has his/her own RPM space where all the members of the Multidisciplinary Team working with the family (MT) are asked to focus at and to cooperate;
- each practitioner of the MT is provided with a login and password to access only to care plan he/she work with;
- when you log-in you can see what other members of the MT added;
- in the log of "Meetings with family", practitioners can easily and quickly report for each family the meetings with other colleagues and/or members of the family, recording date, place, duration of the meeting, people present, goals, tools used and a brief comment about the meeting.

All the data are stored in a central database and can be retrieved by a local/city administrator (data only about the city he/she is in charge of) or by the full administrator (data about all the children that are used for research purposes).

RPM-Android

RPM-Android is a novel tablet application that aims at providing integrated support for social practitioners working with parents and children 4-11 years old. RPM-Android provides professionals with the same core functionalities as RPMonline, and augments them along the following two directions.

1. According to the principle of participatory research, RPM-Android makes it possible to involve parents and children in the intervention process by adapting its user interface (UI) to the level of experience of the person looking at the displayed information.
2. RPM-Android provides retrieval and storage of information from/to the centralized database of RPMonline while on the field, and it can operate even without a network connection.

To all parties, RPM-Android provides a streamlined, intuitive human-machine interface that leverages on hardware facilities in tablets such as the touch screen, the camera, the on-board accelerometer. Such a nontrivial design made it possible to extend some functionalities of the app to non-professionals and even to children 4-11 years old. In the rest of this section, we will first explain how core RPMonline functionalities are implemented in a streamlined, intuitive way by leveraging on tablet features which are not available in web-based applications such as RPMonline; we will then elaborate on the two directions that make RPM-Android unique.

RPM-Android, as RPMonline, supports the key functionalities of assessment, micro-planning, evaluation, and a log of meetings with families. Such functionalities are accessible via a touch-based UI whose aspect perfectly mimics the multidimensional model of the Child's World.

Fig. 1 The Multidimensional Model of the Child's World as i appears in RPM-Android

The UI – and the whole app as well – is currently in Italian, but further languages can be added with limited effort thanks to the multi-language facilities in the Android platform.

The book icon in the upper right corner provides immediate access to the log of meetings were each member of the Multidisciplinary Team can easily record each meeting reporting date, duration, place, people involved, topic, tools used, and a short description or notes about the meeting.

The knob on the right selects whether the UI should show the full range of available information or a reduced set, suitable for parents or children. A representation of the multidimensional model occupies the middle of the screen and it is the best example of how ideas in RPM can be adapted to exploit functionalities in tablets. A picture of the children, acquired with the tablet camera, shows who is at the centre of the intervention process; thanks to the presence of a touch screen, touching a dimension (e.g., "Stare bene" – "Being well") immediately takes to the corresponding assessment page.

Each dimension displays the status of the assessment in a graphical fashion: the darker the dimension, the more data have already been entered. When the assessment is complete, the dimension starts to gently float. An icon in the top-right corner of a dimension notifies where a planning action has been defined. The dimensions are written in a child-parents understandable way, and not in professional language, in order to foster the fully involvement and participation of the family.

When the knob is set to "Operatore" (i.e., practitioner), the full set of information for assessment and planning is available. When the knob is moved to "Genitore" (parent) or "Bambino" (child) and a dimension is touched, new UIs are shown that display a reduced amount of information in a clear and engaging fashion, so that parents and even children can interact with the tablet and can thus be involved in the assessment. Different dimensions need, of course, different UIs: we hereby describe one UI that targets parents and two UIs for children.

Radar chart (parents). A radar chart summarizes the results of the quantitative assessment (CWQ), thus allowing to share them with the parents in an understandable fashion. Multiple datasets, corresponding to evaluations along all dimensions at different times, are superimposed so that improvements and failure points are immediately apparent. If the need arises, one or more datasets can be hidden by the click of a button. We designed the radar chart so that it can be panned and zoomed via standard touch screen gestures: given the amount of information that can be displayed in the chart, we think the possibility of zooming in on a subset of it is a must.

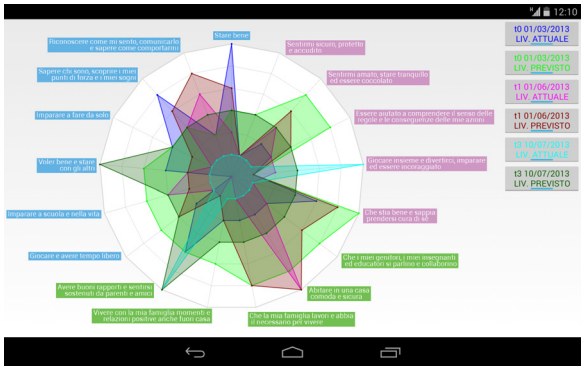

Fig. 1. Radar chart in RPM-Android

Score acquisition (children). The purpose of this UI is to acquire a simple score, expressed on the same 6-level scale professionals use for the assessment (see Section 3). This score makes the voice of the children heard along dimensions – such as being well – where this is possible. Different versions of this UI have been developed. In a first version, the child expresses her/his mood by moving the Android device down or up in the air: the position of the tablet is detected via the embedded accelerometer, and transformed into a numerical score. Audible feedback about the score is given back to the child via the chirp of a bird: the pitch of the chirp increases with the score. In another version of this interface, the child states her/his mood by whistling or vocalizing: the app samples the sound, detects the dominant pitch via spectral analysis and assigns a score accordingly. In this case, the feedback to the child is visual, i.e., a bar whose length is proportional to the score.

Fig. 3 Score acquisition by whistling or vocalizing

Further UIs have been developed: we are planning an experimental validation to understand which solution is more engaging for children.

Eco-map (children). An eco-map [9] (dubbed "MAPPA-MONDO" in our app) allows a child to interactively draw the connections in her/his life and specify the quality of the relation with each individual. It is not necessary for the child to draw individuals, as they can be picked up from a palette of male and female characters. For each individual a name can be typed in, maybe with the help of the professional performing the assessment. A picture of the child is automatically retrieved from the child's profile and placed at the center of the map. The colour of the arc connecting the child with each character can be changed – by clicking on it – from green (supportive relation) to red (stressful relation) and yellow (ambivalent relation). Characters can be repositioned on the map by dragging them, so that room can be made for further characters. All in all, our tablet implementation of the eco-map is faster to draw and more flexible than its pencil-and paper counterpart, thus freeing a fraction of the short attention span of the child for more productive activities. The eco-map UI can be used for dimensions such as "Voler bene e stare con gli altri" (to love and to be with others).

To conclude this section, we briefly elaborate on some purely technical considerations. First of all, the app – as we have already stated – is truly mobile, as data can be uploaded and downloaded into RPMonline even while on the field: there is no need to re-type anything after leaving the family. If no network (Wi-Fi or cellular) connection is available, data are temporarily stored into the tablet and can be synced back into RPMonline at a later time, when connectivity is restored. A password system ensures each professional can see only the subset of families s/he is supporting. If multiple professionals modify the same data while offline, the app detects the conflict at sync time and provides a way to resolve it. Some words must also be spent on why Android was chosen for development, and why smartphones are not supported. RPM-Android builds on Android because it is the most open mobile ecosystem: the operating system and core libraries are available – even in source form – at zero cost; no royalties must be paid to distribute the app; Android devices are available at low (and plunging) prices thanks to competition between hardware vendors. All in all, this ensures that RPM-Android can be widely adopted at minimal costs for professionals and families. In the Android ecosystem, tablet devices were choses instead of smartphones because displays in smartphones are too small to type a significant amount of information – as required by professionals – in a comfortable fashion, and they also make it difficult to display complex information such as an overview of the triangular model or a full-blown radar chart.

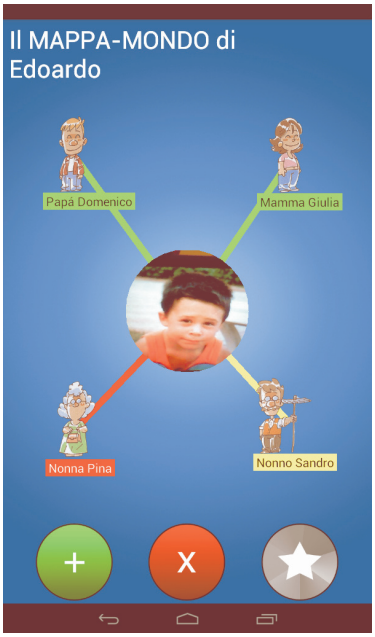

Fig. 4 Eco-map

1.3 Development and validation

The app has been developed with the substantial contribution of students Filippo Beraldo, Filippo Damuzzo, Loris De Marchi, Edoardo Degli Innocenti, Gianmaria Parigi Bini, Pier Tirindelli, from the Department of Information Engineering. After development, validation is now in progress. Since the UI, and any choice on how information is displayed, play such a central role in RPM-Android, the first real-world test we decided to perform was a usability test. The test was administered to a small set of professionals in Venice and Genoa which were part of the P.I.P.P.I. project from its early stages. The degree of familiarity of such professionals with the web-based RPMonline tool was variable, but all of them were definitely skilled about the

intervention process defined in P.I.P.P.I. and implemented by both RPMonline and RPM-Android. The test – which did not cover UIs for parents and children – was performed in two stages.

- In the first stage, each professional was given a tablet and the functionalities of the app were shown to her/him by one of the authors of this paper. Then, the professional was free to interact with the tablet as s/he liked. During the whole process, the professional was encouraged to give feedback about her/his sensations and to ask questions. Feedback and questions were annotated for later analysis.
- In the second stage, each professional was asked to perform a series of 6 tasks without the supervision of an expert (i.e., an author of this paper). The tasks covered the basic activities of assessment, planning and logging. After having performed the tasks, the professional was asked to fill in a 16-question questionnaire about her/his experience.

The response was definitely positive: all of them stated PIPPI-Android organizes information in an engaging fashion and can become a useful tool that speeds up day-to-day operations. Some concerns were raised about the typing speed on the virtual, touch-only keyboard provided by the Android platform, but professionals were aware a trade-off must be made between ease of typing and ease of carrying a compact device without accessories. Incidentally, such concerns corroborate our choice of not supporting smartphones, where typing issues would be exacerbated.

Conclusions

Building on the implementation of the Child's World made in RPMonline, the novel tablet application RPM-Android facilitates and supports practitioners in their everyday practice with vulnerable families. Furthermore, it fosters participation of parents and children to a deeper level and makes the process of "doing together" a resource for their resilient trajectory. Indeed, the first feedbacks of practitioners shows the all the potential of the app and encourage us test it on the field. Our first steps along this directions will be a broader test with a bigger number of professionals and a validation of UIs for parents and children with a group of families involved in the implementation of P.I.P.P.I.. As a further benefit of these tests and within a participatory approach, families will contribute to the improvement of tools to support other families in need.

Abstract

Kinship foster care (KFC) is the child protection alternative most used in many countries, including Spain. Nevertheless, KFC is the least attended child protection alternative by professional supports. Fostered youth, as part of a foster family system, has specific needs of support due to family history and process of separation and adaptation to a new family, even if it is with relatives. This article presents a *Support program for teenagers in kinship foster care* developed by the research group GRISIJ. The program is based in a need analysis assessment. The most relevant needs found are: characteristics of Foster care in kinship family; family history; foster family and foster child; biological family and foster child; self-awareness; healthy family life; free time; the future after fostering. These needs were transformed into an educational group program which goes from problem intervention to resilience intervention. The program has 9 sessions of 2 hours each and has being piloted with a group of kinship fostered youth. As result some changes have been introduced in the program, especially in the area of managing their personal histories. Here we present the revised program, as well as a reflection of the main changes introduced to promote resilience after the experience.

Keywords: Kinship foster care, youth, resilience, support program.

Introduction

Kinship foster care is a child protection alternative defined by the connection between the foster parents and the fostered children. Spanish law, same as in other countries, recommends it as a primary option when a child has to be separated from their birth family, but only, if their relatives are able to address the child's needs. So, it's not a surprise that Kinship foster care is the most frequently used type of family foster care in Spain [1], as in other countries [2], [3]. But, several studies [4], [5] show that kinship foster families receive less training and less support than non-kinship caregivers [6], [7]. As a result, kinship families have specific needs that are currently unfulfilled.

The fostered youth are the most important element of this family system, and in terms of receiving support they are the most forgotten. They have experienced adversities due to family history and the process of separation and adaptation to a new family situation, even if it is with relatives [8], [9]. As all adolescents, they are in the process of building their own identities but they have the additional task of being confronted with a series of questions about their past, present and future family background which makes the process even more complex [10], [9]. It is therefore, logical that previous research has proven that the fostered youth has specific needs [11], [12], in particular the research highlight difficulties of sharing their foster care experience and dealing with their family history [9], [13], [14].

If we want to help these young people what are the basic issues we must consider? Information from research encourages to explore the perspective of resilience with this youngsters. According to research about resilience we know that youngsters can overcome the traumatic experiences that they have suffered in childhood by helping them to clarify the doubts and to teach them how to overcome the emotional issues and learning how to express their emotional life in a different way [15], [16]. This means that the use of resilience strategies with these youngsters is a major educational goal to achieve [8]. But, how we can enhance resilience in fostered youth? As Rutter [17] has demonstrated, working to enhance protective factors reduces the impact of the risk and works against the patterns of negative behavior. While on the positive side it contributes to and maintains the young person's self-esteem and self-efficacy, and opens up new opportunities for them. In this sense, working to increase resilience, both in terms of internal strengths (problems-solving skills, emotional control, divergent thinking, personal skills, future orientation, day to day coping skills) and of external strengths (family

relationships, school relationships, and we would add, community relations) can be of great help to the young person [18]. Grotberg [15] suggested that professional interventions promote resilience if they deal with emotional difficulties. And Lee [18] add three lines of work to be developed in group through educational activities: (a) improving skills, especially those involved in handling emotions, resolving problems and setting goals, (b) reinforcing the sense of belonging, and (c) improving optimism by advocating hope, coping with challenges and positive thinking.

Taking this into consideration and using the information from the previous research carried out by the GRISIJ, it became evident that the young people also needed a specific support program to help them progress within their kinship family, their parents and in their personal life. In these regard, we proposed an educational program designed to reduce the risks and promote their resilience.

The objective of this article is to present the *Support program for teenagers in kinship foster care* developed by the research group GRISIJ, explaining the changes that have been introduced after the program has been tested.

Methodology

The research is based on a cooperative action research developed in two phases:

a) The design program involved 57 fostered youths, 79 professionals and 15 academics from different areas in Spain divided into two phases. The first phase of the design was to assess the needs of young people in foster care. Because of that we carried out focus groups with youth and professionals. The second phase of the design was directed to work with professionals with the purpose of creating the first draft of the educational program.

b) The program was tested with a group of adolescents in collaboration with the professionals of one of the specialized social services. This phase involved 12 fostered children between 13 and 18 years old, 3 professionals (social educators), 3 students (master degree) and 5 academics. We gathered information after each session: the professionals and children fill out a questionnaire. At the end of the program we gathered more comprehensive information by collecting information from a focus group with youngsters and a focus group with professionals.

Results

1.1 From needs to an educational group program

We transformed the needs of the adolescents into an educational group program which goes from problem intervention to resilience intervention [19]. The needs of adolescents justify the use of a comprehensive model of attention where it must be included emotional, cognitive and behavioral dimensions in permanent interaction. In general terms, the objectives and contents of the program were the following:

- *Regarding the Emotional dimension:* helping to deal with emotions in aspects such as: the willingness to accept its their own history, feelings and the memories of their family, the willingness to show respect towards their parents and the circumstances that led to the separation, to accept their feelings of ambivalence and insecurity, as well as contacts with their parents.
- *Regarding the Behavioral dimension:* developing skills to deal competently with foster care issues (history, visits, origins, roles, relationships, etc.) and allow integrate better into their community.
- *Regarding the Cognitive dimension:* enabling a greater understanding and a greater knowledge of the aspects related to the process of fostering and its implications (duties and rights, differential aspects, conflict situations, society's resources, proposals for the future, etc.), and valuing the influence that these have on adapting the family and society.

From the resilience perspective, the program aims to create support through the participants, increase their social resources, improve their personal skills and improve their family relationship.

The table 1 summarizes the objectives and the contents of the *Support program for teenagers in kinship foster care*.

OBJECTIVES	CONTENTS
	Characteristics of fostering
Understanding the meaning of foster care. Awareness of the responsibilities of the different members. Analyzing the feelings that are produced in the fostering (alliances, coalitions, loyalties, etc.). Recognizing the foster care as a family model.	Legal Aspects of Fostering in Extended Families. Responsibilities, rights and duties as a fostered person. Functional role of each member of the family structure. Advantages and disadvantages of fostering.
	Identity and family history
Awareness of the right to know their history and their family situation. Analysis of the feelings and the consequences of discovering their origins. *Recognizing their own strengths, as well as those from the context.*	The search for identity. The emotional situation with regard to fostering. The process of deciding what information to ask for, and how and who to ask. The origins. *The personal, family and social strengths.*
	Foster family
Analyze the changes and the process of adaptation to the foster family. Promoting reflection on the bonds and communication between young people in foster care and their foster careers. Analyze the fit between the rules of family life and fostered adolescents' behavior.	Assertive, fluid and positive communication. The rules for living together as a family. The behavior of fostered adolescents.
	Biological family
Analyzing the bonds and the feelings of young people towards their biological parents. Valuing the importance of the bonds and the feelings with regard to their siblings. *Learn strategies to improve the bonds and communication between the fostered youth and their parents.*	Frequency and quality of contacts with the biological family. Feelings toward their parents. The quality of the bonds with their parents and siblings. The visits and contacts. Communication and expression of affection.
	Self-awareness
Identifying what concept fostered adolescents have of themselves. Analyze the changes perceive by adolescents when they reach adolescence. Reinforcing self-esteem by identifying positive aspects. Reinforcing an adjusted and positive perception of themselves.	Identity, self-concept and self-esteem. The bond of attachment. Puberty and adolescence: physical, emotional and social changes. Positive Self Esteem.
	Healthy coexistence
Identifying attitudes and lifestyles that are positive for health and coexistence. Becoming aware of sexuality as a positive experience. Generating an analysis of perceptions and beliefs that may promote sexual risk behavior.	Health as physical, psychological and social well-being. Self-esteem and self-efficacy as a preventive effect of risk behavior and health protector. Positive social coexistence and social skills: empathy and assertiveness. Sexual behavior and identity. Sexual risk behavior: myths, beliefs and truths.
	Free time
Understanding the value of free time and its use. Recognize the elements that influence the decision-making. Analyze the risks associated with drug abuse. Experience physical activity as an element of well-being and health.	Active and positive idea of leisure based on creativity Information and strategies for the prevention of risks involved in the consumption of drugs Physical activity, leisure and healthy development.
	The future: after fostering
Discovering the alternatives to foster care once	Alternatives or situations after fostering.

adulthood is reached. Thinking about the importance of devising a project for the future. Thinking about the proposals that will help them to adjust their interests and needs in their paths through life and in their careers.	Situations of connecting with, and disconnecting from, the family. The personal, academic, professional, family and social future. Paths through life.

Table 1. Objective and contents of the support program for adolescents

All of these were specified in 9 sessions (table 2). Each session has clear objectives that are shared with the participants, and each session has a specific focus. The program runs for a specific duration – two hours each session, on a weekly basis for 9 weeks.

Session 1	Welcome
Session 2	What does it mean to be in foster care?
Session 3	Myself
Session 4	My foster family and me
Session 5	My biological family and me
Session 6	Knowing me better
Session 7	Taking care of ourselves
Session 8	My free time options
Session 9	After foster care

Table 2. Title sessions of the Support program for teenagers in kinship foster care

1.2 The program after being test

During the trial, the adolescents attended regularly. And, once the program has finished, they requested to continue with the group. All the sessions took place as planned, with the exception of session 3 (content of identity and personal history). For young people was difficult to manage issues related to their biological family and talk openly about their parents. So, the major changes introduced in the program after are in the area of managing their personal histories.

Despite this, we identified benefits in all the systems:

- The adolescents told us that the program allowed them to share their anxieties, to identify with other young people, to talk freely about issues that interested them and helped them to develop their informal support network.
- Professionals also noted that group work is more rewarding than individual work. After the experience, professionals are more motivated to implement support groups with young people in the future. Also they noticed that individuals attending the sessions are subsequently easier to work with.
- Families and other significant adults also observed improvements, small but significant, in the adolescents' behavior, and in their relationship with them. The families and teachers ask professionals to continue with the group for better family and school relationships.

More relevant information to enhance program benefits was found. Related to participant selection and group size, after the experience, professionals and children agree that the population that makes the best use of the program is adolescents from 12-16 years old who would like to participate voluntarily and who are not currently experiencing crisis. The ideal group size is 8 to 16 participants. Related to methodology, to manage the group, the ideal number of professionals is two. The professionals need to understand that: a) groups function as a support mechanism sharing of similar experiences; b) the contents of the program help young people to connect with their personal experiences and the group dynamics should allow adolescents to have interactive discussion and take an active role within a group setting; and c) introduced the resilience perspective helping adolescents to think how to envisage the future despite current adversity.

Conclusions

The program tries to respond to the fostered needs of adolescents. These needs are consistent with our expectations and with previously published papers [12].

After being participated in the program, we found that a positive change will be the result of an effort to support young people and their kinship families. The support program allows young people to reflect upon their

situation, and to alter their attitudes using their emotions and actions. The youngsters expressed that they understand that foster care is not an issue; they can recognize the features that distinguish foster care from a variety of other situations and family models.

Then, the comprehensive model use in the support program presented here (cognitive, behavioral and emotional dimension) offers the possibility of promoting resilience because, as Grotberg [15] defends, the program helps to address the emotional difficulties experienced by fostered youth, and furthermore, include the possibility to identify the internal and external strengths of young people, suggested by Lee [18]. On one hand, the support program gives young people opportunities for participation, establishing a new support relation with the professionals and become more aware of what resources are available. And on the other hand the program minimizes risk factors by providing better social resources, i.e. creating an informal network amongst the group, by helping them learn life skills and by setting clear, firm boundaries, and a better understanding of the relationships within the foster family.

Moreover, this program brings about a change in the professionals' intervention concerning foster care: from individual to group intervention, from problem intervention to prevention, promotion and resilience intervention.

Despite of everything mentioned, more research is needed to analyse the effectiveness of the program to promote resilience in other groups and move towards evidence-based interventions.

Abstract

P.I.P.P.I. is a research-training-intervention program funded by Italian Ministry of Welfare and developed as an intensive care program for vulnerable families. P.I.P.P.I. is inspired by Pippi-Longstocking, whose life is a particular resilience metaphor, and stands for Program of Intervention for Prevention of Institutionalization. It aims at preventing child placement supporting parenting through a resilience based care process within an ecological perspective participation and multi-professional and intensive-intervention are key.

Tools were used with children and parents, in order to give them voice, to collect their points of view on their life situation, and therefore to develop a shared care plan where everyone is a main character of the intervention.

The main tool is RPMonline, an online-tool developed by University of Padua, that is based on the British Assessment-Framework and it is used for each child to assess, plan and evaluate intervention.

The first implementation (2011- 2012) involved more than 200 practitioners working in 10 Italian cities with 10 vulnerable-families each city (122 children 0-11 years old, 89 families). Data were collected using questionnaires to measure parents' satisfaction, children's behaviour (SDQ), families' social support (MsPSS), and family-functioning (Assessment-Framework). The second implementation (2013-2014), currently in progress in the same cities to consolidate and extend P.I.P.P.I., involves about 500 practitioners and 241 children (166 families). The third implementation has started on January 2014 as the first national scaling up of the program involving 50 cities, 500 families and about 2.500 practitioners.

The results of first implementation and the available data of the second one will be presented to give evidence to the program and to show how a participatory resilience based practice can foster social work with families and promote their improvement.

Keywords: vulnerable families, placement prevention, family participation, resilience based tool

The intervention program and its background

P.I.P.P.I. stands for Program of Intervention for Prevention of Institutionalization and is inspired by Pippi-Longstocking, a vulnerable and very strong girl whose resilient life is known all over the world.

P.I.P.P.I. [1] is an intensive care program for vulnerable families, funded by Italian Ministry of Welfare developed from the 2 main goals of European Community which aim at decreasing the number of children that live out-of-home and improving the effectiveness of child placement and Child Protection Services. These two main goals deal with Europe 2020 - Fighting poverty and social exclusion, and with Recommendation Rec (2006) 19 of the Committee of Ministers to member states on policy to support positive parenting. According to European Community, P.I.P.P.I. works to promote "the conditions for positive parenting, by ensuring that all those rearing children have access to an appropriate level and diversity of resources (material, psychological, social and cultural) and that broad social attitudes and patterns of prevailing life are receptive to the needs of families with children and also those of parents" (art. 3).

The theoretical framework underpinning PIPPI is the bio-ecology of human development by Bronfenbrenner [2,3], with its awareness that, to promote child wellness, it is necessary to work with all the people involved within the child's world. Hence, the self core of P.I.P.P.I. is:

- working on parental problems related to child neglect, that is intended as a significant deficiency or a failure to meet to child's needs recognized as fundamental on the basis of current scientific knowledge [4];

- preventing child placement by balancing risk and protective factors;
- supporting parenting through multi-professional and resilient-based-intervention [5];
- being a research-training-intervention program were participation and working together are key in every level and context (university, services family).

Goal and intervention

P.I.P.P.I. is designed according to the formula SI=f(E,C,P) that underline how Successful Intervention has to be considered as an intervention leading to socially significant outcomes that are made of three main factors: Evidence (What/Effective Intervention), Context (Where/Enabling Contexts) and Facilitation/Process (How-Who/Effective Implementation Methods) [6,7].

The general aim of P.I.P.P.I. is to implement and evaluate an intensive approach, structured and flexible at the same time, for family care process, able to decrease children's risk of placement out-of-home and/or facilitate family reunification by:

- articulating interventions between the different areas of activity involved around the needs of children,
- promoting the full participation of parents and children in the whole care process, building analysis, assessment and plans together to meet their needs, starting from the point that "the best predictor of success is the engagement of families" [8,9].

1.1 Outcomes of the implementation

Final Outcome (Referring to families)

- to ensure the safety of children, to foster their optimal development, to help to improve their future by avoiding the placement out-of-home;
- to improve the psychosocial functioning and cognitive development of children within the different contexts of life.

Intermediate Outcome (Referring to families)

- to enable parents to positive parenting;
- to empower parents in learning how to adequately respond to development needs of their children.
- the psychological availability of parental figures and responsible and sensitive behaviour to the needs of children improve.

Proximal Outcome (referring to practitioners and therefore aiming at building communities of practice and ensuring replicability of the intervention)

- to foster parent participation and collaboration through the care process, especially in decisions that impact the family;
- parents have the support necessary for the exercise of their responsibilities towards their children (in a sufficiently intense, coherent and continuous);
- to promote the cooperation between all the professionals involved in the care process and all significant adults caring for the children in order to allow effective integration of interventions that will ensure the well-being and optimal development of children.

1.2 Interventions

In order to support child wellbeing and parenting, different levels of interventions are used according to the needs and situation of each family:

- Intervention of Multidisciplinary Team made of case manager, social worker, home carer, psychologist, teachers, other practitioners, parents, children, other relatives, and every people involved in the promotion of children's wellbeing;
- Home care intervention;
- Parents' group;
- Support Family, that is a family that supports the target family in the informal network;
- Participation of School.

The different types of intervention attempt to supervise the various levels of the ecosystem by Bronfenbrenner and they have been required to work together in a sole care plan, shared with the participation of parents and children. For this reason the practitioners working with a family are members of a multidisciplinary team and are required to work together within a unique care plan in which everyone (parents, children and

practitioners) give his/her contribution to the improvement of the situation according to his/her resources and role.

Subjects and time

P.I.P.P.I. is the result of a collaboration between the Ministry of Welfare, the Laboratory of Research and Intervention in Family Education (LabRIEF, University of Padova), care and protection services, schools and local health authorities of 10 Italian cities (Bari, Bologna, Florence, Genoa, Milan, Naples, Palermo, Reggio Calabria, Turin, Venice) that joined the program for the first and second implementation thanks to a specific fund by the Law 285/1997, implementing it with about 10 families per city.

In the first implementation the Experimental Group consisted of 122 children 0-11 years old belonging to 89 families, and Control Group by 37 children, same age, for 35 families. More than 200 practitioners took part in the program. The second implementation, still in progress, involves 241 children 0-16 years old belonging to 166 families, and 53 children, same age (48 families) for Control Group. More than 500 practitioners are currently involved.

In January 2014, a scaling up of P.I.P.P.I. at a national level started aiming at implementing the program in 50 cities/local authorities in all the Italian Regions. Each city will choose 10 families to include in the program, therefore the implementation will involve about 500 families and approximately 2000 practitioners.

1.3 The implementation Team

The **Scientific Team** is made by researchers of the University of Padua, social practitioners and professionals of the Minister of Welfare, and is in charge of:

- organizing and supporting the use of the necessary planning, assessment and action tools;
- training, and tutoring Multidisciplinary Teams in the evaluation of processes and outcomes;
- collecting and analysing the experimentation results, discussing and presenting them to the scientific community and mostly to all the professionals, taking care of closely and constantly connecting research results with field work.

Each city has its own **Local Stakeholders Team**, made of the Leader of Child Care and Protection Service, Local Health Autority, Heads of County Education Office and N.G.O.. This team:

- plays a political-strategic role which guarantees the continuity of funding, the presence of all the professionals and the possibility to have an actual impact on the community;
- discusses, prepares and is in charge of organizing, monitoring and supporting the specific planning, monitoring and evaluation activities of every single project and of the whole programme in general;
- works to create social consensus on the project.

Each family is linked to a **Multidisciplinary Team** of professionals that is composed in a flexible way of case manager, social worker, home care worker, psychologist, teacher, G.P. ecc. The M.T.:

- has an operational function, i.e. to guarantee quality, continuity and pertinence in child and family care processes, in the implementation of the process and in the use of the existing instruments;
- Is in charge of the operational aspects and of coordinating the programme for its entire length of implementation;
- must be considered as a "variable geometry" group (core of professionals + a number of person and professionals who may join the group when needed and according on the situation and its needs).

The Coaches

In the second implementation, 3 practitioners per city who took part in the 1st implementation, are involved in peer-coaching together with the tutors of S.T. the new colleagues who will enter in the program. In the third implementation, due to the number of cities involved and to their extent, a new approach will be experimented: the S.T. that will not directly tutor the professionals and 2 professionals per city will be selected and intensively trained to peer-coach their colleagues being supervised by M.T.

Methods

The methodology used in PIPPI is based on the principles of participatory research, that aims to co-create knowledge starting from comparison of different actors' points of view. Negotiation is central in participatory research [10]: through negotiation it is possible to discuss practice, rules, routines, ecc. The final

goal is to change and to improve practice. It requires the activation of learning by doing, where participants are subjects, not only objects of the research path [12].

So, evaluation tools of PIPPI answered for a dual purpose:

- Rendicontative evaluation: to verify what happens, in order to determine the accordance with the program provisions and to report it to third parties (accountability);
- Formative and trans-formative evaluation: to allow the creation of new learning and reflexion context, for professionals, but also for families, in order to experiment new practice [11].

Mixed-methods are used, using both quantitative and qualitative tools in three data collections.

For each child the M.T. uses R.P.M.online, It is meant to foster all the process of the care plan (assessing risk and protective factors, planning and evaluating intervention) and aims at empowering the participation of all the actors involved in the intervention (firstly children and parents, and then practitioners, teachers, etc.) giving them voice, collecting their point of view and using their resources. All the tools were chosen because they allow practitioners to self-evaluate their intervention with family and because they can be use also to involved families into the evaluation process.

The main tool is RPMonline, a web-tool based on the Multidimensional Model of the Child's World that consists in the Italian translation and adaptation of the triangle of the Assessment Framework [13] and has been developed by LabRIEF and C.S.I.A. (Information Technology Center, University of Padua) [14].

R.P.M.online is meant to foster all the process of the care plan (assessing risk and protective factors, planning and evaluating intervention) and aims at empowering the participation of all the actors involved in the intervention (firstly children and parents, and then practitioners, teachers, etc.) giving them voice, collecting their point of view and using their resources.

The sides of the Triangle refer to Child's Needs, Parenting Capacity and Environmental Factors that includes respectively 7, 5, 5 dimensions that are provided with a space for assessment (difficulties and resources) in order to record the different points of view about the child and family's situation and a section for care micro-plan (to improve a situation or to empower a strength), where goals to achieve, actions to take and responsibilities are written down.

Where a change, improvement and/or empowerment is expected, each dimension provides a section for care plan where children, family and professionals are asked to write:

- goals, that are the results to reach with the intervention;
- actions, that are what the people have to do to achieve the goal;
- responsibilities, the people who carry out the actions;
- time: the time within which it is expected to achieve the goal (and in any case there will be the verification);
- monitoring: during the intervention, it is necessary to adjust the micro-planning or note key aspects of the process;
- verification: after the intervention, it is necessary to verify the achievement of the goals.

A quantitative scale with 6 levels, from serious problem to evident strength, provides a synthesis in each dimension, in order to outline changes of families. Alongside the triangle, the quantitative scale creates a Child's World Questionnnaire (CWQ) that can be used for evaluating with the family or for a wider evaluation (city or nation-based).

Other measures are used such as the Strengths and Difficulties Questionnaire – SDQ [15], completed by mother, father, home care worker and teacher; the Multidimensional Scale of Perceived Social Support – MsPSS [16], completed by mother and father.

At the end of the third (T2) data collection of the first implementation, one focus group discussions in each city were set up to highlight difficulties and strengths of the research-intervention path.

Results of first implementation

The first gathering of data was done between May and September 2011, both by the control group and the experimental group. The experimental group followed PIPPI interventions, whereas the control group followed the mainstream social work intervention. The long period of data collection was due to practitioners' needs to practice with research tools. Between April and June 2012 data were collected for the second time, only in the experimental group. The last data collection occurred in October-November 2012, both in the experimental and the control group.

Data from the analysis of care plans created using RPMonline show that:

- a unique care plan was provided for each child allowing multi-dimensional narration of the family, involving children and parents voices and promoting cooperation between family and professionals;

- in T0, interventions were mostly planned on problems and risks, while in T1 and T2 data show the planning work not only focused on vulnerabilities but also on resources of families and/or their members (micro-plans in dimensions assessed from serious problem to light problem are respectively in T0 and T2, 85% versus 65% in the side Child's needs, 90% versus 72% in Parenting Capacity and 92% versus 78% in Environmental Factors). The possibility to define goals and actions together with the family, and to walk together to achieve what expected, facilitates the focussing on change and what works better than before. This let to plan also starting from the success and from the achieved outcome, in the next time, and seem to foster the resilient path of families;
- the 70% of the goals planned were totally or partially achieved both in the first verification (T1) and in the second (T2). However, about 15% of the care plans are not evaluable because they are not written in a measurable way. Practitioners still struggle in learning a new way to define intervention plans;
- the quantitative scale, shows on average an improvement in all the evaluated areas (Child's needs: 14,2%; Parenting Capacity: 17,1%; Environmental Factors: 16,5%). Also control group improved, but less than experimental one (Child's needs: 7,8%; Parenting Capacity: 14,3%; Environmental Factors: 17,7%). The Wilcoxon test has shown significant improvements for all dimensions only for the experimental group ($p<.05$).

The SDQ regarding the Experimental Group reports a decrease of problematic situation in children's behaviour for each person that filled in the tool (Father: -12,9%, Home care worker: -22%; Teacher: -18,7%) recognized as significant by Wilcoxon test, except for mothers (-2,4%) who recognized less problematic situations at intake level. This is probably due to the "ghost of institutionalization" they were afraid of and consequently the need to show the situation of their children better that the real one. Statistical analysis confirms the improvement, showing significance particularly on Total Difficulties factor.

Same improvements aren't visible in control group (Father: -3,3%, Home care worker: -8,9%) except for the mother (-14,8%), that registered more problematic situations at intake levels than the mothers of experimental group (percentage change of 22%, shown significant by Wilcoxon test).

Multidimensional Scale of Perceived Social Support showed high level also at the first filling out for both Experimental and Control Groups. Mothers of Experimental Group show a significant variation in the factor "other adult" (8,4%, shown significant by Wilcoxon test), probably related to the introduction of Family support.

Practitioners in the final focus groups reported that PIPPI for them represented:

- a place for a multi-disciplinary and shared decision making;
- an opportunity of reflection in action;
- an opportunity to learn new practices of family's participation;
- an opportunity of document and evaluate their work with families.

Finally, data about care process refer that 8 out 89 children of Experimental Group are not in care anymore, and for 50% of families the intervention was lightened, versus 35% of families in Control Group. Moreover, 55% of the Control Group Families worsened versus 8% of Experimental Group.

Conclusions

Results give evidence to efficacy of the program in terms of goals that were achieved, of positive changing in families and of process of change in social practice that significantly started. The implementation gave evidence to the importance of an holistic and integrated approach in evaluation, planning and intervention with families. On one hand the research show the first implementation let to identify, codify and evaluate an intensive approach of reducing risk of placement care path. On the other hand, it underlines that is key to guarantee an intensive and continuous intervention that need to be promoted by inter-institutional network of services.

Referring to the intervention with families, the main challenging to deal with and to take in account in the future are:

- on one hand practitioners learned how to used the tools, on the other hand it is still difficult integrating tools into everyday care practice;
- the process of multiprofessional intervention was harder than expected because the integration with some services (mainly school and health services) is still difficult and often it's no easy to involve a family of support within the planning process;
- the real involvement and a fully participation of the family in assessing, decision making, planning and evaluating together needs to be improved in order to really develop a resilience based approach in working with families.

To face these challenges and to keep the connection between research and intervention, training for new practitioners were run, tutorials on working with family and planning and organising integrated work within multidisciplinary team are planned for the time of implementation. P.I.P.P.I. on one hand shows and prove change, and on the other shows that changing practice is a long process that requires a co-development between practitioners and researchers. The presence of peer-coaches aims at fostering practitioners and researchers in achieving and realizing the learning and gradual adjustments that are necessary to integrate into practice P.I.P.P.I.'s new model of care process. Coaches also are the first step towards the long-term goal of P.I.P.P.I. that consist in helping each city in being able in the future to take care of the whole implementation process, as the role of the tutors decreases. The 2nd implementation has been key to identify and define with the 3 levels of the Implementation Team the future steps for scaling up the program in a way that:

- is sustainable within the Social Services work, mostly in the current time of social-economical issues, and empowers the full potential of social professionals and M.T.;
- promotes and reaches socially significant outcomes for children and family wellbeing;
- keeps the optimism in social work and empowers all the resources available in the community.

Abstract

Children, who are in the child protection system, in residential care or foster care, have to face different stressful situations brought about by being separated from the family context. To achieve a successful family reunification afterwards these children have to overcome a series of phases throughout the reunification process such as: the notification of the measure (separation from the family) visits and contact during foster care, preparation for the family reunification and lastly the return home and their consequent adaptation.

To help with this process the GRISIJ group used the cooperative research framework (MCI:EDU2011-30144-C02-01) as presented, to find out which strategies strengthen resilience in the different phases of the reunification process, by analyzing the needs felt and presented by the children. Field work was carried out in 2012 with children in child protection and with the welfare staff. Focus groups were formed and interviews carried out in four autonomous regions in Spain. Thirty adolescents and pre-adolescents who were or who had been in child care and protection participated. The needs detected were: help to cope with the distress and confusion, the importance of informal support and the need of the children to participate more themselves in the process. Strategies which helped them overcome this process and achieve a successful reunification were recognized: having certain social skills; a capacity to resolve conflicts, a feeling of control, coping skills, having informal support and take the correct standpoint and attitude towards the measure.

Keywords: Foster care system, strategies to strengthen resilience, reunification process.

Introduction

The investigation which we are presenting falls within the framework of the field of child protection, and specifically it is to make known the strategies promoting resilience and used by the boys and girls who are in residential care or family fostering in order to overcome different stressful situations provoked by the separation from their family context, and which permit them to achieve a successful family reunification.

Separating a boy or a girl from their family is a traumatic experience for all the family as it represents a long and difficult process [1]. However, for the children above all it is especially difficult as it is they who must abandon the family nucleus and must face up to the challenge of living in a protection resource.

Few studies shed information on the necessities of the children in the process of reunification and the strategies they use to come to terms with the situation of entering care. Certain characteristics of the children can influence the reunification system, recognising that the children do have a role in all the process. In a study the children felt that if they had a voice in this process, there would be a greater possibility of a successful exit from the care or fostering. The lack of participation creates feelings in the children far from helping them to face the situation. This diminishes their self-esteem and self-sufficiency [2].

To achieve a satisfactory family reunification the boy or the girl has to overcome a series of phases encountered in any reunification process. These stages are 1. Taking the measure, the initial phase which consists of the period of time between communicating to the family the separation, the proposal of reunification and then the following phase. 2. Visits and contacts, is the phase of maintenance of the connection; it starts with the realisation of the communication of the measure and it ends when the child returns in the strict sense to the biological family home. 3. Preparation for the reunification, this phase takes in the time period from the moment

after the separation of the children from his or her family up to the moment before the reunification. And finally, 4. The follow up phase that goes from the first few days at home until the consolidation and stabilization of the reunification process.

An aspect highlighted by different authors as fundamental to achieve success in the reunification is to know what the children experience and the impact for the boys and girls of the communication of the measure and taking them into care in the initial moment. This is an important and influential element for the rest of the process. The fact that the children can count on information and preparation for them to face up to the changes they produce in the family situation is a necessity identified by many authors [3]. Another element highlighted is the importance of the formal and informal support which guarantee the success and stability of the reunification [4].

From the perspective of resilience and contemplating the children with capacities and resources, it can be seen that it is important to identify strategies that can help them to face this situation with the finality of contributing to their development, resilience and the family reunification. Some authors have manifested that the child's understanding of the difficulty is a vital aspect of the resilience process in the family reunification [5,6,7]. A global comprehension would imply that the children are conscious of the situation, aware of the problem and understand the reasons why the family has had to be separated, and they have the commitment, the undeniable desire to accept and make the changes necessary to facilitate the family reunification.

In response to this situation the GRISIJ group organized cooperative action investigation (MCI:EDU2011-30144-C02-01), which aimed at finding out the strategies promoting resilience in the different phases in the reunification process, starting out from an analysis of the boys' and girls' necessities in the process.

Methodology

To discover and collect the information discussion and interview groups of children were organized from four autonomous communities of Spain. In this study thirty adolescents or pre-adolescents participated: all were or had been in the protection system. We wanted to make known the voices of these children.

Listening to and making the voices of these children be heard has worked in favour of their right to participate and contemplate the questions that affect them and they are themselves [8,9] as well as recognising the right of these children to participate in the process, practice and investigation, as recommended in the new policies and national and international regulation framework.

The selection criteria for the participants were that they had to be between 12 and 20 years old and belong to the selected biological families; that they had been at least a year and a half in residential care or a foster family, and that they had no physical, psychiatric or sensorial disability.

To gather the information semi-structured discussion and interview groups were formed; to process the analysis of the data we used a qualitative analysis methodology. The Atlas-ti, v.6.0 software program was used in the coding process.

Results

The following results from the discussion and interview groups with boys, girls and adolescent participants stand out.

1.1 The communicating the measure phase

The majority of the children interviewed coincided in that they needed more information, although the results did provide evidence of two very different situations; 1. When the motive for the separation was linked to the child's behaviour, they took consciousness of the problem as they could identify the elements of their behaviour that had produced the difficulties. 2. When the causes of their vulnerability grow out of family problems, many children did not know the reason why they had been separated from their family, which made difficult the comprehension and assuming of the information. Some studies have manifest that the comprehension of the difficulties is one vital aspect of the resilience process in the family reunification [6,7,8].

> *"When I entered the centre two weeks passed without speaking with my mother, and I couldn't go out, and see her, like for one month, and this made me think a lot, and so I don't know, it helped me to think about the mistakes I had made and in everything". (Interview with boy)*
>
> *"So they hardly gave me any information, just that I was going away with my sister a while, not for long, and that was it". (Interview with boy)*

This lack of information has repercussions on the emotional control of these children. When they do not know the motive of the separation and they have not been told about the process they feel greater anxiety.

"I started to cry and my sister and I went through it real bad when they did it, but we got to the centre and that was it, we went to play with some children as if nothing was wrong. There was no problem". (Interview with boy)

With respect to the motive for the change, in some cases, above all with little children, they are not taken into account in the process and the relationship with them has to work on their behaviour, asking for their participation in the process.

"When they told me if I did the things right and if I changed, then soon I would go home, that's what made me think "if I am good I will be able to get out of here soon". (Interview with boy)

"They should let us speak too, because we have the right that they listen to us, just as we listen to them". (Discussion group of boys and girls)

1.2 Visits and contacts phase

To control the emotions in the moment of the visits is an important element. The results show that there are children who benefit from a good experience with the visits and for others they represent an emotional unbalancing, above all for the youngest children. The contradiction and ambivalence of the feelings and emotions of the children are made evident. They experience feelings of love and anger towards their parents at the same time. The children have the necessity to maintain contact with their parents, despite the situation prior to the bad treatment. Children also need to identify their educator of reference as a true support in order for them to control their emotions for the visits.

"The majority of times my mother broke down crying as soon as she came through the door". (Discussion group for boys and girls)

"Visits to see my parents, when they started a week had gone by but my mum had to come and in that moment I was still feeling rage and resentment, that is to say I did not want to see her or look at her, did not want to speak to her and, well.. And from then on the sessions went by and they were good, with my father and my mother". (Interview with boy)

"Well, when there was something that made me feel bad, I did talk it over with my educators and they gave me advice and spoke to me about it, and so on". (Interview with boy)

1.3 The preparation for the reunification

The child's feeling of wanting to form an active part of the family unit is experienced as an element for change. In turn the children manifest that space should be given for communication in the moments of the reunification to parents, children and technicians. Another important element in this phase is to adjust or set the expectations on return to the family and work on them as uncertainty in front of the reunification process produces feelings of rage, anxiety and sadness in the children. They see the figure of the social educator as significant for emotional control in this process.

"Then I believe that ... starting over your life from zero if you have been through a super-heavy case, because my case was heavy and I think "huff, how am I going to get over this? But I believe they give you an opportunity to move forward from zero, I believe you are reborn well perhaps not so exaggerated but for me it was and I am proud to have passed through all the centres in the clinic because if you let yourself be helped, they help you, because before I did not let myself be helped, they put in all their effort, isn't it like that? All the educators' effort, and until one wants you can't be helped". (Discussion group of boys and girls)

"Yes, the truth is yes, sometimes I look and I see, it's difficult not to, isn't it? However that is the way it is and sometimes you get tired of being strong because you want to be happy without having to be strong, but hey look…" (Interview with boy)

1.4 Follow up phase

The results show that the children recognise the family progress, although in the moment of the reunification different emotions all crowd in: harbouring rancour toward their parents for the situation that has happened, make a process of adaption to the change, all of this means for them that they are filled with emotions difficult to order and control. The child's perceive the educators as people of support to whom they can turn, who offer them advice and help them to order their emotions.

"Yes, it's been a time during which we received help which made us better, that we can get better as people, more tolerant, more understanding; it has changed me a lot. I have learned and my mother too". (Interview with boy)

"I felt strange, the house was smaller, it smelt different, my father was older, everything very different". (Interview with a boy)

"They always said that they were there for us for anything, to talk or anything, and if anything happened to us we could talk to them and they'd help us". (Interview with boy)

Conclusions

Starting out from the boys,' girls' and adolescents' viewpoints we have been able to identify the priority areas for favouring this reunification. From there our objective is to transform the necessities into contents that form part of the conception of a social-educational action program for families who are in a process of reunification, always from the perspective of more, stronger resilience.

Acknowledgments

This study has been developed by the support of Research Group about Social and Educational Interventions in children and youth (GRISIJ), and financed by the Ministry of sciences and technology in Spain (Ministerio de Ciencias y Tecnología de España) (Ref.: EDU2011-30144-C02-01).

Trajectoire de vie adoptive: quelles résiliences face à la rupture originelle?

Abstract

Resilience is the ability to make sense of the nonsense without cutting yourself from the surrounding world, "to feel a crazy experience and [to] make a coherent narrative" [1]. Making sense is a way to have taking the total discontact of precisely nonsense. [2] Psychological factors of resilience are many, research helped to identify ten: defense / protection; the equilibrium in front of tension (hold on); commitment-challenge; recovery (rebound); assessment; the significance / evaluation; positivity of self; accountability; creating and opening to the world, attachment [3].

Having lived a childhood abandonment releave most often the nonsense. This life experience can brake the feeling of existence, generating the emergence of psychic conflicts that involve conflicting evidence both emotionally and cognitively that it is difficult to connect and understand them. Resilient capacities are then needed to find and create a good mental balance.

We went to meet 18 young adults aged 20 to 25 years which having been adopted. From their narrative skills, their attachments to their restorative lines, we propose to observe how in their mental construction, they bring meaning and develop resilient behavior. We present situations Baku, Maeva, Corneille, Samy and others that each in their own way develop resilience in different areas of expertise.

Keywords: Adoption, Attachment, Abandon, Resilience.

Regard sur la résilience

Le concept de résilience est multiple et aujourd'hui utilisé dans des situations variées. Il reste toutefois cette notion de traumatisme face auquel un sujet mettra en place différents comportements qui évolueront en fonction de ses besoins développementaux et psychiques. La rencontre avec la résilience ne se fait pas aux mêmes périodes de la vie selon les personnes. C'est lorsqu'un événement est perçu comme venant déstabiliser l'assiette narcissique, lorsqu'il vient mettre en péril le sentiment d'identité personnelle amenant à une variation du sentiment d'existence que la résilience peut apparaître. Les potentiels de chacun diffèrent, les ressources internes ne sont pas toujours identiques et les désirs de vie peuvent être différemment exprimés [3].

La résilience possède une double fonction de « résistance à la destruction et la construction d'une existence valant la peine d'être vécue » [4]. On comprend en cela le principe évolutif et dynamique de la résilience mais aussi son caractère aléatoire en ce sens où en fonction de la situation traumatisante, le comportement résilient pourra varier. Ces variations peuvent être dues à l'individu lui-même mais aussi à son environnement familial, les deux s'entrecroisent et s'imbriquent [5]. En partant de l'idée selon laquelle la résilience n'est pas une dimension mais un résultat, celui de multiples processus [3,6], nous avons, au cours d'une recherche fondamentale, proposé neuf processus caractéristiques de la résilience. Ces caractéristiques ont été repérées à partir de l'étude de sujets ayant connu une ou des situations traumatiques dans leur parcours de vie (diagnostic de cancer, ruptures de liens multiples, maltraitance, handicap). Un dixième processus a été ajouté par la suite.

La défense / Protection correspond aux personnes alternatives qui jouent le rôle de tuteurs développementaux dans la trajectoire de vie. C'est la potentialité de se raccrocher mentalement à un modèle qui aidera à trouver des réponses face à des situations d'adversité. *L'équilibre face aux tensions (tenir le coup)* est relatif aux capacités de flexibilité de l'individu, sa souplesse adaptative et son habileté à développer de nouvelles stratégies lorsque les anciennes sont devenues inefficaces. *L'engagement-défi* répond au besoin d'expérimenter le risque et la prise d'initiative pour s'affirmer et se sentir exister ou se prouver sa propre existence. *La relance (rebondir)* correspond à la dynamique positive du sujet, ses capacités à refaire surface, à reconstruire après le traumatisme. *L'évaluation* est en lien avec les potentialités d'analyse et de ressourcement lorsqu'on fait une

synthèse des possibilités dont chacun dispose. Cela concerne la conviction intime que l'on a de trouver une issue plus favorable à la situation. Le processus de *Signification / Valuation* nous amène à la notion d'autonomie, autrement dit la possibilité de se constituer ses propres valeurs pour donner du sens et faire des choix. Prendre des décisions argumentées et les assumer est une forme de la résilience.

La positivité de soi est relative aux capacités d'humour qui vont de pair avec la confiance en soi. C'est encore croire au bonheur et trouver la vie belle, coûte que coûte. Le processus de *responsabilisation* peut être compris comme le fait de se sentir responsable de ce que l'on est, de ce que l'on peut devenir, il participe à l'instauration de la résilience [3]. *La création* serait en quelque sorte l'aboutissement du processus résilient, lorsque par les différentes potentialités recensées nous amènent à créer un espace de pensée qui permet de trouver une solution favorable face à la difficulté. C'est une façon de laisser trace de soi, de générer du mouvement psychique, relationnel.

A ces neuf processus, nous avons ajouté celui *d'Ouverture au monde et d'attachement* qui ramène le sujet à son contexte social présent et originel dont il ne peut se départir. C'est parce que les réponses trouvées pour gérer l'adversité ou le traumatisme sont à la fois personnelles et relationnelles qu'elles permettent au sujet de rester connecté à la réalité. Nous pouvons penser que nous avons tous ses potentialités résilientes en nous plus ou moins enfouies, faisant face à plus ou moins de résistances psychiques. Il est parfois nécessaire qu'une intervention extérieure vienne aider à la découverte de ces ressources insoupçonnées.

La trajectoire de vie liée à l'adoption comporte le plus souvent de multiples événements de vie qui peuvent chez certains générer du déséquilibre et des difficultés psychiques. Les recherches portant sur l'adoption montrent que les jeunes adolescents ayant vécu la rupture, le rejet, la détresse affective, la vie institutionnelle, parfois la maltraitance, peuvent se développer tout à fait sereinement malgré les événements aliénants composant leur trajectoire de vie [2]. La situation d'adoption semble fonctionner comme l'impulseur du comportement résilient en proposant au jeune la création d'un attachement de type sécure et un fort soutien social familial facteur de protection.

L'adoption en fournissant une famille à un enfant qui en est dépourvu, donne la possibilité d'échange verbal, de mise en paroles des vies de chacun. Par la capacité d'écoute et l'attitude ouverte au dialogue, notamment en raison de la préparation qui est faite auprès des couples adoptifs, la détresse est parlée ou montrée et partagée. « Tous les chagrins sont supportables si on en fait un récit » [7]. Les observations témoignent d'une plus forte résilience individuelle « chez les enfants qui ne sont pas séparés de leur famille ou qui, en cas de séparation, ont trouvé un substitut, si possible chaleureux et un milieu d'accueil culturellement familier » [8].

La famille, pensée selon ses capacités de résilience [5] évite le désert affectif. En fait, aucun enfant ne peut devenir résilient seul. Les ressources internes sont uniquement acquises si l'enfant a trouvé pendant sa petite enfance « une bulle affective qui permette de graver dans sa mémoire un processus de stabilisation interne qui l'incitera à chercher le tranquillisant dont il a besoin. Ensuite, ses ressources internes seront imprégnées par la stabilité du milieu » [9]. L'adoption permet l'évitement du syndrome abandonnique c'est-à-dire le sentiment de n'avoir jamais été aimé de manière stable. Lorsque les relations familiales sont faites de communication claire et ouverte, d'expression des émotions, de solidarité et d'ouverture vers le monde extérieur autour de narrations et de croyances qui cimentent le groupe et sa cohésion, alors chacun de ses membres peut développer des capacités résilientes face aux traumatismes de la vie [10].

Les événements de vie dans la trajectoire adoptive initiateurs de comportements résilients

Même si chaque histoire d'adoption est une rencontre singulière, il existe des étapes qui sont communes à l'ensemble des enfants adoptés. Chacune de ces étapes fera l'objet d'une activité de représentation mentale plus ou moins positive, plus ou moins aliénante. Nous pensons que lorsqu'au moins une de ces étapes suscite des représentations négatives, des émotions fortes envahissantes, des points de blocage, alors des comportements résilients peuvent être mis en place par le sujet venant en quelque sorte compenser cette partie de l'existence faisant traumatisme. Nous comprenons le traumatisme non pas comme l'événement en lui-même mais plutôt comme l'effet de l'événement sur le psychisme. Nous rappelons ici succinctement les différentes étapes de la trajectoire adoptive.

1.1 Le contexte originel familial

Chaque enfant adopté s'interroge à un moment de sa vie à propos de ses origines. Dans quelles conditions est-il né ? A-t-il été désiré ou résulte-t-il d'un acte violent ? Qui sont ces parents capables de se séparer de leur enfant ? Tout enfant adopté va avoir une activité de représentation à propos de son histoire et des événements émotionnels qui la composent. Une forme de loyauté filiale existerait dans l'activité représentationnelle poussant certains adoptés à prendre la responsabilité ou à assumer la culpabilité de leur abandon ou l'attribuant à leur famille adoptive. La famille d'origine est rarement représentée sans valeur. On voit

fréquemment apparaître des orientations professionnelles singulières qui viennent réparer cette étape de l'existence (sage-femme, aide-soignant en maternité, infirmier en pédiatrie…).

Se représenter ses origines et les événements qui ont orienté vers la trajectoire adoptive, amènent aussi à questionner le sens de l'abandon, de la rupture originelle. La douleur provoquée par une rupture s'accompagne toujours du sentiment intense de menace pour l'intégrité du soi et pour la continuité de sa propre existence. Une rupture représente la cessation de l'état d'union. Elle provoque la crise identitaire. La rupture nécessite un travail de deuil. L'abandon est une forme de rupture. La cicatrice de l'abandon reste sensible toute la vie et peut à tout moment être réactivée douloureusement par les différents événements de vie.

1.2 Le temps entre l'abandon et l'adoption

Cette période, dans la trajectoire adoptive, est celle où l'enfant est symboliquement seul. Il perd les quelques repères établis dans sa famille biologique. Les conditions de recueil de l'enfant abandonné sont multiples, elles varient d'un pays à un autre et dépendent aussi de l'âge de l'enfant. Ce temps peut être pour certains enfants une période assortie de nombreux déplacements, un temps d'absence d'accroche en raison des ruptures de lien successives. Certains enfants vont expérimenter l'absence de figure d'attachement adulte sécurisante se traduisant par la dépression anaclitique et l'hospitalisme [11]. D'autres vivront des expériences d'errance affective, de maltraitance ou de prise de responsabilités ne correspondant pas à l'enfance. Lorsque ce temps est associé à des impressions négatives, des sensations douloureuses, beaucoup d'enfants « préfèrent » oublier, le refoulement étant alors à l'œuvre. Nous verrons dans les vignettes cliniques que nous présenterons, comment face à l'adversité et au traumatisme de cette étape certains adoptés trouvent des réponses adaptatives positives leur permettant de rebondir.

Cette étape de la trajectoire adoptive comporte également la préparation ou son absence vers une autre rupture : celle de l'adoption. Ce n'est pas tant la préparation effective que nous prendrons en considération mais plutôt le sens que cette préparation peut faire dans la construction psychique de l'individu. Préparer une rupture, c'est mettre de la parole sur le sentiment de désarroi et de cassure, c'est pouvoir exprimer sa souffrance avant même qu'elle soit réellement vécue. C'est éviter qu'elle soit accidentelle et vécue comme une effraction dans le sentiment de cohérence interne. Pour certains enfants adoptés, l'idée de l'adoption ne fait pas sens, ne génère aucune projection, aucun mouvement psychique, alors la rupture définitive d'avec le pays peut être ressentie par l'adopté comme un second abandon, comme un obstacle au besoin vital de continuité. Nous verrons dans les vignettes cliniques, comment certains jeunes adultes adoptés s'adaptent à l'absence de signification de leur histoire afin de tenir le coup, garder le cap et avoir une raison d'être en existence.

1.3 L'amorce du processus de filiation : la rencontre adoptive

Nous parlerons enfin de la première rencontre signant le début du processus de filiation. La rencontre adoptive est souvent déterminante des relations ultérieures. Le moment de la rencontre est crucial et reste pour toutes les familles adoptives un événement de vie chargé d'émotions. Les témoignages sont nombreux pour décrire la violence incroyable du choc du premier jour. Les enfants ayant reçu à l'avance des photos de leur nouvelle famille sont ceux qui développent l'attitude la plus positive. Mais d'autres enfants peuvent se mettre à hurler, partir en courant. Le comportement le plus typique consiste à marquer une certaine réserve, de la timidité, voire à pleurer silencieusement, mais à se laisser apprivoiser dans les 24 heures. Les quelques semaines qui suivent l'arrivée dans la famille de l'enfant sont fréquemment marquées des troubles adaptatifs : difficultés d'endormissement, terreurs nocturnes, troubles énurétiques. Un phénomène protecteur de régression temporelle se met en place : de la recherche de nidification au conflit exacerbé, la régression a une fonction d'amorce de l'attachement. Quel que soit l'âge de l'enfant, cette période est importante pour sa construction psychique, les parents ont un rôle essentiel à jouer par leur présence, leur disponibilité physique et émotionnelle auprès de leur enfant. Lorsque ce moment privilégié d'exploration réciproque de la qualité des sensations nouvelles est absent, cela peut entraîner des comportements de passivité pathologique notamment à l'adolescence car une étape développementale n'a pu s'effectuer.

Résultats d'observation pour 18 jeunes adultes anciennement adoptés, illustrés par des vignettes cliniques

1.4 Méthodologie de recherche

Au cours d'une recherche réalisée en 2012-2013, centrée sur la résilience et le lien social dans l'adoption, nous avons rencontré 18 jeunes adultes âgés de 20 à 25 ans (M_1 = 21,22 ans) anciennement adoptés. L'échantillon de recherche est constitué de 12 jeunes femmes âgées de 20 à 25 ans et 6 jeunes hommes âgés de 20 à 23 ans. Tous ont été adoptés au niveau international (14 de Corée, 1 du Liban, 1 de Madagascar, 2 de

Pologne). Les âges d'adoption varient de 1 an à 13 ans et demi (M_2 = 7 ans), l'âge au moment de l'abandon évolue de la naissance à 10 ans (M_3 = 5 ans). La durée écoulée entre l'abandon et l'adoption va de 6 mois à 7 années et demi, soit une durée moyenne de une année et dix mois (M_4 = 22,8 mois). La composition des familles adoptives se répartit de la façon suivante : Deux jeunes adultes sont enfants uniques, six sont dans une fratrie de 2 enfants, trois en fratrie de 3 ou 4 ou 5 enfants et un est dans une fratrie de plus de 6 enfants. Dans l'échantillon, 4 jeunes adultes ont été adoptés seuls, sans présence d'autres enfants dans la famille au moment de l'arrivée, 5 ont été adoptés en fratrie de 2 ou 3, un est arrivé avec sa sœur biologique, des frères et sœurs adoptifs étaient déjà présents dans la famille adoptive et 8 jeunes ont été adoptés seuls mais une fratrie du couple adoptif était déjà présente dans le foyer familial. La place occupée dans la fratrie est également considérée : 2 sont enfants uniques, 6 sont les aînés de leur fratrie, 3 sont les cadets, 4 sont puînés et 3 sont les benjamins.

Le recueil des données repose sur des entretiens cliniques de recherche inspirés de la grille d'entretien de *l'Adult Attachment Interview* traduite par Pierrehumbert [12] et des dix processus de résilience précédemment décrits [3]. Notre approche est qualitative tout en s'appuyant sur des données métriques obtenues à l'aide d'outils d'évaluation du discours. Ainsi, chaque entretien retranscrit est analysé à partir d'une double cotation avec l'outil Edicode [12]. Celui-ci est « destiné au recueil et à la quantification de l'appréciation subjective, par l'interlocuteur ou par un codeur extérieur, de la mise en forme de l'expérience subjective également du sujet au cours d'entretiens semi-structurés, ceci dans une perspective de recherche clinique » [12]. Une seconde cotation est établie à partir d'une échelle de résilience. Cet outil est en cours de validation statistique et est uniquement utilisé ici afin de mieux saisir les enjeux de la résilience dans le discours de la personne.

1.5 Les capacités narratives

C'est à partir des travaux de Main [13] qu'un intérêt a été porté sur l'interaction entre la qualité de l'attachement pendant l'enfance, les capacités de métacognition et les récits de l'attachement chez l'adulte [14]. Dans cette thématique, Fonagy *et al.* [15,16] se sont particulièrement centrés sur la notion de fonction réflexive, proche de la mentalisation décrite en psychanalyse ou également mise en lien dans la théorie de l'esprit [17]. Il s'agit de la capacité à percevoir, de penser les états mentaux de soi et d'autrui. La fonction réflexive est ce qui permet de donner du sens aux comportements d'autrui à partir d'une capacité de lecture de ses propres émotions, des croyances et des attentes de soi et d'autrui. Les capacités narratives font partie de la résilience dans la mesure où elles permettent d'anticiper les situations, de mieux gérer les relations avec autrui et elles garantissent la différenciation entre soi et l'autre.

Il apparait que les traumatismes de l'enfance peuvent altérer la fonction narrative et ainsi les capacités de mise en discours des personnes. Toutefois, en favorisant l'expression de soi, la mise en pensée des émotions négatives et des événements de vie marquants, il est possible de développer des comportements résilients afin de gérer les traumatismes [1]. Les 18 jeunes adultes rencontrés sont majoritairement dans une volonté d'expression. Même si leur histoire est difficile, par exemple Maeva qui a 20 ans, adoptée à l'âge de 13 ans et demi, a été victime de l'alcoolisme de son père biologique qui la battait. Comme elle, la plupart de ces jeunes adultes parlent beaucoup et expriment les émotions qui surviennent au détour de leur récit. « *Avec cet échange, les souvenirs rejaillissent et on est plein d'émotions* ». Le fait de pouvoir faire un récit de leur histoire de vie semble pour nombre d'entre eux participer à donner du sens. « *Je ne m'étais jamais autant questionnée… c'est bizarre, c'est bien…* ».

Bakou, âgée de 20 ans, adoptée à l'âge de 11 ans en France avec sa petite sœur est dans une forte volonté de participer, de parler d'elle mais il lui est difficile de dire ses émotions, par pudeur, par retenue. L'envahissement émotionnel est présent, l'amenant à faire des pauses pour reprendre son calme intérieur. Faisant suite au décès accidentel de ses parents biologiques, le récit de la séparation d'avec un petit frère est un moment douloureux où elle ne peut retenir ses larmes. Elle refuse d'arrêter l'entretien, elle veut parler, peut-être d'ailleurs plutôt témoigner. Une façon pour Bakou de donner du sens par la narration d'elle-même.

Pour Corneille qui a 20 ans et a été adopté à l'âge de 9 ans avec sa petite sœur biologique, le discours favorise la formulation d'interrogations multiples. « *Que serais-je devenu ? Qu'est-ce que j'aurais pu vivre si je n'avais pas été adopté ? Est-ce que j'aurais pu vivre autrement ? Ça se bouscule là dans ma tête… pfou…* ». Samy, qui a 23 ans et a été adopté à l'âge de 9 ans avec ses deux plus jeunes frère et sœur biologiques, est, dans le premier temps de l'entretien, dans une attitude défensive. Un peu moqueur, il paraît chercher la provocation par des images morbides dans son récit, « *alors voilà, je viens de là, c'est mes racines, je viens d'un arbre qui n'a pas de racines, il est mort et nous c'est pareil ! On est morts voilà, c'est tout… On est des morts-vivants, des fruits pourris, des rebus de la société…* ». A partir de cette entrée en matière, Samy va organiser sa narration, il va évoquer les événements de sa vie qui l'ont marqué, les moments de joie, de tristesse, de stress. En fin d'entretien, il va se remettre en question, allant même jusqu'à nous demander si ce qu'il a raconté convenait.

Une seule jeune femme, Emma, âgée de 21 ans, adoptée à 5 ans, ne présente pas de fortes capacités de narration. Ses réponses aux reformulations sont brèves, les blocages du discours sont importants masqués par de nombreux « *je ne sais pas, je ne me souviens plus, j'étais trop petite…* ». Nous percevons rapidement dans cette situation des difficultés dans les relations à autrui. Elle expliquera son impression d'être en permanence dans un

sentiment de colère envers tout le monde. Cette émotion négative qui traduit son mal-être semble l'empêcher de mettre une logique dans ses idées et dans son récit de vie.

1.6 L'attachement

L'attachement dans l'enfance se manifeste par des comportements ; l'attachement chez l'adulte se traduira notamment par ses propos, son récit concernant son histoire de vie, ses représentations de l'enfance et ses capacités d'accéder à des souvenirs précis relatifs aux relations durant l'enfance. L'attachement a beaucoup plus à voir avec un sentiment profond de sécurité. Ce sentiment de sécurité et de confiance se tisse parce que dans l'enfance des réponses adéquates aux détresses ont été apportées. Le sentiment de sécurité interne est facilité par le fait de se sentir aimé, respecté et estimé par sa famille, ses amis et les autres, il prévient le risque de troubles psychiques de la déliaison.

Dans des proportions proches à la répartition de la population générale pour la sécurité d'attachement (54 à 66%), le taux de préoccupation (11 à 18%) est toutefois plus élevé dans l'échantillon de recherche tandis que le détachement est ici nettement moins élevé (population générale : 21 à 29%). Les jeunes adultes évalués privilégient pour 13 d'entre eux la sécurité d'attachement (72%), pour 4 la préoccupation ou l'attachement ambivalent (22%) et une jeune femme, Emma, est détachée (6%) (Fig. 1).

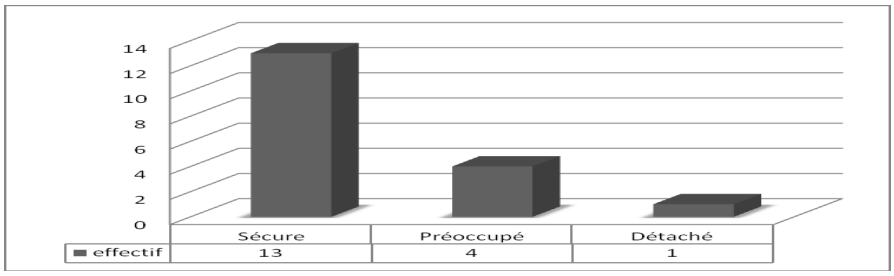

Fig. 1 – Répartition de l'attachement chez les 18 jeunes adultes

Maeva est une jeune femme préoccupée au niveau relationnel, tout comme Samy. Elle estime avoir du mal à faire confiance facilement. Ses parents sont très présents auprès d'elle, elle a un petit ami, mais elle doute souvent de sa sincérité. Elle est souvent dans une forme d'angoisse qu'elle n'a pas anticipée et qui vient lui dicter des conduites parfois agressives envers les autres. Son discours traduit son fonctionnement affectif et relationnel. Elle parle beaucoup, la fluidité est importante mais sa narration manque de cohérence et d'adéquation. En revanche, l'authenticité émotionnelle de Maeva dans l'échange ne fait aucun doute. On est facilement saisi par son récit.

Emma privilégie le détachement relationnel. Sa narration fait état de peu de fluidité, une forme de rigueur dans la cohérence et l'adéquation et sa distance affective et émotionnelle rend son discours relativement inauthentique. Emma n'a aucun souvenir de sa vie avant son arrivée en France, à l'âge de 5 ans. Elle évite d'aborder toute réflexion pouvant susciter un mouvement affectif en elle. Aussi le décès de son père il y a quelques années laissant sa mère s'occuper seule d'une fratrie de trois enfants n'est jamais abordé durant tout l'entretien. Ce n'est qu'au moment de notre départ qu'Emma déclarera « *ah, j'ai oublié de parler de la mort de mon père… oh, c'est pas grave, ça ne me fait rien* ».

1.7 Les conduites réparatrices et la résilience

Les jeunes adultes rencontrés sont, pour une majorité, scolarisés : Bakou est en Première, trois sont en Terminale, sept sont en première année universitaire ou de préparation aux concours, deux en licence 2 et 3, une en Master 1. Quatre sont entrés dans la vie active : une est technicienne de laboratoire, un est militaire et deux jeunes femmes sont au chômage après l'obtention d'un CAP (petite enfance et ébénisterie). Parmi les orientations ou projets professionnels on pourra trouver : militaire, coiffure, école de commerce, langue, comptabilité-gestion, droit, hôtellerie, infirmière, ébénisterie, pompier professionnel.

Parmi les orientations exprimées, nous trouvons Jenny qui, à 20 ans, est en troisième année de Droit. Arrivée en France à l'âge de 6 ans et demi, elle déclare vouloir choisir le domaine des affaires familiales « *parce qu'il y a du travail à faire pour les enfants en souffrance dans leur famille* ». Jenny met en place des conduites résilientes parmi lesquelles on note la souplesse adaptative face à des situations difficiles, elle trouve des compromis psychologiques lui permettant de trouver un équilibre. En relance permanente face à l'adversité, elle démontre un grande prise de responsabilité dans l'ensemble des situations. Son ouverture aux autres et aux relations sociales vient compenser plus de difficultés dans le fait de donner sens aux situations trop envahissantes au plan émotionnel.

Citons enfin Denis, 20 ans, arrivé en France à 7 ans et demi avec son plus jeune frère, qui, au moment où nous le rencontrons, semble « s'assagir » après une période de plusieurs années au cours de laquelle il a mis en place des comportements délinquants. Denis a fugué lorsqu'il avait 16 ans pendant quatre jours et trois nuits, vers l'âge de 17 ans il a volé une moto avec laquelle il a eu un grave accident, ses parents ne comptent plus les fois où la gendarmerie leur a téléphoné au sujet de leur fils. Ses résultats scolaires sont mitigés et il redouble sa terminale. Mais depuis environ un an Denis a une petite amie. Il met en avant des conduites résilientes de responsabilisation en s'attribuant ses échecs mais aussi ses réussites. Il éprouve des difficultés à trouver un équilibre émotionnel, devant se calmer, respirer ou prendre l'air à l'extérieur lorsqu'il est face à une difficulté. Il ne trouve pas de sens à sa vie mais son amie l'apaise et lui donne des objectifs à atteindre. Denis privilégie un attachement sécure, il se remémore avant son adoption la présence de sa grand-mère maternelle qui lui a apporté un sentiment de bien-être et du réconfort, tel un tuteur de résilience. Le domaine de la créativité est encore éloigné de Denis qui est en cours de changement mais a besoin d'être soutenu et encouragé.

Conclusion

Les 18 jeunes adultes anciennement adoptés témoignent de leur difficulté à trouver un sens à leur existence. Malgré des événements de vie marquants voire traumatiques ils parviennent à réparer en partie une trajectoire conflictuelle. Pour la plupart d'entre eux leur famille adoptive est très présente, leur fournissant un étayage sans commune mesure. Une majorité privilégie un attachement sécure et quelques uns font des choix de vie qui semblent venir réparer leur histoire (devenir pompier, être infirmière dans l'humanitaire, être militaire en mission à l'étranger, faire des études de droit pour « *plus de justice dans le monde* », avoir un enfant…). Mais à chaque fois, les conduites résilientes ne sont pas totales, elles sont partielles venant donner des ouvertures psychiques, des possibilités existentielles en gardant toutefois des zones plus fragiles de vulnérabilité. C'est alors dans le cadre d'un espace psychothérapeutique que les capacités de résilience pourront être développées.

La resilience de l'enfant orphelin de mere: aspects psychosociaux

Bouzeriba-Zettota R.[1], Kouadria A.[1]

Abstract

Our study aims to investigate the different psychosocial factors that can intervene in the process of resilience in motherless children. The death of a parent for a child is certainly not perceived similarly by an adult. Its fragility and immaturity would make it vulnerable and it would be even more traumatized if death concerns the mother. This would represent a secure base necessary to establish interaction with the outside world, since the early links between a mother and her child are weaved from the intrauterine life. These attachment relationships are involved in the proper physical, cognitive, emotional and mental subsequent child development and physical break from the mother creates anxiety due to the loss of security, inducing traumatic biological and psychological impact and compromise its harmonious development. This does not reduce every child motherless to his trauma. Resilience allows him to retake the course of its development after exposure to a situation of adversity. Resilience would be the process through which it happens to overcome this lost. It found its origins in some particularities specific to the child himself or his entourage. It is in this context of investigation focused on finding individual skills and environmental resources, we have tried to establish protocols for the observation and evaluation to identify the characteristics of these orphans and their relational and psychoaffective environment that can be or not the source of their resilience before this traumatic situation, the death of the mother.

Keywords: Resilience, grief, orphan, trauma, attachment, separation, intelligence, self esteem, social skills, tutors resilience, social support, social representations.

Introduction Problématique

Le phénomène de résilience a intéressé plus d'un chercheur dans le domaine de la psychologie et plus particulièrement le développement de l'enfant. Depuis les deux dernières décennies, les études qui se sont penchées sur l'habilité des individus à surmonter les traumatismes de la vie, n'ont cessé de s'accroître. La diversité dans les réponses de ces individus face aux mêmes agressions provenant de l'environnement ou émanant de conflits psychiques internes, témoigne de la présence de facteurs multiples intervenant dans ce processus. Cependant la complexité du phénomène de la résilience ne rend pas la tâche aisée, d'autant plus, chez l'enfant que chez l'adulte, du fait qu'il soit encore en pleine croissance, sous l'influence de modifications physiques et psychiques qui compliquent davantage la stabilité de ses caractéristiques propres et de celles de son environnement, et par conséquent, rend plus difficile, l'étude des facteurs de résilience chez lui. De plus, il ne faut pas ignorer qu'il existe une singularité dans les réactions des sujets du fait de la diversité de leur développement propre.

La résilience serait donc un phénomène psychologique qui consiste, pour un individu affecté par un traumatisme, à prendre acte de l'événement traumatique pour ne plus vivre dans l'adversité. Elle décrit également la capacité de l'individu à faire face à une difficulté ou à un stress importants, de façon non seulement efficace, mais susceptible d'engendrer, plus tard, une meilleure capacité de réagir. Cela ne veut en aucun cas témoigner d'une invulnérabilité mais plutôt d'une capacité à ajuster les réponses aux agressions subies, cette forme de résistance est connue sous le nom de «résilience». [1]

Cette résilience trouverait ses origines dans les relations primaires de l'enfant avec sa mère (ou son substitut), ces premières expériences d'attachement serait responsables de la constitution du système psychique des individus et influenceraient d'une manière importante leur résilience face aux différentes situations insécurisantes. [2]

Inégalement que chez l'adulte, la mort de la mère pour l'enfant, constituerait une énorme perte affective qui serait à l'origine d'un traumatisme important, creusant un vide dans son monde et créant de ce fait un être vulnérable au regard d'autrui. [3] L'orphelin aurait-il, dans ce cas, une chance de s'en sortir ? Pourrait-il continuer son développement en ayant perdu sa source principale d'affection et de sécurité ? La résilience chez l'enfant reposerait donc sur la construction d'aptitudes personnelles potentielles ainsi que sur le soutien tiré de

son environnement direct (famille) et indirect (groupe d'appartenance social). Il y aurait de ce fait de multiples facteurs personnels, familiaux et sociaux susceptibles de préconiser la réaction de l'enfant face un choc émotionnel pareil à celui du décès maternel. Quelles seraient donc les caractères personnels de l'orphelin résilients ? Aurait-il des relations familiales favorables ? Bénéficierait-il du soutien de son entourage proche ?

Ainsi, nous nous posons la question sur les facteurs individuels, familiaux et sociaux qui interviendraient dans le phénomène de résilience chez l'enfant orphelin, et précisément de celui qui a perdu sa mère. Nous essayerons de la sorte de rechercher les facteurs intrinsèques et extrinsèques capables de rendre un enfant, privé de la personne avec qui il établit les toutes premières relations de l'existence, d'être résilient. Et notre questionnement principal serait donc le suivant :

Quels sont les facteurs psychosociaux qui permettraient à l'enfant orphelin de mère d'être résilient ?

Méthodologie Utilisée

L'étude de la résilience a connue d'innombrables méthodes d'évaluation. Certains chercheurs ont choisis d'appliquer des échelles préconçues mesurant les facteurs du fonctionnement résilient. D'autres ont construits des échelles ou des questionnaires spécifiques à leurs tendances théoriques et suivant les aspects de leur conception de la résilience. C'est donc pour essayer d'explorer au maximum les caractéristiques intrinsèques et extrinsèques du profil résilient que les enfants orphelins de mère pourraient développer ainsi les facteurs psychosociaux qui les influencent, que nous avons choisi la méthode qualitative du protocole de cas individuel. Entre autre également, pour l'opportunité qu'il offre de pouvoir faire une description exhaustive en faisant intervenir plusieurs variables répondant à la complexité du phénomène étudié. [4]

A travers cette recherche que nous qualifions d'exploratoire, nous avons essayé d'examiner plusieurs aspects de l'enfant orphelin ainsi que ceux faisant partie de son environnement, pour mettre en évidence les facteurs qui interviendraient dans la mise en route du processus de résilience chez lui.

Pour ce faire nous avons procéder à une étude longitudinale brève (à court terme), sur une durée d'une année scolaire (de Septembre 2012 à Juin 2013), pour ainsi observer l'évolution, à plus d'un moment, les cas de l'étude, et ce à travers l'exploration de différents aspects psychosociaux, parfois, à plusieurs reprises selon les différents niveaux du protocole évaluatif.

Nous nous sommes référés à Tomkiewicz (2002) pour proposer l'adaptation de sa classification diagnostique, en désignant les critères de résilience suivants :

Un enfant orphelin est donc résilient : [5]

- S'il ne présente pas d'affection psychologique, psychiatrique ou somatique durable.
- S'il n'a pas eu des conduites ou comportements déviants pouvant nuire aux autres ou mettre sa vie en danger.
- S'il peut suivre des enseignements au même niveau que des enfants de son âge, sans présenter de grandes difficultés d'apprentissage.
- S'il développe des compétences spécifiques réalisant un exploit.

La complexité du processus de résilience exige que son protocole évaluatif soit quelque peu lourd, du point de vue de l'utilisation des outils méthodologiques. Pour cela, nous avons entrepris un suivi multidimensionnel au niveau de plusieurs pôles (individuel, familial et social) auprès des cas de l'étude. Et nous avons choisis, d'évaluer quelques-uns des différents et multiples facteurs psychosociaux de la résilience que nous avons jugé êtres les plus pertinents par-rapport à la nature de notre étude. Ce choix a été porté sur certains facteurs au niveau de chacun des trois pôles comme suit :

1.1 Le pôle individuel

Bien que sur le plan individuel il y aurait plusieurs aspects qui s'impliqueraient dans le processus de résilience, dans la présente étude, nous avons convenu, d'évaluer au niveau de ce pôle les facteurs suivant :

La faculté d'intelligence, évaluée par la mesure du Quotient Intellectuel, grâce à deux outils : l'Echelle de Wechsler VI [6] et Les cubes de KOHS. [7]

L'estime de soi, sentiment profond qu'un individu a de lui-même. [8] Se définit également comme un ensemble d'attitudes et d'opinions que les individus mettent en jeu dans leurs rapports avec le monde extérieur [9]. Elle témoigne d'une certaine maturité psychique de l'enfant, *« le seul facteur qui influencerait fortement l'estime de soi de l'enfant étant la qualité de sa relation avec ses parents »* [10]. De ce fait, ce facteur individuel nous a paru indispensable à évaluer de par son importance dans le processus de résilience. Nous avons fait appel à un test spécifique à cette mesure c'est l'inventaire de Coopersmith.

Les compétences sociales, selon un article de Jean-Marc Dutrénit sur l'Evaluation de la compétence sociale à l'usager: *«…capacité d'établir des relations de réciprocité positive avec ses partenaires»*[11], Hormis cette capacité communicationnelle, R. Pry et ses Coll. (1996), la décrivent aussi comme : *«Capacité ou habileté*

sociocognitives que l'individu manifeste dans son comportement qui lui fournissent tout à la fois une certaine connaissance de la situation et le pouvoir d'agir sur elle.» [12]. Et c'est à travers l'observation directe de l'enfant dans son milieu scolaire et grâce à une grille d'observation préconçue (inspirée des travaux d'Emelie Chanoni et Denis Jacquet[13]) que nous avons pu déterminer le types de compétences sociales de l'enfant. Les entretiens semi-directifs avec son entourage (famille, instituteurs) ont permis aussi à l'évaluation de cet aspect.

1.2 Le pôle familial

Sur le plan familial, la nature du thème de l'étude exige d'elle-même les différents aspects à évaluer. Il apparait de ce fait évident que l'on explore les aspects suivants :

Le type d'attachement de l'enfant, la nature de ces liens d'attachement aurait une importance déterminante dans la constitution de la personnalité, d'après qu'ils soient sécures ou non-sécures. L'évaluation des représentations d'attachement a été effectuée à travers les narratifs d'enfant par le codage des comptes à compléter de R. Miljkovitch et al. [14]. Nous avons également pris en considération les données issues de l'analyse du dessin de la famille.

Les tuteurs de résilience, définit par M. Delage [15] : *« sont donc tout naturellement constitués d'abord par les autres de la famille, ceux avec qui l'individu qui vient de subir une agression psychique est dans un lien affectif fort...»,* ceci représenterait les personnes qui soutiennent (intentionnellement ou d'une façon non-intentionnelle) l'individu en situation adverse pour leur permettre de rebondir et reprendre le cours normal de leur vie. Nous avons, à ce titre, examiné la nature des relations familiales (en utilisant le dessin de la famille et les entretiens), entre l'enfant et chacun des membres, pour à la fois rechercher un membre potentiel pouvant devenir un tuteur de résilience pour l'enfant.

1.3 Le pôle extra-familial (ou microsocial)

Le Soutien social, définit par Lin et al. cité par N. Michaëlis [16], est : *«le soutien accessible pour un sujet à travers les liens sociaux avec d'autres sujets, avec des groupes et l'ensemble de la communauté »,* il est déterminé ainsi par le soutien que peut apporter l'entourage de l'individu à celui-ci qu'il soit une personne, offrant une relation d'aide et de support. Nous avons retenus ce facteur comme étant l'un des plus importants aspects microsociaux qui puissent intervenir pour aider l'enfant orphelin à devenir résilient.

Les Représentations sociales, permettent de découvrir ce qu'un groupe social partage comme idées, croyances, traditions, valeurs, opinions, propres à un objet déterminé, et qui influenceraient, leurs attitudes, comportements, conduites et prises de position envers lui[17]. Notre but étant de connaitre les représentations sociales des sujets faisant partie de l'entourage proche (les proches de l'enfant étant : les membres adultes de la famille de l'enfant, tout le personnel de l'école que l'enfant fréquente) des cas étudiés sur « l'orphelin de mère », pour comprendre le regard porté envers cette catégorie d'enfants. Grâce à deux méthodes préconisées dans l'étude des représentations : l'évocation hiérarchisée et le questionnaire de caractérisation.

Nous justifions le choix du présent protocole évaluatif par la diversité des facteurs personnels et environnementaux contribuant à rendre l'orphelin de mère un sujet résilient, et que nous voulons déterminer. Pour réaliser cette étude, et puisque nous ne pouvions étudier tous les orphelins de mère scolarisés dans les écoles de la wilaya de Skikda (484 établissements) dans la période prévue pour cela, nous nous sommes restreint d'étudier des cas présents dans seulement quelques-unes des écoles (ceux qui ont accepté à coopérer). Les enfants qui ont été sélectionnés pour cette étude, selon les critères précisés précédemment, fréquentent différentes écoles dans la wilaya de Skikda sont au nombre de sept (quatre filles et trois garçons), leur âge varie entre 6 et 11 ans, ayant perdu leur mère depuis un an au moins. (*Tab. n° 1*)

Tab. n° 1 : Répartition des enfants selon leur âge, leur Sexe, leur école, leur niveau scolaire, leur âge à la mort de la mère, la durée depuis le décès maternel et les circonstances du décès materne

Prénom	Age	Sexe	Niveau scolaire	Age à la mort de la mère	Durée depuis le décès maternel	Circonstances du décès maternel
Sonia	07ans et 03 mois	Féminin	2ème Année	16 jours	Plus de 07 ans	Pendant les s/couches Thrombophlébites
Wahid	11 ans et 10mois	Masculin	4ème Année	07 ans	Plus de 04 ans	Cancer du sein
Rassim	9 ans et 01mois	Masculin	4ème Année	07 ans	Plus de 02 ans	Cancer du sein
Hichem	10 ans et 05 mois	Masculin	4ème Année	06 ans	Plus de 04 ans	Cancer
Férial	07ans et 02mois	Féminin	2ème Année	03 ans	Plus de 04 ans	Cancer
Ghalia	06 ans et 01mois	Féminin	1ère Année	Plus 05 ans	01 an	Asthme grave
Basma	07 ans et 08mois	Féminin	2ème Année	Presque 07 ans	Presque 02 ans	Asthme grave

Résultats de l'étude

Les résultats obtenus ont permis de savoir qu'effectivement, il y'auraient chez les cas étudiés, des facteurs psychosociaux pouvant influencer leur processus de résilience. Cependant, les aspects explorés à travers cette étude, ne s'impliquent pas tous, dans ce processus. Un enfant orphelin de mère résilient, serait intelligent, aurait une estime de Soi positive mais ne serait pas toujours socialement compétent. Il aurait systématiquement un attachement de type sécure et aurait au moins dans son entourage une personne pouvant être son tuteurs de résilience. Il bénéficierait d'un soutien social et évoluerait dans un environnement où les individus influencés par leurs représentations sociales interagiraient adéquatement et positivement avec lui.

Par ailleurs, et pour apporter de plus amples clarifications, nous voulons attirer l'attention vers la variabilité des résultats obtenus à partir de l'exploration des différents pôles selon l'influence des facteurs étudiés (*Tab. n° 2*). Ceux-ci, n'étant pas toujours impliqués, même chez des sujets jugés résilients (les compétences sociales), ils étaient quelques fois également, mis en cause chez des sujets jugés non résilients (l'intelligence, l'estime de Soi et les compétences sociales). Cette constatation n'a pas concernée tous les facteurs psychosociaux au niveau des trois différents pôles, il se trouve qu'uniquement sur le pôle individuel, nous n'avons pas pu vérifier toutes les hypothèses correspondantes.

Ainsi nous pouvons en déduire qu'ils y'auraient plus de facteurs impliqués dans le phénomène de résilience, au niveau du pôle familial et du pôle extrafamilial (ou microsocial) qu'au niveau individuel. Ceci irait plutôt en faveur de l'importance accrue, et du rôle indispensable que revêt l'apport de l'environnement familial et microsocial à la mise en œuvre du processus de résilience chez l'orphelin de mère.

Nous pouvons ainsi dégager les facteurs psychosociaux qui seraient plus « significatifs » que d'autre dans l'apparition du phénomène de résilience :

Le type d'attachement sécure chez l'enfant orphelin de mère, serait un facteur important s'impliquant dans sa résilience ;

La présence de tuteurs de résilience dans l'environnement proche de l'enfant orphelin de mère, serait également un facteur important dans sa résilience;

Le soutien social de l'enfant orphelin de mère, semble aussi contribuer à sa résilience.

Nous remarquons ici, que tous ses facteurs relèvent d'une relation d'échange avec l'environnement (qu'il soit familial ou extrafamilial) et non d'une faculté propre à l'enfant. C'est dire l'importance que revêt l'interaction sociale de l'enfant avec son entourage proche.

La résilience ne reposerait donc pas uniquement, sur des capacités individuelles propres à l'enfant, mais elle serait favorisée par des facteurs environnementaux les rendant plus effectifs dans la problématique résiliente.

Toutefois il faut avoir à l'esprit que, la présence de ces facteurs psychosociaux, n'impliquerait pas automatiquement un processus de résilience, nous pensons, qu'il faut admettre que la prise en compte de chaque facteur individuellement ne serait pas judicieuse et qu'il faudrait plutôt s'engager dans une perspective de dynamique résiliente qui serait une résultante de l'interaction de plusieurs facteurs émanant de différents pôles chez le même enfant.

Tab. n° 2 : Les facteurs psychosociaux de résilience

	Sonia	Wahid	Rassim	Hichem	Férial	Ghalia	Basma
La faculté intellectuelle	Intelligence Normale (QI ≥ 70)	Intelligence Faible (QI ≤ 70)	Intelligence Normale (QI ≥ 70)	Intelligence Normale (QI ≥ 70)	Intelligence très Faible QI≤70)	Intelligence Normale (QI ≥ 70)	Intelligence Normale (QI ≥ 70)
L'estime de soi	Estime de Soi Positive	Estime de Soi Négative	Estime de Soi Positive	Estime de Soi Positive	Estime de Soi Négative	Estime de Soi Positive	Estime de Soi Positive
Les compétences sociales	Compétences sociales moyennes	Bonnes compétences sociales	Bonnes compétences sociales	Faibles compétences sociales	Bonnes compétences sociales	Faibles compétences sociales	Bonnes compétences sociales
Les liens précoces d'attachement mère-enfant	Attachement Sécure	Attachement insécure évitant	Attachement Sécure	Attachement insécure désorganisé	Attachement insécure désorganisé	Attachement Sécure	Attachement Sécure
La présence de tuteurs de résilience	Présence de deux tuteurs de résilience	Absence de tuteurs de résilience	Présence de trois tuteurs de résilience	Absence de tuteurs de résilience	Absence de tuteurs de résilience	Présence de deux tuteurs de résilience	Présence d'un tuteur de résilience
Le soutien social	Soutien de la famille adoptive étendue	Pas de relations d'aide ou de soutien	Soutien des pairs et de l'institutrice	Pas de relations d'aide ou de soutien	Pas de relations d'aide ou de soutien	Soutien de l'institutrice	Soutien de l'institutrice

Conclusion

A travers l'exploration de ces différents aspects, propres à l'enfant et à son environnement proche, nous avons pu découvrir l'éventuelle relation d'interdépendance entre certains facteurs et le processus de résilience. Cependant, il apparait que la présence d'un seul d'entre eux n'induit par automatiquement une dynamique de résilience. C'est donc l'interaction de plusieurs facteurs chez le même individu qui pourrait lui permettre d'être résilient. Notons également la diversité dans le degré d'implication des facteurs étudiés chez chacun des orphelins, ce qui nous amène à nous demander si ce serait possible réellement, de dresser un profil commun pour tout enfant résilient ayant perdu sa mère. Cela pourrait être vérifié ultérieurement à travers des études traitant des thèmes similaires avec un échantillon représentatif, pouvant être généralisé.

Abstract

The aim of the study was to reveal the peculiarities of value systems of persons who decided to adopt a child. 70 candidate adoptive parents aged from 21 to 57 (M=36) - 43 women and 27 men – took part in the study. The KVS-3 Questionnaire (part 1) by D. Kashirsky was employed.

The results showed that the most significant values for Russian persons at the time of the decision on adoption of a child are responsibility for themselves and close people, and life harmony, less significant are freedom, independence, enjoying the beauty. The candidates' judgments in assessing the values of love, family life and responsibilities were characterized with categoricalness and may be considered as a risk factor for future adoptive family and, therefore, should be considered by support services for adoptive families starting from the stage of work with candidates in foster parents.

Keywords: value system, candidate adoptive parents

Introduction

Recent years were marked with increase in number of adoptive families in Russia. Research on peculiarities of personality of people who choose to become an adoptive parent and their subjective values, in particular are of interest to psychologists because they allow to open the content side of the personality orientation of this category of people and thus to answer the question about what is important to them, what they tend to prefer to life. The question of personality orientation, according to S. Rubinstein [4], is one of the key in the description of a personality, but it should be noted that this aspect of the analysis of the psychological characteristics of the candidate adoptive parents, unfortunately, did not act as an independent subject of study in contemporary Russian psychology. The aim of our study was to identify the subjective value preferences, which determine the decision to become an adoptive parent.

Methodology

1.1 Subjects

70 candidate adoptive parents aged 21-57 (M = 36), who attended special program for candidate adoptive parents on the basis of the center of psycho-pedagogical support of adoptive families, participated in the study, 43 women and 27 men were among them.

1.2 Measures and procedure

The technique of KVS-3, Part 1, "The significance of spheres of life" (D. Kashirsky), which reveals the particular value orientations of the subject was employed. Respondents was presented a list of 25 areas of life that needed to evaluate a 9-point likert scale. The scale has a high sensitivity and allows to differentiate the shades of meaning attributed to each sphere of life, from its rejection or indifferent attitude to it to acceptance as the most significant.

Results and discussion

The study showed that the most important area of life for candidate adoptive parents are: health (M=6.26), family (M=6.43), love (M=6.54), responsibility (M=5.54), harmonious life (M=5.18), less significant among them are: high social status (M=2.10), belief in God (M=2.94), a pleasant pastime, recreation (M=2.71).

For better undestanding of the results it is necessary to compare the value preferences of candidate adoptive parents with the data obtained on the other ("normal", "normative", "average") sample of respondents of the same age, education level and social status. So, our previous studies indicate that adults (n=61), who were not candidate adopted parents and have no experience of adoption, mentioned the same three most important for them spheres of life: health (M=6.19), family (M=6.07) and love (M=6.06). Similarities between "normative" and "experimental" samples consern lower portions of the compared value hierarchies as well. In the group of "average" adults high social status (M=2.34), belief in God (M=3.29) and a pleasant pastime (M=3.31) also have little significance. At the same time the ratings of values such as harmonious life (M=4.72) and responsibility (M=4.59) have lower priority in the "normative" group, but more important for adults who have expressed a desire to adopt a child.

Quantitative analysis of the results allowed to reveal statistically significant differences between the compared samples. Thus , the family ($U=1571.5$, $z=2.37$, $p\leq.017$), love ($U=1560.5$, $z=2.65$, $p\leq.008$), stability and order ($U=1541.5$, $z=2.51$, $p\leq.012$), as well as responsibility ($U=1307.5$, $z=3.82$, $p\leq.0001$) and harmonious life ($U=1728.5$, $z=1.63$, $p\leq.10$), are more important for candidates in foster parents than for the control group. Searching for and enjoying fine ($U=1570$, $z=2.49$, $p\leq.012$), the recognition and respect of the people ($U=1690,5$, $z=2.05$, $p\leq.04$) and freedom as independence in the behavior and actions ($U=1607.5$, $z=2.43$, $p\leq.014$) have higher ratings in the control group.

Taking into account the results of quantitative and qualitative analysis, it can be concluded that a particular feature of value preferences of adoptive parents is a more pronounced focus on a harmonious life and the value of responsibility; health, love and family values are at the invariant set of value orientations that characterize not only investigated group, but an average adult as well. At the same time it should be noted that, according to statistical analysis, the orientation of the candidates in foster parents on the value of love and family relationships is more pronounced than in the normative group too. Freedom and enjoying fine are of less priority for candidate adoptive parents, compared with the normal sample. So, the value-profile of candidate adoptive parents is quite common for this category of people and can be explained by being at important stage of self-determination, taking on the new role of an adoptive parent. These circumstances explain accentuation of values of love, responsibility, family relations and less pronounced focus on personal values of freedom, independence and aesthetic values of candidate adoptive parents.

In E. Kuftyak's study of the socio- psychological characteristics of adoptive parents in a situation of refusal from an adopted child it was found that one of the risk factors for adoptive family functioning are "idealized and stereotyped ideas about family life in the system values" [3]. The results obtained in our study are in accordance with findings of Kuftyak research – it also revealed more pronounced categorical judgments of candidate adoptive parents in comparison with the control group, resulting in a large number of extremely high scores on values of love, responsibility and family in a sample of potential adopters. It should be also noted that according to our previous research very categorical judgments of candidate adoptive parents are typical not only for the value priorities [5].

So, it is possible to assume that most of candidate adoptive parents experience an increasing importance of altruistic values (e.g. responsibility for family members) and a declining importance of the "ego – needs" (freedom, independence, enjoying fine), and that they idealize a child they are going to adopt. It can be assumed that taking a child from foster care to the family creates a conflict of values ("ideal - a real") in the minds of adoptive parents, which can lead to a more realistic view of family, parenting and the child himself. Otherwise it can lead to child's return to the foster care. Thus the mentioned peculiarity may be considered as a risk factor for future adoptive family and therefore should be considered by the support services for adoptive parents .

Conclusion

So, the empirical study of subjective values of candidate adoptive parents revealed the more important values for this category of people they are responsibility and life harmony. This means that it is especially important for the candidate adoptive parents to be responsible for themselves and for the loved ones, to comply with moral norms and principles , exercise self-control behavior, to predict the possible consequences of their actions and to be responsible for them. It is very important for the candidates to be in harmony with the world and nature, with themselves and others, to maintain a balance between work and leisure, family and career. This finding suggests a higher personal maturity of the candidate adoptive parents in comparison with the most of adult population. It is also possible that the adoption of the child's family just acts as objectifying needs of this category of people in the inner and outer harmony.

The study revealed an increase in the importance of altruistic values (family, love of family and the responsibility for them) and a decline of importance of the "ego - needs' (freedom, independence, enjoying fine) idealization of an adopted child in candidate adopted parents.

Candidate adoptive parents experience a conflict of values ("ideal - a real"), which may become a risk factor for adoptive family as well as their categorical judgments in assessing the values of love, family life and responsibilities.

Thus, the study found out the peculiarities of value orientations of the candidate adoptive parents, useful for deeper understanding of psychological characteristics of the person at an important stage of self-determination.

Resilient lives and autobiographical suggestions italian national training process in the field of intercountry adoption

Macario G.

Trainer and psycho-sociologist, (ITALY)
macario.g@gmail.com

Abstract

This report will consider the intertwining between two virtuous factors. On one hand, the multi-factorial and interdisciplinary approach that increasingly characterizes the concept of resilience today.

On the other hand the contributions of autobiographical method that enhances the history of the individual in the family and in different contexts where they belong, contributing to the spread of the 'narrative turn' in society and emphasizing the value of writing.

The area will be referred to the training for inter-country adoptions in Italy, active continuously since 2001, and we will try to find a shared area between resilient lives and autobiographical suggestions, that tell us about the person but at the same time helps us to understand the society that surrounds it.

Keywords: autobiography, resilience, writing, international adoptions, narratives.

Introduction. about adoptions, resilience and autobiography

"A scarecrow tries not to think about. It's too painful to build an inner world full of atrocious performances. You will suffer less when you have wood in place of the heart and straw under the hat.

Is enough, however, that a scarecrow encounters a man alive that infuse a soul, because it is, again, tempted by the pain of living. (...) Then, the scarecrow begins to speak again and sometimes even write his own autobiographical chimera. "[1]

The identification of a plural class defined by Boris Cyrulnik of 'hidden children', which opens in-depth analysis of the world of adoption as non-traumatic factor, represents the starting point of a reflection characterized, as much as possible, by interdisciplinary.

The subject of resilience, or better the resilient lives, is extremely important for the world of adoptions and, particularly, for inter-country adoptions. Cyrulnik confirms this approach when he says: "The adoption is not a trauma: indeed, it is a meeting that allows evolution resilient."[1]

On the other hand, the autobiographical suggestions, always present in the adoptive paths, are spreading in a growing number of contexts, which apply an autobiographical approach (Among the various significant initiatives on this subject that have been made throughout the country: -the project of Adoption Center of ASL Province Milan 1 on the value of the adoptive tell stories ("Once Upon a Time" - Seminar on 22 October 2008);

-the regional project of Regione Piemonte-ARAI "Tale of me: the value of the narrative between parents and adopted children,"), [2] oriented to the construction of a proper autobiographical method. The confirmation of the possibility that adoptive experience could usefully contribute to implementation of the autobiographical method comes from the most national autobiography expert and a leading expert at the European level, Duccio Demetrio. Demetrio, in his speech to the European Conference in 2010, (Commission for intercountry adoptioni, Resilience and autobiographical approach in intercountry adoptions', Florence, 8-9 june 2010.) identifies the adoption as autobiographical transition and, in this regard specific that: "...the representation of the adoptive event, can better be defined thanks to narrative attentions, or better, narratological, since adoption, and not only that, it is a story generating life stories to meet, re-examine, re-organize and forget too."[3]

Focused on adoption: writing, autobiography, resilience.

Comparison with our own adoptive history begins in the early days, of course, but it does not end with the attainment of adulthood. Adulthood involves, as also indicates Marco Chistolini, a re-signification of its own adoptive history gaining greater self-awareness, particularly with respect to their origins[4].

The search for information on the origins, for some years the center of attention in Italy (In addition to the recent specialized training conducted by the Commission for inter-country adoption in 2012, entitled "Access to informations on the origins in international adoptions. Legal, psycho-social and relational.", deserves to be mentioned the most recent book of the Instituto degli Innocenti cf [5])., and the subject of recent significant legal rulings, makes it possible to take action on the part of the adopted person inquiring about his past and possibly establish a contact with the biological parents. In Italy, there are very few people active in this kind of search but the possibility of being able to start has to be consider a resilience factor.(See the recent ruling of the Constitutional Court, judgment of 22 November 18, 2013, n. 278 declaring the unconstitutionality of article 28, paragraph 7, of the Law of 4 May 1983, no. 184, in the part that does not allow the court to consult again the mother who has refused to recognize the child, even many years after.)

The autobiography, on the other hand, is considered to be an experience of re-identification, and Demetrio tells us, "The autobiographical writing is nothing more than the re-writing of our history; it goes back into the scene, we again becomes, somehow, protagonists and characters of our life, we are back into the game as if you go up on a stage."[6]

The autobiographical writing is considered a real tool to be used in the field of adoption, however, not only with adults.[7] The autobiographical writing is also considered a clinical tool in an autobiographical perspective but different from clinical therapeutic perspective.[8]

Adoption is generating multiple autobiographical stories, but they are just the different possibilities of writing that Demetrio enhances saying: "There is always something more in a script."[3]. Firstly, writing is a valuable opportunity for the author to find himself considering explicit and implicit areas dictated by the unconscious. Second, are those who have responsibilities for education, parenting, guidance or treatment that can identify more signs of comfort or discomfort of the narrator: the motivation to writing, or running away from this, allow a better understanding of the levels of self-consideration expressed by the adopted person.

If we consider the writing a sort of additional adoptive parent, we can define an experience in itself potentially 'resilient', which helps us to resist the wounds of life.

Demetrio, recognizing the central importance of the contribution of Cyrulnik about adoption as a possibility of a resilient evolution, underlines that writing can facilitate the emergence of an 'internal biographer' adoptee. The internal biographer, in fact, may be central for the mental health of the adoptive person because places themselves at the center as a major character of the story, one 'scribe' in the service of its author. This specific factor,-characterized at the same time by storytelling and writing- is not resilient only because it makes the person self-sufficient. Becomes central because it amplifies the role of the 'facilitator of storytelling' (which could be defined as 'external biographer'), whether the parent as a co-goer of everyday life of the adoptee, is also the operator that assists and supports its growth path.

However, the author that has been adopted and that writes about himself trying to observe better provides the best narrative synthesis that can help understand the close interconnection between the various factors stated. Here is what Daniele Callini tells us in his book entitled "44 steps"[9]:

"The rigor and method I've learned from Dad Franco. (...) The speed and instinct decision-making are a resource of Mamma Cristina (adoptive parents). (...) I have no doubt in saying that I have assimilated the courage of my mother. Moreover required enormous courage to give birth to a child that you do not want or are not able to keep. The tenacity, strength and endurance, I think I have received them from my natural father. Even if I do not know who he is, I feel that these resources are a gift from him."[10] A summary 'masterful', certainly resilient.

Resilience and training of operators for intercountry adoptions

"A good education for resilience requires the establishment of programs and projects that facilitate the child, in his family and in the community, building solidarity networks and the opening of a space capable of facilitating a positive development. The prospect of integration between the various professional underlies the assumption that considers the whole person, and not parceled depending on the context or the historical moment in which it appears."[11]

This passage taken from the introduction to the volume cited, edited by Cyrulnik and Malaguti, can significantly represent at least two of the cornerstones of the training activities for inter-country adoptions made in the last 15 years in Italy by the Commission for inter-country adoptions in collaboration with the Instituto degli Innocenti in Florence.

On one hand, the formation made in favor of the operators involved in international adoptions in Italy- from 200 to 300 for each year- has always sought to combine the best reading of the changing environment and tools that can be used with an enhancement of ' natural powers' of the prospective adoptive couples, adoptive parents and adopted children of the same.

As it says Franca Olivetti Manoukian: "Everyone who lives and coexists in a social context is called to share the guidelines which this discomfort should be addressed with. Operators are more competent than others simply because they have available elements of knowledge and experience to identify and to guide how to treat the discomfort."[12]

The perspective of empowerment, connected not only to the professional aspects but also to those educational parenting, has transversely concern dozens of topics in-depth over the years. By intercultural aspects to the specific teen, by the scholastic inclusion in the post-adoption - where ample space is given to the possible interpretations of the 'new development resilient' theorized by Cyrulnik[13] -to the adoptive sib ships, by professional and self-help groups to the assessment of the couple and special needs, just to name a few. Regarding assessment of the couples -to give just one example, very significant and in line with other European studies-[14] it was possible to deepen the evolution from a predominantly evaluative approach to an accompanying perspective during the entire adoption process.

On the other hand, the reference to the integration between the different professions has always been a leitmotif of in-depth training, characterized as inter-professional training (psychologists, social workers, judges, the three most consistent professionalism), but also interdisciplinary (psychological, social, anthropological and legal, the predominant contributions) and inter-organizational (teams adoptions of public services, the authorized agencies, the juvenile courts and prosecutor's offices, the organizations).

The effort of identification in the problems of the adoptive couple's perspective and adopted children, and the subsequent identification of additional factors to promote resilience was then even more significant during training experiences made in Eastern Europe in 2004-2005[15], and during joint training Brazil-Italy in 2009-2010.[16]

A further authoritative confirmation of the central inter-professional aspects in the world of adoptions comes also from two authors of the systemic approach that state: "... the more you support the training for all those people (judges, social workers, counselors) who approach the families 'dare to take', the more it contributes to social welfare."[17]

The European Conference of 2010 on adoptions and resilience, mentioned in the opening and already mentioned in the previous steps, has led to synthesis many other elements taken up in subsequent years. Along with the autobiographical suggestions already detailed, there was more and more often the centrality of the resilient lives that we would like to understand in order to better support the different contexts of growth of adopted children.

The multifactorial and interdisciplinary approach that characterizes resilience is becoming even more important in the considerations on the same occasion by Elena Malaguti. Malaguti has analyzed the process of resilience not only in reference to the individual but also to a group (family, community. .), that, in particular difficult moments, must be able to put in place resources to reorganize in a positive way his own path and life plan, according to an evolutionary approach.

Resilience is so spontaneous but requires stress to activate, becoming an opportunity for personal and social emancipation. There can be several theoretical models: cognitive-behavioral, medical, eco-systemic and clinical. Remains "a complex object that is by its nature not predictable, chaotic and does not meet the natural laws" that "does not work according to linear patterns but in a systemic and dynamic way," "as a function of the interactions and transitions occurring stable between a person in permanent development and its environment." (Malaguti, E., Research on resilience and prospects for inclusive education. Adoption and beyond, Abstract intervention at European Conference - Florence 8-9 June 2010.)

The *Lectio Magistralis* of Beràstegui Pedro-Viejo,[18] finally, starting from the studies and research on inter-country adoption in the European context, has made a significant contribution to deepening the three fundamental concepts of risk, resilience and recovery. Some authors have questioned whether the adoption itself may represent a 'risk factor' for the problems of adaptation implies for a child, already vulnerable to abandonment. [19] [20]

The research, however, –Berastegui stated- shows that adopted children often exhibit behavioral problems, cognitive, social and educational, to a greater extent than their peers not adopted, but if you compare them with their peers institutionalized or other living situations of hardship the comparison is reversed into opposite parameters. [21]

Facing the risks and trauma in childhood, we can highlight the significant differences between protection (when there is no harm in situations of risk), reversibility or recovery (recovers the normal path), resilience (with the resumption of development path that keeps track of the pain suffered) and executive functions (despite the problems, the child reaches a certain functionality in everyday life).

As specific insights, the three themes explored in the national training in the previous year - the school integration in the post-adoption, the adoption of sibling groups and the specificity of adolescents in adoption- were developed with a specific focus on resilience and autobiographical approach.

For a search of shared area

In conclusion, I would use a methodological cue usefully applied in the analysis of educational models to verify assonance and dissonance between 'education' and 'therapy'. There is no doubt, in fact, that there are characteristics of the specific scope of education and there are others definitely attributable to the therapeutic area.

It is also true that there is a common area where identified characteristics apply to both education and therapy. And yet, some other features and tools that have a priority in the educational effectiveness, sometimes favor therapeutic outcomes, while the reverse is true even when therapeutic interventions mainly involve non-negligible changes in education.

The intent is not so much to build long enumerations, but to keep in mind, on a qualitative level, that there is a resilient approach (section 3rd) and autobiographical approach (section 2nd). Both of these fields of study and research have led to a particularly close relationship with the practice, and it is the identification of specific target areas-in this case the adoptive context- that can help to operate in a limited area, and then compare between those different fields of intervention.

Alongside the adoptive area, for example, I will mark another possible area, the hospitality of residential boys and girls. An interesting reflection is the one developed by Andrea Canevaro on educating the resilience that weaves in various ways also autobiographical references.[22]

So here are some references to elements necessarily unsaturated and deepened, located in the shared area:

§ The EMPOWERMENT, like exploitation the potential of the individuals, certainly not out of context;

§ The SELF-EMPOWERMENT, which allows, getting the abstractness that is often translated the concept of empowerment, the expression of new desires, opinions and possibilities;

§ The NARRATION, as a tool that gives meaning to your path (for the construction of their own path in life, to the search for origins, for overcoming traumatic nodes, etc.).

§ The SINGLE CENTRALITY, such as re-centering on the individual (both the adopted child as well as the adoptive parent) in the network of relationships and social context (current membership and, possibly, of origin);

§ The SELF-TRAINING, like equidistant perspective between self-referentiality and dependency, 'vitality' factor, able to capture the support and advice you need.

I'll entrust the closing, in line with the spirit of this contribution, to an adoptive parent a bit special, Leo Ortolani, creator of Ratman, a well-known Italian comic book character, which describes a path adopted that last nearly a decade.

Ortolani says, describing the flight to Colombia to get to know the two girls Lucy and Johanna:

"And then I feel that I still do a lot of things that I did not just in time, I had to prepare myself better, that everything is going well suddenly, that 2001 was yesterday and you cannot do things so fast, I still need a bit 'of time, a month, a few days, it cannot happen now, not me, not so, do not ....

Passengers are requested to fasten their seat belts (...) We are landing at the airport in Cali."[24]

The effectiveness autobiographical-narrative interpreted in an ironic-resilient way.

Abstract

Introduction: Adoption is one of the major protective factors in the adjustment of children who lived experienced abandonment and institutionalization (Zeanah et al., 2009). Studying effects of early deprivation in adolescence is particularly useful, because adolescence is a critical period of development and because this period allows considering the effect of an enduring positive experience in the adoptive family. Moreover, parent's secure attachment representation can help repair early negative experiences, particularly considering their reflective function.

In this paper we will analyse the effect of adoption in relation to early deprivation in a sample of 28 Italian adolescents, adopted before the age of 6 and observed in adolescence (11-16 years). These results are part of an international research project (Pierrehumbert, 2009), collecting information on internationally adopted children.

Method: Early deprivation was rated from biographical informations provided by parents (age at adoption, changes in pre-adoptive care, period in institution, etc.) and from a retrospective form of the Disturbance of Attachment Interview (DAI)(Smyke. A. & Zeanah, 1999). Adolescence adaptation was rated by CBCL/YSR(Achenbach & Rescorla, 2001), filled by both parents and by adolescents. Measures of different aspect of parental caregiving representation, was derived from the Parent Development Interview (PDI)(Aber, Slade, Berger, Bresgi, & Kaplan, 1985), a semi-structured interview, exploring the parental representations of the ongoing relationship with their children, addressed to adoptive mothers and fathers separately. Each interview has been video-recorded, transcribed, and rated on a 4 point scale. Through correlation, we analyzed the relationship between early deprivation and adaptation in adolescence, considering the effect of parental attachment measures. We hypothesized that risk factors in pre-adoptive experience negatively correlate with adolescent's adaptation rated by CBCL/YSR, and that parental positive caregiving representation, particularly parental competence, could moderate this relationship.

Results and conclusions: Contrarily to our preliminary hypotheses, the level of pre-adoption risk was not associated with the behavioral adjustment in adolescence. This could be due to the protective effect of living for a number of years in a supporting adoptive family. With respect to the caregiving characteristics, our results are less encouraging: apparently, maternal competence does not influences adolescent's adjustment, and only the relationships between actual difficult experiences are evident. Further research could help disentangle the influence of different variables affecting adopted adolescents' behavior adaptation.

Keywords: adoption; adolescence; behavioural problems; Parent Development Interview; Disturbances of Attachment Interview; CBCL; YSR

Introduction

Adoption is one of the major protective factors for the recovery and adjustment outcome of children who previously experienced abandonment and institutionalization [1].

Age at adoption and the experience of institutionalization have been largely considered as risk factors for the adoptee's later adjustment [2, 3, 4]. Since the interest towards adoptive sample comes from the experience of attachment disruptions lived by these children, it is also important to test whether multiple changes in caregiving could affect the adolescence adjustment [5].

David Brodzinsky, one of the most important American experts in the psychology of adoption, considers family relationships as the most important background factors in the adopted child's adjustment [6]. Through continuous reiteration over time, the offering of a new and positive relational model can play a significant role on the change of the child's attachment representation [7] . It is within the context of sensitive,

thoughtful and reflective relationships with their caregivers that adoptive children learn to feel safe, to explore, to make sense, and to grow [8].

Studying the effects of early deprivation in adolescence is particularly useful, because adolescence is a critical period of development and because this period allows considering the effect of an enduring positive experience in the adoptive family. Indeed, adolescence represents a critical period for adopted children. In addition to the typical issues faced by every individual in this period of life, the variety of physical and cognitive changes of adolescence implies, among adoptees, the development of concerns about identity issues such as who they are, where they come from and what they will become [9]. Literature has also shown that adoptees, in the urgency of developing a stable identity, tend to face the typical adolescence issues before their non-adoptive peers [10]. Thus, among adoptees the possible difficulties linked to this period of life may occur even before entering the teen-ages.

In this perspective, our research will analyse the effect of adoption in relation to early deprivation in a sample of 28 Italian adolescents (11-16 years), adopted before the age of 6. These results are part of an international research project [11], collecting information on internationally adopted children.

We hypothesized that risk factors in pre-adoptive experience negatively correlate, and that time spent in the adoptive family positive correlate, with CBCL/YSR adolescent's adaptation. Moreover, we explored the relationship between parental characteristics and adolescent's adaptation.

Method

1.1 Procedure

The sample recruitment was carried out through social services and agencies for international adoption. Eligibility criteria were to be 10 to 16 years old at assessment and to have been adopted internationally (between birth and 9 years of age). Informed consents were given to both parents and adolescent before collecting the data.

1.2 Sample

Participants include a total of 27 adolescents (51.9 boys) and their adoptive parents. The adolescents' average age at assessment was 13 years old (SD=2 years). They had been adopted internationally from various geographical areas (52% from Asia, 22% from South America, 19% from Eastern Europe and 7% from Africa). Parents chose to adopt mostly because of infertility (82%). At placement, adolescents were 13 years old (SD=2 years). With respect to siblings, 14.8% are only children, whereas the remaining adolescents have one or more siblings (biological siblings, biological children of the adoptive parents -18.5%-, and adopted as well) (see Table 1).

Table 1 Sample (N=27)

	M	DS	Range	N	%
Girls				13	48%
Age	13	2	10-16		
Age at adoption (months)	44	31	1-111		
Adopted for infertility					81,5%
Siblings					85,2%
Years spent within the adoptive family	10	3	3-16		

1.3 Measures

Early deprivation was rated through biographical informations provided by parents (age at adoption, changes in pre-adoptive care, institutionalization, etc.) and through a retrospective form of the Disturbance of Attachment Interview (DAI) [12]. Adolescence adaptation was rated by both parents and their adolescents through CBCL/YSR [13]. Scores for parent's attitude were derived from the Parent Development Interview (PDI) [14], a semi-structured interview exploring the parental representations of the ongoing relationship with their children, addressed to adoptive mothers and fathers separately. Each interview has been video-recorded, transcribed, and rated on a 4 point scale. On the basis of PDI, 5 scales have been created in order to synthetize the numerous informations present in the interviews. To this purpose, items were chosen both on a theoretical basis and looking at their correlations. Thus, their internal consistency was controlled through Cronbach's alphas (>.70, see Table 2).

Table 2 PDI Scales

	Scale composition	Cronbach's alpha
Parental capacity	6 items (Coherence; Richness of perceptions; Reflective functioning; Parental competence; Level of child focus; Attachment awareness and promotion)	.922
Positive parental experience	2 items (Joy/pleasure; Warmth)	.867
Negative parental experience	3 item (Anger degree; Disappointment/despair; Hostility)	.883
Child's positive description	2 items (Child happiness; Child affectionate)	.735
Child's negative description	2 items (Child aggression/anger; Child controlling/manipulating)	.760

1.4 Data Analyses

First, descriptive analysis of risk factors and different informant adolescent's adaptation were performed. Through correlation we analyzed the relationship between early deprivation and adaptation in adolescence, considering the length of the adoptive experience and of parental experience and competence. Due to the ordinal level of some variables, in order to compare dichotomous risk groups, we used non-parametric exact tests (Mann-Whitney Exact Test, Montecarlo Method).

Results

1.1 Descriptive analyses

1.1.1 Pre-adoption risk factors

Age at placement is very heterogeneous in our sample (M=4 years old; SD=3). 85% of the adoptees had experienced institutionalization, at least for a few months. It is hard to control for the number of changes in caregiving, but we can state that they range between one and three.

With respect to the level of attachment disturbance during the first year of placement, 21 families (10% of fathers and 90% of mothers) answered the retrospective form of DAI. At placement, the average score of attachment disturbances is 7.4 (SD=3.2) whereas one year later the same scores decreases to 2.3 (SD=2.3) (see Table 3).

Table 3 Pre-adoptive experience

	M	DS	Range	N	%
Pre-adoptive care					
- Biological family					25,9%
- Foster-care					22,2%
- Institution					85,2%
- Placements			1-3		
DAI					
- At placement	7.4	3.2			
- After 1 years	2.3	2.3			

1.1.2 Behavioral adjustment

Data on adolescent's adjustment, rated bay self-report (YSR) and parent-report (CBCL, filled by mothers) are reported in Table 4, both for the total sample and for boys and girls separately. Internalizing scores are significantly higher for girls, as underlined also on normative samples. On average, behavioral problems in our sample are similar to those observed in a cross-country comparison on adopted adolescents [15].

Table 4 Behavioral problems scores: self- and parental-reported

		Our sample				Roskam et al., *in preparation*			
Problem scale	Max score	YSR (*N* = 25)		CBCL (*N* = 24)		YSR (*N* = 309)		CBCL (*N* = 309)	
		M	SD	M	SD	M	SD	M	SD
Internalizing	62	13,88	10,94	11,38	8,45				
Boys		**7,77***	6,21	10.18	8.07	10.44	10.32	9.69	9.60
Girls		**20,50***	11,27	12.38	0,96	11.78	9.30	8.54	8.24
Externalizing	64	11,48	9,43	7,50	8,08				
Boys		12,08	11,98	8,73	10,84	13.46	8.86	12.21	11.31
Girls		10,83	6,07	6,43	4,98	12.56	8.94	8.76	8.68
Total	210	45,52	24,56	30,92	22,58				
Boys		37,15	24,16	31,64	24,83				
Girls		54,58	22,52	30,31	21,88				

(*) Mann-Whitney Exact Test, Monte Carlo Method, p < .005 (Two tails)

1.1.3 Parental representations

In Table 5 the average scores for the 5 major scales derived from mothers' interviews are reported.

Table 5 Mothers' PDI principal scores (N = 27)

	Range	Mean	SD
Parental capacity	6-24	16.26	4.39
Positive parental experience	2-8	5.74	2.30
Negative parental experience	3-12	5.33	1.98
Child's positive description	2-8	5.19	1.73
Child's negative description	2-8	3.81	1.52

Parental capacity highlights aspects linked to parental attachment, investment in the parenthood, coping strategies and sensitivity towards the child. Parental experience and child description, both divided into positive and negative, respectively refers to the perception of the pleasure linked to the experience of being a parent, and to whether the parent describes the adoptee in a positive or negative way.

1.2 Risk factors and adjustment during adolescence

In order to highlight the effect of possible risk factors, correlations between variables concerning pre-adoptive experience and behavioral problems were run, but contrarily to our hypotheses, no significant results emerged (p> .05). Since possible differences could be found within adoptees who have experienced a higher amount of pre-adoptive distress, risk variables (institution, number of changes, age and level of attachment disturbances at placement) were recoded into dichotomous variables, considering their distribution within the sample (half subjects in the higher range and the other half in the lower range). By comparing them through the Mann-Whitney Exact test, a unique significant result emerged: adoptees who differed with respect to the DAI scores (high *versus* low presence of disturbances at placement), showed significantly different internalizing problems (see Table 6). Adoptees who scored higher on attachment disturbances, during adolescence manifest a higher level of internalizing problems, even when controlling for gender.

Table 6 Maternal-reported behavioral problems with respect to high/low DAI scores

		Internalizing *	Externalizing	Total
	N.	M (DS)	M (DS)	M (DS)
Lower score	9	6,67 (5.39)	5,44 (4,82)	20,11 (17,21)
Higher scores	10	14,60 (8,67)	10,20 (11.35)	39,60 (25,90)
Total	19	10,84 (8,19)	11,35 (8,94)	30,37 (23,81)

(*) Mann-Whitney Exact Test, Monte Carlo Method, p < .05 (Two tails)

On the contrary, having lived in an institution, having experienced multiple changes in caregiving, and having been adopted later does not influence, in our sample, the rate of behavioral problems in adolescence.

1.3 Parental competence and experience

Concerning the relationships between parental competence and experience, and adolescent's adjustment (see Table 7), we found a systematic effect of externalizing problems (both self- and maternal-reported) on negativity of child perception and parental experience.

Table 7 Parental caregiving representation and adolescent's adjustment

	YSR (N=25)			Mother's CBCL (N=24)		
Mother PDI Scales	Intern.	Extern.	Total	Intern.	Extern.	Total
Parental capacity	-,14	-,19	-,25	-.11	-.07	-.11
Positive parental experience	,01	-,36	-,26	- .22	- **.42 ***	- .35
Negative parental experience	-,17	**,50***	,24	. 02	. 23	. 19
Child's positive description	-,20	-,25	-,34	- .10	- .31	- .19
Child's negative description	-,30	**,56****	,19	-.07	**.47***	.23

Contrarily to our hypothesis, higher scores on parental capacity do not correspond to lower behavioral problems among adoptees. Parental experience is negatively associated with externalizing problems, and positively associated with child's negative description, meaning that adoptees who show higher externalizing problems have mothers who describe their parenthood experience as more negative and their child as more aggressive and controlling.

Discussion and conclusions

Our results are preliminary and descriptive, and our sample size is still limited. Nevertheless, we can highlight the absence of relationships between early risk factors and adjustment in adolescence. Indeed, contrarily to our preliminary hypotheses, the level of pre-adoption risk was not associated with the behavioral adjustment in adolescence in our sample. Only the high rate of attachment disturbances at placements seems to be correlated with a higher level of internalizing problems during adolescence. Since just a few studies analyzed the effect of pre-adoptive risks among adolescents, this unexpected result could be link to the reparatory value of having lived several years (on average 10) within the adoptive family. The daily and continuous experience in a good familiar environment could limit or even help canceling the role of negative experiences underlined by the adoption literature [7]. Nevertheless, this effect could be enhanced by a selection bias: even if we cannot control for the number of request sent by adoption agencies and services, we know that just a small percentage of families accepted to take part in our study, and these families could be the better adjusted.

Concerning the caregiving characteristics, our results are less encouraging: apparently, parental competence is not influencing adolescent adjustment, and in our sample only the relationships between difficult experiences (i.e. present and manifest, such as adolescents' externalizing problems) are evident. Deeper analyses will help better differentiate maternal and paternal role, individual profiles, and the interrelation between different risk and protective factors. For instance, analyzing in a longitudinal perspective each individual path will allow a deeper understanding of the time spent in the adoptive family.

Abstract

In his famous ERA (English Romanian Adoptions) study Michael Rutter and his team found a percent of about 25% of children adopted from Romania, from very bad conditions in institutions, as being resilient. Following this observations the concept of resilience was extended to include the genetic heritage as well as the cultural framework.

Our study is based on the evaluation of 56 adoptees within Romanian adoptive families. The evaluation of adopted children and adoptive families was done within a national research project on domestic adoption, FISAN (Factors which supports the success of adoption), funded by the Minister of Education in Romania, between 2008-2011.

The resilience is considerate within our study as being the equivalent of child's secure attachment toward his/her parent or another significant person.

The complex procedure of evaluation as well as the statistic work on the data will highlight the important emotional and social factors which support the resilience of the adopted children.

Keywords: resilience, adoption, adolescents, identification

Introduction

Within human development, the resilience is a fascinating topic. When adverse existential conditions expose at risk the development of the person, the resiliency is pushing a new bounce back and even is bringing new quality in development. The concept was developed in relation with 'invulnerable' and 'invincible' children thriving despite the scarce conditions for their life. In a classic longitudinal study [1] followed 505 individuals, from their birth, until their 40s, in the Island of Kauai, Hawaii. Despite the poverty and associated adversities faced during their life, a third of them developed in a healthy, resilient way.

[2] talks about having personal capacities which can contribute to resilient outcomes following stressful conditions as well as about resilience which is a 'dynamic' process in place only in relation to adverse conditions. Based on the large existing literature, the authors mentioned "two critical conditions: (1) exposure to significant threat or severe adversity; and (2) the achievement of positive adaptation despite major assaults on the developmental process."[2].

Due to this definition to talk about the resilience of adopted children is just compulsory. The adoption of an abandoned child brings to the child traumatized by abandonment as well as by possible events before and following the abandonment a new chance for re-bounding. Adoption as a new chance is tightly connected with the resilience process of the adopted child. During the last years more and more professionals and researchers talked about interventions aimed to stimulate the resilience [3]. Even there are not yet very many voices to claim the resilience of the child as the goal of the adoption, the resilience of the child should be a pervasive objective of the child protection system in any country. Michael Rutter [4] and his team highlighted the resilience of Romanian children adopted in UK. His study is probably one of the most known in the literature focused on child's adoption. Following the Romanian children adopted from terrible traumatizing environment in institutions in Romania, 25% of those children, placed in adoptive families in UK, managed very well and found their way for a healthy development. They were resilient despite all the traumatic past conditions in their life.

The theoretic framework of our research

Our study is based on the evaluation of 56 adoptees within Romanian adoptive families. The evaluation of adopted children and adoptive families was done within a national research project on domestic adoption, FISAN (Factors which supports the success of adoption), funded by the Minister of Education in Romania, between 2008-2011.

We intend to explore here the resilience of 12 Romanian adopted children, aged 11-16. Despite the traumatizing early life these children could develop a secure attachment toward their adoptive parents. The secure attachment is the guarantee for mental health and for pervasive healthy development [5]. We do not identify the secure attachment with the resilience but we consider the secure attachment as being the sign of the child's resilience as well as assurance for further life's adversities. More than that, taking in account the cascade theory [6] we consider the secure attachment as a barrier of the aversive events cascade in the life of children who started their life unfortunately through a traumatic event: the abandonment.

Procedure

The 12 adopted teens were assessed and identified as having clearly secure attachment. The evaluation was done with Friends and Family Interview/FFI [7]. FFI is a semi structured interview assessing attachment representations in late childhood and adolescence. "The FFI holds significant research and clinical value in its unique approach to eliciting and systematically rating autobiographical narratives from an age group that has been notoriously difficult to assess from an attachment perspective."[8]. From the scientific point of view, a cross-country comparison on the invariance of FFI, focusing on the coherence in attachment narratives confirmed the validity of the coherence assessment with no difference between Romania and Belgium [9]. In our qualitative investigation we will try to identify within the narratives of the 12 adopted teens the aspects which reveal their resilience. Following the analysis done by [10] on the concept of resilience we will pick up for our investigations the common protective factors which she selected based on the work of [11], [12], [13], [14], [15], and [1].

These are:

(1) Positive relationship, (2) sense of personal worthiness, (3) believes in her or his self efficacy, (4) sense of humor and (5) high expectations.

In order to find the items above within the attachment narratives of the 12 adopted adolescents we focused on the following questions in FFI:

1. Who are the persons you are close to?
2. Tell me how you are?
3. What do you like about yourself?
4. How are you at school? Did you have recent examinations?
5. What are your three best desires for your future?

Beside these items we take in considerations some common aspects within the narratives of these securely attached adopted children.

We are working on our data using the qualitative discourse analysis method focused on the narratives of the respondents and based on the 5 relevant items mentioned above.

Results

In respect to '**positive relationship'** all these children in the sample here are securely attached. This means that they have at least one exceptional positive and healthy relationship with him or her attachment figure. We further investigated their positive relationship through the question: *Who are the persons you are close to?* The 12 adolescents mentioned first the mother but half of them mentioned also the father and the friends. Grandparents and siblings are also mentioned (3 times, grandparents; 2 times, sibling).

The **"sense of personal worthiness"** was mostly investigated through the question: *Tell me how you are?* or *What do you like about you ?* The respondents mentioned very different aspects considered as personal worthiness: the courage, the talent to learn new languages, the pleasure to learn mathematics, the interest for learning, the way of thinking and even "I like the way I look".

There are two answers more elaborated:

1. *I like my way of thinking which is a bit different comparing with my classmates… I am not interested on the things which are common interest among peers…*
2. *My qualities are connected. Being creative I need social relations. I cannot be creative without others. For instance I like to write and I write about people. What I like the best on me is my altruism.*

All 12 adolescents **"believe in her or his self efficacy**". The questions used to explore the self efficacy were: *How are you at school? Did you have recent examinations?* or even T*ell me about you?* All the respondents mentioned the good results in the school, insisting on different disciplines according with their interest. Two answers are relevant in this respect:

1. *Excepting the 5th form I was always the best in my class…yes, we had some examinations and I had good results and some of my classmates were jealous on me…but I ignore them and doesn't matter what they say I follow my dreams..and do what I want to do…*
2. *I can be shay sometimes…But I like to make acquaintance with new friends and I like to fight. If I have some problems or something I cannot do it I will work on that till I become good…*

The **sense of humor** is quite common within the sample of adolescents. As an answer to the question: *Tell me how you are…*, out of 12 respondents, 8 are explicitly mentioning:"*I like to laugh…"* Mostly this assertion is followed by the mentions of different significant persons within the child social environment: mom, the father or friends.

The **high expectations** item is explored through the question: *What are yours three best desires for your future?*

The answers have a large variety but all of them have the power to orientate the future development of the respondents. The 12 adolescents mentioned within their narratives the wish to continue attending the school despite the fact that to this precise question only 8 respondents were explicitly mentioning the school. The dreams of the children in our sample are always positives even they are more or less realistic. We give here two answers: when answer is formulated at general level;

1. *To be always beloved, to have what I need...I do not talk here about money…never to feel alone.*

The other one is more realistic in its expectations:

2. *To study and to become doctor. To have my job and to manage by myself and not to overload my mom…to have a dog.*

Discussions

Being a qualitative research the size of our sample is very convenient. The items found globally within the literature on resilience gave us a simple tool to work on the data. This is a superficial and easy way to demonstrate an idea which is common: the secure attached children are resilient. But the question raised through our analysis is connected with **the stability of attachment quality and the dynamic of resilience.** According with our results we can expect that these adolescents will show always as being resilient persons; they proved once their resilience when being abandoned and placed in institutions after words, before being adopted, and being successful within their new family in setting-up a secure attachment. The literature on resilience stresses the variety of manifestations and the dynamic of resilience [2]. The person can be resilient in one situation but the same person will behave differently exposed to a new stressful situation; on the other hand, being resilient in one domain does not mean an overall resilience in any other existential field. This common idea within the literature on resilient is somehow in opposition to the theory of developmental cascades: "…effectiveness in one domain of competence in one period of life becomes the scaffold on which later competence in newly emerging domains develop: in other words, *competence begets competence*." [6].

We consider the respondents who are securely attached as being resilient. This is hazardous as the resilience can be proved only within the analyses of the past events. It would be better to say just that they are better equipped for behaving resiliently when confronting life's adversities.

Conclusions

Within the little sample here of securely attached children we found all the most common items mentioned as being the protective factors in case of resilience.

This conclusion stress one of the aspects always mentioned within the literature on resilience: the importance to benefit of the support of a trustful significant person. Having secure attachment means having attachment figure ready to protect, to calm down the anxieties and to support. An adolescent in our sample, stated the relationship between secure attachment and resilience in the best way. She answered the question regarding the temporary separation from her parents by saying: "when I was separated it was like walking on a stream and I can fall down any time…but when they are there I know there is a support under me and I cannot fall down."

Especially due to their age, when the developmental task is to build-up the self-identity, the dreams on the future are like a powerful drives for these adolescents.

On other aspect which is not investigated within our study, through the instrument which we used, but just came up during the narratives of the children is the way in which they are equipped to ask for support when they need. All of them mentioned resource persons in such situations. Mostly of them mentioned mom but also friends or other relatives. The healing process post trauma include the capacity to ask for support and not to deal alone with adversities, feeling abandoned by other people.

We also have to mention another particular aspect: all these securely attached and resilient children have some talents or practice arts or sports. We consider that this way to express them self is for highest importance for the resilience of the adolescents. Arts and sports impose rules and limits which also contribute to self-development and self-education. As we found in the research done on students, the capacity to push them self to overpass the comfortable limits in doing some tasks is a common item for the resilience. It is like resilience is asking for self-organization and capacity to rise and keep standards for you.

The last aspect which we found and we have to mention here is the importance of pets for these securely attached and resilient children.

The particular aspects mentioned above which can be involved in the process of building up the secure attachment as well as the resilience needs and deserve further explorations.

nsabelni@mail.ru, psymath@mail.ru

Abstract

The aim of the present study was to examine peculiarities of mother's image of adopted child and its role in emotional parent-child relationships. The sample consisted of 36 adopted children, their 32 adoptive parents and 35 nonadopted children living with their biological parents and their 35 parents and 20 children from orphanages.

Parents were administered Semantic Differential by Osgood revealing the peculiarities of mother's image of ideal child and their adopted child, Unfinished Sentences by Yaparova, Patrent Attitude Questionnaire by by Varga and Stolin and Family Drawing. Children were assessed with Kerns' Attachment Scale, WHOTO scales by Friedlmeier and Family Drawing.

The data were subjected to qualitative and quantitative analysis. The results revealed peculiarities of biological and adoptive mothers' images of their adopted children and their attitude to the child. There was a significant association between children's security of attachment and adoptive mothers' attitude to the child, between child's peculiarities of mother's image of her adopted child and child-parent attachment relationships.

The implications of the study for the practice of psychological help for adoptive families are discussed.

Keywords: child-parent attachment, adoptive families.

Introduction

Raising a child in a family environment, in any of its variants, is the most suitable to his or her mental, social and emotional development [1], [2], [3]. In the last 10 years in Russia the number of children being adopted has increased. Many children in Russia are late adopted (placed to the family at age 3-8 years and later). Late adopted children usually have difficulties in building relationships with adoptive parents due to their unfortunate experience of attachment to caregivers in the past. Growing body of research has emerged with respect to adjustment of adopted children and the factors underlining their adjustment. Very often the quality of attachment to adoptive parents serves as an indicator of child's adjustment. There is evidence that the attitude of the adopted child to the family and his adoptive parents as to a source of support and the development of secure attachment relationships between family members can be considered as one of the most important features of effective adaptation of the adopted child to the family [4]. Different factors implicate the development of secure attachments in adoptive families. Our research is aimed at the study of the condidions of the development of secure attachments in adoptive families and examining peculiarities of mother's image of adopted child and its role in emotional parent-child relationships in particular.

Method

1.1 Subjects

The sample consisted of 36 late adopted children aged 6 - 9, living in adoptive families more than 2 years, and their 32 adoptive parents residing in Barnaul, Slavgorod, Zarinsk and rural areas of the Altai Territory (Russia) and 35 nonadopted children of the same age living with their biological parents and their 35 parents and 20 children from orphanages.

1.2 Measures and procedure

Parents were administered Semantic Differential by Osgood revealing the peculiarities of mother's image of ideal child and their adopted child, Unfinished Sentences by Yaparova, Parent Attitude Questionnaire by Varga and Stolin and Family Drawing. Children were assessed with Kerns Attachment Scale, WHOTO scales by Friedlmeier and Family Drawing. For Family Drawings analysis we employed Fury attachment coding system.

Results

1.3 Adopted children's attachment to their adoptive mothers

1.3.1 Attachment figures of adopted children

In the majority of cases adopted children named adoptive mothers, peers, mainly siblings and friends as attachment figures. Most of children (91%) placed adoptive mother on top of the attachment figures hierarchy. Comparing foster children with children of biological families and orphanages, we found that in general they more commonly called adults ($t=2.12$, $p\leq.05$) as objects of attachment, indicating the experience of their relationships with adults as more significant than for their peers from other social situation of development. Another feature of the adopted children - unlike the children raised in biological families they less often mentioned parents for proximity-seeking function less often, they more often prefered to cope with their negative emotions alone.

1.3.2 Security of attachment

The results obtained with Kerns' Attachment Scale showed that 57.2% of adopted children had insecure attachment to the mother and 42.8% - moderately secure attachment, highly secure attachment was not noted in any of the adopted child. Comparing these data with the attachment security of children from biological families, where children had no experience of long-term separation from close adults, we found out that they were more securely attached to their parents than adopted children to their adoptive mothers ($U=70$, $Z=2.43$, $p\leq.014$). Drawings show the absence of signs of emotional disturbance in 31% cases. In the drawings of 29 % children there were the signs of avoidant attachment, 11% - of anxious-ambivalent and 11% - of disorganized attachment.

1.4 Mothers' attitude to an adopted child and representations of him

1.4.1 Mothers' attitude to an adopted child and his security of attachment

According to the data earned from "Unfinished Sentences" 78% of parents have a positive attitude towards their adopted child, 15% - neutral attitude, 7% - negative. The vast majority (78%) of adoptive parents have positively colored image of their families and praised it in comparison with other families. Describing their children they used epithets "prosperous", "happy", "great", "best", "very successful", "right", "friendly". 22% of parents rating their families had difficulty, they could not finish the sentence, "In comparison with most other families ...". In the statements relating to the image of the child, the positive emotional attitude to the child was shown by the majority of adoptive parents (52%). They considered the child as a joyous event in their life, "happiness", 10% - as the "responsibility", and only a quarter of parents - focuses on a child as an "independent person, who needs attention and understanding" . We should note that adopted children of the last group of parents showed the highest security of attachment. This fact allows us to conclude that attention to the child's needs and motivations, associated with care and sensitivity of the parent, contributes to the establishment of secure attachment relationships within adoptive families. 78% of adoptive parents who participated in the study, described the nature of their relationship with the child as a warm, close, friendly. Almost all of them emphasize the importance of trust in the relationship with the child. The greatest variety of responses we got in saying "The most important motherhood / fatherhood for me ...". They consider most important for them responsibility, love, happiness, fulfillment of duty, etc.

The results of the analysis of adoptive family drawings showed that 47.2% of mothers had a positive image of their adopted child and that they experienced positive emotions associated with relationships in the family, other mothers' figures had signs of emotional distress related to the family situation. 29% of adoptive mothers did not feel close to their adopted children. For example, four mothers symbolically excluded themselves or their children from the family situation, one mother separated children from parents by symbolic barriers, one of the drawings illustrated a situation punishing of children for disobedience.

The analysis of the "Parent Attitude Questionnaire" responses of adoptive and biological mothers revealed the following differences between the groups. Adoptive mothers experiencing difficulties with the general emotional acceptance of their adopted children. They scored lower on the scale of "acceptance" than mothers who were raising their biological children (U=95, Z=1.57, p≤.10). There was no significant difference between mothers of two groups in their scores on the scales "cooperation", "symbiosis", "control" and attitude toward the child as to a "little loser". So, one can see that adoptive mothers seek to establish cooperative relationships with the child, but cannot accept him as he is - with his interests, feelings, thoughts. Then we analyzed correlation between children's security of attachment and mothers' attitude to them in biological and adoptive families. It appeared that authoritarity and attitude toward the child as to a "little loser" in adoptive families were related to the security of attachment to the mother (r=-.54, p≤.05 and r=-.56, p≤.05 respectively). In biological families the security of child's attachment to mother correlated only with the child as a "little loser" (r=-.48, p≤.05).

1.4.2 Mothers' representations of an adopted child and his security of attachment

The analysis of representations of adopted child and ideal child showed similarities of these images in the following characteristics "charm", "volubility","compliance".Student's *t*-test for dependent samples allowed us to establish differences in mothers' characteristics of real child and ideal child, united in factors «evaluation» (t=2.96, p≤.01) and «strength» (t=3.86, p≤.001). Mothers would like their adoptive children to be more conscientious (t=2.82, p≤.05), honest (t=4.06, p≤0.001), strong (t=2.43, p≤.05), independent (t=3.88, p≤.001), self-confident (t=4.01, p≤.001), self-sustained (t=3.39, p≤.01) than they really are. Comparison of adoptive and biological parents's images of the child showed that the image of the ideal child of biological parents comparing with the same of adoptive parents is stronger (t=2.59, p≤.05) and more honest and less stubborn. Biological mothers value their children as more etermined (t=3.55, p≤.001), good (t=2.71, p≤.01), independent (t=2.88, p≤.01), more sociable and less irritable (t=6.07, p≤.001) comparing with adoptive mothers.

Using correlation analysis, we found an association between adoptive mother's image of her child and security of his attachment to her. Positivity of the mother's image of adopted child correlated with the security of child's attachment (r=.41, p≤.05). The extent of differentiation of mother's image of her adopted child was also correlated with the security of his attachment (r=.32, p≤.05).

Conclusion

Being adopted a child meets new parents who take an important place in his hierarchy of attachment figures. High significance of the relationships with new parents affects the peculiarities of this hierarchy. They put adoptive mothers at the top of the hierarchy more often than peers from non adoptive parents and children from foster homes. They prefer parents for safe haven and for secure base functions, but this doesn't concern proximity seeking. Having prior experience of dysfunctional relationships with close adults they feel more alienated from their adoptive parents than children living with biological parents.

The results support an association of peculiarities of adoptive mother's representations of adopted child and attachment relationships in adoptive families.

The study revealed differences between adoptive and biological families in regard to the association between children's quality of attachment to mother and her parental attitude to him.

The majority of parents has positive representations of adopted child and are satisfied with family relationships but not all of them experience emotional closeness with them. The results show that mother's positive emotional attitude to the child and to the family, differentiated image of her adopted child, being reflective to the child's needs and motivations are associated with secure attachment to the mother of the adopted child.

Limitations of the study are due to a small sample size and the peculiarities of the group of adoptive families. Adoptive families taking part in our research represent a small proportion of adoptive families, only those who visit the psychological centers for such kind of families.

Building resilience in mother-child residential centers: risk and protective factors

Arace A., Scarzello D.

Department of Philosophy and Educational Science, University of Turin, Italy
angelica.arace@unito.it, donatella.scarzello@unito.it

Abstract

Objective. The research analyzes, through a survey follow-up with a sample of 64 mothers entered, on submission of the Juvenile Court, in a mother-child assisted living center in Northern Italy, the variables that influenced the success (child custody to the mother with the project of autonomy of the family) or failure (children abandoned by their mother or given up for adoption by the Court) of the paths in the residential center. ***Design.*** In line with the model process-oriented [1, 2], which emphasizes the interplay between amplification and reduction of risk and following the distinction of Baldwin et al. [3], we analyzed the role of the individual, familiar and contextual distal and proximal risk factors, and proximal protective factors in influencing resilience. ***Results.*** Regression analysis indicates that positive outcomes are possible when the amount of protective factors allows a compensation for the risk factors; among the latter, those that have the greatest impact on outcomes are proximal factors. Protective factors are able to counter the vulnerability caused by distal risk factors, supporting the parental resilience.

Keywords: Mother-child residential centers, resilience, risk factors, protective factors, distal factors, proximal factors

Introduction

The most recent studies on the evaluation of parenting skills in severely dysfunctional situations passed a conception of risk based on the model of linear direct causality or on the multifactorial causation perspective to adopt an approach defined process-oriented [1], which recognizes the complexity of dynamic between risk and protective factors and highlights the centrality of the mechanisms of resilience for the adaptation in adverse conditions [2, 4, 5].

In accordance with this dynamic perspective, objective of the study is to analyze the parenting under conditions of deprivation, as in the case of parent-child pairs in the residential centers, trying to identify the protective processes which, acting as compensation with respect to risk factors, can promote an evolutionary process, facilitating the recovery of responsive caregiving.

Methodology

The sample consisted of 64 mothers, entered in a mother-infant residential center in Northern Italy with their children, on submission of the Juvenile Court, due to situations of serious injury to children (mainly neglect and maltreatment). The average age of the mothers was 26 years (23 years old at the time of child's birth), with a range from 16 to 44 years (d.s. 5.54); 31% of them has other children, in some cases (28.3%) already forced moved from the family. 54.7% of children are males and 45.3% are females; the range of age was, at the time of inclusion in the residential community, between 1 month and 6 years (48.4% aged less than one year, 34.4% between one and three years and 17.2% older than three years). The length of stay in the mother-child community is for 21.9% of mothers less than 6 months, for 43.8% between 6 months and 1 year and for 34.4% between 1 and 2 years.

Through follow-up survey on mother-infant dyads, we identified two groups of subjects: in the first, accounting for 59% of the cases (which will be referred to as Resilient Group), the protective resources have allowed to recover an adequate parental function, resulting in custody of the child to the mother with a project of autonomy of the family unit; in the second, 41% of the cases (which will be referred to as Not-Resilient Group), dysfunctional dynamics have not changed significantly, resulting in interruption the relationship between mother and child (the children were abandoned by their mother or given up for adoption or custody by the Court).

Through the comparison between the two groups, we tried to identify those factors that have supported, or vice versa inhibited, the mechanisms of resilience and adaptation. Variables selection was made on the basis of literature about the risk assessment of parenting skills in dysfunctional conditions (eg., [6], [7]). These variables were found in the information folders of the subjects, prior authorization in accordance with privacy regulations, and encoded in a checklist of 22 items able to detect the presence/absence of individual, family and contextual risk and protective factors, taking into consideration only those variables that could be reconstructed for all subjects.

We have followed the distinction made by Baldwin et al. [3] between distal and proximal factors, already used in previous research [8]: the distal risk factors, while not exerting a direct influence on adaptation, decrease the ability to use personal resources to cope with the difficulties. The proximal factors constitute the "day to day" which directly influences behavior, and can amplify or reduce the risk.

Results

1.1 Distal risk factors

The distal factors considered concern the family of origin of mothers (in particular, the presence of psychopathology and/or dependency in one or both parents, separation or divorce of parents, abusive parents, children removed from their families) and the mother's experiences prior to the inclusion in the residential mother-child center (institutionalization, deviant behavior, addiction problems, forced removal of other children).

1.1.1 Family of origin of mothers

The history of mothers' childhood and adolescence reveals typical characteristics of multiproblematic families [9], with the presence of symptoms of psychosocial distress in multiple family members. The parental figures were often addicted to alcohol and drugs and/or had mental health problems. Most of the mothers in our sample experienced severely disfunctional primary relationships, where prevailed dynamics of conflict and violence both within the parental couple (as evidenced by the high number of separations and divorces), and between parents and children (as evidenced by the numerous situations of maltreatment or abuse), which led interventions to protect children: frequently more than one child was in fact removed from the family and included in residential communities for minors.

Although these risk factors are present in both subgroups, in the life stories of Not-Resilient mothers it is observed a significant prevalence of addiction problems in one or both parents (Tab. 1): the importance of such distal risk factor is interpretable as a consequence of role reversals in attachment relationship [10] that often occur in families with addicted parents.

Tab. 1. Problems in the family of origin: A comparison between Resilient and Not-Resilient group

	TOTAL SAMPLE	**RESILIENT GROUP**	**NOT-RESILIENT GROUP**	χ^2	***Cramer's V***
Presence of psychopathology in one or both parents	51.7%	66.7%	33.3%	ns	ns
Presence of addictions in one or both parents	64.5%	45.0%	55.0%	6.30 ($p < .01$)	.45 ($p < .01$)
Separated or divorced parents	76.3%	54.5%	45.5%	ns	ns
Maltreating parents	84.3%	50.0%	50.0%	ns	Ns
More than one child moved away from the family	84.6%	63.6%	36.4%	ns	ns

1.1.2 Mother's experiences prior to the inclusion in residential centers

The majority of mothers in our sample had previous experiences of institutionalization (75%), addiction problems (64.5%) and deviant behaviors (58.3%), primarily related drug dealing and prostitution. In 28.3% of cases the Court has decreed the removal of other children.

The presence of these risk factors increases the probability of a failure in the recovery of parental skills: in fact, all the mothers in the Not-Resilient Group did experience institutionalization, dependency and deviance (Tab. 2). Also the previous forced removal of other children is significantly higher in the group of Not-Resilient mothers: as evidenced by statistic analysis, this is the main risk factor that adversely affects the outcome: in fact it could reinforce, in the mother but also in the educators, an image of inadequate parent. However, distal risk factors analyzed are not deterministically associated with the inability to recover the parental function, as already widely supported in the literature and highlighted by the presence of these risk factors also in the Resilient Group, even if with lower degree.

Tab. 2. Mother's experiences prior to entry into the Community: A comparison between Resilient and Not-Resilient Group

	TOTAL SAMPLE	RESILIENT GROUP	NOT-RESILIENT GROUP	χ^2	*Cramer's V*
Experiences of Community for Minors in childhood	75.0%	62.5%	100%	7.31 ($p <$ .001)	.43 ($p <$ .001)
History of addiction	64.5%	52.4%	100%	5.81 ($p <$ .01)	.45 ($p <$ .01)
History of deviant behaviors	58.3%	43.8%	100%	5.71 ($p <$ .01)	.51 ($p <$ .01)
Other children removed by order of the Court	28.3%	3.8%	64.3%	17.73 ($p <$ .001)	.67 ($p <$ .001)

1.2 Proximal amplification and reduction risk factors

Proximal factors analyzed are related to the mother, the child, the partner and community context.

1.2.1 Proximal amplification risk factors

Among the maternal proximal amplification risk factors, we considered the presence of maternal psychopathology and abusive relationship with the child. Mental health problems (borderline personality disorder, intellectual retardation and severe depression) affect the 37.5% of the sample, resulting an important proximal risk factor: 68.2% of psychopathological mothers is part of Not-Resilient group, while only 31.8% is part of Resilient Group (Tab. 3).

The 50.9% of the mothers is also abusive or neglectful; 87.5% was in turn victim of abuse within the family during childhood. Having behavior of maltreatment to the child is a relevant amplification risk factor: 70.8% of maltreating mothers is part of the Not-Resilient Group, while only 29.2% is part of Resilient Group (Tab. 3). This result underscores that the risk is further connected to intergenerational transmission of traumatic experiences, caused by the absence of reduction risk factors rather than having lived such experiences in the past: in fact, the majority of Resilient mothers, despite having been abused by their parents, not repeat such dysfunctional relationships with their children.

Maternal age and child age don't discriminate between the two groups. Instead, it is an observable effect of the variable child's gender: male children are more at risk of maltreatment (67.7% of the male children is physically abused by the mother versus the 27.3% of the daughters; Chi square 8.43, $p < .001$), as noted in the literature (e.g. [11]).

1.2.2 Proximal reduction risk factors

Among the proximal reduction risk factors, we have taken into account the time spent in the residential community, the educational alliance with the community and the presence of a collaborative partner.

The literature shows that the Community can creates the conditions for change internal working models constructed by primary dysfunctional relationships [12]. The time spent in the community constitutes a protective factor, which is directly proportional to the increase of cooperation in the educational project. Our data indicate that nearly 66% of mothers who have been in the residential center with their child for more than six months was able to activate a process of resilience, with a positive outcome. On the contrary, for 80% of cases in which the mother has been in the community less than six months, the outcome was negative (Tab. 3).

Some longitudinal studies about institutionalized girls who are victims of violence and deprivation have identified the presence of a stable marital relationship as protection factor for the assumption of the parental role [13]. In our sample, the father of the child is often absent or unknown (43.8% of cases). In cases where mothers have instead a stable bond with the baby's father, often partner has problems of addiction to alcohol and drugs (26.6% of cases), deviant behavior (14.1% of cases) and is abusive towards his female partner (29.7% of cases) and children (7.8% of cases). The presence of the partner often doesn't support the path of evolutionary maternal change, reproducing the dysfunctional dynamics of her previous history. This means that the mere presence of a stable bond is not a protective factor that increases resilience, while determining factor is the active collaboration of the partner in the educational project. Only in 26.6 % of cases it was possible to obtain a collaboration of father with a supportive role to the mother: in these cases the path in the community often ended with the independence of the whole family. Instead, in cases where the partner was hostile toward educational intervention, the project often ended in failure and the forced removal of the child (Tab. 3).

Tab. 3. Proximal amplification and reduction risk factors: A comparison between Resilient and Not-Resilient Group

	TOTAL SAMPLE	RESILIENT GROUP	NOT-RESILIENT GROUP	χ^2	*Cramer's V*
Presence of psychopathology	37.5%	31.8%	68.2%	6.45 ($p < .01$)	.50 ($p < .01$)
Abusive relationship with the child	50.9%	29.2%	70.8%	22.76 ($p < .001$)	.69 ($p < .001$)
Presence of a collaborative partner	26.6%	93.8%	6.2%	10.67 ($p < .001$)	.45 ($p < .001$)
Time spent in the Community (more than 6 months)	78.2%	66.1%	33.8%	7.78 ($p < .05$)	.37 ($p < .05$)
Presence of an educational alliance with the Community	65.6%	77.5%	22.5%	18.94 ($p < .001$)	.57 ($p < .001$)

Overall it can be concluded that the presence of abusive relationship with the child is the most significant amplification risk factor, while both the presence of a collaborative partner and the construction of a educational alliance with the community constitute important protective factors.

1.3 Resilience: Between risk and protective factors

The next step in the analysis was to compare, using analysis of variance, the two groups of mothers in relation to the weight of the risk and protective factors as a whole: the results indicate that the major differences in the two paths concern the proximal factors: the proximal risk factors are significantly more numerous in the Non-Resilient Group ($F(1, 56) = 22.68$, $p <. 001$), while the protective factors in the Resilient-Group ($F(1, 56) = 21.45$. $p < .001$). The differences in the distal risk factors do not appear to be significant, confirming the fact that they represent a vulnerable position, but can be amplified by other risk processes or compensated by protective processes that support parental resilience.

Finally, the binomial logistic regression (Method = Enter, CI 95%) confirmed the goodness of the model (Chi square = 33.49, $p <. 001$), which allows to classify correctly 86.2% of cases on the basis of the

factors taken into account. Starting from similar conditions of vulnerability and risk, proximal amplification risk factors and protection factors are confirmed to be those that guide the path (Tab. 4).

Tab. 4. Binomial logistic regression

Variables in the equation (Absence of resilience)					
	B	**E.S.**	**Wald**	**df**	**Sig.**
Distal risk factors	.075	.215	.122	1	.727
Proximal risk factors	1.214	.396	9.400	1	.002
Protection factors	-1.122	.374	8.975	1	.003
Constant	-.216	1.184	.033	1	.855

Conclusions

The results confirm the validity of the analysis model and indicate that resilience is possible when the protective factors are present in such an extent as to compensate for the risk factors. Among the latter, those that have the greatest impact on outcomes are proximal factors; protective factors are able to counteract the vulnerability caused by distal risk factors, supporting the parental resilience.

Overall, the stories that have been reconstructed from the analysis of the records identify situations severely deprived, in which the transition to parenthood is put at risk from the psychological vulnerability of the parent and from a highly dysfunctional past relationships, in line with several studies that identify the repetition of the experiences of rejection, violence or abuse suffered in childhood from parents as a risk factor that affects powerfully in predicting interventions of forced removal of the child from the household [14, 15, 16]. Similarly, studies of follow-up [17, 18, 19, 20] highlight that psychopathology, mental distress and parental addiction are risk factors associated with abuse, neglect, recurrent maltreatment and the permanent removal of children from the family.

The data suggest, however, that, even in largely dysfunctional families, there are protective factors that promote positive change, countering the vulnerability caused by distal risk factors and activating processes of resilience: an assessment of parenting skills that recognizes the complex interlacing between amplification and risk reduction processes, allows, as already indicated by Di Blasio [2], to bring out those resources which, if properly supported, involving the possibility for the parent to recover or construct adequate parental functions.

The social construction of breastfeeding in public: an incursion into the discussion forums

Cristescu Delia S., Petruț Paula A., Tăut D.

dianataut@psychology.ro

Abstract

Introduction: Breastfeeding is a natural phenomenon with an essential role in the harmonious development of the infant. Therefore, WHO (World Heath Organization) recommends exclusive breastfeeding up to 6 moths of age. In this period the mother is required to breastfeed on baby's demand, a behavior that is hardly possible in some social contexts. *Objectives*: This exploratory study investigates the social representations of breastfeeding in public from mothers' points of view. These social constructions are highly influential in the decision to breastfeed in public spaces and have implications for the decisions regarding the type of feeding (breastfeeding only, mixed or formula feeding) as well as the extent of exclusive breastfeeding. *Methodology:* We used a qualitative research method. Using an inductive (data-driven) as well as a deductive (theory-informed) approach, we conducted a latent thematic analysis of the comments from 2 discussion forums ("desprecopii", "miresici"), on the topic of public breastfeeding.

Results: Thematic analysis revealed 5 main themes which are relevant for the phenomenon of breastfeeding in public. The themes discussed in this study are: 'fifty shades of grey', from natural to ostentatious; (de)sexualizing breastfeeding, child's needs above the social norms, child's age sets the limit and breastfeeding in the spectator's eyes. *Discussion:* Results of thematic analysis revealed the ambivalence of mothers towards breastfeeding in public as well as the multiple facets associated with this seemingly natural gesture. The implications for policies and interventions are discussed.

Keywords: online discussion forums, mothers, breastfeeding in public, thematic analysis, Romania;

Introduction

Breastfeeding is a natural and ideal way of providing young infant nutrients that they need for a healthy growth and development. WHO recommends exclusive breastfeeding up to 6 months of age with continue breastfeeding along with appropriate complementary foods up to 2 years of age or beyond [2]. The majority of mothers are aware of the benefits of breastfeeding, but the rates of this behavior are in a continuous decrease. Statistics from 2009 show that in Romania: 88.3% of infants are breastfeed at least once, 15.8% are exclusive breastfeed up to 6 months and only in 12% of infants the breastfeeding is early initiated. Given the lack of standardized data regarding exclusive breastfeeding, as well as the dramatic changes in the prevalence of breastfeeding, the comparison with other countries is difficult. Still, some statistics suggest that in Sweden, for instance, the prevalence of breastfeeding was around 80% in 1998, with 48% of the mothers still exclusively breastfeeding at 6 months [3, 6].

The literature points out that only 1% to 5 % of all mothers cannot actually breastfeed, because of poor milk supply [3]. Therefore the question about the causes underlying such small percents of breastfeeding mothers is all the more important. One of the possible factors is public disapproval of breastfeeding in open, visible spaces [4]. The mother may experience conflicting feelings regarding breastfeeding: on one hand she is aware that human milk is the best possible food for the infant, but on the other she feels pressured to conform to social expectations regarding acceptable breastfeeding behavior [7]. Thus, the expectancy of refraining from breastfeeding in public can weight heavily the decision to sustain exclusive breastfeeding up to 6 months, as it considerably limits the mothers' social activities

The present study explores the social representations of breastfeeding in public as depicted in online discussion forums dedicated to this topic. The analysis of discussion forums can be a valuable source of insight as individuals tend to self-disclose more in these contexts than in real settings [2]. Forums are a valuable source of information for the mothers and reflect, to a certain extent, the social norms that circumscribe breastfeeding in public. Also, they are rather unstructured, agenda-free discussion mediums, which makes them all the more suitable for capturing the richness of breastfeeding phenomenon [5].

Methodology

We used thematic analysis, inductive approach proposed by Boyatzis (1998) and we analyzed the latent content of data, from a constructivist perspective. Boyatzis proposes a model for thematic analysis and guidelines for the themes and codes development (e.g. [8]). This analysis was doubled by taking a deductive approach, informed by previous research regarding social representations of breastfeeding in public [4]. The steps in applying thematic analysis were: familiarizing with data, coding, forming initial themes, reviewing of themes and defining and finding names for the themes [9].

1.1 Sample, data collection, analysis

Through Google search engine we identified discussion forums from Romania, related to breastfeeding in public. The search terms were: "forum + mothers", "breastfeeding + Romania" and "public opinion + breastfeeding". The search yielded 4 discussion forums, of which 2 were excluded because they contained also other topics related to breastfeeding. The total sample size consisted of 350 comments (2009-2013) that were included in the analysis (Table 1). We used individual comments as units of analysis and we eliminated those comments unrelated with the topic. The focus of our analysis was mother's representations of public breastfeeding together with their emotions and opinions about different aspects of public breastfeeding.

Results

1.2 Participants characteristics

Participants were represented by mothers. The demographics were unknown, because online discussion forums do not explicitly require such information. However, the majority of mothers were breastfeeding at the time of participation in the online discussions. We identified 3 categories of mothers: 1) mothers that were not breastfeeding in public, but they approved this behavior; 2) mothers who were neither breastfeeding in public nor did they approve it and 3) mothers that were breastfeeding in public and they also approved it.

1.3 Discussion forums characteristics

The discussions were often in contradiction, with mothers taking position and defending their opinions, making use of different arguments. Seldom, mothers used personal attacks or strong language. The results will be presented according with the themes we discovered, combining both comments pro and against breastfeeding.

1.4 Themes revealed by thematic analysis

1.4.1 'Fifty shades of grey': from natural to ostentatious

The accounts pertaining to the acceptability of breastfeeding in public gravitate between breastfeeding as natural gift towards the child versus breastfeeding as an ostentatious, aggressive self statement. The first category comprises mothers who see breastfeeding as a natural gesture and the primary function of breasts: *"[Breastfeeding] is a manifestation of love that infant requires" (C, 2010). "It is so natural, breast are designed to feed a baby" (C, 2007)*. From this perspective, breastfeeding must not ask and receive attention outside the mother-child dyad: *"I don't look tot other people to see if I look weird in their eyes, I am concentrated on my breastfeeding" (I, 2010).*

However, other comments highlight that this very intimate feature of breastfeeding should be a strong argument for why it must take place outside malicious and curious eyes. Breastfeeding is an important event for both the mother and the child and it must take place in a secure environment: *"I avoided to feed my child in*

public not because I was embarrassed but because, for me, breastfeeding is extremely intimate and personal and I didn't want to share it with a stranger" (I, 2012).).

Other depictions draw breastfeeding as an embarrassing act. For the mothers from this category it is vital to avoid this behavior in public places: *"I am distinctly more bashful and I wouldn't take my breast out only to breastfeed my offspring on the street where he starts to cry"* (P, 2008). Some mothers who feel embarrassed by the idea of breastfeeding in public also think that this sort of display may be actually ostentatious, which is why people generally disapprove it: *"People generally don't like ostentation, especially when it comes to sensitive subjects like breastfeeding, fertility, genetic diseases, so when it comes to things that have an intimate component and especially over which man does not have full control" (D, 2010).* However, there seem to be boundaries here, too: it is not so much the breastfeeding itself that is embarrassing but rather the attitude of the mother who is breastfeeding, as one of the mothers stated: *"Mothers that breastfeed in public do not shock me, only those that give in exhibitionism, that are fixing their eyes to study the reactions of those passing by…it is not breastfeeding that stirs reactions, but the way it is carried out" (A, 2008)*.

At first sight, these strong held opinions against public breastfeeding can be seen as rigid and impossible to change. They are also the reason for why some women choose formula instead of breastfeeding*: "I think that the Romanian mentality is one that makes many women end up giving should they want an active and normal life" (A, 2010).* The change of mentality should be an insidious process, that would not directly attack the majority's beliefs: *"It can be changed only in a few dozen years, when the child that are breastfed now will do the same thing in their families" (S, 2010)*.

Forums discussion revealed that although we know that a behavior doesn't help us, one cannot swim against the flow*: "I can't breastfeed in public, yes, "bashfulness" inoculated to me inhibits me from doing it but I admire the mothers that can do it!" (A, 2010).* This assumption is not valid for all mothers, for some of them the motherhood had made significant changes in their beliefs: *"When I was pregnant I was telling myself that I will never breastfeed in public because I am bashful and I was imagining that my breast will 'wave out'. I was wrong, there is no bashfulness when your baby cries for milk and my breast didn't actually wave out" (K, 2011).*

1.4.2 (De)sexualizing breastfeeding

The discourse of mothers from the forums oscillates between ostentatious breastfeeding, seen as a manifestation of sexuality and breastfeeding seen as a natural gesture: *"breastfeeding can't be compared with anything!...not to even sex, you see relatively nothing" (M, 2012).* For mothers breastfeeding is a routine act, but for other people can be a gesture full of sexuality. Women tend to leave sexual life in background, when they become mothers, therefore they don't see breasts as a sexual object: *"as long as I had breastfeed, 11 months, I was feeling more a mother than a wife" (B, 2011).*

The majority of mothers consider that breastfeed in public is achievable if some conditions are taken into consideration. Two of them are most common and they are referring to breastfeed in a less public space and covering the breast. The say that infant needs a quite place so he cannot be disturbed and with covering your breasts, you respect your intimacy: *"in any case I don't admire those mothers that show their breasts in front of everyone only because they are breastfeeding. Even if something intimate is seen, at least we must see a slightest intention of covering at all" (R, 2010).* If the mother respects her own intimacy, she proves common sense and respect for people around*: "covering the breast during public breastfeeding I find it a proof of common sense and respect for people around. Breastfeeding in not shameful, but you have to mask the moment, is uncomfortable for children, young people, for men even, especially for those who didn't have this kind of situation in their family" (A, 2011).* Covering the breast gives breastfeeding a less sexual connotation.

Another opinion is that woman are more disgusted regarding breastfeeding in public than man, not because second category look at breasts as an sexual organ*: "I haven't heard of man disgusted that a mother is breastfeeding, more often this requires a certain respect, and in the worst case indifference! Only woman disapprove public breastfeeding! This says something…"* (R, 2009).

On the other side of the fence, mothers militate for breastfeeding as a gesture full of sexuality, whatever mothers do. Breast are seen first of all as a sexual organ: *"I have nothing with public breastfeeding, but I must say that: in the case of a generous cleavage that small part of the breast is not seen, ie areola and nipple, that breast is seen as a sexual organ that is sucked, caressed and massaged in the course of sexual act and here you see something that is sucking. Even sucking, no matter what it is candy, ice cream or I don't know what is a gesture full of sexuality"* (M, 2010). For parents it may seem a normal gesture but: *"for men and others is an exciting gesture…it seems that a breast full with milk is a fetish for some"* (X, 2010).

Although mothers know that breast is seen as a sexual organ, they don't feel guilt for this assumption: *"I know where all this anti-breastfeeding bitterness starts, but as a mother, that is breastfeeding, I don't have the guilt. For me is absolutely necessary to breastfeed my child, a mother can hardly bear the hunger crying of her child"* (A, 2010). In the same time, the idea of normality is emphasized: *"I think that normal men don't look at breast full of milk in a sexual sense"* (I, 2010). In conclusion some mothers cannot pass across the sexualizing of breasts and others say that: *"I felt that my milk containers are belonged only to the baby"* (A, 2010).

A gesture full of sexuality or not, breastfeeding is subject of critics from a social point of view also. Consequently, through the lenses of some mothers, breastfeeding in public violates some unwritten social norms. However, these norms are difficult to reconcile with the baby's immediate needs for food and maternal warmth, all of which are provided together with breastfeeding.

1.5 Child's needs above the social norms?

Given that infants' have immature nervous and digestive systems, breastfeeding on demand and not on schedule is the safest way to ensure that they benefit from the right amounts of milk. This feeding scheme has benefits for mother also: by breastfeeding on demand they avoid discomfort and heath problems like mastitis or breast pain. The resolution to this conflict (respecting child's rights by breastfeeding on demand versus avoiding public embarrassment) is not simple. Some of the mothers considered that infant needs come first and public breastfeeding is a way of respecting the rights of both mother and child: *"It is the child's right to be fed and mother's right not to be stuck in the house 24 hours/day" (S, 2012).* Mothers think that one should not stay indoors, just because they are breastfeeding and public opinion may disapprove this: *"Breastfeeding didn't stop me go outside the house; I didn't even consider this a possibility" (L, 2010).* Others solve the conflict by using their own expressed milk in a bottle when feeding the child in public or by undergoing complicated routines so that breastfeeding always takes place in the intimacy of one's home: *"Just once I breastfed in may car…Otherwise I am always calculating my time and I am very stressed to be home in time. Indeed in the beginnings I barely left my home. And yes, I missed society and ceiling fell onto my head" (L, 2009).*

Some other resolve the conflict by minimizing the importance of breastfeeding as a proof of love and care towards the child, arguing that love can be expressed in other ways too. From this point of view, love is a 'scapegoat' used for not complying with the rules of common sense: *"If you think that breastfeeding your child on the street is a love declaration, I think we speak for the sake of speaking. In society, there are unwritten laws pertaining to education and common sense" (E, 2010).* Society requires mothers to comply with its rules and motherhood doesn't absolve them from taking norms into account. Some of the breastfeeding mothers take responsibility for their social isolation and this makes them feel as they are outcasts together with their children. The consequence is that they choose, at some point, between formula feeding and staying at home, at the child's expense*: "Do you know why is so much easier to use formula? The baby has no place in the market, mall, and park. He/she is allowed to go out only after he/she was breastfeed and until he is going to be hungry again. A mother who wants to spend more time outside, in both her and child's benefit, betakes to artificial food so that she can quickly cobble together some food for baby" (L, 2010*). Mother's discomfort and stress of tight schedules and avoiding public dismay sets breastfeeding far from the idyllic portrayal and makes formula feeding look like a viable solution for both the infant and the mother: *"I am pro breastfeeding, if it is possible, but sometimes it is so stressful and exhausting and it is no pleasure to feed your baby, than you better give him formula, for his own sake.*" (A, 2012).

1.6 Child's age sets the limit

This ambivalence (child's needs versus social norms) is resolved, by some others, by clearly setting an age limit up to which breastfeeding as a response to child's needs is understandable.

Thus, for majority of those who approve, child's age of 2 years old is accepted as the upper limit to the infant breastfeeding: "I find absolutely normal to breastfeed a few months old infant that relies exclusively on human milk in the park, or anywhere else. But to breastfeed a child of 2 years old in public spaces, I find it exaggerated and ostentatious" (A, 2010). A major consequence of this belief is that mothers tend to give up breastfeeding at six months or earlier, because it is not anymore socially accepted: *"I have around me women that give up breastfeeding after a week and is not because they want to go to the hairdresser, but because "you don't see anyone doing that", so it is not normal"* (D, 2010).

Some others, who are for public breastfeeding at any age, even after complementary food is introduced, use infant's rights as an argument of their choice. They also talk about providing comfort, safety and reassurance to the child, who is exploring the environment: *"Infants at 5 moths and children at 2 years see the world differently and need breastfeeding differently. If for the first category breastfeeding is primary a food source, the last one sees breasts as a way of gaining relief and support. It is an abuse not to offer it"* (300, 2010). This last category of mothers does not take into account the expectancies of people around and deal with the potential stigma attached to prolonged public breastfeeding: *"I breastfeed anywhere, in the park or at the MD's office… wherever my infant demanded. I am not afraid of breastfeeding him when he will have 2 years old, although my sister-in-law told me that when children start walking, keeping with breastfeeding will make you look "worse than a cow". Well, for the health and good of my child, people can call me so"* (I, 2010). The fragile, ambiguous criteria used for establishing when and whether public breastfeeding is deemed acceptable are further revealed by mothers' accounts.

1.7 Breastfeeding in the spectator's eyes

Mothers that are breastfeeding in public spaces stir admiration and not disgust in some of the woman that saw this portrait: *"I don't see anything upsetting or embarrassing in a mother's breastfeeding. I even admire her because she does that for her child, especially when they are so many mothers that want to breastfeed but cannot from various reasons"* (R, 2010). Women from this category describe other gestures that being more disturbing: *"is very dear for me to see mothers that breastfeed. I feel disgusted only when I see on the street sexy women dressed with no more that 10 inches of material"* (B, 2010).

Flipside is given by the frustration of mothers that couldn't breastfeed, especially caused from medical problems. For this category of mothers, breastfeeding should not become a trend, but to keep on personal decision of each woman: *"to no end would have come to me some women in the park, six years ago, to convince me to breastfeed and me to explain them that I don't have milk, from unknown reasons I cannot breastfeed my child…it would have deepened existing frustration and wouldn't have helped me"* (D, 2010). Mothers that wouldn't agree with this statement, use as arguments comparisons of breastfeeding with other promotion activities: *"is like saying that organizing marathons to educate population about sport benefits is an act of insensibility for those that are paralyzed"* (A, 2010).

Discussion

With increasing virtual communication, discussion forums have become a valuable source of information for qualitative research, although some practical issues are discussed (e. g. [10]). This study had the purpose to explore mother's representations concerning public breastfeeding. Also we wanted to describe the socio-cultural context, that allows or not public breastfeeding. Our analysis revealed more themes that revolve around public breastfeeding. These includes: child's needs, the age of child that is breastfeed in public space, how breastfeeding can be seen as a gesture and the sexualizing of this behavior.

Mothers that are pro breastfeeding in public spaces, use as argument primacy of child needs. Those mothers represent breastfeeding as a natural, normal gesture that can be done in public settings without breaking any rules. Child's needs are also important for mothers that cannot breastfeed in public, but for them this is an intimate, embarrassing and maybe ostentatious gesture. Sexualizing breastfeeding is pulled out harder from mothers that cannot breastfeed in public spaces. Those that can breastfeed in public don't feel guilt for the sexualizing of breastfeeding they see the breast only as the organ that gives milk to the baby.

Another theme is breastfeeding in the spectator's eyes. Frustration and admiration are two of the spectator's emotions. Mothers that are pro public breastfeeding don't take into consideration emotions of people around them. They can stir admiration from mothers that approve this behavior and frustration from mothers that couldn't breastfeed, especially from medical problems.

This, except of accomplishing the objectives, reveals what are the core problems of breastfeeding in public. Exploration of this issue should be a point of interest for the specialist from heath psychology.

The limits of the study are those well known of qualitative research. Another limit is that the code and themes were developed by a single person, assuring the consistence of analysis but ignoring other perspectives on data.

The flawed mother-son psychological union as non-resilience to manhood challenges

Cruceanu Roxana D.

Romania
roxana.cruceanu@yahoo.com

Abstract

Structured as a personality rebuilding route, the present analysis discusses how an abnormal childhood generates a problematic adulthood. The focus is on the possessive, dominant mother and the obedient son, a combination that leads to subsequent deviant behaviour and inadaptability of the grown-up man. Although many aspects are to be envisaged with this subject, my priority is to look at the adult's wounded masculinity and faulty erotic involvement as the maintenance of the primal fusion, prolonged endlessly. Relying on certain theories put forward by psychologists like Jung, Fromm, etc., these men's existence with an identity crisis in the centre is recorded here both as fear of maturation and as a mechanism of defence against the cruelty of the world.

Keywords: Devouring mother, the Law of the Father, infantilism, the symbiotic union, frustration, identity, alienation, eroticism, society, metrosexual.

Introduction

"Young Juan now was sixteen years of age, / Tall, handsome, slander, but well knit; he seemed/ Active, though no so sprightly as a page, / And everybody but his mother deemed / Him almost man, but she flew in a rage / And bit her lips (for else she might have screamed), / If any said so, for to be precocious / Was in her eyes a thing the most atrocious" [1].

This doom-laden scenario, excellently drawn by Byron in his *Don Juan*, may be placed at the core of any analysis discussing the issue of the possessive mother who rejects the idea of her son's maturation and the devastating impact such an attitude has upon the man to be. For, if the mother has an essential role in her offspring's education and development, she can also become his worst enemy when trying, consciously or not, to enslave him and suffocate his true personality. In other words, she can be either a creator or a destroyer.

For centuries, the relationships between mothers and sons have been questioned and handled as one of the major themes in psychoanalysis, literature or drama. Many scholars from a wide range of different disciplines have sought to understand and explain the complicated mechanisms lying behind the concept of mother-son union. This brief survey does not envisage all the aspects in connection with the matter, but it encapsulates some of the principal dynamics of the mother-boy bond with a focus on the mother's deviated behaviour as a source of the adult's infantilism, egocentrism, flawed eroticism, wounded masculinity and consequently inability to perform his role. Such a person becomes non-resilient to manhood challenges, a loss perceived both at the private and social level.

Excessive Devotion or the Devouring Mother

It is true that the abnormally strong mother-son dependence is more frequently expected to occur in father absent households, where "the mother should seek more resources from her son and should attach an increased value to the resources she receives from him" because she "presumably shifts positive affect from the husband to the son" [2], as it is true that the fixation of the mother on the child is also likely to appear in married couples, when the woman does not allow her partner to interact sufficiently with the boy and impose his law, choosing to monopolize her progeny's universe from birth to adulthood. In both cases, the devouring mother is the echo of a frustrated woman, who hides her animosity towards life under the mask of virtue and unselfishness. Therefore, she is oversolicitous and "overconcerned not because she loves her child too much, but because she has to compensate for her lack of capacity to love him at all" [3]. It is because of this dissatisfaction that the boy who grows up in such an environment will never become a man in the real sense of the word.

Beginning with a fusion, the mother-son union ends in separation, a course of action that is difficult but necessary. The child no longer orbits around the maternal axis; this renunciation to his androgynous primal

attachments involves evolution and shapes individuality. With the tyrannical mother, whose dominance is characterized by Lacan as emasculatory [4], the split is undone and the son stagnates to a pre-oedipal phase, undisturbed by the decisive intervention of the father. At this point, mother and child have a connection in which "each strives to see itself reflected in the other; each defines the other's identity, a kind of primordial master-slave dialectic. It is a relation of reciprocity without exchange" [5]. Fundamentally, this is the period when the child accepts being the illusory phallus for the mother, before the symbolic castration performed by the father, a recompense which awakens the infant's awareness about the impossibility of the game. After that, the baby can move to the next level, the mirror stage, when identity begins to be constructed and the sense of self or ego is formed once the infant recognizes itself in the mirror. It is the first major step towards freedom, but also the basis of a painful alienation, forever followed by attempts to cover over.

For the virile woman, this dissociation means losing her almightiness and, if her masculinity is accompanied by narcissism, the situation becomes even more complicated. She sees in the child a prolongation of her own self, a supplementary reason for the mother to take pride in him, to appreciate the 'progresses' he makes under her attentive observation, in accordance with her own desires and requirements. It is the love for the baby, who though has nothing to offer concretely, feeds his mother's conceit. The infant's growth produces a rupture in the chain, because he ceases to be an object easy to mould. Hence, such a mother hangs on to the continuation of her son's babyhood, a condition that is maintained artificially by wrapping her progeny in the diaper of noble aims and aspirations to round off her creation. She transcends herself in her boy, the easiest way of taking action and doing something she interprets as grandiose.

That is the reason why this feminine typology will do everything to obstruct the father himself or any father figure who wishes to inflict what psychoanalysis calls the Law of the Father. If she is successful, the repercussions are serious and permanent, or at least that is what Lacan suggests by showing that the Name-of-the-Father is the fundamental significant allowing the significance to act normally. This fundamental significant confers identity to the subject, because it names it and positions him in the symbolic order, indicating the oedipal interdiction, the 'no' to the taboo of the incest. If the significant is foreclosed, the result is psychosis [6].

The father is the prohibiter, the establisher of certain limits, the voice of obligation. Whereas the mother is equivalent to unconditional love, the father stands for conditioned, deserved affection. He teaches the child discipline and demonstrates that one must do certain things for the others, a concept that is very different from maternal adoration which demands very little and offers everything in exchange.

After the pre-oedipal stage, the male parent intervenes upon the mother, depriving her of the imaginary phallus, breaking the androgyny between the two and imposing a new conduct of his wife towards the offspring. Then, a direct confrontation father-child follows, in which the latter is released from the impracticable phallic mission – lethal in the long run – and can at last identify himself with the father. It is a process in which the infant outgrows his oedipal desire by internalizing the Law embodied by the father, a Law that compensates for the renunciation to his former longing to the mother. Now, the boy gains his right of "phallic speaking subject" [5].

If the mother is reasonable, she cooperates with the father in order to help her boy to evolve harmoniously. In "the ideal case, mother's love does not try to prevent the child from growing up, does not try to put a premium on helplessness" [3]. But the authoritarian mother has a different theory. The result? A childish man with an anesthetised heart and mind, with masculine impulses carefully and constantly repressed. In short, a puppet on a string deprived of will and vital force.

Adulthood, Anxiety, Alienation

The three a's, perceived here as complementary notions, stand for the main aspects portraying the manhood of a person raised by a devouring mother. They are the perpetuum mobile for the dynamics of such a man's lifestyle and decision-making. We have already seen the mechanism lying behind the genesis of the immature grown-up, a personality rebuilding route, which is one of the keys to unlock the perplexing thinking of the grown-up surrounded by frustration and confusion. The burden imposed by an irresponsible mother is too heavy to carry: it is the skeleton hidden in the closet that he will never cease to discover and will always haunt him, irrespective of age or the place he is in. In fact, we believe that we may speak about the adult's zero evolution in fundamental matters and zero resilience to existential hardships as this non-development instituted by the female parent is synonymous with stagnation. What is more important than the 'birth' of the man condemned to permanent infancy refers, however, to the concrete manifestation of this handicap acquired in early childhood.

Men suffering from an identity crisis are difficult to detect, especially if they act as sane, rational persons. Very often, they are successful, even admired by their entourage and perceived as role models. Under normal circumstances they may function well, but under less favourable conditions they become depressed and anxious. Furthermore, they are unable to surpass their infantile superficiality, which, sooner or later, will prevent them from dealing with public and personal duties and will expose them as useless or ridiculous. Can such a

disappointment be avoided? Hardly, considering that the source of these men's deviance has deep roots in their traumatizing infancy, when the mother refuses to be aware of the consequences of her irrational conduct. Obviously, 'mother's boys' fail to develop a healthy self-esteem, to become confident in their chances of achievement and convinced of their own human value. That happens first and foremost because "the tie to adults who are 'unfit' as parents, unbroken closeness to them, and especially identification with them, may cease to be a benefit and become a threat" [7].

1.1 The Infantile Lover

Perhaps sentimental life is the most revelatory chapter of their anxiety. To have the power of doing what is apparently bad for him, the individual must be unfaithful to his primal Eros, to leave his first love, to forget the mother, or rather her imago. If not, his affectivity is sterile. Some of these men become homosexual, an allegorical homage they pay to their mother, who remains thus the only significant feminine presence in their destiny; some others are heterosexual, but not pillars of the family, as generally expected. Among her many strategies, the domineering mother uses as one of her main weapons the suppression of eroticism in her boy for as long as possible, since sexuality would hasten the son's realization of his inadequacy as imaginary phallus. And, when sexual initiation does occur, despite the mother's effort to avoid it, instead of representing a new mental and spiritual revolution in the cycle of maturation, a cry for autonomy, an ascesis, it becomes a regression. The explanation is very simple: the conscience of the puerile man is reduced to the instinctual creed that the psychological mother-son union implies safety and wellbeing. Emotionally lethargic, he resents adulthood and visualises the world of the grown-ups as frightening, unacceptable. He understands motherhood as mirage that relates any major human travel to the depth of the womb. Irrespective of the number of initiating events, the plunge is into the mother, who means shelter. Therefore, he dismisses alienation by the simple physical presence of any 'clone' of the biological mother. The fiancée, the wife, the mistress are designed in his mind as an army of obliging mothers. After 'plotting' with the natural mother – who is now replaced – to cheat life, he strives to do the same with his beloved; thus he never gives up the self-identification with the imaginary phallus, the gift for all his protectresses. Once again, he makes a step back instead of a step forward, so as not to be too estranged from the matrix, the shield that wards strokes off. He does not internalize motherhood as the starting point of knowledge, but compresses the entire Universe inside the mother, be her the real one or a surrogate, clinging to an androgyny that brings about the hope of happiness.

Jung comments upon the mentality of such a man by explaining that his Eros is passive like that of a child; he wants to be made prisoner, absorbed, wrapped and devoured. He looks somehow for the magic circle around the mother, with its protective and nourishing virtues, the state of the child absolved of any worry, when the world is the one coming to him [8]. The concrete travel through life is not satisfactory because civilization does not surrender, is harsh and must be conquered by strength. He may be in the middle of the most important events, yet he is not there mentally; he is a fugitive, hiding from coldness, intolerance and wickedness in mother's arms.

The tragedy is that the baby-adult cannot offer genuine love; his possessive mother has already taken care of this aspect. The child, and later on the adolescent is made to breathe but through her and implicitly taught to love all the other women only at a superficial erotic level and only if they are able to sacrifice themselves for him. If he is lucky enough to find a partner who accepts that his "aim is to be loved, not to love" he feels at ease, "can display a great deal of affection and charm and that is the reason why these men are often so deceptive" [3]. The lover in herself is not important; the mother within matters, which indicates that all the women he chooses are seen as a whole, different as they may be. He is addicted to each, as long as they bring the world to him and is willing to please them, to obey them blindly, a sort of submission that imitates the symbiotic union. Yet, if the partner becomes 'selfish' at a certain point, namely if she demands her right to be taken care of, to be respected and cherished for what she is, not for what she does to support her consort, the man suddenly feels betrayed and abandoned. His beloved is accused of unfair treatment or ingratitude, and consequently replaced rapidly.

It is hence very possible for this masculine prototype to become a true seducer. He is envied for his numerous conquests, for his long list of 'victims'. However, there is nothing to envy here. He acts like a "Don Juan, who needs to prove his male prowess in sex because he is unsure of his masculinity in a characterological sense" [3], because he feels weak and needs to compensate for his debility by being erotically assertive. In addition, his every affair is a search for a secret ideal, for a new fusion that provides comfort so as to revive the memory of the first mother. At each encounter with a woman, he is reincarnated as a new-born baby, condemned to restart the pre-Oedipal cycle, a Sisyphean sentence that stops progress. Our charmer subscribes to the Lacanian theory which views desire as metonymy, in the sense that one lost love, one lost paradise is immediately displaced onto another, in an endless attempt to grasp the real mother [5]. His tacit message for his female companions is clear: 'I adore because I need you', never 'I need you because I adore you', a reversed word order that makes all the difference between the baby and the man.

1.2 Mother's Boy and the Consumer Society

In a civilization that operates with normal values, the male depersonalized as a result of his mother's pathological influence can mislead the others for a while and be regarded as a respectable, mature citizen; nevertheless he ends by being unmasked and probably marginalized, or at least not taken seriously. But the modern world is ailing as a whole, suffers from angst, solitude and is deprived of identity. So long live the infantile man! He has finally found the propitious environment. Humans have been transformed into "alienated automatons" [3] by the consumer society. Shallowness and the copy-paste example are generally applied and accepted rules. Not knowing what to do or how to do it if one does not follow the universally established patterns is something common nowadays. Collective free will is as paralysed as that of the child dominated by his mother, and thus most men – and women for that matter – resemble those persons who have remained attached to the skirts of the mother, even when that is not the case. Since we all live in "the denial of the real" [9: 34] the male prototype we have dissected so far does no longer seem so abnormal. On the contrary: he is perfectly integrated within the new pattern.

For instance, his continuous flight from one mother to the other is synonymous with the contemporary insatiable desire of moving from one signifier to another – be they objects or concepts – and both stratagems of escaping the truth are based on lack. Or, let us not forget the art of simulation. The man infantilized by his mother usually pretends to be self-possessed and self-confident, which is not very different from the unfortunate current tendency to fake almost everything, interpersonal relationships and knowledge included. If there is not any absolute value at present and the authentic connection between people is lost, the only thing left is "gaining the approval of others, soliciting their judgement and their positive affinity" [9], without proving oneself. It looks as if the modern individual had borrowed some deceptive techniques from the anti-model we have tried to describe.

Under these circumstances, we cannot be sure if the supposed inner emptiness of the metrosexual is generated by a flawed connection with an unsuited mother or by the general trend of depersonalization. Perceived by most scholars as a man focused on his grooming and appearance, spending time and money on shopping and beauty centres and preferring jobs that involve rather fame and adulation than effort, the metrosexual becomes a dominant masculine figure of this epoch. Were we to rely on his narcissistic personality and rumoured vacant ego, we would be tempted to assume that he is the product of a devouring mother. This belief would be enforced by the fact that his ancestor, the dandy, a fashionable of the past, presumably had this problem. Striving for originality and uniqueness – perhaps too hard to be credible – the dandy's "selfhood was a matter of surfaces" [10] and he is known to have reserved all his affection for the mother, ignoring the male parent and his Law. Although his deviance has never been clearly recorded as caused by a devouring mother, the hypothesis is not excluded.

But dandies represented a small group of unconventional personalities, more or less tolerated by their entourage and labelled as eccentric. Metrosexuals are a mainstream; their manifestations are characterized as normal in a world where essence is absent anyway. Several legitimate questions then arise: is the depersonalized modern man the victim of an engulfing mother or of an engulfing society? How can we treat the symptoms of alienation if we do not know its source? And ultimately how can we expect the new generation of men to hold the entire earth and to fertilize the field of the world (Jung 1994 a: 142) when they often undergo emasculation twice: from resentful mothers and from an embittered society?

Conclusions

When the psychological umbilical cord between the mother and the boy is not cut, the son is forever pushed towards a universe of pre-oedipianism, as a mechanism of defence against the cruelty of the world. His infantilism as an adult brings about discontent for himself and disappointment for those who need to rely on him either in his capacity of companion or in his capacity of social pillar. He is emotionally dysfunctional and, although this handicap may not be extremely visible, he becomes a burden that others have to carry. Unfortunately, in modern times the immature man is everywhere, because the devouring mother has a new ally: the consumer society, which destroys the sense of self as efficiently as she does.

Cognitive resilience factors for parental distress in the case of parents having children with externalizing disorders

David Oana A.

Babeş-Bolyai University Cluj-Napoca (ROMANIA)
oana.david@ubbcluj.ro

Abstract

Although it is currently acknowledged that parents of children presenting externalizing disorders are experiencing high levels of distress, there is little knowledge on specific resilience mechanisms involved in this relationship. The aim of the present study was to investigate the cognitive resilience mechanisms involved in parental distress, in terms of the interplay between different levels of parent parental attitudes, like their self-efficacy and locus of control in predicting their anger. 132 parents participated to this study, whose children met the criteria for child disruptive behavior according to the ASEBA System (Child Behavior Checklist/Teacher Report Form, by scoring over the clinical cut-off of one type of assessment). Results obtained show negative relations between holding a high level of self-efficacy and an internal locus of control and reporting high levels of anger by the parents. Implications of the findings are discussed in light of developing innovative interventions for developing the resilience of the parents of children presenting externalizing disorders.

Keywords: parental distress, cognitive processes, child externalizing disorders.

Introduction

While parenting a child is found to be not an easy job, parenting a child presenting disruptive behavior is uniquely challenging and can be extremely stressful. Great research efforts have started to be devoted lately to understanding factors that contribute to parental emotional and behavioral self-regulation processes. Furthermore, there are increasing efforts to address parental self-regulation aspects in parental programs for reducing child disruptive behavior [1] and such programs might be enhanced by additional investigation of mechanisms important to parental self-regulation in this population.

An important variable found across all studies to moderate the efficacy of parent training programs, regardless of child diagnosis, is difficulties in parental affect regulation [2], and oppositional behavior. Parents of children with conduct disorder (CD) and oppositional defiant disorder (ODD) show poorer abilities to regulate anger, and a higher incidence of corporal punishment and abusive/excessive discipline [3]. Parent anger has been associated with dysfunctional discipline strategies, child noncompliance, child abuse, and various emotional problems during childhood [4]. It has been found that emotional support and nurturance diminish as parent anger increases [5].

Conceptualization of the cognitive mechanisms of parental stress and anger and the mechanisms through which they lead to parenting deficits are not well developed. Parental perceived control over the misbehavior and self-efficacy are processes that have been considered to affect discipline responses. Parents who perceive that they lack control over their child misbehavior are more likely to experience negative emotions than those who believe they can control the misbehavior [6]. Although the evaluative component of parental cognitions has received some attention, this research has yet to reflect the full range of cognitive processes emphasized in the literature on levels of cognition. Recently, it was shown [7,8] that specific irrational cognitions mediate the role of the general cognitions on parental distress, and that irrational beliefs mediate the effect of the self-efficacy on both parental stress and satisfaction.

A first goal of the present research is to investigate the cognitive structures responsible for causing distress in parents of externalizing children. The first hypothesis proposes that inferential cognitions are impacting parental anger through the means of parent's evaluative cognitions.

Methodology

1.1 Participants

Participants were 132 parents from an ongoing study on the effects of parental programs in reducing child disruptive behavior, whose children met the criteria for child disruptive behavior according to Child Behavior Checklist (by scoring over the clinical cut-off of CBCL;[9]). 116 were mothers and 14 were fathers of the children (63 boys and 67 girls). Children were aged 4 to 12 years, with a mean age of 6.20 (*SD*=2.04).

1.2 Measures

1.2.1 The Parental Anger Scale (PAS; [10])

The PAS is a self-report measure of parental anger state consisting of 30 items. The items are rated on a 6-point Likert scale that vary based on the specific item. Initial psychometric investigations yielded one and two factor structure of the scale (Anger Expression and Anger Behavior) and showed good psychometrical properties (alpha=.93; [10]).

1.2.2 The Parenting Sense of Competence Scale (PSOC; [11])

The PSOC is a 16-item measure assessing parents' views of their competence on two dimensions: satisfaction with their parenting role (reflecting the extent of parental frustration, anxiety, and motivation); and feelings of efficacy as a parent (reflecting competence, problem-solving ability, and capability in the parenting role). The total score, satisfaction score, and efficacy score show a satisfactory level of internal consistency (r = .79, .75, and .76 respectively [11]).

1.2.3 Parental Locus of Control Scale - Short Form Revised (PLOC-SFR; [12])

The PLOC was developed to provide a locus of control measure specific to parent-child interaction, toward the end of obtaining better prediction of child and family variables. High scores on the scale indicate an external locus of parenting control and low scores indicate an internal locus. The reported alpha coefficient for internal consistency is .92 for the total scale, with good construct and discriminant validity [12].

1.2.4 General Attitudes and Beliefs Scale –Short Form (GABS-SF; [13])

The GABS-SF is a 26-item self-report measure for irrational cognitive processes (e.g., demandingness, awfulizing, global evaluation, low frustration tolerance). Items are cognitively worded and include sets of irrational and rational worded items. Adequate psychometric properties have been reported in the literature [13]

Results

We investigated possible relationships between demographic variables, affective states, cognitive mechanisms and parenting.

Table 1. Correlations between parental anger and the cognitive variables considered

	Parental Anger
3.Rational cognitions	.02
4.Irrational cognitions	.25**
5.Parental efficacy	.34**
6.Parental locus of control	.23**

***. Correlation is significant at the 0.05 level (2-tailed).*

Variables demonstrating a relationship with parental distress and dysfunctional parenting were then entered into regression equations as predictors of distress and parenting. Mediation analysis was performed for

variables showing significant bivariate relations, in accordance with the published criteria [14]. The conservative Sobel test was used to evaluate the indirect effect of the independent variable on the dependent, via the mediator.

Irrational cognitions, together with parental locus of control were entered in a regression equation with parental anger as dependent variable. The model accounted for 10% of the parents 'general distress (*R* square =.10; $F(2,130)=5.47$, $p<.05$). Mediational analysis showed that when parental locus of control was entered in the equation, the relationship between irrational cognitions and parental anger was no longer significant. Sobel test shows that the path mediation is not significant.

We further entered parental efficacy together with irrational cognitions in a regression equation with parental anger as dependent variable. The model accounted for 15% of the parental anger (*R* square =.15; $F(2,130)=9.70$, $p<.01$). Mediational analysis showed that parental irrational cognitions mediate partially the relationship between self-efficacy cognitions and parental distress. Sobel test shows the mediation is not significant.

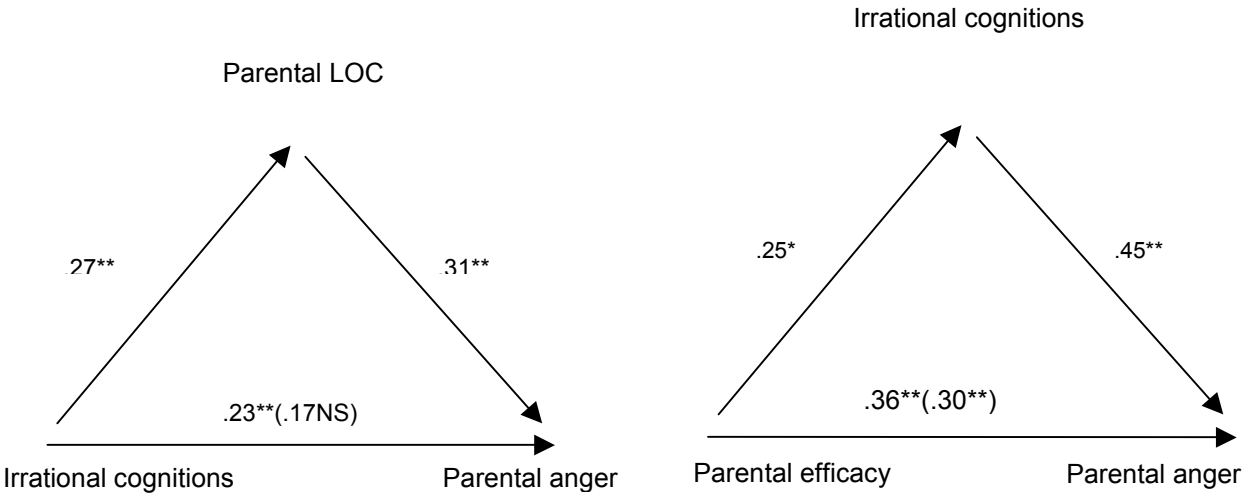

*Fig. 1 Mediational diagram for models testing the interrelations among irrational cognitions, parental locus of control, parental efficacy and distress. All values are beta coefficients. Values in parenthesis show relationships between predictor variable and the dependent variable when the mediating variable is included in the model; *p<.05; **p<.01; the value of Sobel test for the first mediation is .74NS and for the second is 1.13NS.*

Conclusions

Overall, in terms of the mechanisms to explain emotion regulation processes in parents of children presenting disruptive behavior, path for parental global appraisals causing parents' dysregulated affect is trough parental locus of control. Results obtained show that perceived external control for the child behavior and parental irrational cognitions are contributing to causing parents to feel distressed. We proposed that in case of parents of children with disruptive behavior that are biased towards considering that their child is controlling their life, this determines rigid evaluations how things should be or themselves being worthless, which causes parental anger and dysregulated affect. Surprisingly enough, compared to the findings on parental stress of parents of non-clinical children [8], the path tendency underlies the mediating role of external locus of control for child misbebehavior in causing parental anger. Our findings have thus showed a reversed path tendency towards the irrational cognitions activating parent's inferences on external control for their child misbehaviour, which in turn causes them to feel angry. However, the causality path has not been found significant.

In line with the appraisal theory of emotions [15], we have found that parental anger is linked to a high level of evaluative cognitions and distorted representations of control for child behavior. If parents have strong hot/ evaluative cognitions about being in control, then the lowest possibility that they are not in control will stir emotions. This may be one reason why focus on inferential parental cognitions (locus of control, parental self-efficacy) which are connected with probability of an event occurring, is insufficient for getting better in terms of parent's distress. In other words, in the presence of general cognitive vulnerability given by rigid expectations any distorted interpretation parental make on their child behavior will cause them to feel distress. Thus, the predictive value found for irrational cognitions is in line with research in cognitive sciences showing the importance of targeting evaluative cognitions in parents in order to overcome the distal causes of parental anger. Future studies should to explore the incremental efficacious curve provided to traditional parent training programs by enhancing their emotion-regulation component with reappraisal based strategies for achieving a better child adjustment.

Abstract

The postnatal depression raises several mental health related issues in newborns and their mothers. Also, postnatal depression remains one of the most underrecognized psychiatric condition that are encountered in obstetric setting. The present research aimed to investigate the rate of postnatal depression and the sociodemographic and obstetrical parameters that are significant correlated with postnatal depression. A cross-sectional research was performed on eighty mothers monitored in the Ambulatory of "Bega" Obstetrics Clinic from Timisoara. Postnatal depression was assessed using Edinburgh Postnatal Depression Scale (EPDS), using a cut-off ≥ 10. A significant number of mothers have scored 10 or above in EPDS (N=43; 53.75%). Mothers with postnatal depression have had a lower level of education ($p = 0.004$) and a lower individual income compared with non-depressive mothers ($p < 0.05$). Among obstetrical parameters, primiparity ($p = 0.002$), complications during pregnancy ($p = 0.04$) and prematurity ($p = 0.034$) were significant more frequent in mothers with postnatal depression. In conclusion, postnatal depression is a common psychopathological phenomenon in our region, and we consider that obstetricians should recognize the pregnant women that are at increased risk for postnatal depression.

Keywords: postnatal depression, risk factors, obstetric, sociodemographic.

Introduction

Available data from international literature have evidenced that perinatal depression, which occurs during antenatal and postnatal period, is more frequent than was believed previously [1]. These researches have stressed that, at least in part, the postnatal depression has yet begun from the antenatal period and lasts several weeks after delivery. Starting from this observation, we can assume that at least in certain cases, there is a temporal continuum between depressive symptoms that are experienced by new mothers in both periods, antenatal and postnatal [2]. Undoubtedly, postnatal depression could be subsyndromatic in antenatal period, but increasing in its intensity after delivery. Quite often, the postnatal depression is circumscribed just to the postnatal period and not being preceded by any depressive symptoms in antenatal period. Nevertheless, the old myth about the protective role of pregnancy against depression has been removed.

Not less important, it is the high prevalence of anxiety disorders occurring in perinatal period of women, without any relation with depressive syndromes, giving the new direction for future researches in this domain [3].

Taking into account the earlier age of new mothers with postnatal depression comparatively with their childless counterparts, the clinicians should consider the increased potential of index postnatal depressive episode to evolve toward a bipolar affective disorder [4].

In accord with current data, the postnatal depression appears in about 10 – 15 % of mothers during the first 12 month after delivery [5]. These figures indicate that the postnatal period should be considered at least as vulnerable for depression occurrence like any other period of the women life. From the methodological point of view, it is very important to clearly delineate the postnatal period in the determining of postnatal depression prevalence. This is because there is a difference between two diagnostic manuals. Thus, while DSM-IV-TR defines postnatal period as being four weeks after delivery, in a different manner according to ICD-10 diagnostic criteria, the postpartum period consists of six weeks after delivery [6], [7].

Away from being elucidated the etiopathogenesis of postpartum depression, the scientific community still debate the determining role of several biologic and psychosocial factors, which could play a significant contribution. Therefore, alteration of estrogen levels and increased level of prolactin were suggested as being involved in the pathogenesis of postpartum depression [8]. Moreover, serotonin transporter gene polymorphisms were found to be associated with this pathology, and therefore this genetic mechanism could be considered as the common biological substrate underlying both types of anxiety and depressive symptoms [9], [10]. Other presumed biological factors that could be involved in the etiopathogenesis of postpartum depression, we can mention: the occurrence of antithyroid antibodies caused by increased immunity reactions (immunologic rebound) correlated with low levels of cortisol once the placenta was eliminated (placental source), GABA-ergic dysfunction, diminished plasmatic level of ß-endorphins, decreased insulinemia with consequently diminished transport of tryptophan, etc [11], [12], [13], [14], [15].

From other perspective, the contribution of psychological factors in postnatal depression was equally investigated like that of biological factors. Regarding the psychological factors that were evidenced as having a causative role in postpartum depression, the following could be cited: lack of social support and difficulties in couple relationship, unwanted pregnancy, emotional and physical abuses in childhood, dysfunctional coping styles along with dysfunctional cognitive beliefs, etc [16], [17], [18],[19], [20].

Last but not least, we consider that sociodemographic and obstetric factors should be considered as being as important contributing factors for postnatal depression like the other aforementioned factors. Among these factors it can be mentioned: primiparity, complications during pregnancy, low weight birth, lack of partner, to be unemployed etc [21], [22].

Objective

From the beginning, we had like to mention that the current research is part of a larger research on postnatal depression.

One of the objectives of our research was to identify the sociodemographic and obstetric factors that are significant associated with postnatal depression. Also, we propose to assess the potential predictive role of sociodemographic and obstetric factors in determining of postnatal depression occurrence.

Method

1.1 Participants and study design

The present study was a case-control cross-sectional study conducted on eighty mothers at 6 – 8 weeks after delivery that were monitored at one site represented by the Obstetrics Ambulatory belonging to "Bega" University Clinic from Timisoara, Romania. The accidental sampling method was used to recruit the participants in the current study. Women giving birth at the above mentioned institution were recruited during their regular postpartum and post hospital discharge care medical follow-up visits for health status monitoring.

The recruitment period of eligible subjects lasted from January to June 2013 at the site mentioned above. Subjects were recruited under the supervision of a senior obstetrician. All selected participants provided informed consent, and an in-person interview was conducted.

The eligibility criteria consisted in no history of psychiatric disorder, age between 18 and 45 years old and participation to all periodical medical visits that were requested during the perinatal period.

During the recruitment period, 111 mothers were eligible to participate in the study and of these, 80 (72.1%) agreed to participate, 10 (9.0%) had a positive psychiatric history for depression, 5 (4.5%) didn't complete all the scales, and 16 (14.4%) declined to participate.

The study was conducted according to the Declaration of Helsinki, the European Guidelines on Good Clinical Practice, and relevant national and regional authority requirements and ethics committees.

Socio-demographic data (Table I) such as current age, marital status, professional status, educational level, residency, along with obstetrical data pertaining to type of birth, gestational age, birth weight and complications during pregnancy were recorded from medical chart reviews.

1.2 Measures

The level of depression was measured by the Edinburgh Postnatal Depression Scale (EPDS), which is a 10-item self-rating scale designed to detect postnatal depression, conceived by Cox et al. The total score of EPDS range of 0 to 30. The EPDS scores were dichotomized as follows: a global score of at least 10 means the presence of depression while a global score less than 10 indicates the absence of postnatal depression, as previously recommended in primary care settings by Cox et al [23].

1.3 Data Analysis

SPSS for Windows version 17 has been used to analyze data. Chi-squared test was used for categorical variables and two tailed t-test for continuous data analyses. A non-parametric rank test (Mann-Whitney U-Test) was used to analyze ordinal variables originating from two independent subsamples. For the correlations, rho Spearman correlation was determined in the case of ordinal dependent variables and Pearson correlation for dependent numeric variables.

The sample set was stratified according to the EPDS cut-off point score – the two strata consisted of depressive mothers and mothers without depression. Hence, the analysis compared the pursued variables between the two subgroups.

In order to evaluate the predictive potential of obstetric and anthropometric variables of new-born at the moment of delivery, a binary logistic regression analysis was performed using "Enter" method. Binary logistic regression has took into account the following obstetric and neonatal variables: primiparity, mode of birth (caesarean versus natural), complications during pregnancy and the prematurity.

Results

As presented in Table I, more than half of the assessed mothers (N=43; 53.75%) have met the criteria for the presence of postpartum depression during the investigation. The average age of mothers was 28.9 years old (SD=4.78), with no difference between depressive and non-depressive mothers (independent samples t-test; t=0.54; p=0.585). The overwhelming majority of mothers were living in the urban area. In somewhat expectedly manner, the majority of young mothers had a good professional status, in the sense that they were either employed or student; however there was no significant difference regarding the professional status between depressive and non-depressive mothers (Chi-square; X^2=2.56; p=0.109). Also, there was no difference between mothers with and without postpartum depression according to marital status (Chi-square; X^2=0.03; p=0.854). With respect to educational level, there was a significant difference between the two strata (Mann-Whitney U test; U=594; Z= – 2.86; p=0.004), mothers with postpartum depression had lower educational level compared to non-depressive mothers.

Table I. The sociodemographic data of both entire sample and stratified sample sets (depressive vs non-depressive mothers)

N	Entire sample (N=80)	Depressive mothers (N=43)	Non depressive mothers (N=37)	Significance of differences
Age (SD)	28.9 (4.8)	29.2 (5.5)	28.5 (3.8)	p = 0.585
No. Educational level, University and Lyceum (%)	76 (95.0%)	39 (90.7%)	37 (100%)	p = 0.004
No. Residency, Urban area (%)	69 (86.3%)	35 (81.4%)	34 (91.9%)	p = 0.208
No. Professional status, Employed and Student (%)	68 (85.0%)	34 (79.1%)	34 (91.9%)	p = 0.109
No. Marital status, Married (%)	71 (88.8%)	38 (88.4%)	33 (89.2%)	p = 0.854

Note. The listed percentages are reported to either strata considered separately.

The obstetrical and anthropometric variables of studied mothers and their babies are shown in Table II. Primiparous mothers were more frequent among depressed compared to non-depressed subjects (Chi-square; X^2=9.617; p=0.002). Mode of birth was not significantly associated with postpartum depression (Chi-square; X^2=2.534; p=0.111). There was a statistical significant difference with respect to the presence of complications during pregnancy that were more frequent in depressive than in non-depressive mothers (Chi-square; X^2=4.206; p=0.04). Complications during pregnancy include any health problems occurring in the aforementioned period requiring either a specialty treatment or hospitalization. Also, the study revealed that prematurity, defined as the birth of a baby of less than 37 weeks gestational age, was significant most common in newborns delivered by depressive mothers than the ones without depression (Chi-square; X2=4.483; p=0.034).

Table II. The obstetrical and neonatal parameters in investigated mothers (depressive vs non depressive mothers)

Obstetrical and neonatal parameters	Entire sample (N=80)	Depressive mothers (N=43)	Non depressive mothers (N=37)	Significance of differences
Primiparity (N, %)	22 (27.5%)	18 (41.9%)	4 (10.8%)	p = 0.002
Cesarean mode of birth (N, %)	51 (63.75%)	24 (55.8%)	27 (44.2%)	p = 0.111
Presence of complications during pregnancy (N, %)	14 (17.5%)	11 (25.6%)	3 (8.1%)	p = 0.040
Presence of prematurity (N, %)	17 (21.3%)	13 (30.2%)	4 (10.8%)	p = 0.034
Low birth weight (N, %)	12 (15.0%)	8 (10.0%)	4 (10.8%)	p = 0.330
Normal APGAR score at 5 minute (N, %)	75 (93.8%)	39 (90.7%)	36 (97.3%)	p = 0.224

Note. The listed percentages are reported to either strata considered separately.

Related to binary logistic regression results, we found that the primiparity was the single obstetrical predictive factor associated with the occurrence of postnatal depression (OR = 4.74, 95%CI 1.32 – 17.05). On the other hand, with an OR of 4.74, the probability of a primipara to develop post-partum depression is 82.6%, with a 95% CI (57% to 94%). Of the total 43 patients with post-partum depression, the model correctly detected 34, which corresponds to a sensitivity of more than 79%. The overall percentage of successful prediction was of 71.3%, due to the high rate of false positives (37.2%).

Discussion

When it is self-reported by using EPDS, postpartum depression represents a very frequent psychopathological condition that is shared by more than half of new mothers from our study. This huge percentage could be argued through two possible explanations. First, as it is well-known, the self-assessment tools are more prone to bias with a lesser degree of confidence than other types of standardized diagnostic instruments [24]. Second, it is very possible that due to the present socio-economical context of our country, along with its negative dynamic in last years, the percentages of mothers who are depressed in the postpartum period are higher than in other more developed western European countries. In our cultural space, there are more expectations related to socio-familial roles of women than in males, as most women must perform multiple roles such as to be a mother, housekeeper, good wife, and if possible to also have a job. In this latter regard, our results show that almost 90% of studied mothers worked up to birth. The increased proportion of mothers living in an urban area could at most indicate the higher level of education and easier access to ambulatory medical services, compared to women living in rural areas. Unfortunately, there still are evident discrepancies regarding the aforementioned factors between rural and urban areas in our country. One interesting observation in our study was the significant association between higher level of education and the absence of postpartum depression. Other previous studies have shown that higher education can be a resilience factor against postpartum depression [25].

Interestingly enough, postpartum depression was associated with different obstetrical and neonatal factors in our study. Somewhat expectedly, primiparity was shown as being the most significantly associated obstetrical parameter with depression. In line with other reports, mode of birth was not significantly associated with postpartum depression [26], [27]. In addition, mothers with postpartum depression were more likely to have obstetrical complications during pregnancy [28]. It is plausible that these stressful psycho-emotional factors that are outside the of mother's control could contribute to the development of postpartum depression. Moreover, as others have shown as well, postpartum depression was more frequent among mothers who delivered a premature child [29]. In contrast, postpartum depression was not associated with low birth weight and low APGAR score,

possibly due to our low sample size. According to our research, the primipara women are at the highest risk to develop depression in postnatal period. Certainly, further larger studies are needed to clarify this topic.

Abstract

The study was conducted within a broader longitudinal NIH-funded study on resilience in South African mothers and children affected by HIV/AIDS – the Promoting Resilience in Young Children Study. The study qualitatively evaluated a 24-week support group intervention programme which was designed to enhance adaptive behavior of latent-phase children affected by maternal HIV/AIDS. The participants (n=139) were purposefully selected from among previously identified HIV-positive women (n=220) with children between the ages of 6 and 10 years at clinics in the Tshwane region, South Africa. Data were collected over a period of five years in multiple waves of intervention implementation. The data collection strategies comprised of group process notes, care worker focus groups, quality assurance questionnaires and field notes. The findings of the study showed that the content, methods and processes employed in the group-based sessions were effective and culturally sensitive. The group provided a buffer for the children and supported them in coping with their mothers' illness. The children displayed normative values through their religious coping styles, their quest for and display of respect and their unambiguous assertion of right and wrong. A specific finding of this study was that the children created a space in which to order their thoughts, behaviors and emotions within the intervention. This provided them with parameters in their adverse circumstances to display adaptive behavior. The study suggests that support groups should be incorporated into intervention programmes dealing with latent-phase children affected by HIV/AIDS.

Keywords: HIV-affected child, adaptive behavior, latent child, theory-based support group intervention program

Introduction

A large group of South African children are exposed to the psychosocial and economic effects of HIV/AIDS. Sub-Saharan Africa carries over 69% (nearly 1 in every 20 adults) of the world's HIV/AIDS burden [1]. The children who live in families where their mothers are infected with HIV, experience the same kind of anxiety and fear as children who live in families disrupted by other life-threatening diseases such as cancer [2]. However, there is often an added burden on them – stigmatisation, discrimination and related economic stressors accompany their daily struggle to adapt to their living circumstances [3,4]. Stigmatisation by itself has the possibility of increasing the impact of HIV/AIDS on children's lives. In various cases the parents do not disclose their HIV status to their children because of the associated stigmatisation involved in disclosure.[5] Furthermore, the symptoms of the illness and possible negative family dynamics, for instance maternal depression, make it difficult for the child to make sense of his/her situation [6]. In South Africa the effects of HIV/AIDS on victims and their families, often living in single-parent households [7] and poverty and experiencing high levels of violence, are exacerbated by the limited support they receive from the community. The children of HIV-positive mothers consequently experience uncertainty in their environment, compounded by the added insecurity brought on by their mother's state of health [8].

Fortunately, HIV is no longer an early death sentence as current antiretroviral medicine and new treatment options make it possible for HIV-infected patients to have a near-normal life expectancy. These medical advances make it even more important for researchers to support mothers and children in managing their HIV diagnoses and prognoses to such an extent that the family can adapt to their new circumstances and experience a fairly normal family life [5].

Rigorous research focusing on the evaluation of programs designed to enhance the adaptation of latency-aged children to maternal HIV/AIDS and psychosocial support for families in these circumstances over an extended period are scarce. [6,9]. Research regarding the impact and effect of the different bioecological systems of the child and his/her family affected by HIV/AIDS are of particular importance, to ensure that a program is holistically evaluated. The change of emphasis in HIV/AIDS programs, shifting from focusing on the physical support to children to the added psychosocial support to children in their context, had an impact on current research regarding the planning and evaluation of programs to support children affected by maternal HIV/AIDS [6].

The study is a secondary data analysis of a larger NIH funded longitudinal randomized controlled study. For the purpose of this study, resilience is postulated as the umbrella concept of adaptive behavior. Resilience is made operational in adaptive behavior. Resilience is a continuous process that constitutes protective factors which buffer children exposed to adverse circumstances. Resilience can thus logically only exist when children have been challenged by or experienced adverse life circumstances – in this instance maternal HIV/AIDS and poverty. The aim of this study is to qualitatively evaluate and rigorously assess the efficaciousness of a group-based intervention program to enhance adaptive behavior (resilience) of children who are affected by maternal HIV/AIDS.

Methodology

1.1 Participants and recruitment

Mothers with children between the ages of 6-10 years were recruited by research assistants from nearby hospitals and clinics. The eligibility criteria for inclusion in the study were: (1) child was not infected by HIV; (2) child is cared for by his/her mother for at least 5 days a week and (3) child stayed in area of intervention sites. Informed consent from all the mother and child participants was obtained by the research assistants prior to the intervention. Each mother participant received an incentive of R40 (US$4) as compensation for traveling costs and each child received a toy worth R10 (US$1).

The study sample consisted of 139 children (76 boys and 63 girls) from two regions in the Tshwane district in the Gauteng province, South Africa. At the time of the data collection the mean age of the child participants was 8.2 years. The socioeconomic data indicated that a large group of mothers were unemployed at the start of the intervention sessions. A small number of the mother participants were married and almost half of them were not married but had a partner. Only 12.20% of mothers indicated that they (or others) had disclosed their HIV status to their children.

1.2 Measures

The data for the evaluation of the intervention program were collected through multiple sampling strategies. The researcher utilized socio-demographic questionnaires, session notes completed by multiple care workers for each group session, focus groups with group facilitators, group evaluation feedback forms and field notes.

1.3 Description of the intervention

The intervention program was developed in collaboration with a team of child development experts from the University of Pretoria and Yale University. This theory based intervention was developed after a meticulous study of the most recent advances in the study of resilience. The cultural environment of the South African child and the children's developmental level were also taken into consideration [10]. The content (refer to Fig.1) was discussed with advisors in the community to ensure that it is culturally sensitive and relevant. The first part of the intervention program consisted of 14 sessions where the children attended the sessions separately from their mothers and the second part of the program consisted of 10 interactive sessions with their mothers. Each session was led by two care workers. The care workers or group facilitators were volunteers in the community and they received a small stipend. Counseling on-site site with social workers was available to them. The care workers received weekly debriefing sessions with a senior social worker and a psychologist to cope with the emotional demands of their work.

Separate sessions 1-14	
Week 1	Introduction and getting to know each other. ' Let's get to know one another'
Week 2	Developing relationships within the group 'Let's get to know one another'
Week 3	Describe self and self in family 'Who am I?'
Week 4	Describe self and family within community 'My community'
Week 5	Identify strengths within self 'What do I look like? I have, I am, I can!'
Week 6	Identifying coping that is linked to strengths identified 'What can I do/ What am I good at?'
Week 7	Problem solving 'How can I do it?'
Week 8	Protecting self and identifying boundaries 'Protecting myself'
Week 9	Social skills 'Socializing with peers'
Week 10	Identifying emotions (focus on self) 'How do I feel?'
Week 11	Identifying emotions (focus on other and communication skills)
Week 12	Survival skills (Part 1), 'Look and learn'
Week 13	Survival skills (Part 2), 'Look and learn'
Week 14	Identifying meaning, purpose and future orientations 'Let's live life'
Interactive sessions 15-24	
Week 15	Mother and child getting to know each other (Part 1) 'Knowing me, knowing you'
Week 16	Mother and child getting to know each other (Part 2) 'Knowing me, knowing you'
Week 17	Mother and child getting to know each other (Part 3) 'Knowing me, knowing you'
Week 18	Creating a legacy. (Part 1), 'Let's make a family memory'
Week 19	Creating a legacy. (Part 2), 'Let's make a family memory'
Week 20	Interaction between mother and child (Part 1), 'Let's have fun'
Week 21	Interaction between mother and child (Part 2), 'Let's have fun'
Week 22	Mother and child sessions revisited (Separate session), 'Where are we at now?'
Week 23	Planning for the future. 'Let's dream together'
Week 24	Family celebration. 'Let's celebrate life'

Figure 1: Content of child group-based intervention sessions

1.4 Data collection and analysis

The data of 12 support groups who received the group-based intervention over a period of 24-weeks as treatment were used to qualitatively compare the post-treatment data. A multiple case study design was followed and data were collected from the group facilitators (care workers), mother participants, child participants and the research coordinator. The attendance per session was on average eight children. The text obtained through the documents and focus groups were coded and analyzed for themes. The data were numbered using the group and ID number of the participants to ensure that the text could be traced back to the original context. Themes and categories were generated and the data findings were interpreted and compared to the literature findings. The themes of the emergent concepts were re-coded to establish improved defined categories. The collection of data continued until saturation was reached and the research questions could be answered.

Results

Information obtained from the intervention session notes mostly confirmed the findings from the focus group discussions with the care workers and the group evaluation questionnaires of the mothers and children. Four major themes were identified: (1) Resilience/adaptive behavior indicators (2) Identified risk factors; (3) Identified protective factor: Normative values are displayed despite chaotic life circumstances and (4) The content, methods and processes employed in the group- based sessions.

1.4.1 Resilience/adaptive behavior indicators

The three themes that most frequently occurred during the group sessions were identification and verbalization of own and others' emotions, communication and sharing.

The children were willing to share their pleasant and unpleasant emotions. The group provided a safe environment for the children to explore and display a repertoire of emotions ranging from joy to aggression. The children showed emotional support for each other. They experienced that sharing and displaying emotions have a healing effect.

"*KM 502 said he can see his mother on her face if she is not happy, after that all agreed with him. He then try and make her happy. He doesn't feel happy if his mother is not feeling happy*" - 7:10

During the group sessions the children were able to communicate their ideas and emotions. Communication helped rectify misunderstandings and this improved, among other things, the relationship between mother and child. The safe environment of the group enabled children to disagree with their mothers. The group sessions empowered withdrawn children to become leaders.

"*When talking with puppet socks mothers were amazed because we explained to them what and how your child said is how you are talking to him/ her at home. They said they know each other better now and they enjoyed doing activities with their children*" - 4:17

Sharing occurred between group members, between mother and child and between children and group facilitators, as evidenced by the notes of the care workers and their observations. The children shared emotions, information and normative values regarding their personal world and their external world (family and school). They also shared constructive and negative information in the safe environment of the group.

"*During the puppet play, they were sharing information on how to play and say during the play. When playing making a friend scenario they were talking positive things and encouraging each other*" - 4:1

1.4.2 -Identified risk factors

Many children feared and reported abuse (emotional, physical and sexual abuse) in their close family proximity (specifically uncles). They displayed fear when they reported situations where family members threatened them with violence if they did not take part in illegal behavior such as buying liquor, although legally under aged. From the data it seemed that they were able to discern between right and wrong behavior. Their distrust in the police to whom they were supposed to report this abusive behavior contributed to their general feeling of insecurity. Their day-to-day exposure to violence in the community where they resided enhanced their feelings of insecurity.

"*During the stone game most of the group members told their stories using violence in the family and there are much of guns and shooting and stabbing in the community*" – Group facilitator

"*KM 627 and KM 679 said that their uncles beat them when drunk. KM 670 just cried and she didn't want to talk when we spoke about the uncles. KM 616 says she is scared of her uncle because he raped her*" – 10:8

Food scarcity was a prominent result of the poverty the children experienced. In attending the group sessions the children's physical needs were taken care of, if only for a short period of time. They received nutritious lunches and food parcels.

"*KM 539 said he will kill himself on island and the food is finished. The will kill himself before hunger kills him*" - 8:12

The children displayed internalized and externalized behavior problems related to their mother's illness, as evidenced by the group session data. The children were able to express their fear of losing their mothers through illness. They knew their mothers were ill, but it seemed from the care workers' observation of the group sessions that the children were not aware of the implications. In most instances they took up the responsibility to care for their mothers. There seems to be a correlation between the mothers' physical wellness and the children's psychological wellbeing and behavior, according to the data as obtained from the group session notes of the care workers.

"*KM 179 he was bullying other children and he said he feels pain when somebody passed away and he is worried when is mother is sick, he thinks she is going to die*" - 2:10

1.4.3 -Identified protective factor: Normative values are displayed despite chaotic life circumstances

Respect, pertaining to different areas of life, was displayed during the group sessions. The normative area referring to religion and group rules and the area referring to respect and disrespect towards parents and other adults were especially important. The children indicated that they desired to be respected as human beings by adults and other children. Data from the study showed that the group interaction taught children what respect is and how to show it.

"*KM 441 was not respecting group rules he was making noise and he said he is not interested but the group asked him to go outside and he can come back when he is ready, he did so and came back to group*" - 6:11

Religion was the most important positive coping mechanism displayed and reported by the children, as observed by the care workers. The data from the study showed that they received comfort and also offered comfort to others through their religion. Their religious practices included attending church and Sunday school, prayer, reading the Bible by themselves and with their families. The children requested that the Bible be read to them during the group sessions. The children experienced their mothers and grandmothers as a further source of support while coping with challenging life circumstances. The group facilitated the teaching of coping strategies, identification of strengths and other assets in their life.

"*KM 714 had a Bible cutting amongst his cuttings. He explained to us that the Bible is a good book to read for it can comfort him and others who are in pain or trouble and it also guides him to be a person with good manners and respect for peers and older people*" - 12:19

1.4.4 -The content, methods and processes employed in the group-based sessions

The mothers and children indicated that they experienced the group sessions as positive. The themes that were identified by analyzing the question to the children of 'what did you like best about the group' are, in order of importance, the opportunity to play with friends, games that challenged them, the refreshments they received at the group, the opportunity to learn new things, the chance to make new friends, the help they received from each other, the lessons they learnt in respecting parents and peers, the group climate of respect and no tolerance for fighting and they indicated that they enjoyed being asked questions. The type of activities that the children themselves indicated as enjoyable in the group were writing, reading, painting and drawing activities. The children especially enjoyed the activities where they could play with their mothers. Being actively kept busy and games with puppets, making food for mothers, body mapping, board games, dancing- and singing activities where mentioned as most enjoyable. The children indicated that they felt comfortable in the group. They understood what was expected of them in the group. The group provided the opportunity to make new friends according to the children.

"*The group mates, they were friendly, supportive, co-operative and kind. I know myself better than before. I used to enjoy the meals*" – KM 588

The majority of the mothers who completed the mother evaluation form indicated that they experienced their children's behavior as more positive after the child group intervention.

"*Her school performance has improved. My daughter is more responsible, she washes her clothes when I am not at home, she cooks and cleans, she didn't do this before we came to the groups*" – KM 202

The group facilitators indicated in their evaluation of the support group manual and intervention that they felt that the activities were appropriate. All the care workers furthermore mentioned that they thought the intervention definitely had a positive impact on the children's behavior.

"*Children enjoyed coming to the group because at home there are problems like no food and domestic violence. When time gone by you saw positive changes in them. They talk more, smile more, are more caring and they talk about how they feel. The group accommodated each other*" – Facilitator B, Care worker focus group.

Conclusions

The response of the children and the mothers to the intervention was positive. An overwhelming number of children indicated in their group evaluations that they understood the group process, the content and what was expected of them in the group. The children felt comfortable in the group because they experienced a sense of belonging and acceptance from the group members and care workers. They could communicate their feelings and they felt safe enough to share positive and negative emotions.

The group sessions supported the children by enhancing their communication skills and ability to talk about their emotions. The children could therefore voice their opinions and discuss their feelings with their mothers. The joint sessions assisted the mothers in listening and playing with their children. Both the children and the mothers benefited from the support sessions and indicated that they not only enjoyed the sessions, but also recognized the importance thereof. This two-way communication enhancement made it easier for mothers to discuss situations with their children and to model positive coping skills. The children's anxiety levels regarding their mothers' illness were lessened as this could now be discussed. The group thus provided a buffer for the children and supported them in coping with their mothers' illness.

The evaluation of the content and methods used in this study indicated that they were age-appropriate and positively experienced by all interested parties. The six-month duration of the intervention study was also seen as adequate, as indicated by the data collected. The culturally sensitive content and methods used in the support group sessions were important factors in achieving the aim of enhancing adaptive behavior. The cultural adaptability of the group sessions was furthermore enhanced by the group facilitators who were members of the same cultural group and their ability to speak the language of the group.

A specific finding of this study, after examining the data as presented, was that the children showed a strong need for order in their lives. The children in this study were exposed to a chaotic environment of single-parenting, family unemployment, relationship instability, persistent poverty and violence. The uncertainty of the mother's illness, as most of the children were not told about their mother's illness and they only observed the symptoms of the illness, caused further chaos in the children's lives.

Their experience of a lack of control over their mother's illness contributed to this uncertainty. The children in the groups displayed normative values through their religious coping styles, their quest for and display of respect and their unambiguous assertion of what are right and wrong. Latent-phase children are

furthermore developmentally inclined to exhibit a "black and white", rule-driven thinking style. Norms provide guidelines, boundaries, safety and control in uncertain [11].

Children's individual and meaningful belief systems are important to *"create a strong framework to positively cope with life issues*" [12, p.252]. Adaptive behavior or resilience is actualized in adverse circumstances when a child creates, through inner strength, a sphere or space to order his/her thoughts, behaviors and emotions that provides him/her with the parameters wherein he/she can function adequately. The children thus created their own inner safe sphere in which order is possible amidst chaos.

The intervention program created order in their minds and emotions. Pedagogically it is well documented that ordered thinking subsequently creates order in a child's emotional life [13,14].The researcher in this study asserts that order is an essential protective factor created by the children, enabling them to cope with chaos. Order was an implicit goal of the programme, not actively sought, but the effects thereof added value to the program. Order was established through the implementation of specific activities, for instance the climbing the tree, emotional thermometer and homework activities to establish a routine in the group sessions. The group session dates were pre-planned to allow for the sessions to take place on the same day, at the same time and for activities to be presented in the same order in every session.

In the first session of the group intervention the session contents were discussed with the children and the sequence, as presented, remained constant throughout all the sessions. At the beginning of every session the activities and order in which they would take place were first explained to the children before the sessions commenced. People have the tendency to believe they can influence life outcomes and that there is a correlation between their actions and outcomes [15]. A traumatic event in a person's life violates a person's sense of control and the attempt a person makes to regain this control is an effort to reduce the stress related to the trauma.

People can experience a perceived level of control over stressful life events by using different attribution styles. A factor causing ongoing trauma for children in adverse situations is often the sense of loss of control in their lives [12]. The researcher in this study is of the opinion that order was a crucial skill for the children to integrate, in order for them to feel that they had gained some control over their stressful life events and consequently their adaptive behavior was enhanced. The importance of the group sessions to create order is thus posed as a significant factor in the development of a support group intervention for children.

The children in the support groups had limited to no protective factors working in their favor and despite this they presented with factors such as respect, religious coping skills and a value system of knowing right from wrong that helped them to survive in their environment. The program supported the children in enhancing their 'self-created protective factor' by means of an ordered process in which the session, program content and other time factors were presented. By creating protective spheres they ordered their life worlds which had been thrown into chaos because of the presence of cumulative risk factors such as their mother's unknown and indefinite illness and the violent and poverty-stricken environment they were exposed to. The resilient child has to be able to negotiate the multiple risks in his/her environment to be able to adapt competently, despite the presence of significant risks and adversity. With this sphere as protective factor there is order in their circumstances and thoughts which furthermore help stabilize negative effects. Moreover, these findings attest to the importance of the role children themselves play in actively architecting their outcomes and influencing their ultimate adaptation to adverse life events [16]. The distinction made between external and internal protective factors and the presence of both are not necessary for building a child's resilience. Generalizability of the intervention findings to other areas or age groups affected by maternal HIV/Aids should be made with caution. However, in this sample of children the study poses that inner factors could have a dominant role to play in enhancing adaptive behavior and subsequently resilience. The origins of this internalized norm-driven behavior and whether it was because of upbringing, culture, a person's own inner striving for boundaries or another reason could ultimately not be established in this study. Further research in this area is proposed.

Abstract

Objective: In the field of therapeutic patient education (FTE), we propose to expose data from a clinical research on the theme of the therapeutic alliance, taking into account the dimension of the attachment, coping and resilience. **Method:** Our study was conducted at four resources sites in patient prevention and education in the region of Picardie (Abbeville, Amiens, Soissons and Saint-Quentin), and focused on eight diabetics. Using a semi-structured clinical interview, we developed and analyzed a collection of data couplant life story and history of the disease. We supplemented these data by passing of three scales assessing the attachment internal models, coping strategies and resilience of subjects. **Results:** The thematic content analysis of the interviews reveals data on coping with the disease. The therapeutic alliance between the diabetic patient and the caregiver is a partnership and influences the patient in the process of acceptance of the disease and understanding of treatment. In addition, the results obtained in different scales are consistent with the hypothesis that secure attachment internal model, coping strategies and the potential of resiliency of the diabetic patient prove crucial to fostering engagement in the therapeutic alliance. **Discussion:** In this study, we adopted an approach that is both qualitative and quantitative. This study opens up new lines of research. It highlights the interest of the therapeutic alliance in the educational support of diabetic patients in order to improve the empowerment of care. For this, the educational care of these patients should consider their attachment styles, their ability to cope (coping) to their disease and their potential for resilience. Furthermore, this research shows that the educational support offered by poles prevention teams is an example of "assisted resilience." Further studies should be continued on a larger clinical group.

Keywords: Therapeutic alliance, attachment, coping, patient education, resilience, suffering.

Introduction

Notre recherche s'inscrit dans le cadre de la psychopathologie clinique et elle a pour but d'étudier le vécu de l'alliance thérapeutique par le patient diabétique pris en charge en éducation thérapeutique. Pour ce faire, nous tenons compte de l'histoire du patient et de celle de sa maladie, ainsi que de ses ressources internes telles que son modèle d'attachement, ses stratégies de coping et ses potentialités de résilience. Notre étude s'inscrit dans une démarche exploratoire, face à une problématique nouvelle, qui n'a pas été abordée antérieurement.

Notre exposé est organisé en trois parties. La première est consacrée à la présentation synthétique et à l'articulation des notions de diabète, d'éducation thérapeutique du patient, d'alliance thérapeutique, et de celles d'attachement, de coping et de résilience. Le dispositif de recherche organise la deuxième partie. Les résultats et la discussion sont présentés dans la dernière partie.

Le diabète est parmi les plus fréquentes des maladies chroniques. Cette affection particulièrement grave constitue aujourd'hui un véritable enjeu de santé publique en France. Cette maladie chronique et invalidante comporte différentes formes, dont le point de regroupement est l'hyperglycémie chronique. On distingue les diabètes primaires (type 1, type 2, gestationnel) et les diabètes secondaires. Dans notre étude, nous abordons essentiellement le malade atteint d'un diabète de type 2. Les conséquences de ce type de diabète peuvent être lourdes pour la santé du sujet et entraver son autonomie. La maladie met le patient face à des questions de

souffrance et de mort. Le malade passe par plusieurs phases psychologiques allant du choc causé par l'annonce de la maladie à l'acceptation ou la résignation [1].

Pour éviter l'apparition des complications de la maladie avec notamment une perte de l'autonomie, des mesures thérapeutiques sont mises en place. Celles-ci concernent l'instauration d'un traitement médical judicieux réévalué régulièrement et suivi scrupuleusement, l'établissement d'une alimentation adaptée et la pratique d'une activité physique minimale. L'efficacité des traitements proposés dépend étroitement du mode de vie (habitudes alimentaires, sédentarité), de l'observance thérapeutique et de la compréhension de la maladie. Il apparaît que les modalités de traitement nécessitent que le patient s'approprie sa maladie et devienne en quelque sorte acteur de celle-ci. Pour l'aider dans cette démarche, l'éducation thérapeutique du patient (ETP) constitue une offre de soins fiable, réputée opérationnelle [2, 3].

Selon la Haute Autorité de Santé [4], l'éducation thérapeutique du patient fait partie intégrante et de façon permanente de sa prise en charge de soins. Elle comprend les activités organisées, y compris un soutien psychosocial, conçues pour rendre le sujet conscient et informé de sa maladie, des soins, de l'organisation et des procédures hospitalières, et des comportements liés à la santé et à la pathologie. L'ETP vise à donner au malade des connaissances et des compétences lui permettant de mieux gérer sa maladie (et son traitement) et de maintenir, voire d'améliorer sa qualité de vie. Elle nécessite l'intervention d'une équipe pluridisciplinaire formée. Elle n'est pas envisageable sans la participation du patient. Elle conduit inévitablement à réfléchir à la relation entre le malade et le soignant en termes d'alliance thérapeutique.

L'alliance thérapeutique a pris une place très importante dans la littérature psychothérapeutique [5, 6, 7] en clinique comme en recherche. Elle est indispensable au processus thérapeutique. Elle fait référence aux liens de confiance et de collaboration active et mutuelle qui vont se mettre en place entre le psychothérapeute et le patient, au sujet des buts et méthodes de changement. Elle est un partenariat permettant au malade de proposer, plus ou moins explicitement, la relation qui lui convient.

Dans le champ de l'éducation thérapeutique du patient, l'alliance thérapeutique est peu prise en compte. Quelques publications récentes [2, 3, 8, 9] abordent les relations entre ces deux processus. Les écrits reprennent le plus souvent la notion de « partenariat » dans leur développement, et rapportent l'intérêt de l'alliance thérapeutique pour favoriser le changement de comportement du patient.

À la suite de cette présentation des repères théoriques sur l'éducation thérapeutique du patient diabétique et sur l'alliance thérapeutique, il nous paraît important de considérer les concepts majeurs d'attachement, de coping et de résilience en préalable à notre recherche clinique.

D'après Bowlby [10], l'attachement désigne un système comportemental spécifique permettant au jeune enfant d'établir et de maintenir des contacts physiques et de proximité avec un de ses parents. Ce lien primaire est vital. Face à une situation de stress chez l'enfant, il y a activation du système d'attachement dans le but ultime d'être sécurisé. Bowlby note également l'importance des représentations d'attachement chez l'enfant liées à l'expérience personnelle d'interaction avec sa mère, favorisant un modèle de relation. Il introduit le concept de « modèles internes opérants » (M.I.O.) pour désigner ces représentations, tout en relevant leur aspect dynamique. Il les nomme « opérants » parce qu'ils orientent la perception des choses et guident le sujet dans les situations interpersonnelles. Les modèles de soi et des autres sécurisés représentent une ressource interne pour l'individu lui permettant d'évaluer positivement les expériences angoissantes, de s'y adapter de manière constructive et d'améliorer ainsi son bien-être [11]. À l'inverse, avec un modèle relationnel insécure, qu'il soit de type «préoccupé», «détaché» ou «désorganisé», l'adaptation aux expériences stressantes se révèle plus difficile.

Au total, la théorie de l'attachement propose une perspective intéressante pour notre étude centrée sur l'alliance thérapeutique. L'examen de cette théorie nous amène à penser que le modèle relationnel d'attachement sécure peut être considéré comme un facteur favorisant l'engagement du sujet dans l'alliance thérapeutique.

Que dire du coping? Il désigne l'ensemble des efforts cognitifs et comportementaux par lesquels un sujet est en mesure de réagir à une situation difficile, c'est à dire mettant à l'épreuve ou excédant les ressources de la personne [12]. Il joue un rôle majeur dans le bien-être physique et psychologique du sujet. Les auteurs [12, 13] distinguent deux types de coping : le coping centré sur la résolution du problème et le coping centré sur les émotions. Dans le premier groupe, le sujet fait des efforts pour gérer ou diminuer le problème qui est la cause du stress (résolution planifiée, efforts, plans d'action,...). Dans le deuxième groupe, la personne cherche à réguler la réponse émotionnelle causée par un agent de stress, sans agir directement sur le problème posé (évitement, minimisation, culpabilité, …). Dans le champ qui nous occupe, la situation de maladie chronique provoque des mécanismes de coping. Le patient cherche à « faire face » à la maladie qui le déstabilise, le perturbe.

Le terme de «résilience» a d'abord été utilisé en physique pour désigner la caractéristique mécanique qui définit la résistance aux chocs d'un matériau, de l'acier en particulier. Transposée métaphoriquement au domaine psychique, la résilience indique la capacité de se reconstruire après une épreuve difficile. Le modèle de la résilience humaine a été proposé en réponse à la question du traumatisme, événement externe, inattendu, intense qui fait irruption dans la vie du sujet, au traumatisme chronique qui met à l'épreuve ses capacités d'endurance. Manciaux *et al*. [14] considèrent la résilience comme la capacité d'une personne ou d'un groupe à se développer d'une manière favorable, à continuer à se projeter dans l'avenir en dépit d'événements

déstabilisants. Cette définition renvoie à un comportement adaptatif efficace, à un processus de (néo)développement favorable. Elle met en évidence l'aspect dynamique de la résilience, en référence au rebond psychologique signalé plus haut qui caractérise le fonctionnement résilient. Dans notre recherche, l'étude de la résilience s'avère intéressante pour saisir comment le malade continue à se développer, à vivre en dépit de sa pathologie. Une manière d'identifier les potentialités de résilience peut être abordée par l'écoute de la capacité de mettre en sens une expérience insensée, d'en faire un récit cohérent [15]. Ces potentialités peuvent être également évaluées à l'aide d'une échelle.

Ce détour par la présentation des concepts d'attachement, de coping et de résilience nous amène penser que ces caractéristiques psychologiques, propres à chaque patient, vont favoriser la qualité de l'alliance thérapeutique.

Objectifs et méthodologie

Notre étude part de la richesse des Pôles de prévention et d'éducation thérapeutique d'Abbeville, d'Amiens, de Soissons et de Saint-Quentin (de la région Picardie) dans le champ des maladies chroniques. Nos objectifs sont:

- étudier le vécu de la maladie du patient diabétique (en lien à son histoire de vie) et celui de l'alliance thérapeutique dans l'accompagnement éducatif.
- évaluer le modèle d'attachement du patient, ses stratégies de coping et ses potentialités de résilience, afin de vérifier si ses caractéristiques internes contribuent à son engagement dans l'alliance thérapeutique avec les soignants.

Nous formulons les hypothèses suivantes:

- l'alliance thérapeutique aide le malade diabétique à investir ses soins proposés par l'équipe d'éducation thérapeutique.
- l'engagement du patient diabétique dans une alliance thérapeutique avec les membres de l'équipe d'ETP dépend de ses caractéristiques psychologiques telles que sa stratégie relationnelle gardée du vécu de l'attachement sécure, ses stratégies de coping et ses potentialités de résilience.

Nous avons proposé notre protocole de recherche à un groupe clinique de huit malades diabétiques. La méthode de collecte de données utilisée a été l'entretien de recherche semi-dirigée, basée sur l'histoire de vie et celle de sa maladie du patient diabétique. Nous avons ensuite proposé la passation de trois échelles d'évaluation : le Camir de B. Pierrehumbert *et al*. [16] pour évaluer les stratégies relationnelles passées et présentes du malade (en lien aux modèles interne d'attachement) – outil utilisé dans une autre étude [17] - , l'épreuve de Coping de Graziani *et al.* [18] pour repérer les stratégies d'adaptation du patient à sa maladie, l'échelle de résilience pour adultes de Hjemdal *et al.* [19] afin d'évaluer les facteurs de résilience du patient.

Résultats

Nous résumons les données d'entretiens à partir de deux axes : l'histoire du sujet et celle de sa maladie, le vécu de l'ETP et celui de l'alliance thérapeutique.

L'Histoire de vie des patients diabétiques comporte des traumas pour certains (séparations difficiles dans l'enfance et deuils répétés non élaborés). Des sujets témoignent d'un manque de cohésion familiale. Actuellement, certains malades se sentent seuls, d'autres ont un entourage familial plus ou moins aidant. Enfin, la plupart des patients ne renoncent pas à réaliser leurs projets (ex : voyages). Dans l'histoire de leur maladie, les sujets mettent en avant des antécédents familiaux de diabète et témoignent d'anciennes habitudes alimentaires néfastes. L'irruption de la maladie chronique dans leur vie a représenté un bouleversement. Dans l'expérience de la maladie, les personnes rapportent un vécu douloureux, avec des complications sévères : amputations, rétinopathie, neuropathie, perte de poids, manque de force musculaire. Elles témoignent d'une méconnaissance de la maladie et d'une vision négative de celle-ci: *«la maladie est un fardeau»*, avec un ressenti d'infériorité, ce qui accroit leur difficulté à vivre avec cette atteinte: *«je suis nul, je suis fragile», «je ne peux obtenir ce que je veux»*. Enfin, ils soulignent le caractère contraignant du traitement qui implique une autosurveillance constante. (Les propos des patients sont retranscrits en italique.)

À propos du vécu de l'éducation thérapeutique et de l'alliance thérapeutique, les patients rapportent le dynamisme des équipes. Ils ne sont pas seuls, ils sont accompagnés dans leur démarche de soins par les soignants. L'alliance thérapeutique se manifeste lors des rencontres individuelles et lors des ateliers thérapeutiques. Elle est facilitée par l'attitude professionnelle de l'intervenant qui favorise la création d'une relation soignante d'adulte à adulte. Le soignant a le souci de l'autre. Les patients sont informés et se sentent écoutés dans leur souffrance. Lors des ateliers (atelier du diabète, du pied, de cuisine, ….), les soignants et les malades ont des activités partagées. Les échanges créent des relations de réciprocité, *«de confiance réciproque»*. Par ailleurs, l'ETP permet aux patients de pendre leur traitement avec beaucoup de sérieux et d'application.

L'alliance thérapeutique au sein de l'ETP favorise la résilience des patients. Ces derniers reprennent confiance en eux et continuent à vivre en dépit de leur pathologie. Lors de nos entretiens, ils rapportent la présence d'indices qui peuvent être interprétés comme un positionnement subjectif résilient :*« Avec les soignants, j'ai assimilé la maladie », « je la (la maladie) dépasse, je le fais en étapes quoi…. »*, *« la maladie suit son cours, mais tout va bien (il rit) »*, *« la maladie m'a rendu plus fort »*, *« je m'en sors, je suis un battant ».* Au total, comprendre la maladie est pour eux une manière de reprendre une maitrise (au moins partielle) de leur vie.

L'alliance thérapeutique aide donc le malade diabétique à investir ses soins proposés par l'équipe d'éducation thérapeutique (hyp1). Plus précisément, en relatant l'histoire de sa maladie articulée à celle de sa vie, le patient souligne tout l'intérêt de la mise en place d'une relation de confiance et de collaboration avec les membres de l'équipe d'ETP pour mieux gérer sa maladie et son traitement.

Par ailleurs, la passation des échelles cliniques révèle les résultats suivants. Au Camir, les résultats indiquent des liens d'attachement majoritairement insécures de type préoccupé ou de type détaché. Le style préoccupé se caractérise par le sentiment d'avoir peu de valeur pour les autres. Ceux-ci sont en revanche perçus de façon positive en leur accordant un caractère aidant. Le style détaché renvoie à une perception de soi positive et considérée comme « due à soi-même » associée à une perception des autres comme peu susceptibles de procurer le soutien attendu lorsque nécessaire. Deux patients présentent un modèle de type sécure : ce qui signifie l'importance accordée par le patient à sa propre valeur. Celle-ci est associée à une perception des autres comme disponibles et aidants en cas de besoin.

À propos de l'échelle de coping, la plupart des patients emploient des stratégies d'adaptation vigilantes, actives centrées sur la résolution du problème. Il s'agit de trouver des solutions, d'accepter la meilleure stratégie possible en affrontant la situation, de lutter pour arriver à ce que le sujet veut, de redoubler d'efforts, d'établir un plan d'action. L'évolution personnelle compte également pour eux : changer, évoluer, découvrir ce qui est important dans la vie. Et un bon nombre de patients recherchent un soutien social : ils demandent un conseil, une aide concrète. Ils recherchent de l'information. Ils veulent parler à quelqu'un de ce qu'ils ressentent.

L'échelle de résilience permet d'évaluer la présence de facteurs de protection essentiels à la récupération et au maintien de la santé suite à l'épreuve de la maladie. Les résultats obtenus sont élevés. Ils indiquent de fortes potentialités de résilience. Les facteurs les plus marqués concernent les compétences personnelles et sociales, et le support social.

En résumé, nous observons que les patients diabétiques rencontrés ne subissent pas passivement leur maladie, ils essayent de faire face (coping). Ils emploient des stratégies d'adaptation vigilantes, actives centrées sur la résolution du problème. De plus, en raison de leurs compétences personnelles et sociales, et d'une demande de support social, ils présentent de fortes potentialités de résilience. Toutefois, pour de nombreux sujets les liens (précoces) d'attachement sont « insécures ». Ces résultats confirment partiellement notre deuxième hypothèse (H2). L'engagement du patient diabétique dans une alliance thérapeutique avec les membres de l'équipe d'ETP dépend de ses stratégies de coping (centrées sur la résolution du problème) et de ses potentialités de résilience (axées sur les compétences personnelles et sociales, et le support social). Toutefois, les résultats à l'échelle de Camir ne permettent pas de confirmer notre hypothèse. Deux patients seulement présentent un modèle d'attachement de type sécure favorisant leur engagement dans l'alliance thérapeutique. Les autres sujets présentent un modèle de type insécure. L'adaptation à leur maladie diabétique se révèle plus difficile et entraine plus ou moins de demandes à être accompagné. Le besoin de sécurité apporté par les soignants est important pour ces sujets pour ne pas se décourager, par la maladie.

Discussion

À partir des propos tenu sur leur diabète, nous observons que la maladie a un impact considérable sur la psychologie du patient. Elle opère une rupture, instaurant un avant et un après, ou rien n'est plus jamais comme avant. Elle est vécue comme une menace intense touchant l'intégrité physique et psychique: *«je suis abimé à jamais»*, nous dit un patient.

Le malade, pris en charge au pôle de prévention et d'éducation thérapeutique, se sent accompagné, aidé à vivre autrement sa maladie. Le vécu de l'éducation thérapeutique s'organise, se réfléchit, évolue au rythme des rencontres et favorise le changement de comportement. L'ETP donne au malade des connaissances et des compétences lui permettant de mieux gérer sa maladie. Elle l'aide à faire des choix, à changer, évoluer, à découvrir ce qui est important dans sa vie. Elle favorise l'expression, les échanges, la collaboration et la mise en sens de l'expérience de la maladie. Les rencontres individuelles et/ou collectives (ateliers) rendent possible le travail thérapeutique. Le patient souligne le rôle du contexte relationnel dans lequel se déroule l'ETP. L'alliance thérapeutique implique une dimension affective, correspondant à l'établissement d'un climat favorable à un échange (relation de confiance et souci de l'autre), et une dimension cognitive (accord sur le problème et les moyens employés pour le résoudre). Elle comprend également le partage d'une responsabilité dans la résolution du problème, relation de collaboration qui apparaît dans l'ensemble des entretiens: *«je suis impliqué dans les ateliers»*, *«c'est différent de l'hôpital, une fois qu'on y est on subi, alors qu'ici on ne subit pas»*.

Par ailleurs, dans le récit sur sa maladie, on note une augmentation de sa confiance et de l'estime qu'il se porte. Cette amélioration du self est liée à sa participation à un ensemble d'actions menées dans le cadre de l'ETP. Elle est également liée à ses stratégies de coping centrées la résolution du problème et à ses potentialités de résilience. Le fait d'être actif dans sa prise en charge, d'avoir acquis un savoir et une (relative) maîtrise de sa maladie, lui rend la situation provisoire tolérable. Cela ne va pas sans difficulté, sans moments de découragements. On peut dire ici que par la problématique diabétique prise en charge par l'équipe d'ETP dans un esprit de partenariat, le patient entre en résilience, c'est à dire se donne le moyen de s'adapter à sa maladie. La relation humaine instaurée est accueillante, réciproque et salvatrice.

Conclusion

Dans notre modeste recherche, nous retenons que L'ETP avec sa part d'alliance vise à accompagner le patient et le rend (plus) résilient en vue de son autonomie. Le professeur Ionescu [20] développe la mise en pratique clinique de la résilience. Il utilise l'expression de «résilience assistée» pour désigner les techniques et moyens favorisant le développement ou le maintien de la résilience auprès de populations à risque. Les données de notre étude révèlent que l'accompagnement éducatif proposé par les équipes des pôles de prévention constitue un exemple de «résilience assistée». Cet accompagnement avec sa part d'alliance thérapeutique adaptée à chaque patient, en fonction de ses ressources internes, vise à faciliter la mise en évidence de ses «forces». Le patient se juge et s'adapte à sa maladie, avec les moyens que l'équipe soignante lui donne. (Cette équipe concrétise en quelque sorte la formule de l'écrivain français P. Valéry: «il faut enrichir chacun de ses dons».) Ce qui signe une modalité de résilience assistée.

Cette étude comporte une limite, la taille de notre groupe clinique. Malgré cette limite, les données recueillies sont riches de sens pour la pratique clinique avec les patients diabétiques et les équipes du pôle de prévention et d'éducation thérapeutique. Cette étude préliminaire mérite d'être poursuivie. Elle pourrait nous aider à proposer d'autres recherches sur le plan régional en intégrant une population plus importante.

The correlation between resilience and cognitive schemas among people with psychiatry diagnosed parents

Crăciun A.

andra.craciun.psi@gmail.com

Abstract

The growing attention given to resilience is a mark of the passing from the study of pathogenesis to sanogenesis, a scientific trend which investigates one's resources that help staying healthy. The present paper proposes to contribute to understanding resilience as a process by analyzing its connection to cognitive schema. For this purpose a study of 60 participants has been conducted: 30 of them formed the experimental group (people with parents who reported receiving mental health services) and other 30 forming the control group. The study hypothesis viewed the impact of the psychological condition of parents over the resilience and cognitive schema which occur among their children and identifying the prediction quality of the cognitive schema in relation to the subject's resilience. Also the study evaluated the degree of influence of age and gender differences on resilience. The following questionnaires where applied: The Young Cognitive Schema Questionnaire, the 14 Resilience Scale and the Ego Resilience Scale. The data has been processed using SPSS -13.0. It was confirmed that resilience is possible in the case of people with parents who experienced mental health disorders; also it was concluded that there is a significant impact of cognitive schema over resilience. In addition, we have come to the conclusion that there is an impact of the psychological condition of parents in the development of certain cognitive schemas of their children, especially of the ones related it.

Keywords: resilience, mental health, resilience and cognitive schema

Introduction

Resilience defines positive psychology which is focused on the study of a person's resources, the elements that support survival, outgrowing traumatic or extremely stressful events in a constructive manner allowing us to continue our lives stronger and wiser. Positive psychology is separated by other currents through the attention given to the way people succeed in remaining healthy using their own resources (approach knows as salutogenesis); thus, the focus on identifying the symptom is replaced by identifying and promoting resources, psychological elements which support and guide us through difficult times, which we are all exposed to.

The study and knowledge of resilience guide us through both clinical and psychotherapeutic approaches: as long as we keep resilience and a main, general objective of our intervention, the chances to reach the therapy and client's objectives of obtaining health and well-being rise considerably.

As for the frame of resilience's development, we can refer to Young's hypothesis (apud [1]) according to which connectivity, autonomy, the feeling of self worth, reasonable expectations and realistic view of limitations should be main objectives a growing child should reach in order to develop healthy. In some cases though, parents and nurturers make this journey difficult for thei children. This is the reason why the present study connects resilience to a problematic environment, respectively to the families where the parents confront mental illness.

Among adults, resilience is mostly approach as a coping issue, facing an event with specifically traumatic potential [2] and also as a capacity to efficiently activate one's own resources and strategies. On the other hand, among children, resilience is analyzed from the view of the environment which the grow in, whether we speak of social phenomena, such as poverty or family dynamics, such as abuse. The parents' care is essential for the child's growth because, as Munteanu and Munteanu [3] remind us, the reactions to stress may be amplified in the case where the basic needs are not met (respectively, when the child feels hungry, tired, ill, unsafe, doesn't feel loved and wanted). Also, it is better to assure the routine that the baby has costumed to, in order to keep the stability and continuity of the environment and life of the baby. Some authors consider that those children who have parents with mental illness are exposed to higher risks of also developing a type of

disorde [11], of experiencing emotional and behavioral issues or lack development of social abilities [11]. Therefore, a parent's psychological condition is considered a risk factor of developing mental disorders among children. This risk can be genetic-related or related to the disorder's consequences as far as parenting style and secondary difficulties are concerned – both marital and social [11].

1.1 Study regarding resilience and cognitive schema

1.1.1 Previous studies

According to Mykota [8] resilience has been studied: in correlation to intercultural change and constraint, as a response of the community to war and terror, in relation to behaviors which sustain health, as a result of education related to the environment or as an element of rural economic renewal. Resilience has been included in studies which considered a large are of subjects, including social psychology and the effects of mass events on an individual level.

Resilience has been studied since the 1960's, by observing the children with schizophrenic parents in order to identify the patterns manifested during and after a long term exposure to risk factors (having a parent with psychological disorders is considered a chronic risk factor). In the context of these studies, Garmezy, during 1974, has shown that a part of the children displayed surprisingly positive outcomes regarding their adapting patterns [9].This discovery was made on a background of considering these children as being atypical cases. Luthar [9] reminds us the results of the 1970 studies according to which children with schizophrenic parents have succeeding to stay healthy by maintaining their empathy and compassion towards the ill parent.

Ionescu [3]identified three steps of using resilience as a concept in the social-human sciences. In the first step, the attention is upon the individual and it is considered that resilience in an equivalent of the good adaptation capacity, manifested in the present or the past of the individual in confronting risks and adversity. The second step assumed the understanding of the resilience processes and mostly included longitudinal studies. Several process which build the subject's resilience were identified (coping and defensive mechanisms were mostly studied). The third step in the study of resilience consisted of understanding the natural resilience in order to build the basis of assisted resilience – the resilience promoted by specialists of mental health.

The research of resilience has developed from the attention over the successful adaptation of children facing threat and adversity to reporting resilience as a common phenomena, result of human basic adaptation operations [4].

Same authors have shown that several biological risk factors might be ameliorated by certain personal characteristics, such as the pleasant temperament – being desirable, social, optimistic, hard working [4] or the ability to obtain support from the family (Garmezy, Devine, 1984, Werner, 1994, apud. [4]).

Munteanu [3]concluded several studies on resilience, stating that: resilience leads to successfully outgrowing difficult situations, through personal development, with positive consequences in the group; when the stress factors the person is exposed to simultaneously or consecutively are accumulated, the person's resilience becomes lower; resilience manifests in certain situations, according to the adaptation exigences, without necessarily manifesting at all times and situations experienced by the person. The mentioned author also states that resilience of be viewed from a progressive perspective and in relation to the person's chances of social and professional reinsertion.

1.1.2 Objectives

The present study intends to identify a possible impact of cognitive schema on the development of resilience as a process. Also it intends to analyze the impact of a mental health disorder of the parent towards the development of the child's cognitive schema and resilience.

1.1.3 Method

In order to conduct this study, the following hypothesis have been proposed:

1. Resilience is possible in the case of people whose parents experienced mental health issues: resilience has been identified through the values obtained following the application of the 25 Resilience Scale and Ego Resilience 14, and also according to the correlation score between the two instruments.
2. Cognitive schemas predict resilience: the cognitive schemas evaluated by Young's questionnaire being considered adaptive as long as their score is medium.
3. The presence of the parent's psychological disorder is relevant for the development of the cognitive schemas: the parent's mental illness have been grouped according to the type of disorder (in the sample involved n our study, four types of disorders have been identified: affective, personality disorders, alcohol dependency, psychotic disorders).

4. Age correlated to resilience: in other words, as older we get, the higher the resilience will be.
5. There are gender differences that view the development of resilience: the female gender has been associated to low resilience and predilection of depressive disorders, which might lead us to consider being female as being a risk factor.

In order to evaluate and define the variables of this study we used the following instruments: Resilience Scale 14, developed by Wagnild and Young (1993), is a questionnaire of 25 self-analysis items, and identifies the resilience degree of the subjects. According to previous studies, resilience as measured by RS positively correlated to the satisfaction towards life, self esteem, self-reported health, self-actualization, stress management and social support and negatively correlates to depressive symptoms and anxiety [7].

Another utilized instrument was the Ego Resilience Scale: the ego resilience reffers to the dynamic capacity to modify the control level of the ego in response to what the situation offers [6]. It is a personality construct which contributes to the understanding of behavior, emotions and motivation. Thus, this instrument brings information regarding the proactive aspect of resilience.

In order to evaluate the cognitive schemas, the Young Questionnaire has been selected: the author [5] has defined the term of primary non-adaptive schemas as being major themes related to one's self and one's relationships to others. These are developed during childhood, and become more and more complex in time. There are several versions of the questionnaire, the 114 items being selected for this study; it represents the short version and it evaluates 18 cognitive schemas, namely: emotional deprivation, abandon/instability, lack of trust/abuse, social isolation, defects/shame, failure, dependency/incompetence, vulnerability/disease, non-developed Self, subjugation, self-sacrifice, emotional inhibition, inflexible standards, hyper-critic, grandiosity, insufficient self-control/self-discipline, looking for approval, negativity/pessimism, punishment. The items are scored on a 6 point Likert scale, from 1 (completely untrue to 6 – perfect description). The instrument disposes of a high degree of reliability (α Cronbach =.96); so is the case of the coefficients of each sub-scale.

1.1.4 Participants and procedure:

The participants to the study have been randomly chosen, based on the condition to be 18 years old and to lack a psychiatry record history.

For the experimental group, we selected people whose parents experienced at least once in their past an episode which required psychological or psychiatric intervention and also were given a psychiatric diagnosis; the control group included people coming from families which never appealed to such services. Where possible, the parents of the control group have been evaluated in order to verify the presence or absence of a psychological disorder which might not have been identified. The clinical screening instrument SCL-90 was used; no parent with mental health issues has been identified.

The parents of the experimental group subjects have been divided into four groups according to the diagnosis which was given to them: affective disorders, ethanol dependency, personality disorder and psychotic disorders. Four of the subjects chose not to declare what their parent suffered from. The experimental group included 30 people aged between 18 and 50 (mean = 32; the age of eight of the subjects has not been communicated), 15 female and 15 male; the control group also included 30 people, aged between 18 and 60 (mean age = 28) out of which 17 were female and 13 male. The participants completed three questionnaires: the Resilience Scale, Ego Resilience Scale and the Young cognitive schema questionnaire. The obtained scores were inserted in SPSS and analyzed in order to test each of the proposed hypothesis.

In the first phase, the normality of the distributions was tested using descriptive procedures. As for the distributions descriptors, the following data was obtained: the Resilience Scale Score – for the control group: mean = 138, sd = 2,29; for the experimental group: m=130, sd=4,26; Resilience Scale Score: for the control group: mean = 45, sd = 0,97; the experimental group: m=39, sd=1,47. Ego Resilience, control group: sd=12,58; experimental group, sd=8,09; The Resilience Scale: 23.35; minimum scores: Resilience Scale, in the experimental group = 71, control group = 119; Ego Resilience, experimental group = 18, control group = 36; maximum scores – Resilience Scale, experimental group = 75, control group = 170; Ego Resilience, experimental group = 56, control group = 56; Skewness indicator, experimental group, Resilience Scale = -0.43, Ego Resilience = -0.77; control group: Resilience Scale = 0.46, Ego Resilience = 0.25. We may say that the obtained scores are relatively symmetric around the mean. The Kurtosis indicator – experimental group: Resilience Scale = 0.29, Ego Resilience = 1.14, control group, Resilience Scale = -0.08, Ego Resilience = 0.20. The notice that in the case of the Ego Resilience scores, in the experimental group, there is a tendency towards extreme scores.

The scores obtained for each cognitive schema have been converted to z scores, as a high score of the schemas identified by the Young Questionnaires have a dysfunctional connotation (a high score of the cognitive schema cannot correlate to high scores of resilience).

Before testing each hypothesis, the correlation between the two instruments which evaluate the subject's resilience was measured. For this purpose the Pearson correlation test was applied, as the correlation score obtained by the Resilience Scale and the Ego Resilience was 0.05, which confirms the correlation between the two instruments (also, the significance rate of 0.003 indicates an existing correlation between the two).

1.1.5. Results:

In order to verify the first hypothesis, namely the possibility that the people raised by parents suffering from mental illness to be resilient, we applied the Paired Sample T test which analysed the scores of the Resilience Scale and the Ego Resilience scores, both for the experimental and the control groups. According to the obtained p score (0.000) both in the case of the experimental and the control group, we may confirm the hypothesis and state that resilience is possible among the people raised by parents with psychological issues.

In order to test the second hypothesis (namely that the cognitive schemas predict resilience), we applied the linear regression analysis both for the cognitive schemas correlated to the Resilience Scale and the Ego Resilience. The obtained p score (significance limit) allows us to confirm the hypothesis (according to a 0.05 limit), thus the Young cognitive schemas do predict resilience.

The third research hypothesis stated that the presence or the absence of mental health issues of a parent might influence the development of their child's cognitive schemas and was tested by applying the t test for independent samples. Following the application of this statistical analysis, we may assert that the following cognitive schemas are influenced by the presence or absence of the psychological illness of a parent (according to a significance limit of 0.05): lack of trust, tendency of social isolation, perception of one's own deficiency, fear of failure, inhibition, non-realistic standards. On the other hand, the cognitive schemas which were not affected by the parent's mental condition are the following: fear of abandon, dependency, independent development of personality, submission, self-sacrifice, claiming one's own rights, need of approval, negativity and punishment.

The forth hypothesis, according to which there is a correlation between age and resilience was tested applying the Pearson correlation test, both for the Resilience Scale scores, according to both age and Ego Resilience scores. The results did not allow to confirm the hypothesis – therefore, there was no correlation found between age and resilience.

The last hypothesis which was tested consisted of verifying the correlation between gender and resilience. The hypothesis was also rejected as no correlation between gender and resilience was found – both in the case of Resilience Scale and Ego Resilience ($p>0.05$)

1.1.6. Limitations of the study:

The present study confronted inherent limitations which will be taken in consider in regard to ulterior studies of resilience and building programs to support its development. One first limitation consists of the small number of subjects who participated to the study, although the minimum necessary number for a statistically valid study was reached. The higher the number of subjects, the better the statistical exigences are covered and the results are more relevant assuring a better understating of new concepts, such as the resilience. Another limitation is that the evaluation of all the subject's parents in the control group was not possible, therefore we were not able to truly determine if the confronted mental illness or not, as this criteria of dividing the subjects in the experimental or the control group was the appeal to mental health services. This verification was not possible due to the participant's availability. We also mention the absence of a clinical interview as a limitation of our study: such interview should bring a complete image regarding the participants' personal history and approaching it from the view of stressful life events, offering so more details related to the presence of resilience on an individual level.

The presence in the experimental group of participants' parents diagnosed with disorders of all DSM clinical categories would also be an advantage for future research. Thus differences could be made between the impact of a higher class of disorders on the ulterior development of the child. Also, clarifications should be made regarding risk factors which these children are exposed to, being raised by mentally disordered parents and also the strategies they used in order to outgrow these challenges.

As for building a program focused on building resilience among children facing difficult environments, it isn't enough to stop at studying the correlation and contribution of cognitive schemas regarding resilience as a process. The effort can be continued by also studying the behavioral dimension of the resilience and also the study of the emotional resources involved in the process. It would also be important to investigate which are the specific needs of the children raised by parents diagnosed with mental disorders (such as the need to be informed about the parent's condition, the need of prediction and safety, the need of support from the mental health services and social assistance and others).

Conclusions

As we have shown in the present study, resilience can be found among the people whose parents have experienced mental health issues. Although this fact has been reported in the professional field in the past, we considered it was necessary to test this hypothesis before initiating a more detailed analysis of resilience on the available samples of population.

The statistical analysis which has been conducted confirms the main hypothesis of the research, respectively the fact that cognitive schemas can predict resilience. In the present study, the dysfunctional cognitive schemas interfere with the optimal development of resilience.

The analysis of the psychological influence of the parent on the child's cognitive schemas indicated the fact that certain schemas are not affected by this criteria. This result leaves room for a new hypothesis, namely that these children are forced to mobilize their resources in order to take care of them selves independently.

The results obtained following the analysis of correlations between age, gender and resilience seem to offer relevant information regarding resilience as a process. As far as age is concerned, there were no significant correlations identified with age. Thus, we cannot assert that, once aging, a person can develop optimal resources to build resilience, although we might be tempted, on an empirical level, to consider that life experiences and confronting several obstacles might bring us better adaptation. These results remind us of one of the approaches of resilience, according to which it represents an activation of resources which already exist in our minds, brain and organism. We can go further in proposing one more hypothesis – whether resilience is inherent or not.

Abstract

Introduction: Without appropriate and continuous treatment, schizophrenia results in academic failure, job loss, celibacy, and stigma.

Objectives: The aim of this paper is to identify in patients with schizophrenia, resilience factors which influence the long term course.

Methods: The study includes all patients diagnosed with acute and transient psychotic disorders or schizophrenia admitted in the 2nd department of Timisoara Psychiatric Clinic from 2005 till 2013. We analyzed factors such as: positive family history for psychiatric disorders, educational level, occupational and marital status, adverse life events (ALE), social supportive network (SSN), the number of psychotic recurrences, duration of hospitalization, and possible statistical correlations between them.

Results: 224 patients (89 men and 135 women) were included, 146 (65%) with schizophrenia and 78 (35%) with acute and transient psychotic disorders. The patients with acute and transient psychotic disorders had fewer recurrences compared to patients with schizophrenia. Family history, marital status, employment, educational level, and SSN did not influence the number of recurrences or the duration of hospitalization. A statistically significant higher number of recurrences were found in patients without ALE.

Discussions: The lower number of recurrences in patients with ALE could indicate a higher resilience. Patients with acute and transient psychotic disorders have fewer recurrences, than those with schizophrenia, but some of them are at their first episode of psychosis (FEP).

Conclusion: The presence of ALE (possible non-endogenic psychosis) was found as a resilience factor.

Key words: schizophrenia, resilience, recurrences, hospitalization lengths, adverse life events

Introduction

According to the stress-vulnerability model, the intensity of an individual's response to stress is directly proportional to his vulnerability and inversely related to his resilience. According to Windle and collaborators, resilience is the result of negotiating, managing and adapting to significant sources of stress or trauma [1]. Masten and Powel emphasize the positive nature of adaptation to significant adversity. Stress is a broad concept. Its significance and intensity depend on both objective and subjective factors. Being a dynamic process [2] resilience involves the development of psychosocial competences at a given age, social context and historical time [3]. Resilience is not an extraordinary human quality but an ordinary one [4]. It implies flexibility and elasticity [5]. By contrast to what defines normal mental health, in individuals suffering from mental disorders regulation of cognition, affect, and behaviour is impaired [6]. Without appropriate and continuous treatment, schizophrenia results in academic failure, job loss, social isolation, and stigma. According to Harrow and collaborators, less resilient patients with schizophrenia have frequent, severe, and slow recovering episodes [7]. In this respect, attention should be focused on those pharmacological and psycho-social interventions that may increase resilience, or buffer stress. Being a complex concept, there are authors who express doubts about the usefulness of studying resilience. However, others advocate for the continuation of scientific work in this field [8]. Moreover, there are hopes that resilience oriented studies may contribute the development of new drug treatments [9].

The aim of this paper is to identify in patients with schizophrenia resilience factors which influence the long term course (duration of the episodes and number of recurrences).

Methodology

The study includes all patients admitted in the 2nd department of Timisoara Psychiatric Clinic, from 2005 till 2013 that were diagnosed according to ICD 10 (the 10th revision of the International Statistical Classification of Diseases) with acute and transient psychotic disorders (F23), or schizophrenia (F20).

The patients were divided in two samples according to their diagnostic group (F20 and F23). Most of the patients with an F23 diagnosis are at their first episode of psychosis (FEP).They were included in the study because some of them developed in time schizophrenia switching diagnosis from F23 to F20. Patients with persistent delusional disorders (F22), schizoaffective disorders, (F25), schizotypal disorder (F21), induced delusional disorder (F24), organic, or psychoactive induced psychosis were excluded.

The study is retrospective. Information was obtained using patients' files and electronic data bases. The following recorded data were examined: risk/resilience factors (family history of psychiatric disorders, educational level, occupational status, marital status, social supportive network/SSN and adverse life events/ALE), the number of psychotic recurrences, and the duration of hospitalization per episode. We analysed which risk/resilience factors have a statistical significant influence on the duration and number of psychotic episodes.

Results

1.1 Sample description

Of the 224 patients, 135 (60.3%) were women and 89 (39.7%) men. From the 224 investigated patients, 78 (34.8%) were diagnosed with acute and transient psychotic disorders (F23) and 146 (65.2%) with schizophrenia (F20).

In Table 1 is presented the sample distribution according to the diagnostic groups. The patients with schizophrenia had the following forms: paranoid (F20.0), hebephrenic (F20.1), undifferentiated (F20.3), residual (F20.5), and simple (F20.6). The patients with acute and transient psychotic disorders had the following types: acute polymorphic psychotic disorder without symptoms of schizophrenia (F23.0), acute polymorphic psychotic disorder with symptoms of schizophrenia (F23.1), acute schizophrenia-like psychotic disorder (F23.2), acute predominantly delusional psychotic disorder (F23.3), other acute and transient psychotic disorders (F23.8), acute and transient psychotic disorder, unspecified (F23.9). Most patients (59.4%) had a diagnostic of paranoid schizophrenia (F20.0).

Table 1. Sample distribution according to diagnostic groups

Diagnostic group	No. of patients	%
F20.0	133	59.4
F20.1	8	3.6
F20.3	1	0.4
F20.5	3	1.3
F20.6	1	0.4
F23.0	10	4.5
F23.1	23	10.3
F23.2	13	5.8
F23.3	20	8.9
F23.8	9	4.0
F23.9	3	1.3

Patients' age varied between 17 and 69 years, with an average age of 37.5 years (std.dev.=12.2).

Distribution of sample on education levels, marital and occupational status is presented in Table 2. Most patients (49.5%) have a high-school education, and almost a third (30.4%) has a higher education level (post high-school). More than half (55.3%) of the subjects are not married. Less than a third (29.0%) is married, and an important part of the subjects are divorced (12.9%). More than 60% (60.2%) of the subjects are not involved in a stable relationship. Most patients have been retired due to the psychiatric illness. A large part of the sample has never worked (19.6%).

Table 2. Sample distribution according to educational level, marital and occupational status.

Education level groups	No. of patients	%
Classes 0-4 (primary school)	4	1.8
Classes 5-8 (secondary school)	41	18.3
Classes 9-12 (high-school)	111	49.5
Post high-school education	68	30.4
Marital status		
Not married	124	55.4
Married	65	29.0
Divorced	29	12.9
Widowed	6	2.7
Occupational status		
Studying	18	8.0
Retired (due to illness)	95	42.5
Never been working	44	19.6
Working	49	21.9
Unemployed	11	4.9
Retired (age)	7	3.1

Of the total 224 patients, 88 (39.3%) have a positive family history of psychiatric disorders. 64 patients (28.6%) have experienced an ALE prior to the onset of the psychotic episode. Most patients, 197 (87.9%) have a SSN. The average number of hospitalizations for the investigated sample was 3.6 (std.dev.=4.4), with an average hospitalization duration of 23.7 days (std.dev.=14.3).

1.2 Risk/resilience factors and hospitalization lengths

Regarding the duration of hospitalization there is no statistical significant difference between patients with or without a family history of psychiatric disorders (t=-0.35, p=0.72): average duration of hospitalization for patients with a positive family history of psychiatric disorders is 23.3 days (std.dev.=14.9) versus an average duration of hospitalization of 24.0 days (std.dev.=13.9) for patients without a positive family history of psychiatric disorders.

The ANOVA test results show that the level of education does not influence the duration of hospitalization (F=0.52, p=0.66). Also, the ANOVA tests show that there are no statistically significant differences in the duration of hospitalization between subjects with different occupational status (F=1.38, p=0.24).

The marital status of the subjects (specifically if the subject has a life partner or not) does not seem to influence the duration of hospitalization. The mean duration of hospitalization of patients with a life partner is 23.1 days (std.dev.=12.9) and the mean duration of hospitalization for patients without a life partner is 24.0 days (std.dev.=14.9). Though the mean duration of hospitalization for patients with a life partner is lower than for patients without a life partner, the difference is not statistically significant (t=0.42, p=0.67).

The presence or absence of a SSN does not influence the hospitalization duration (t=0.62, p=0.53). In our study, the average hospitalization duration for subjects with a social support network is slightly higher than the average hospitalization duration of subjects without a SSN (23.9 days versus 22.1 days).

The presence or absence of ALE before the episode onset seems to have no influence on the duration of hospitalization. The means of hospitalization days for subjects with/without ALE is very similar (23.4 versus 23.9 days) and the difference is not statistically significant (t=-0.23, p=0.81).

Comparing the two main diagnostic groups, F20 and F23, the T test shows there is no statistically significant differences between the means of hospitalization duration (t=0.20, p =0.84). The mean hospitalization duration for patients in the F23 group is 24.0 days (std.dev.=16.2) while for the F20 group is 23.6 days (std.dev.=13.3).

1.3 Risk/resilience factors and recurrences

Regarding the number of episodes, there is no statistical significant difference between patients with or without a family history of psychiatric disorders (t =-1.94, p = 0.06): the average number of episodes for patients with a positive family history of psychiatric disorders is 4.3 (std.dev.=4.9) versus an average number of episodes of 3.2 (std.dev.=3.9) for patients without a positive family history of psychiatric disorders. The number of episodes is higher for patients with a positive family history, but the difference is not statistically significant.

The ANOVA test results show that educational level does not influence the number of episodes (F=0.25, p=0.89).

The ANOVA tests show that there are differences among subjects with different occupational status regarding the number of episodes (F=7.8, p=0.00). Post hoc tests indicated that differences are significant between subjects working and the ones retired due to illness (p=0.00), and subjects not working and the ones retired due to illness (p=0.00).The average number of episodes for subjects retired due to illness is 5.34 (std.dev.=4.95), while for subjects not working is 2.21 (std.dev.=3.49) and for subjects working is 2.14 (std.dev.=2.06). The average number of episodes is highest for the subjects retired due to illness and lowest for subjects both working and not working. Therefore, we must consider the reverse causal relation: namely that the occupational status (specifically, the "retired due to illness" status) does not influence the number of episodes, but rather that the above mentioned status has been achieved due to the high number of episodes.

The marital status (specifically if the subject has a life partner or not) does not influence the number of episodes. Mean number of episodes for subjects with a life partner is 4.07 (std.dev.=4.2) and the mean number of episodes of patients without a life partner is 3.4 days (std.dev.=4.4). While the mean duration of hospitalization for patients with a life partner is lower than for patients without a life partner, the average number of episodes is higher. The results are not statistically significant.

The presence or absence of a SSN does not seem to influence the number of episodes; there is no statistically significant difference (t=0.71, p=0.47) between subjects with or without a SSN.

The presence or absence of ALE before episode onset influences the number of recurrences. The average number of episodes for subjects with ALE is significantly lower than the average number of episodes for subjects without ALE (2.54 versus 4.07).

There is a statistically significant difference between the average number of episodes of subjects in the F20 diagnostic group and the subjects in the F23 diagnostic group (t=-7.17, p=0.00). The subjects with F23 diagnosis have an average number of episodes significantly lower than the subjects in the F20 diagnostic group: 1.03 episodes (std.dev.=1.16) versus 5.02 (std.dev.=4.83). This shows that subjects with schizophrenia have a higher number of episodes than subjects with acute and transient psychotic disorders.

Discussions, Conclusions and Limitations

In our study, factors such as educational level, marital and occupational status don't influence either the duration of hospitalization, or the number of episodes.

In patients with a social supportive network, the average hospitalization duration is slightly higher than in those without it. While family might be a protective factor functioning as a buffer for ALE, it may also represent a stress factor when high expressed emotions (hostility, criticism, or intolerance) represent a rule [10]. Patients with a positive family history of psychiatric disorders have a higher number of psychotic episodes than those without a family history.

The presence/absence of adverse life events prior to the onset of the psychotic episode has a statistically significant influence on the number of episodes. The lower number of recurrences in patients with ALE may indicate a higher resilience. The absence of apparent triggers (ALE) may reflect a higher sensitivity to subliminal stress.

Patients with acute and transient psychotic disorders (F23) have fewer recurrences than those with schizophrenia (F20), probably because most of them are in the early phases of their disorder. Differences in the cathamnestic period are a limitation of the study. The role of the affective co-morbidity (possible in patients with F23.0 and F23.1 diagnoses) as a resilient factor was not assessed.

Abstract

Resilience is a dynamic process that develops qualities and aims at overcoming adversity. Having Bipolar Disorder (BD) is an adverse experience, considered serious mental illness (SMI) and characterized by cyclical and extreme moods fluctuations between mania/hypomania and depression. The objective was the study of resilience, process and factors involved in adults recovered from BD.

This is a qualitative study using semi-structured interviews and focus groups with people recovered from BD belonging to the mental health network from the Basque Country (Spain), and clinical experts in the treatment of BD. All the content from the focus groups and interviews was transcribed and analyzed according to conventional content analysis.

People recovered from BD affirmed having experienced a resilient process. It was described as progressive, dynamic and non-linear experience. During the resilient experience inner strength emerged, providing hope and confidence in improving and displaying and developing interrelated internal and external qualities in order to overcome the BD. Some of the resilient qualities developed involved a self-analysis, being responsible for own mental health, searching for emotional, physical and social balance and wellness, self-reinvention or reorienting a personal life project, activating some positive personality characteristics (traits), employing conflict resolution ability, and finding external (formal and informal) support. Resilience arose after experiencing a life crisis (i.e. turning point) and the person was determined to overcome it.

People recovered from BD reported having experienced resilience. The resilient qualities found coincide with the traditional qualities of resilience, while others are specific to BD. It is recommended to continue the study of resilience in longitudinal studies to analyze whether resilience predicts recovery.

Keywords: Resilience process, Resilience factors, Mental Disorder, Bipolar Disorder, Qualitative study.

Introduction

The study of health is showing a shift from an epidemiological to a salutogenic approach, which aims to study phenomena that enable a satisfying and healthy life despite adverse life circumstances. Positive psychology asserts that the study of positive human traits enable understanding how to build qualities that not only help to resist and survive, but also to grow or thrive, and to reduce, regulate and prevent mental illness as a side effect [1]. Some autobiographical reports show that although bipolar episodes are traumatic and disruptive, there is the possibility that people with BD can experience wellness and manage their disease and live a fulfilling life, describing a variety of strategies to achieve it [2]. Nevertheless, the positive reports of living with Bipolar Disorder (BD) remain largely absent in the current research literature, studying instead the high rates of suicide, substance abuse, criminal behavior and divorce.

BD is a mood disorder characterized by recurrent and cyclical periods of extreme moods, including depression –during which sadness, inhibition and ideas of death prevail- and mania –which is a phase of exaltation, euphoria and grandiosity- or hypomania [3]. BD is a chronic disease with periods of remission and relapse. Along the course of the disease, the patient may develop psychotic symptoms, rapid cycling, psychiatric and medical comorbidity, and cognitive and psychosocial impairment. Patients have a high risk of committing suicide.

This illness remains in the top ten causes of Years Lived with Disability (YLD) at global level, accounting for 2.5% of total global YLDs [4]. It is incorporated by the WHO as one of the six most debilitating conditions [5] and also classified among the Serious Mental Illness (SMI) [6]. According to the World Health Organization World Mental Health Survey Initiative (WHO; [7]), the aggregate lifetime prevalences were 0.6% for bipolar type I disorder (BP-I), 0.4% for BP-II, 1.4% for subthreshold BP, and 2.4% for Bipolar Spectrum Disorder (BPS).

To be in line with the focus of current salutogenic approach and cover the lack of knowledge of positive qualities that contribute to recovery in this high health burden disease, the present study aims to study psychological resilience in BD.

According to several authors such as Grotberg [8] and Luthar, Cicchetti, & Becker [9], the resilient term must be understood as a universal and dynamic process in which both personal and interpersonal skills, as well as internal forces interact to allow positive adaptation despite adversity. Other authors argued that individual psychological variables are an essential part of resilience in terms of adverse circumstances [10]. Moreover, Richardson [11] and Grotberg [12], not only describe resilience as a disruptive and reintegrative process for accessing resilient qualities towards overcoming adversities, but also as a phenomena that strengthens protective factors and drives to personal growth through adversity and disruptions.

There is evidence of the importance of resilience to overcome adverse events and somatic health and physical problems [13] as well as mental ones [14]. Grotberg maintains that resilience is recognized as a contribution to the promotion and maintenance of mental health and quality of life [12]. For instance, a study found the presence of resilient qualities in a sample of eight participants in remission of various mental disorders, including BD [15]. Meanwhile, it has been shown that resilience could play an essential role in personal recovery and in improving psychosocial functioning and quality of life as well as in reducing symptoms in people with schizophrenia [16]. However, the review of the scientific literature by the major search engines documentation (Web of knowledge, Ebscohost, Pubmed and Google Scholar), and the combination of keywords, "resilience" or "resilient "and "bipolar disorder" did not produce any results in reference to psychological resilience.

Therefore, the primary aim of the study was to explore from a qualitative perspective the resilience process phenomenon and the positive qualities or factors involved in into a clinical adult sample of people recovered or functionally improved from BD. It is hypothesized that resilience is experienced by these individuals and it will be described as a multidimensional process. Also it is expected to find a number of resilient components similar to those studied in other diseases and adversities, and a few BD specific resilient components. Moreover, it is supposed that people affirmed having experienced a resilient process will also display high rates of posttraumatic growth and quality of life.

Methods

1.1 Design

This is a phenomenological qualitative study. Multiple triangulation technique was used: a) Methodological triangulation (semi-structured individual interviews and focus groups), b) Data triangulation (focus groups composed of both people recovered or functionally improved, as experts in the area), c) participants with BD also completed a battery of tests.

1.2 Participants

Participants came from various psychiatric services and Mental Health Centers of Basque Country (Spain): Mental Health Center Bombero Echaniz and Uribe-Kosta from Biscay, and Santiago Apostol Hospital from Álava.

The inclusion criteria for the individual interview and focus group patients were: (1) be functionally recovered or significantly improved from their BD diagnosis (BD type I, type II, and not Specified diagnosis were accepted). Additionally, a psychiatrist of each BD participant had completed the *"Clinical Global Impression Scale for Bipolar Disorder Modified (CGI-BP-M)"* [17]. To be eligible to participate, participants symptoms had to had been rated as "normal" and "mild" in severity. (2) Be between 18 and 65 years old. (3) Have appropriate levels of expression, understanding and insight to carry out the study. (4) Participate based on informed and voluntary consent. Patients who (1) did not meet the above criteria and (2) that also had other psychological, biological or physical conditions that would impede participation in the study were excluded.

The inclusion criteria for participating experts in the focus group were: (1) Possess more than two years of experience in treating patients with BD, and (2) agreeing to participate in an informed and voluntary way.

1.3 Procedure

The study satisfies ethical aspects of informed consent, voluntary participation, and confidentiality. Participants gave the informed consent to participate and they also allowed the interview to be taped in audio. Therefore, each interview and focus group were fully transcribed on paper.

Conventional content analysis [18] of each individualized interview and focus group was performed following steps proposed by Morse & Field [19] in order to identify most relevant topics, allowing to obtain a final model of resilience in BD.

The first draft overall model of resilience was obtained from the individualized interviews in which patients were asked about their resilient experience, and about qualities used during this process. Later, a patient focus group was carried out in order to discuss their resilient experience and validate created first resilient model. This allowed to generate a second draft model of resilience, which was presented to six mental health professionals that participated in the expert focus group. They discussed and validated the second draft model of resilience from their objective view of the topic. Last, a final model of resilience in BD based both on users view and on professionals view was created.

1.4 Instruments

Patients had to complete standardized questionnaires about their symptoms of bipolar disorder "*Bipolar Spectrum Diagnostic Scale (BSDS) Spanish Version"* [20], general resilient level "*Spanish Version of the Resilience Scale 25 (RS-25)"* [21], posttraumatic growth "*Short Form of the Posttraumatic Growth Inventory (PTGI-SF) Spanish version"* [22], quality of life "*Brief Quality of Life in Bipolar Disorder (Brief QoL.BD) Spanish Version"* [23], and socio-demographical and clinical data. Additionally, the subjective rating scale for recovery level from 0 "I have not experienced any recovery" to 100 "I am completely recovered" was administered.

Experts completed the "*CGI-BP-M"* [17] of their patients to report the severity of symptoms at present.

1.5 Statistical Analyses

Descriptive statistics and frequencies were performed, using the statistical package SPSS for Windows version 20.

Results

1.1 Cuantitative Data

According to CGI-PB-M (Overall) and BSDS mean scores, participants showed no significant active BD symptoms. Furthermore, patients indicated to be highly recovered in the subjective rating scale for recovery (See Table 1).

Table 1: Participants scores at the interview and focus group moment on symptoms and re

	Mean	*Sd*
	n = 15	
CGI-PB-M_overall	1.60*	0.83
BSDS	2.73**	2.40
Subjetive Recovery rating scale	85.00	11.01
Age at BD onset	25.00	9.71
RS-25	137.80	16.97
PTGI–SF	32.87	7.23
Brief QoL.BD	48.80	6.89

* Score between "Normal (1.00)" and "Minimal (2.00)" at Overall Symptom Severity.
** Score below the cut off value of 13 points necessary for screening BD.
RS-25 range: 25-175; PTGI–SF range: 0-50; Brief QoL.BD range: 12-60.

Of the 15 patients enrolled (11 women , 4 men), nine of them from Santiago Apóstol Hospital, and six from Mental Health Center Bombero Echaniz and Uribe–Kosta, with a mean age of 42.87 years old (SD = 11.99), 7/15 were married, while most of the rest were single (6/15) at the time of the interview or focus group. Although 8/15 patients had university degrees, and 4/15 worked in a job related to their university degrees, the

majority of patients (11/15) were occupationally inactive at the time of the interviews were taped (mainly by occupational disabilities resulting from the BD).

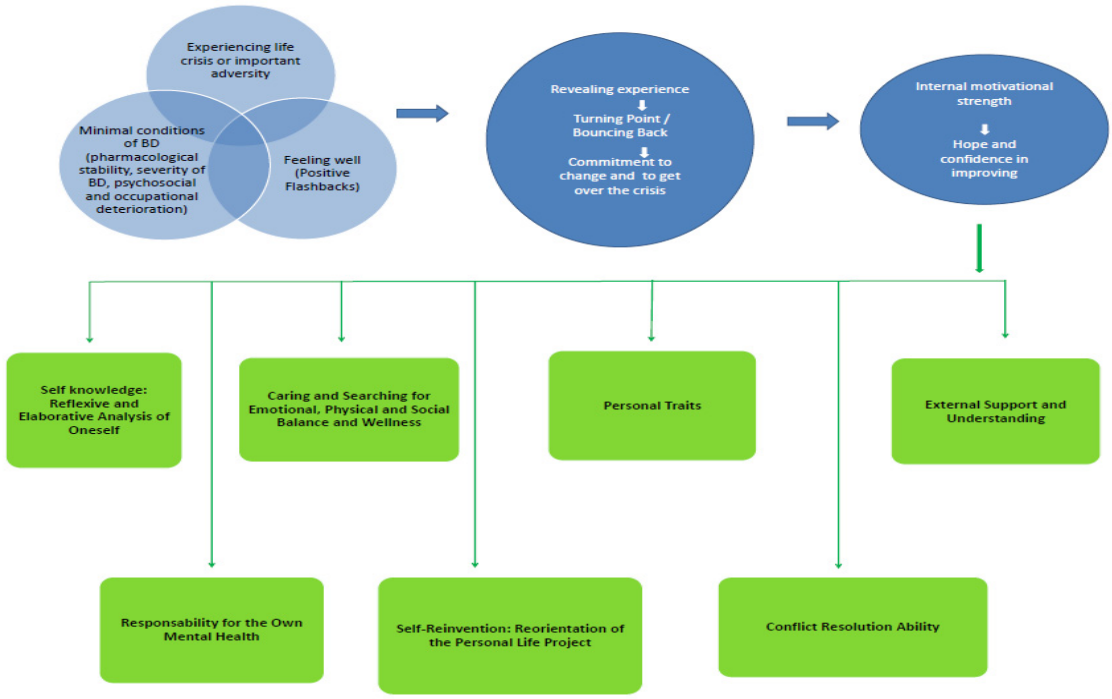
BD came out in early adulthood (See Table 1). All were receiving prescribed drug therapy (predominantly antipsychotics, mood stabilizers and anticonvulsants) and most had also received individual and / or group psychological therapy. Some participants indicated the presence of thyroid-related diseases as a side effect of the lithium carbonate.

Participants show medium-high levels of intrinsic factors in resilience, posttraumatic growth, and quality of life indicated by the mean scores of RS-25, PTGI–SF, and Brief QoL.BD (See Table 1).

1.2 Cualitative Data

All patients affirmed having experienced a resilient process. Resilience was described as a progressive, dynamic and non-linear process. The qualities or factors that contributed to the origin and function of resilience in BD are described in the diagram presented in Fig.1.

Fig. 1 Factors that contribute to the origin and functioning of Resilience in Bipolar Disorder Process



Participants agreed that resilience was originated when, having a minimal mental health conditions, went through a bipolar crisis, and experienced positive flashbacks that made them feeling well. This situation worked as a revealing experience which driven them to a turning point. In this context, they referred feeling an enhanced commitment to change ones beliefs and attitudes and being determined to face the crisis. These generated an inner strength or motivation and increased hope and confidence in order to get over the adversity.

In this context, participants narrated the development and activation of interrelated positive qualities which enabled them to overcome the BD. They developed seven main resilient qualities:

1) Self-analysis: They agreed that self-knowledge about personal strengths, weaknesses, goals, values, and hobbies allowed them to redefining their identity and to differentiated it from the illness.
2) Being responsible for own mental health: They stressed the importance of knowing BD, and trying to regulate it through the management of early warning signals and the adherence to psychopharmacological treatment. That gave them sense of empowerment above their lives. They also narrated the importance of dealing and re-establishing personal limits.
3) Searching for emotional, physical and social balance and wellness: They highlighted the advantage of having a discipline and a healthy life-style, as well as having or searching for an interpersonal and occupational network in order to perceive emotional support. Participants agreed that enjoying in relaxing and distracting activities were also necessary so that they could set aside their suffering.

4) Self-reinvention or reorienting a personal life project: These factors implied to undertake adapted goals that nurture one´s inner life. They also narrated the need for self-realization and personal growth, which it was also strengthened as a result of resilient process.
5) Activating some positive personality characteristics (traits) such a self-worth, courage, perseverance, humility, extroversion, optimism and sense of humor.
6) Employing present focused conflict resolution ability or being able to do an objective analysis of the problem and available resources. This allowed them to adapt their goals and to find out and get needed support to solve their problems. Creativity, assertiveness and social skills were also emphasized.
7) Finding external support both formal (psychopharmacological therapy) and informal (family, friends and colleagues).

Conclusions

The study provides evidence that resilient process is an experience in people recovered from BD. The resilient qualities found coincide with the traditional qualities of resilience [8, 9,10] such as hope, optimism, creativity, dreams, self-control, and subjective wellness, while others are specific to BD, such as BD knowledge, redefinition of identity, and adherence to treatment. On the other hand, a few studies have explained a number of factors related to recovery from BD such as identity development, self-management, and development of social roles [2], when actually, they are resilient factors that leads to recovery. On the other hand, study provides evidence that people recovered from BD who have go across a resilience process, also show medium levels of quality of life and posttraumatic growth.

The study involved a small number of people. However, data saturation was obtained in individualized interviews and multiple triangulations were carried out, thus giving more validity to the results. An added limitation was that all patients with TB were recovered, so precautions should be taken when generalizing the results to people with active TB. However, being the first study in the area, had to prioritize to interview people who had experienced more likely resilience.

It is recommended to continue the study of resilience in longitudinal studies to analyze whether resilience predicts recovery. The severity of BD and the resulting socioeconomic and health burden [24] could be reduced through the development of specific resilience programs for people with BD that promote recovery.

Abstract

Purpose of the presentation: The presentation will discuss the role of resilience in caregivers in the evolution of the response to the call to moral responsibility for taking care of their loved one with Alzheimer's. Conceptual and methodological frameworks: Twenty family caregivers of a person with Alzheimer's disease were interviewed in semi-structured in the context of the methodology of grounded theory interviews. Philosophy of alterity of Levinas has served as a framework for interpreting the data. Results: The study revealed a particular evolutionary process of responding to the call to moral responsibility of caring. This process begins with resilience which, although itself positive because it allows a transformation where the caregiver is stronger, however, helps to constantly push the boundaries so that the actual limit of home support the person with the disease becomes exhaustion. Discussion: The results allow the following observation: the resilience of caregivers is high. Although this resilience is socially useful and necessary to meet the needs of people affected by Alzheimer's disease, it nevertheless should not take it for granted and ignore the possible consequences for the caregiver. The response to the call of the responsibility of caregivers is a process that is necessary to know for intervening in time, because caregiver burnout does not have to be the final phase.

Keywords: moral responsibility, Alzheimer's caregivers, resilience, fatigue, Levinas.

Mise en contexte de l'étude

Dans le cadre de notre étude, nous voulions comprendre comment se construit la responsabilité morale des aidants au regard du traitement pharmacologique de leur conjoint atteint d'Alzheimer. Pour ce faire, deux objectifs spécifiques ont guidé l'ensemble de l'étude : 1) comprendre le processus de construction de la responsabilité morale des aidants à l'égard de leur proche et 2) décrire l'engagement des aidants face au traitement pharmacologique dans la perspective de cette responsabilité morale. Nous avons choisi la théorisation ancrée de Strauss et Corbin [1] comme méthode, l'interactionnisme symbolique de Mead [2] et l'éthique de l'altérité de Lévinas [3] comme cadres théoriques, ainsi que l'entrevue semi-dirigée comme outil de cueillette des données. Les schémas d'entrevue ont évolués en cours de collecte pour construire la théorie en émergence. Les entrevues abordaient l'histoire du diagnostic, le sens de la maladie et du traitement, l'interaction aidant-aidé et le sens de leur responsabilité à l'égard de l'autre. Nous avons souscrit à la méthode de réduction et d'interprétation des données proposée par la théorisation ancrée, laquelle comprend le codage, les mémos et les schémas en guise d'analyse des données. La validation fut assurée par la méthode interjuge. La majorité des 20 participants (60%), recrutés selon un échantillonnage théorique, sont des femmes. Les participants sont âgés entre 44 et 83 ans, 68 ans en moyenne. Notre étude à fait ressortir six déterminants de la responsabilité morale en amont de l'engagement dans le traitement: 1) les transformations de l'aidé atteint de la maladie, 2) les transformations de la relation aidant-aidé, 3) les fondements derrière le choix d'assumer la responsabilité de soin, 4) l'actualisation de la responsabilité à travers la promotion de valeurs morales, 5) le processus d'évolution de la réponse à l'appel de la responsabilité morale et 6) la manière avec laquelle les aidants parviennent à développer leur propre manière d'assumer leur rôle, soit la singularisation de la responsabilité [4, 5]. Nous discutons ici des résultats relevant du cinquième déterminant, celui relatif à la réponse à l'appel de la responsabilité.

Réponse des aidants à l'appel de la responsabilité morale

Conforme au précepte, dans une perspective lévinassienne, que les aidants sont appelés à être responsables, notre étude a mis en évidence un processus d'évolution dans cette réponse à l'appel de la responsabilité envers leur proche. Ce processus représente un des six déterminants de la responsabilité morale des aidants et se décline en 4 phases que nous décrivons brièvement ici. (Notons ici que ce processus de réponse à l'appel de la responsabilité émerge d'entrevues effectuées dans le cadre d'une étude transversale auprès d'aidants qui assument ce rôle et donc ne représente pas les multiples possibilités de réponses, dont celle de ne pas endosser cette responsabilité.)

1.1 Phase 1: Résilience

La première réponse des aidants à l'appel de la responsabilité semble être la résilience. La résilience est un concept polysémique étant à la fois intrinsèque à l'individu, processus complexe et résultat [6]. Elle réfère ici à un trait de personnalité et à un ensemble de qualités personnelles qui permettent à l'individu de se développer [7] et de se transformer positivement face à l'adversité en interaction avec son environnement [8]. Nous employons la résilience dans la perspective américaine ou conjoncturelle, laquelle réfère à l'expérience de stress majeurs ou d'épreuves causant un choc émotionnel intense et un déséquilibre psychique durable, sans toutefois qu'il s'agisse de traumatismes [9]. Les participants présentent quelques caractéristiques propres aux personnes résilientes comme l'estime de soi, les habiletés de résolution de problèmes, l'esprit critique, l'humour, l'autodiscipline, l'optimisme, la créativité, l'humilité, la flexibilité et la résistance, tant physique qu'émotionnelle, face aux exigences requises: «*J'ai découvert que j'étais encore plus adaptable ou flexible que je pensais à des nouvelles situations, encore, malgré mon âge!* » (Pierre). La résilience semble mobilisée dès le départ dans le parcours des participants et se manifeste, dans un premier temps, par l'adaptation et l'ajustement face au diagnostic : « *Quand il a donné le diagnostic, je me suis dit : aimerais-tu mieux qu'ils te disent qu'il a un cancer en phase terminale? L'Alzheimer, on parle de 10 ans, le cancer c'est six mois, deux mois* » (Murielle). Plus qu'une simple réponse adaptative au stress cumulé, la résilience implique également une certaine transformation et reconstruction de soi [9]. À cet effet, nommons les transformations des rôles au sein de la dyade aidant-aidé amenant les participants à modifier leur conception des rôles traditionnels et à apprendre de nouvelles tâches. De plus, ils accroissent leur considération pour les autres, découvrent leur bienveillance. Il s'agit d'une découverte de soi, du développement d'attitudes et de compétences interpersonnelles nouvelles: «*Du jour au lendemain, tu deviens infirmier, puis tu deviens homme de maison*», disait Armand.

1.2 Phase 2: Renoncements et deuils

Pour certains, prendre soin de son proche est un don de soi: «*Il faut l'accepter, il faut se donner, c'est un don*» (Armand). La prise de responsabilité exige effectivement des renoncements, comme mettre de côté des projets de retraite, de voyage ou d'activités sociales. De plus, les participants doivent admettre que les choses ne seront plus jamais les mêmes, que la maladie les oblige à revoir leurs priorités et leurs besoins : « *Je n'ai pas besoin de cadeau, je n'ai plus besoin de rien (…). [Ses enfants disent]: Ah, il aurait dû t'acheter des fleurs! Non! Non!… J'ai fait mon deuil de tout ça, là. Non, je n'ai pas besoin de ça »*. (Carmen). Au-delà des renoncements qui ne paraissent pas toujours faits dans la douleur et auxquels les participants s'ajustent parfois assez facilement, il est question de deuils. De fait, les participants parlent du deuil de la personne qu'ils ont connue et aimée dont l'intégrité du soi est atteinte. Cet aspect revêt en revanche un caractère beaucoup plus souffrant pour plusieurs: «*Et puis tu vois ton conjoint partir par morce*au pleurs) » (Julie). Les participants doivent également faire le deuil de la relation antérieure et de la vie à deux qui ne sera plus possible en raison de l'obligation de recourir éventuellement à l'hébergement en institution. Les renoncements ou deuils, comme seconde réponse à l'appel de la responsabilité, marquent un point de non-retour dans le parcours des aidants, car ils tracent les premières frontières des limites de leur responsabilité morale.

1.3 Phase 3: Anticipation de limites face à la responsabilité

L'agnosie dont est victime leur proche est l'une des transformations qui fragilisent profondément le rapport relationnel et le problème auquel les participants réfèrent le plus souvent comme étant la limite du projet de maintien à domicile. La difficile décision d'hébergement semble d'ailleurs plus envisageable pour les participants lorsque le proche ne pourra plus les reconnaître comme le dit Murielle dans cet extrait : « *Moi, le matin où il se lève, puis il ne me reconnaît plus, il sort d'ici. Je ne vivrai pas avec un étranger* ». Les problèmes relatifs à l'hygiène constituent la seconde limite qui circonscrit leur responsabilité: «*Si je suis obligé de la torcher à tous les jours, malgré que c'est venu sur le bord (rires) (…) je ne m'entêterai pas*». (Gérard). En fait, les problèmes d'hygiène et d'agnosie, plus que d'autres, semblent mettre en péril la poursuite du projet de

maintenir leur proche dans son milieu de vie. Ainsi, l'anticipation de limites constitue la troisième réponse à l'appel de la responsabilité morale.

1.4 Phase 4: Émergence de limites réelles de l'aidant face à sa responsabilité

Le processus de réponse à l'appel de la responsabilité morale s'amorce par la résilience, laquelle, parce qu'elle rend l'aidant plus fort, contribue par ailleurs au repoussement des limites. Au final, l'épuisement constitue la limite ultime lorsque les participants répondent à cet appel au-delà de leurs limites: «*C'était une négociation infernale. Puis à un moment donné, tu deviens toi aussi fatiguée, fatiguée. Nous autres, c'est le cas de le dire, ils nous ont à l'usure! Oui parce que quand il est rentré [en hébergement], moi, je me sentais usée là*» (Lorraine). Outre le fait qu'il puisse provenir de cette volonté de répondre à l'appel de la responsabilité au-delà de leurs limites, l'épuisement des aidants peut également être associé à la difficulté des aidants à répondre à l'image qui émane des fondements de leur responsabilité, ou encore à actualiser leur responsabilité en résolvant des dilemmes éthiques quotidiens, deux autres déterminants de la responsabilité morale dont il n'est pas question ici.

Discussion

Dans le contexte du vieillissement de la population et de l'augmentation du nombre de personnes dépendantes qui l'accompagne, la résilience des familles semble nécessaire à l'accomplissement du rôle de proche aidant. La littérature dans ce domaine aborde le plus souvent cette résilience à travers le paradigme de stress et de coping de Lazarus et Folkman [10] selon lequel, face à des agents stresseurs importants qui menacent ou dépassent leurs ressources, les aidants utiliseront différentes stratégies d'adaptation cognitives et comportementales pour gérer la situation. Or, «le coping apparaît comme une forme de résilience ou plus exactement peut contribuer à décrire une certaine approche du processus de résilience, à partir d'une perspective essentiellement comportementale et consciente» [8].

Ainsi, comment cette résilience de départ peut-elle conduire à l'épuisement en fin de parcours ? Le processus de réponse à l'appel de la responsabilité morale décrit ici constitue une partie de la réponse à cette interrogation. Premièrement, nous constatons, avec Cyrulnik et Werner, le travail inachevé et non absolu de la résilience [9]: bien que les participants amorcent leur parcours d'aidant avec résilience, cette dernière n'est pas forcément sans limites et comprend des ruptures. L'épuisement en étant une illustration flagrante. Deuxièmement, les renoncements et les deuils quotidiens auxquels sont confrontés les aidants dont la perte de l'autre malgré sa présence physique, seconde phase de notre processus de réponse à l'appel de la responsabilité morale, constituent des facteurs de risques multiplicateurs qui ne sont pas compensés [11] favorisant la rupture de résilience. En revanche, l'anticipation de limites à la prise de responsabilité pourrait agir comme facteurs de protection, car ils permettent de modifier la réaction à la situation [12] ou faire obstacle aux effets causés par les facteurs de risque [13]. S'imposer des limites constitue en effet une réponse adaptative efficace à une responsabilité devenue trop lourde. Toutefois, la valeur protectrice de cette prise de position des aidants est lacunaire dans la mesure où leur résilience les amènera à repousser encore ces limites une fois atteintes. Ainsi, un déséquilibre se crée entre les facteurs de risques augmentant la vulnérabilité et les facteurs de protection susceptibles d'accroitre la résilience.

Peu d'études semblent soulever des effets négatifs de la résilience appliquée à la problématique des aidants. Fitzpatrick et Vacha-Haase [14] avancent que la résilience représente un concept dynamique et multifactoriel qui inclut notamment le fait d'être réaliste. Or, selon eux, le réalisme fait en sorte que les aidants éprouvent une satisfaction moindre dans le rapport avec leur proche, car ils sont alors en mesure de reconnaître, puis d'admettre, les détériorations de la relation. Cette relation dyadique constitue par ailleurs la dimension centrale de l'expérience d'être aidant [15 à 18]. Le degré d'intimité partagée au sein de la dyade aidant-aidé influence notamment la manière dont sera assumée la responsabilité [19, 20]: continuité, réciprocité relationnelle, ou, au contraire, détachement ou sentiment d'obligation de prendre soin [21]. Le réalisme engendré par la résilience des aidants constitue dès lors un facteur de risque menaçant la relation, laquelle est un important facteur de protection contre l'épuisement des aidants. Ainsi, aux troubles psychocomportementaux de l'aidé [22, 23], aux capacités adaptatives moindres et à la vulnérabilité au stress de l'aidant [24], à la mauvaise perception de l'auto-efficacité de l'aidant dans son rôle [23], à la mauvaise qualité de la relation aidant-aidé [25]; déjà reconnus comme des facteurs explicatifs du fardeau, peut-on ajouter *trop de résilience* ? Les données recueillies dans notre étude ne nous permettent pas de proposer un nouveau déterminant du fardeau ou de l'épuisement des aidants. Mais elles nous autorisent toutefois à soulever la question des effets pervers de la résilience qui renforce l'appel de la responsabilité morale de prendre soin: «*C'est lui qui a la priorité là. Il a besoin de moi là, je vais être là*», nous confiait Claire en entrevue.

En terminant, sans proposer de réponses claires à la question de départ, nos résultats permettent d'amorcer une réflexion sur le rôle de la résilience dans l'épuisement des aidants. Nous avons avancé, pour y

répondre, que c'est vers le processus de réponse des aidants à l'appel de leur responsabilité morale qu'il faut se tourner. Nous avons fait ressortir que ce processus peut conduire à l'épuisement, dans une perspective lévinassienne où la responsabilité est irrévocable une fois interpellée par la vulnérabilité de l'autre. Il semble donc possible pour les professionnels de la santé de travailler avec les aidants pour qu'ils gèrent mieux cet appel de la responsabilité. Il se s'agit pas ici de tenter de renforcer la résilience, sachant qu'elle comporte un risque pour leur santé. Au contraire, c'est en discutant avec les aidants des limites envisagées à leur responsabilité envers leur proche, puis, une fois ces limites atteintes, en leur rappelant la nécessité d'évaluer s'il est encore réellement possible pour eux de continuer. Les interventions sociales basées sur le concept de résilience se concentrent généralement sur les ressources des individus et de leur environnement et sur les moyens de les rehausser encore davantage. Ne devrions-nous pas plutôt chercher à repérer également les risques d'une trop forte résilience? Car être résilients ne rend pas les aidants invincibles. Et l'épuisement, contrairement à ce que l'on serait porté à croire, pourrait être la conséquence d'une trop grande résilience.

La deficience intellectuelle protege-t-elle du traumatisme ?

Gwoenaël E.

Psychologue clinicien, Psychopathologue (Ile de La Réunion, FRANCE)
ethevegwoenael@yahoo.fr

Abstract

This clinical study did not aim to answer to this question that might seem provocative, if not expose the situation among many others hat led to its emergence; and consequently we wondered about the "resilience" factors. Working for ten years in the field of intellectual disability and having had to accompany, in this context, about thirty people exposed to traumatogenic events, we felt that these people had fewer clinical signs of trauma on the medium and long term their contemporaries. Different situations that led to this reflection have in common the points: a cross between the mental integration capabilities (memory abilities, psychoaffective immediate impacts) and potentially traumatic events (rape, exposure to violent deaths ...); an area where the person is already facing various vulnerabilities (intellectual disability, somatic problems, domestic violence, alcohol, serious educational deficiencies, social misery ...). In a clinical vignette (history, description of patterns and trends), which are defined in the preamble "resilience" and "disability" will emerge these questions: a moderate intellectual disability it would be more resilient? What links appear between resilience and mental development? We move forward to empirically say that in the context of intellectual disability and trauma, resilient capacity would highlight the influence of bio-psycho-social development.

Keywords: Resilience, Average Intellectual Disability, Trauma.

Introduction

En une dizaine d'années en tant que psychologue dans un Institut-Médico-Educatif auprès d'une population parlant le créole réunionnais, j'ai été amené à accompagner une trentaine de situations traumatogènes (viols, exposition à des morts violentes…) impliquant des jeunes déficients intellectuels (déficience légère à profonde), âgés entre 11 et 16 ans. J'ai toujours été interpellé par le fait que les personnes présentant une déficience intellectuelle moyenne (21 cas sur 32) manifestaient beaucoup moins de signes cliniques post-traumatiques que leurs pairs. Elles sont en effet plus impactées par les changements dans l'attitude de l'entourage (centration de l'attention, rapports, entretiens…) que par l'événement lui-même, toujours rapporté par un tiers. Ce qu'elles expriment par ailleurs très bien : « Sak ma la fé té pas bon ? » (Ce que j'ai fait était interdit ?)... Après avoir défini « résilience » et « déficience intellectuelle », nous illustrerons les liens entre eux par la situation de Jean.

Definitions

1.1 La Résilience

Dans son acception en Physique des matériaux, la résilience renvoie à la capacité pour un matériau à absorber l'énergie en se déformant sous l'effet d'un choc. D'observations empiriques en études systématisées, un pont conceptuel est fait avec la psyché humaine [1] [2] et plus largement avec la société humaine [3] [4]. Parler de résilience, serait aborder les capacités d'intégration et d'élaboration d'un individu face à un impact potentiellement traumatique ; cela suppose donc que la personne dispose d'un matériel cognitif, biologique, émotionnel, volitionnel, social… Mais qu'en est-il de ce concept dans le cadre de la déficience intellectuelle ?

1.2 La Déficience Intellectuelle

Dans la suite de la conceptualisation tridimensionnelle de Wood P. [5] sur la Classification Internationale du Handicap et de la Santé Mentale (CIH) ("Fig.1"), nous aborderons la déficience comme un « manque ». Plus exactement comme un « manque d'efficience ». L'efficience pouvant être perçue comme la

capacité à utiliser de façon optimale l'ensemble des outils à disposition pour parvenir à un résultat, la déficience sera perçue comme le constat d'un manque et pas seulement comme une conséquence d'une maladie.

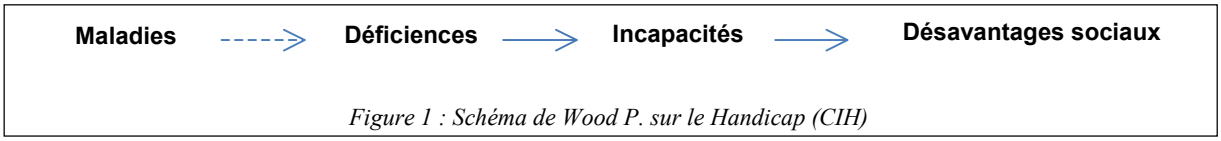

Figure 1 : Schéma de Wood P. sur le Handicap (CIH)

Par rapport à l'intelligence, il ressort des différents champs théoriques, et plus encore des différents auteurs, que le terme «intelligence» est relativement équivoque (concept? construction? singulier? multiple…?). Même s'il n'apparait pas d'unanimité quant à un sens commun, il y a un accord relatif quant à son développement; à savoir l'implication de la maturation cérébrale, de l'expérience acquise, des interactions et des transmissions sociales. Il y aurait donc, dans le cadre de la déficience intellectuelle, un manque à l'une ou plusieurs de ces dimensions.

Finalement, «Le déficit intellectuel renvoie à l'insuffisance d'efficience intellectuelle, représentant un des aspects cliniques importants d'une déficience mentale, rendant un sujet incapable de répondre de manière adaptée aux exigences du milieu» [6]. Deux dimensions importantes sont à prendre en considération : celle de la *limitation du développement intellectuel* et celle de *l'insuffisance du comportement adaptatif*. Illustrons cela avec l'histoire de Jean.

Vignette clinique

1.3 L'histoire de Jean

Jean est vu pour la première fois à l'âge de dix ans. Il est en internat. Il présente un syndrome d'alcoolisation fœtale avec retard staturo-pondéral et troubles sévères du comportement. Il ne s'exprime qu'en créole et est dans un fonctionnement où le plaisir immédiat domine. Il bave beaucoup, est très diffus, très marqué physiquement par son syndrome et présente une déficience intellectuelle moyenne homogène (évaluation WISC-III). C'est le 11ème enfant sur 13 d'une famille recomposée. La mère a 7 enfants d'une première union et le père trois. La famille bénéficie d'une «action éducative en milieu ouvert» (AEMO) pour carences éducatives graves, alcoolisation chronique, violences conjugales. Chaque week-end Jean est exposé aux violences familiales et se retrouve livré à lui-même. Alors qu'il a 11 ans, il est violé par un des jeunes de son groupe de vie. Deux ans plus tard il découvre le corps de sa mère qui s'est suicidée. A aucun moment, malgré l'intensité des événements, Jean n'a manifesté de signes cliniques péri- ou post-traumatique [7]. Avec ses capacités certaines de verbalisation mais de compréhension limitée, il aurait en quelque sorte été «protégé» par sa déficience. Jean a aujourd'hui 20 ans. Il est dans un Etablissement et Service d'Aide par le Travail (ESAT) où tout se passe très bien. Il vit chez une de ses tantes (tutrice), et semble avoir traversé tout cela *comme si* rien ne s'était passé.

1.4 Questionnements

L'absence de signes post-traumatiques se retrouve chez les 21 jeunes suivis. Pour un niveau d'efficience mnésique équivalent (Quotient Intellectuel entre 35 et 45), et une même tranche d'âge, nous assistons à des ajustements (pour 85 % d'entre eux) en réponse à des changements dans les attitudes de l'entourage, plutôt qu'en réponse à l'événement lui-même. Pour reprendre Bin K., *"Si un évènement se manifeste pour moi, il peut être divisé (...) en phénomène "extérieur" et en impression "intérieure"* [8], impression qui n'est pas toujours en adéquation avec les impressions sociales (famille, culture, croyance…).

Sont-ils pour autant résilients? Au sens physique (Cf. § 1.1), il y a une capacité certaine d'absorption sans aliénation ou débordements. Dans une approche socioconstructiviste [9], il y a des ajustements à l'environnement (débordements émotionnels transitoires liés aux attentes des autres).

L'insuffisance d'efficience intellectuelle viendrait se confronter avec le vécu événementiel et les attentes sociétales. Cela ouvre à une constellation de dynamiques entre la génétique, les liens sociaux, les capacités d'élaboration (mentale et verbale), les expériences de vie et les modèles à disposition.

Conclusion

Parler de déficience intellectuelle et de résilience n'est pas qu'un constat évaluatif de capacités ou de difficultés, c'est une histoire, l'histoire d'une personne, d'une famille, d'un accompagnement, de leurs interrelations... Les approches sont à n'en pas douter plurifactorielles: biologiques, psychologiques, sociales. S'interroger sur la résilience c'est s'interroger sur les facteurs (visibles ou non) qui vont permettre ce processus.

Si l'environnement a un impact certain sur le vécu d'un événement, les forces et faiblesses d'une personne prendraient un sens autre quant à l'absorption de cet événement.

L'appropriation des événements telle que vécue par la personne déficiente intellectuelle moyenne nous amène à repenser la **« résilience »** en **«résiliance»**: une jonction entre «**résig**nation» et «a**lliance**». Tout autant que je puisse me résigner (consciemment ou non) à mon Histoire, je suis susceptible de m'y allier et non plus seulement d'y être aliéné. Cela ne veut pas dire qu'il n'y a pas d'impacts, mais que ceux-ci ne vont pas empêcher un développement ultérieur sain. D'un point de vue empirique, il y a une capacité certaine à rebondir si tant est qu'il y ait un besoin de rebondir.

Abstract

Introduction: The obsessive-compulsive disorder can be disabling and traumatizing, especially at a young age, and its psycho-social consequences being an element very difficult to pass.

Objectives: This paper intends to describe the key elements of the phenomenon of resilience in the case of person who experience the obsessive-compulsive disorder.

Method: We use the case study providing an example of a successful history of one person suffering from severe obsessive-compulsive disorder. The history of the case was analyzed through interviews with the patient and key people in care; there have been administered standard instruments which aimed at resilience, adjustment and personality.

Results: The data obtained suggest methods of adjustment, as well as psycho-social factors which might support resilience.

Conclusions: Personal, contextual and interactional premises of resilience are possible in the case of people who suffer from obsessive-compulsive disorder. The case analysis shown might be a good starting point for the extension of resilience study in people who suffer from obsessive-compulsive disorder.

Keywords: obsessive-compulsive disorder, resilience, recovery, coping

Introduction

The obsessive-compulsive disorder is one of the most difficult and overwhelming psychiatric condition, with well-known variability and heterogeneity. It has a lifetime prevalence of up to 3% (in some studies), is explained (insufficiently) through various models (genetic, neurobiological, neuropsychological, infectious, psychological, environmental, interactional, and so on), without finding a satisfactory or covering model, so that there exist sufficient predictors and precise guiding for intervention.

The long-term duration of the ilness is associated with a less favorable evolution [1], and the patients with partial remission are more vulnerable to relapse than the ones with total remission. [2]

It is known the fact familial adversities (for instance, socio-economical disadvantage, teen parenting, parental separation, parents' mental health issues, stressful events of the family life) increase the vulnerability to mental health issues, especially when these tend to appear together with a accumulated effect, suggesting that not their type but their number might have a higher influence. [3] The patients with OCD who have close relatives with the same disorder or with a syndromic variant are in proportion to 20 – 25% from the total number of those who suffer from OCD. [4]

As far as the resilience concerns, Ionescu (2013) affirms that, in the absence of a universally accepted definition, there is an accord related to two essential points: (a) resilience characterizes a person who lived or is living a traumatic event or chronic adversity, and which proves to have a great adjustment and (b) resilience is the result of an interactive process between his/her person, family and surrounding environment. [5] Moreover, for an individual, to be resilient assumes engaging on an unexpected road and exceeding the troubles in which he/she passes, and this itinerary opens free and germinating perspectives. [6]

The case that we shall present, passed through multiple adversities, the most terrible one being the severe and disabling obsessive-compulsive disorder, which stopped him for a good period and which he not only resisted to but also passed it, and much more than that, he succeeded to change his life and give a new meaning to it.

CASE Report

1.1 Case History

Alex is 37 years old, lives in Timişoara, single child. His parents, with medium studies, are of a modest condition, his father has some health issues (vascular issues), his mother has an anankast type of personality and with recurrent syndromic and subsyndromic obsessive-compulsive disorder manifestations. They frequently had tense moments, with repeated fighting, including in front of the child.

Because the parents used to work a lot and had no time to take care of Alex, at the age of 4 he is given to a lady in order to be raised by her, and his parents used to visit him once in a while or take him home in the weekends. Though that separation is mentioned as being traumatic, Alex mentions that he became very close to the lady, in the care of whom he was given, whom he describes as being tenderhearted, kind and forgiving. Until her death, he shall consider her as his real mother. Before the junior high, when he was still in the kindergarten, he comes back to his family, a moment which was mentioned as being traumatic as well. His new „mother" used to visit him once in two weeks and had an excellent relation with Alex. He found the same environment at home, with his parents being busy, a tense, dominating, stubborn and pessimistic and very religious mother, and a kind father, frequent quarrels and common shortcomings from those time.

Around 14 years of age, the first signs of the obsessive-compulsive disorders appeared with arithmomania behaviour, obsessive memories followed by checking and touching behaviours integrated to some magical thinking methods (for instance, he touched the wall in order to be successful with girls).

In 1999 – 2000, an obsessive thought which greatly scared him appeared: „If I cut my veins of my legs, what would be like?" For a period, this thought tortures him, and then it appears more rarely.

In 2002, Alex and other friends decide to lose their virginity and hire a prostitute. The event is consumed and is followed by a disappointment („it wasn't such a big thing") and then by a strong guilt with a religious component included („I have sinned in front of God and what I did cannot be forgiven"), after which the obsessive-compulsive symptoms began to massively appear. Such „all sort of conditionings" („whenever you see ... , you shall remember you did something foolish"). More rituals appear (for instance, related to touching or avoidance), doubts and verifications („this or that?"). Everything becomes malign, any detail might generate an obsession and, consequently, a compulsion. Obsessions get a more diverse theme, verifications become more textured, arithmomania behaviour become more and more, rituals more nuanced. The functional limitation becomes greater and more overwhelming. He can no longer write without being preoccupied with the details of the letters, he can no longer read without having doubts (at the first time in the meeting, he could not write a full sentence). Since he was at the end of faculty years, he could not longer prepare his graduation thesis. His mother was not supportive at all, she was rough, accusing him of not praying more, and his father, though calm and supportive, became more and more burdened and did not know how to give a helping hand.

In the same year, he went to his first psychiatric consultation and is admitted to „Eduard Pamfil" Psychiatric Clinic from Timişoara, trying different therapeutic schemes but without significant results. He also starts cognitive-behavioral psychotherapy in hospital and things begin to shape well but hard. Therapy is interrupted when the therapist goes on vacation after a long and hard work, and the time allotted to Alex is brief and concise, all the time intervening something that would short down the meetings. Alex is also disappointed in this first stage.

In the same year, a second admission to the clinic follows and the individual therapy is systematically started over, doubled by sessions of familial therapy, continuing with interventions after discharge as well. Finally, the medication therapeutic scheme is stabilized, in which the main role has one late generation neuroleptic.

After few months, in the following year (2003), his progress can be significantly seen. Symptoms reduce significantly, he starts gaining autonomy, starts over leisure activities, domestic activities or educational activities, too. In 2004, he succeeds in passing the graduation exam. His father's health conditions get worse and he starts taking care of him. They get out for walks together, he reads to him, they do crosswords together, they talk...

In 2005, his father dies after a stroke. Alex passes well over the event, even if the therapy team is waiting for a relapse. After this event, which Alex finds shattering, the family remains without the father's financial help. Alex looks for a job, he finds small kind of jobs (merchandiser, seller, and so on), and meanwhile he continues with his medication treatment and the individual psychotherapy (with a reduced frequency). He assumes even more

seriously the family responsibilities. „I was provoked to get out of my shell and do the things my father was responsible for."

In 2007, he finds a stable job, closer to his qualification, a job where he handles quite well, and he is appreciated for his work, enthusiasm and optimism, he has excellent relation with his coworkers. Currently, he works for the same job, he is appreciated to the same degree and he is as much as satisfied. Finding a stable job brought a new meaning to him, he feels useful.

He lives with his mother, with whom he has some tense moments, whom he handles quite easy. He acknowledges that the disorder has changed his life. In a good way. When asked about his hypothesis on the disorder, he acknowledges that the main vulnerable factor was the familial environment, with frequent quarrels, and what started the disease was the "prostitute incident", and the factors which maintained the disorder belong to the fact that, on the conditions of symptoms severity, no chances of hope could be seen, he had no trust in him, he had no will, his mother did not support him („my father used to come each day in hospital to see me, my mother used to come once a week"). What helped him : the desire to be again useful, to have an independent life, to find his friends again, to become the one he was before the disease; medication, therapy, "but also the desire to regain what I have lost, to be the same or if I could, even more...", the friends who had fun, happy people from the street or seen outside the hospital window, the desire to live a normal and simple life („so I can watch TV without problems, to follow a football game, to watch a movie, ...basketball, ...ice-cream, ...small things..."), the family support, including his mother's. Most of all, he wants a family with a wife whom he get along very well, children too. In his own house... And this depends mostly on him. And if this will not happen, well life goes on...

When referring to his own person with seriousness, Alex emphasis on sociability: he considers himself a sociable and friendly person, empathic as well, he is decent, likes to entertain people, is appreciated by others, but also with a tendency to be liked by others. He enjoys life, is tenacious when he is interested, faithful, good in what he does, skillful, gentle, understanding, with a sense of humor, incurable optimistic. He is at peace with himself, very happy with „the new person" he became.

1.2 Evaluation

In the remission stage, Alex was evaluated from five perspectives: the personality perspective, the cognitive adjustment methods perspective, the metacognitive adjustment perspective (thoughts control), the cognitive insight perspective, which can provide an image for the flexibility as well as for resilience.

1.2.1 Evaluation instruments

5 instruments were used:

1. DECAS (Sava, 2008) – personality inventory based on the „Big-Five" model with 97 items. [7]

2. Thought control questionnaire (TCQ, Wells and Davies, 1994), comprises 30 items whose answers aim to information from 5 fields: distraction, punishment, reappraisal, worry, social control. The instrument measures methods of adjustment to unpleasant , intrusive / unwanted thoughts, forming self-adjusting metacognitive strategies. [8]

3. Cognitive-emotional coping evaluation questionnaire (CERQ, Garnefski, Kraaij and Spinhoven, 2001) is a multidimensional instrument which measures the cognitive adjusting strategies used for emotional adjustment, after the person had lived certain negative events or situations. [9]

It comprises 36 items whose answers aim to 9 fields: *self-blame* – thoughts through which we blame ourselves; *acceptance* – thoughts through which we resign; *rumination* – thoughts through which we continuously think to the feelings and ideas associated with the negative event; *positive refocusing* – thoughts about pleasant things and not the event itself; *refocus on planning* – thoughts connected to the steps that are to be taken for confronting the event; *positive reappraisal* – attributing a positive significance to the event in terms of personal development; *putting in perspective* – thoughts through which we minimalize the event gravity, compared to other events; *catastrophizing* – explicit accent on the gravity, theory provoked by the event; *other-blame* – attributing the responsibility on other for what happened.

4. Beck Insight Cognitive Scale (BCIS, Beck et al., 2004) is an instrument that measures the cognitive insight, consciousness capacity of it's own mental function, to recognize personal cognitive distortions, to evaluate and test them, as well as to take into consideration some more realist interpretations of events. [10, 11] The cognitive insight has two concrete dimensions in two subscales: self-reflection, that is the availability to admit the possibility of failure or error, corrigibility and recognition of the wrong reasoning and self-certitude, namely the tendency to excessive trust in oneself, excessive trust in the validity of personal beliefs. [10, 11]

5. Resilience scale (Wagnild şi Young, 1993) is an instrument with 25 items that follows a theory of resilience, aiming at five components [12, 13, 14] and which can be applied online. [15] The five resilience components are: life with a meaning, perseverance, soul balance, trust in oneself and existential solitude (to make feel good with your own person).

1.2.2 Evaluation results

As far as personality concerns, the Alex's DECAS profile shows high scores to extraversion (sociable, active, optimist, and so on) – T = 61.70 and to agreeableness (understanding, malleable, cooperative, and so on) – T = 65.50, balanced scores at openness – T = 51.50 and emotional stability – T = 50.50, low score to conscientiousness (confused, inconsistent, untidy, but also flexible, tolerant to unstructured tasks, and so on) – T = 35.20.

As for the thought control, Alex tends to accomplish it more through distraction (D = 18) and through social control (S = 14), then through punishment (P = 10), worry (W = 11) or reappraisal (R = 11).

As far as cognitive adjustment concerns, Alex tends to use mainly positive refocusing (15), refocus on planning (15), positive reappraisal (15) and putting into perspective (14), and least to use catastrophizing (6), other-blame (6) and rumination (8).

Alex has a modest capacity of cognitive insight, with levels close to self-reflection and self-certitude (Sr = 11, Sc = 10, BCIS Composite Index = 1).

The result to the resilience scale is a moderate one (142).

Discussions

The data do not suggest a spectacular profile only insofar as they many times contradict the expected perspectives on evolution. Alex confronted with different adversities: social, familial, financial, and psychopathological. He overcame them and became not the person he was before, his recovery assumed becoming a „new person". All that happened was expected to happen, according to the data in the field, to place his destiny more towards persistence, chronicization of the obsessive – compulsive disorder and, implicitly of functional impairment. Thing did not happen, though the evaluation results do not show unusual qualities or coping strategies. The only constantly differentiating aspects are sociability and optimism, probably insufficient for explaining resilience.

The coping strategies mainly used, as well as aspects revealed at the personality level might be eventually explained through the concept of *emotional flexibility*, a coach type of resilience indicator with reference to the ability to flexibly answer to the change of emotional circumstances. [16]

Conclusions

The data of this case can bring confusion due to the fact that it do not register in all its aspects, in a clear frame in which to mention without any doubt the vulnerability or the protective factors. In fact, these factors, in general, cannot be described as different facets of the same coin, being necessary their „unpacking" [17], and this case might seem to suggest this fact.

The case presented might be an example of salutogenic approach [18], in which the factors that promote health, recovery, resilience are more relevant than those factors that suggest the ways through which people fall sick: beyond the risk - health, beyond the remission - life quality, beyond the repetition - resilience.

Abstract

The presentation proposes a brief analysis regarding the psychosocial situation of people with muscular dystrophy in Romania, both in terms of individual situation and in the concrete nature of the relationship between society and the individual. The analysis represents a challenge because it is a less explored topic in scientific papers from Romania. Muscular dystrophy is an incurable hereditary disease, which often cannot be detected in an early stage. The disease occurs most often in adolescence, so that a perfectly healthy child can become a sick person dependent on others, and finally, came to be an adult dependent on society. In addition to locomotor disability, the cause of the disease, the whole organism is affected, acting even on vital organs. Thus, the needs of a person with muscular dystrophy go beyond the borders of locomotor mobility needs. The lack of official data on this category of people is an impediment in understanding the disease evolution. For a better understanding of the situation of a muscular dystrophy person, the article structure focuses on analyzing the factors / issues that provide an overview on this problem. In the first part it was taken into account the theoretical framework of the disease, surprising the means through which social protection is provided for people with muscular dystrophy, both in terms of legislative and institutional. While in the second part of the article, we intend to capture stages of disease, development and social impediments through a case study applied to a person with muscular dystrophy, detailed aspects through statements and interpretations / perceptions of her and of an NGO representative. Moreover, we also focused on factors that contribute to their social integration/ reintegration.

Keywords: disability, muscular dystrophy, individual, protection, psychosocial impact.

The challenges of proposed theme

1.1 The general theoretical framework

According to the International Organization for People with Disabilities, disability is defined as "*the result of interaction between a person with a disability and the barriers related to social and attitudinal environment that she can hit*" [1]. This is perceived as a social condition and not a medical condition.

According to the definition given by the World Health Organization (WHO) disability is the *"restriction or absence of (resulting from a disability) a capacity (ability) to perform an activity in the manner or to the level considered normal for a human being"* [1].

At European level, disability is seen as a problem of society as a whole. This is transposed into training and permanent adaptation of all parts oregarding life, in order to include and maintain people with disabilities into the mainstream of social life. At national level, in legal terms, a person with disabilities is classified as "handicapped person". The most relevant legislation in this domain is the Disability Law 448/2006, regarding the protection and promotion of rights of persons with disabilities, amended in 2010. According to the law *„handicapped person, in terms of this law, are those who, because of some physical, menthal or sensory problem/ disorder, are missing the abilities to develop normal daily activities, needing special protection measures to support recovery, integration and social inclusion"*[2]..

Today, the term "disability" is often used to indicate the disadvantage or to decrease the activity caused by the contemporary society way of organization, which gives little importance to people with disabilities, excluding them from social life.

Physical disability is characterized by the inability of an individual to perform specific tasks, such as the flexibility of a person, and also the ability to move objects (by her/him) from one place to another. Moreover, physical disabilities is a sum of heterogeneous group of conditions, based on various causes. The most common of these are: nervous system disorders, spinal cord injuries, muscular dystrophy, cerebral palsy, cardiovascular disease, etc.. Physical disabilities can take different forms, can occur at any age and may be temporary or permanent, fluctuating, stable or degenerative and can affect the whole body or body parts [3].

Muscular dystrophy (MD) is a group of rare inherited disorders characterized by progressive damage to body muscles, resulting in muscle weakness and disability. Muscular dystrophy is translated through progressive weakening of muscles, particularly skeletal muscles (voluntary controled by the brain). As the the disease evolve, the necrotized muscle fibers are replaced by connective tissue and fat [4]. There are several types of muscular dystrophy: Duchenne, Becker, Emery-Dreifuss, limb-girdle form, facioscapularhumeral, distal, oculopharyngeal, congenital, etc. [5]. Currently, there is no cure for this type of disease, the therapeutic measures have the aim only to slow down the disease evolution.

1.2 Social protection of people with muscular dystrophy: legislative and institutional approach

From a legal perspective, protection of persons with disabilities, muscular dystrophy by default is provided, primarily, by several regulations which will shortly be presented below.

According to *Article 50 - Protection of persons with disabilities* from *Constituion,* the State carries out a national policy of equal opportunity, treatment and prevention of disability, in order to have an effective participation of persons with disabilities in community life, respecting the rights and duties of parents / guardians [6].

Another regulation is *Law no. 448/2006* regarding the protection and promotion of rights of persons with disabilities, republished in 2011, with subsequent amendments. In the domain of education, according to Article 15, paragraph (1) "*Persons with disabilities have free and equal access to any form of education, regardless of age*". In terms of accessibility, Article 61 refers to the promotion and implementation of the concept *Access for all*, in order to prevent the creation of new barriers and new sources of discrimination [2]..

The Article 1 of *Law No.202/2002* regarding equal opportunities and treatment between men and women it covers the measures which promote equal opportunity and treatment between men and women, in order to eliminate all forms of discrimination based on gender, in all spheres of public life in Romania. According to Article 2 of the same law, such measures are applied in education, employment, health, culture and information, policy, participation in decision-making, provision and access to goods and services, and in other areas covered by special laws [7].

According to Article 2 of *Law no. 116/2002* on preventing and combating social exclusion, the subject of the law is "to ensure effective access, in particular for young people, to elementary and fundamental rights, such as the right to a job, housing, healthcare, education as well as the establishment of measures to prevent and combat social exclusion and mobilizing institutions responsible in this field"[8].

From an institutional perspective, the main national actors whose work has an impact on the protection of individuals with muscular dystrophy are:

- *The National Council of Disability from Romania* develop services that bring into focus and raise the awareness on policy change, attitudes and practices regarding disability, towards the European and international policies which promote the disabled person as the main subject of social policies, actor of his own integration, active participant in making decisions that concern directly his own person [9].
- *National Institute for Prevention and Combating Social Exclusion of People with Disabilities*, in achieving its goals, it performs a series of tasks, including: develop educational programs, special protection programs required for disabled persons (prevention, rehabilitation, socio-professional integration), develop the standard in the promotion of their rights [10].
- *General Directorate of Social Assistance and Child Protection* ensures the implementation of social policies and protection measures for people with disabilities. Services developed in this Department meet the constantly changing needs by promoting and implementing projects targeting all categories of beneficiaries of social assistance [11].
- *General Directorate for Persons with Disabilities* coordinates at central level the activities for special protection and promotion of persons with disabilities rights, developing policies, strategies and standards in promoting the persons with disabilities rights, ensuring proper monitoring of the application of the regulations [12].
- *National Organization for People with Disabilities in Romania*– aims to create favorable conditions for equalization of opportunities in order to affirm and have a full integration of people with disabilities in Romania at all levels of community life: social, professional, educational, cultural, sports, etc. [13].

- *Association of People with Muscular Distrofy from Romania* runs integration activities for people with muscular distrofy, actions to support their family, educative actions for their tutors, traininng actions for the association members in order to make them know their rights, cultural and leisure activities [14].
- *Information and improving quality of life Center for people with muscular dystrophy* aims to defend the rights of people with muscular dystrophy and provide the medico-psycho-socio-professional framework and spiritual support in order to improve the quality of life and their integration into society. The association also aims to support, in some cases, people in need both because of disability and poor material situation. [4]
- *The Association for Supporting Physically Disabled Children from Romania* provides lobby and advocacy services, social networking (camps, leisure activities etc.); Counseling for parents; transport; material support for families that are having children in care/young people with physical and/or associated disability (within the donations received by the organization); Distribution of aids and hygienic and sanitary materials: wheelchairs, walkers, crutches, diapers etc. [15].

Perceptions and attitudes concerning the issues of people with muscular dystrophy - case study

If in the previous section we have shown briefly those institutional and legislative means through which are respecting the rights of people with physical disabilities, and by default of those with muscular dystrophy, in the following we will capture perceptions across the issues faced by them. Thus, we will present the particularities of persons suffering from muscular dystrophy. The scientific approach consists in providing a qualitative interview with a NGO representative, and one with a person suffering from muscular dystrophy, based on specific semi-structured interview guides. The approach was oriented towards a series of features aiming the inclusion/exclusion of them, such as education, public opinion, accessibility, access to the labour market, financial dependence/independence, and so on, designed to surprise psychosocial impact due to the effects of the disease upon persons with muscular dystrophy.

There are several types of dystrophy, as shown in section 1.1., but we will focus on the psychosocial impact that it caused by **progressive dystrophy limb-girdle form.** This type of dystrophy is "a form of muscle fibre injury involving limb-girdle muscles (at shoulder or pelvic level)" [16]. The severity of this type of dystrophy (being an incurable disease that leads to a series of disorders on vital organs), lead to a major psychosocial impact experienced at individual level: *„Even if there is no treatment to cure the disease (incurable) for muscular dystrophy, through different medication or therapies may be obtained a slowing down the course of disease. I can say that it is a disease that in time affects the whole body. From kidneys, heart, liver, to everything".* (woman, person suffering from muscular dystrophy)

Integration of people suffering from muscular dystrophy is influenced by, among other things, the **educational level.** Even if Romania had an upward trend line in terms of education, people with disabilities have a lower probability of attending school, according to the WHO Report - About Education (2011) in 2002 only 59% of children with disabilities aged 7 to 15 years were enrolled in a form of education [17]. The lack of education regarding this group of people has a major psychosocial impact on individuals, with evidence on its direct impact on quality of life, taking into account the impact created on the financial situation. Often parents are the ones responsible for this situation. As a protective method correlated with financial difficulties, they keep their children away from education. Keeping them away from the external environment, social exclusion of people with disabilities is inevitably reached:*"I will give you an example; we have a young girl, 22 years old, and has only 4 classes. [...] She grew up in a family where the parents had gaps and did not know what to deal with first. [...] Most of them are illiterate. Even if you are in a family, the family is the one who does not send them to school as a protective measure. They think that the child might get hurt".* (NGO representative)

There are a series of factors that lead to exclusion of education to the people suffering from muscular dystrophy. First of all health status, then a number of factors such as accessibility, physical and financial dependence on others. A final reason identified would be the lack of trust across the access to the labour market, especially in small towns. Specific courses adapted to their skills and preferences could lead to both personal development and might increase the value of their own power: *"It looked pretty hard for me to commute, especially since I have an seriously car sick, or to stay at home or in the host was just as hard because I needed help and there was nobody to go and live with me. Then at the faculties nearby are many stairs and so I cannot manage to climb them, so I have to give up. Especially since I live in a small town and employment opportunities were minimal.* [...]*To do other studies currently I do not wish, however I would like to make some pastry / cook classes because I am passionate about culinary arts."* (woman, person suffering from muscular dystrophy)

Education and health status are the main factors that influence **access to employment** in respect of people with muscular dystrophy. So we cannot talk about a specific situation across the social and professional integration, given that very few people with muscular dystrophy are active in the labour market. According to the report "Diagnosis: Excluded from the labour market. Barriers to employment of people with disabilities in

Romania " were active in the labour market only 12.7% of disabled people aged 18-55 years [18]. The perception of the diseased person interviewed across from a possible hiring is negative, considering that the companies barley provide jobs for healthy people and a muscular dystrophy sufferer would not be in the preferences of employers: "*There are many healthy people staying at home because they have nowhere to work. So my chances of ever hiring me are quite small. [...]Additionally everyone is looking to hire healthy people able to work".* (woman, person suffering from muscular dystrophy)

The absence of muscular dystrophy sick persons on the labour market is the main factor, interdependent from all the other already mentioned, which leads to their **financial dependence on others**. Their financial resources are only the compensations received from the State or the disability pensions, which are insufficient to cover the needs of a patient with muscular dystrophy: "*My financial resources are small enough in my opinion: a disadvantage allowance 250 lei and now I managed to take a disability pension after the new law, which is 350 lei. [...] I am a person both physically and financially dependent on others. [...] the money she receives are not enough even for paying all the bills, not speaking about buying food, or fruits, or something to wear and other things necessary for women. [...] not to mention any medicine, there is no arguing on this."* (woman, person suffering from muscular dystrophy)

Financial situation directly affects the **access to health services.** Lack of access to quality services steadily lead to acceleration of the disease condition, and thus to an unstable emotional state. Moreover, the access to more specific health services for muscular dystrophy patients is essential, there cannot be taken into consideration other factors that are required for an individual (e.g. labour market access) if nothing is done to improve their health status: „*Unless they have access to hospital services, is useless to think about the insertion on the labour market.*" (NGO representative). Most of the times, because of the lack of funds, people suffering from for muscular dystrophy neglect their health. When accessing health services they prefer to go to the private hospitals, even if resources are limited, because the public system does not have the necessary modern technology in order to improve their health: *"I go to the doctor just in case that my health status is very bad and I can no longer resist, and then I choose to go to a private hospital. [...] at the family doctor or another doctor I should stand in line for some time, hardly mind me, and they often examine me superficially also claiming to give a little attention [...] the old equipment and the people from there give you a pretty quick treatment [...]."* (woman, person suffering from muscular dystrophy)

In Romania there is only one medical centre specific for people with muscular dystrophy (Neuromuscular Pathology Centre "Dr. Radu Horia" in Vâlcele, Covasna county), which in addition to medical services is also providing counselling services: "*At Vâlcele we have a centre where we try to help them in medical terms. But we try to offer them also all the data they need, moreover, we have activities to educate them and to make them wish for more."* (NGO representative)

Regarding **methods of leisure**, these are limited. Most of the time, people suffering from muscular dystrophy stay in the house and performs various domestic tasks. The acceleration and popularizing of various social networking sites make from the **online environment a refuge** for this category of persons, in addition to the primary ways of spending the free time. The online socializing, creating virtual friends, writing on various blogs, are methods that have a positive impact on the emotional state of these people, representing a place where people cannot judge them: *„Leisure time I have a lot because most of the time I am staying at home. I love to cook, I am really passionate about that and this passion led me to enrol in a culinary site, to create a blog where I can also share and exchange ideas with other culinary enthusiasts. [...]The online environment is a place where you can "meet" wonderful people with which you can tie a friendship [...] in those moments when I am alone is a good refuge for me."* (woman, person suffering from muscular dystrophy)

The balance of the **mental state** of a person is essential, and for a person suffering from muscular dystrophy this state is affected in particular by the health condition and life circumstances [19]. Thus, the absence of such balance based on the isolation from the external environment, is sometimes leading to depression: "*The lack of movement, the fact that you sit more than you work, that you cannot interact too much with others, and you cannot be a normal person are this all leading to depression.."* (woman, person suffering from muscular dystrophy)

In terms of emotional status, **family support** is often the one that creates the balance that these people need, those are the persons with whom they consider themselves "normal" people. At the same time it is not excluded to consult a specialist, if necessary:" *[...] all my beloved ones, especially my mother and my relatives supported me and been with me from the emotional point of view. [...] they always treated me as if I were a normal person, they are going anywhere with me without being embarrassed. [...]But if it would be necessary to consult a psychologist, I would do this [...]"* (woman, person suffering from muscular dystrophy)

The **public opinion attitude** regarding people with disabilities has a major psychosocial impact over them. Thus, for a balanced life from the emotional point of view "people with disabilities are those who should be given equal opportunities to live a fulfilled life and our attitudes towards them contributes to the image they perceive "in their social mirror" [19]. Most of the times public opinion concerning people with disabilities is hostile, and this aspect is felt at full intensity by them and it affects their mental state, reaching to perceive that

they are not included in the society to which they belong:" *It is still quite hostile […]This is also making them frustrated."* (NGO representative) and *„Some people treat me like a normal person, others look away, comment, laugh and even make fun of me. I often feel embarrassed and get to think that my place is just at home and I do not really supposed to go out, to feel how my illness bother the others. [...] there are things that get you down, make you understand that you are different from others that you do not belong in such a society, that those like me, sick people, should be locked up in a distant place or if it is possible not to exist at all, not to bother the healthy and not tangled their lives anymore."* (woman, person suffering from muscular dystrophy)

Conclusions and recommendations

Disability can be considered a specific form of social oppression and focuses on attitudinal barriers, which prevent persons with disabilities to enjoy equal opportunities in domains as education, employment, housing, transport, party, leisure, etc.. In terms of legislative and institutional social protection of disabled people, including those suffering from muscular dystrophy, it is provided by laws and regulations in the domain, as well as by the relevant institutional actors which, in their field of activity, intersects with issues regarding these categories of people.

Due to the specific needs of people suffering from muscular dystrophy is important for Romanian society to greet their integration activities at all levels. It is necessary to intervene in order to reduce psychosocial impact felt by muscular dystrophy patients. The effects of this type of disease on the entire body has a major influence across multiple levels of the individual's life, such as education, access to employment, social life, leisure activities, family life, personal skills, valuing their own powers, etc.. Both families of sick people and Romanian society are responsible for the adaptability of patients with muscular dystrophy. The family is responsible for the intention of excessive protection and society for not giving sufficient understanding / attention to these categories, showing an attitude of ignorance. It would be useful to focus primarily on the education of these patients (including keeping these people in school for as long as possible), regardless of severity of the disease they have, and the development of educational programs according to their abilities. In general, their only direct income is the compensation from the state or invalidity pension, so it is recommended to introduce active measures which may include stimulating methods in terms of employment, insofar for people with disabilities to enter the labour market and for employers to hire them.

People suffering from muscular dystrophy tend to be among the most vulnerable groups because of their addiction to others, both financially and in terms of the physical. This dependence is fuelled mostly by this specific disease, which seriously affects their vital organs in the body. The family environment is the most important factor regarding emotional balance of this category of people, followed by the virtual environment that tends to become a refuge in their moments of loneliness. The refuge in the online environment comes as a result of public hostility at times when they are present and visible in society. Thus, it is imperative, among other things, to run information, sensitization and awareness campaigns through which there will be made known that such persons may become / are "normal" people, as long as society is helping them to become independent.

Abstract

Introduction. Studies in the field of resilience in maltreated children show that the main positive adjustment to trauma involved behavioral and emotional skills, social skills and school success.

Objective. To identify the resilience protective factors in institutionalized children after they were exposed to various forms of abuse within the family.

Methodology. We studied children and adolescents aged between 11-18 years from various child welfare institutions in Timis County where they were admitted for at least 1 year, after they were exposed to various forms of abuse in the family. The control group consisted of children between the ages of 11 -18 years also exposed to abuse in the family but still living in the family. All children completed the Stress Related Growth Scale to assess the consequences of abuse as well as family separation, and Youth Self Report (YSR) of the battery of tests ASEBA (Achenbach System of Empirically Based Assessment) to assess competencies of emotional, behavioral and social and scholar adjustment.

Results. The results showed that children and adolescents in institutions have more social and scholar skills and less behavioral problems as positive factors of resilience but also many emotional problems as a consequence of trauma and institutionalization

Key words: resiliency, children, maltreatment, factors, institutionalization.

Introduction

The impact of maltreatment upon children depends on risk factors, protective factors and the context of maltreatment. Abused child can develop a way of inner development marked by mistrust and rejection which will lead to a lack of social skills. On the other hand maltreatment can have negative consequences for the school performance many children being repeaters or enrolled in special schools.

Also, these children seem inattentive, unable to understand the workload, anxious, unpopular in the eyes of colleagues, which can generate a series of conflicts. In the cases of family maltreatment disclosure and intervention will lead to separation from responsible person (placing abused child in a family or institution), with consequences on the whole family ([1], [2]).

Cases of child welfare system that lead to the placement of children outside the family often show that these children suffer from a complex combination of mental health and psychological problems ([2], [3]).

Entry into the child protection system but also involves difficulties adjusting to new people, to different rules that may have consequences in terms of emotional development and behavior. Regarding resilience in maltreated child, some authors define resilience standard [4] as a high level of functioning in three areas: pro social behavior, lack of behavioral symptoms and school success.

The objective of the study was identification of resilience factors in institutionalized children after they had been exposed to different forms of abuse within the family.

Methodology

There had been studied 69 children and adolescents aged between 11 and 18 years, from different child protection institutions from Timis county, where they have been admitted after being exposed to different forms of maltreatment (emotional abuse, physical and emotional abuse, sexual abuse) within the family and where they are living for about 1 year (Table 1). The control group had been formed from 43 children aged between 11 and 18 years, who had been also exposed to abuse, but still living in the family (Table 1).

Table 1. Characteristics of the participants

		Institution (n=69)	Family (n=43)
Age: mean(SD)		14,23 (1,96)	14,09 (2,21)
Gender n (%)	Male	22 (31, 9%)	17 (39, 5%)
	Female	47 (68, 1%)	26 (60, 5%)
Abuse type n (%)	Emotional	1 (1, 4%)	13 (30, 2%)
	Physical and Emotional	47 (68, 1%)	28 (65, 1%)
	Sexual	21 (30, 4%)	2 (4, 7%)

All the children completed Stress-Related Growth Scale- SRGS, a self-evaluation standardized instrument, which measures the development determined by confronting with a negative event. The Scale is composed of 15 items that evaluate the perception of post-traumatic development in major development dimensions: better social relationships, a greater trust in personal resources, new and improved coping mechanisms. For evaluation of children emotional, behavioral and social and scholar adaptation competencies there had been used Youth Self Report (YSR) from the battery of tests ASEBA (Achenbach System of Empirically Based Assessment). YSR has three scales: competencies scale that measures activities, social school skills of study participants, a scale that measures syndromes, respectively behavior and emotional problems of the children and a DSM derived scale (Diagnostic and Statistical Manual of Mental Disorders) that identifies psychopathological problems of the children according to DSM IV. The instruments were filled in by all children and adolescents from the study after they signed the informed consent form. The results were analyzed according to the mean scores obtained on the two instruments for the subjects in the study group compared with the results obtained from the subjects in the control group; comparative analysis was performed using the test One Way ANOVA's. We also analyzed the results in relation with the type of abuse as well as the correlations between the post-traumatic development, social, school, and behavior and emotional competencies of children and adolescents who participate in the study, using the Pearson's correlation. Statistical data processing was performed using SPSS 17.0 for Windows

Results

The results obtained at Post-Traumatic Development Scale showed that both institutionalized children (mean 21.90; SD 4.60) and family children (mean 20.60; SD 6.01) had related post-traumatic development, slightly better in institutionalized children, both mean scores however being in the range of clinical significance (0 -28). According to children's sex, institutionalized boys had a better post-traumatic development (mean 23,18 ; SD 2,5) while depending on abuse type institutionalized children who suffered a physical or an emotional abuse (mean 23,06; SD 3,52) and those within the family who suffered a sexual abuse (mean 23,5: SD 3,53) had a better post-traumatic development. (Fig. 1)

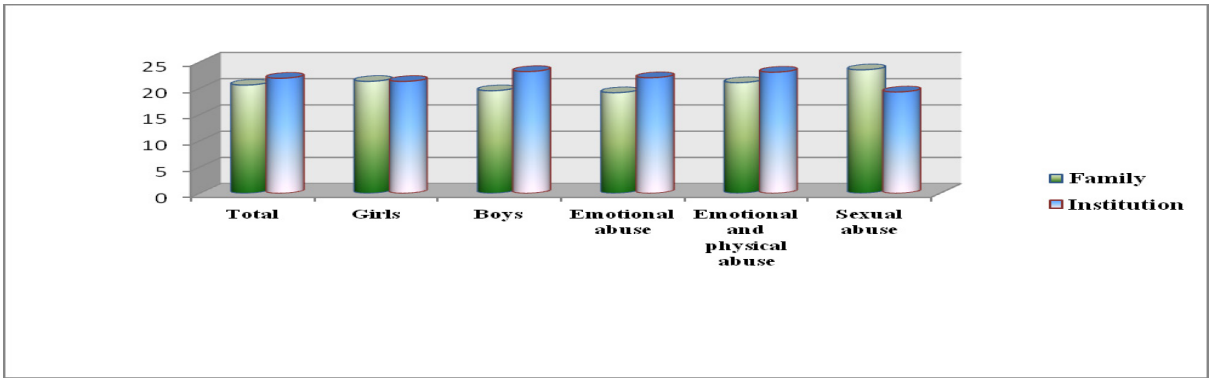

Fig. 1 Mean scores for Stress-Related Growth Scale- SRGS

The results obtained at competencies scales shown that regardless the environment, abused children have decreased school competencies (Fig. 2) , but the remaining children in the family have school skills significantly higher than children inside the institution (p = 0.19), as result of the comparative analysis ANOVA 's. As for the social skills and activities, results were similar for both children inside the institution and children in the family, with a higher score in activities (mean 8.69 , SD 3.08 , respectively mean 8.25 , SD 2.54) compared to the social skills (mean 7.39 , SD 1.95 , mean 6.94 , respectively , SD 2.23), but children inside the institution having many activities and social skills better than those who remained in the family (Fig. 2).

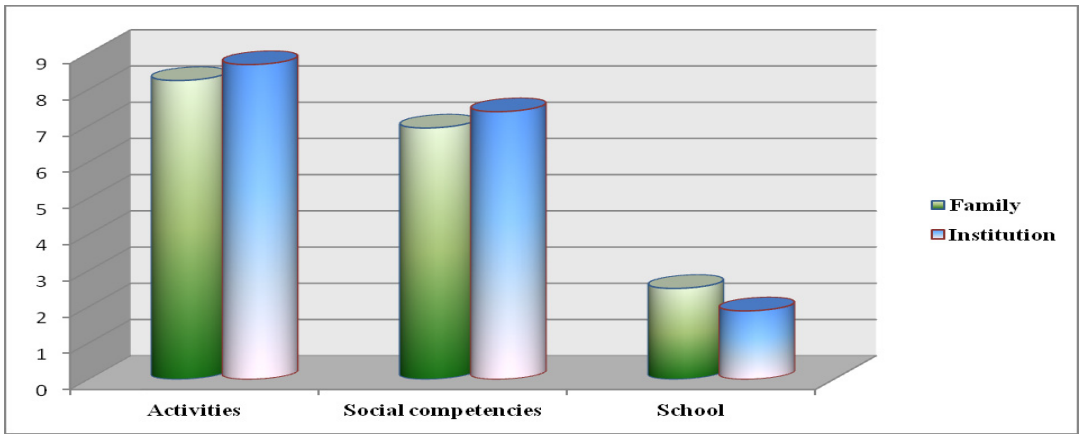

Fig. 2 Mean scores for Competencies Scale

This time also the boys inside the institution are involved in more activities (mean 8.70, SD 3.06) and have more social skills (mean 8.63 , SD 1.95) compared with the other participants in the study. Depending on the type of abuse experienced by children and adolescents participating in the study, the results showed that those who have suffered emotionally and physically and are in the institution participated to more activities (mean 8.48, SD 2.59) and had more social skills (mean 8. 02, SD 1.75) compared to children in the family, but the differences between scores were not statistically significant.

Analysis of results from scales that measure syndromes showed that institutionalized children and adolescents, after abuse and maltreatment had more emotional and behavioral problems compared with those who remained in the family (Fig. 3) with a peak of symptoms in the items anxiety / depression (mean 8.45, SD 4.92), social problems (mean 7.14, SD 3.97) and aggressive behavior (mean 10.54, SD 6.64). Considering the children sex and the type of abuse, the results showed that all the girls participating in the study and sexually abused children and cared for in the institution, had more behavioral and emotional problems, with higher scores at all the items listed above (anxiety / depression, social, aggressive behavior).

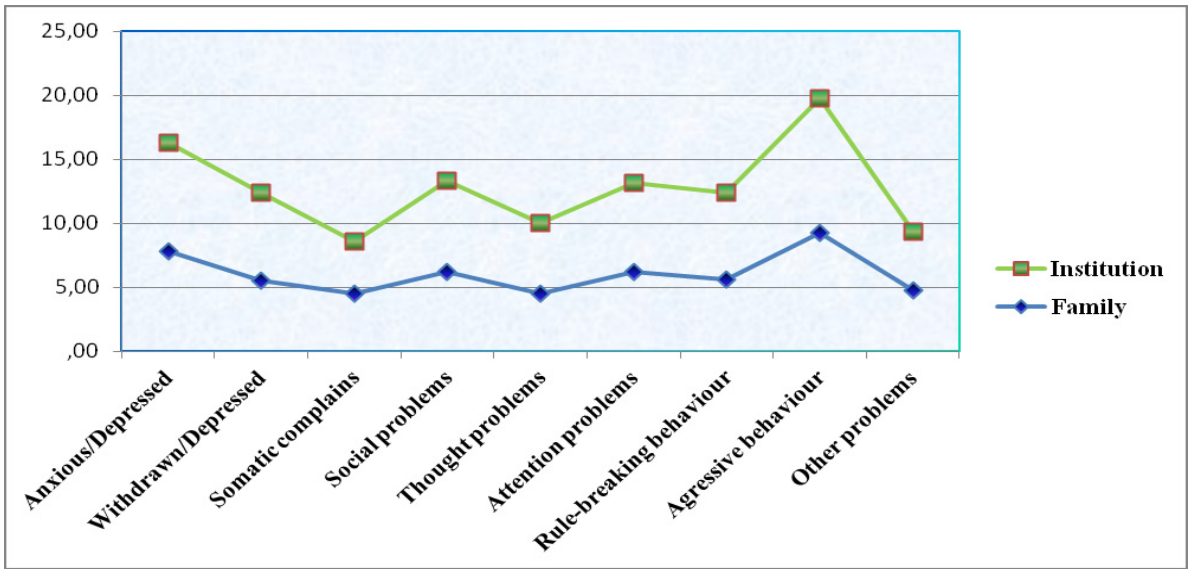

Fig. 3 Mean scores for Syndromes Scale

DSM scales derived results also showed that institutionalized children and adolescents have more psychopathological problems compared to those cared still in the family (Fig. 4), with higher risk of developing emotional problems (mean 8.22, SD 4.45), ADHD (Attention Deficit/Hyperactivity Disorder) problems (mean 5.74, SD 3.1) and conduct problems (mean 6.48, SD 4.97). This time also, all the girls participating in the study and sexually abused children cared for in the institution had more psychopathological problems with higher scores at all the items listed above (emotional problems, ADHD problems and conduct problems).

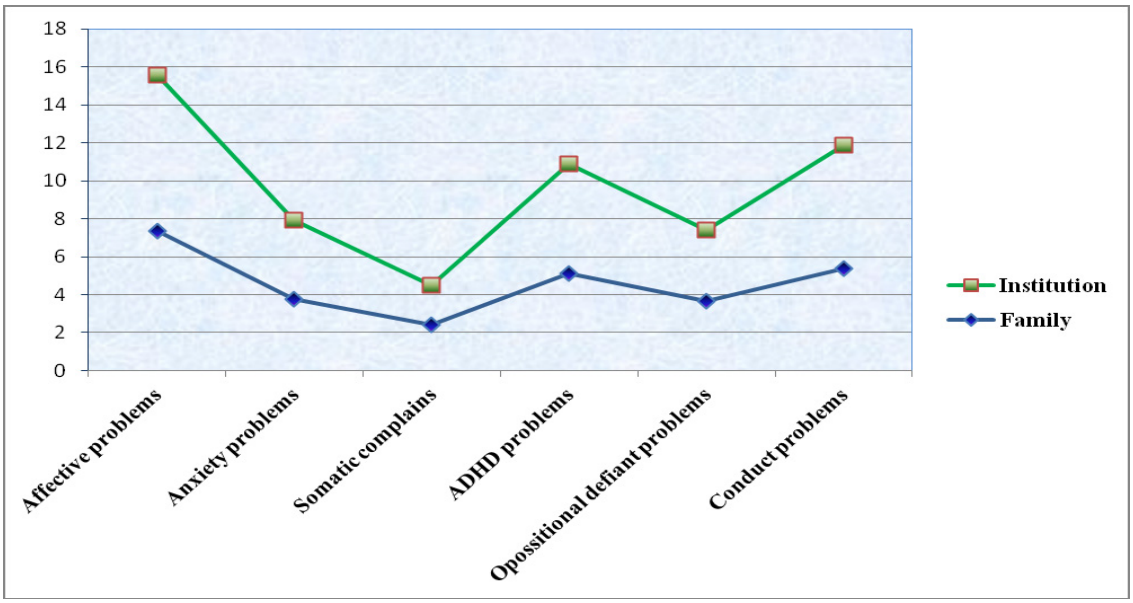

Fig. 4 Mean scores for DSM IV Scale

Correlation analysis between the degree of posttraumatic development, competencies and emotional and behavioral problems of children, has shown that only for the children inside the institution there are many statistically significant correlations, respectively positive correlations between posttraumatic development and social skills ($p = 0.033$), and negative correlations between posttraumatic development and anxiety / depression symptoms ($p = 0.006$), somatic complaints ($p = 0.14$), social problems ($p = 0.002$), attention problems ($p = 0.001$), breaking the rules ($p = 0.031$), Aggression ($p = 0003$), affective problems ($p = 0.02$), somatic problems ($p = 0.031$), ADHD ($p = 0.001$), oppositional behavior ($p = 0.001$) and conduct problems ($p = 0.002$).

Discussions

Recent studies suggest that only a minority of maltreated children develop Posttraumatic Stress Disorder, probably as a result of interaction between risk and resilience factors. In recent years is discussed the importance of resilience to trauma and posttraumatic development phenomenon in children. Children and adolescents who reach a traumatic development show more compassion and empathy for others, psychological and emotional maturity, increased resilience, improving interpersonal relationships ([5], [6].

Many children were taken from their biological parents and were placed in care institutions due to maltreatment. That means that their attachment bonds were discontinued and have lived threats and feelings of insecurity, with severe consequences on the regulation of emotions, attention, and social relations [2]

The idea of this research started from the clinical experience of working with institutionalized children after they suffered various forms of domestic abuse. Often we noticed that although they were removed from the traumatic environment and included in a care institution where they received care, education and adequate tuition, these children had many emotional and behavioral problems, especially anxiety, depression and aggressive reactions. In the present study, however, we intend to identify protective factors involved in resilience of maltreated children in the family related or not to institutionalization phenomenon.

As the results showed, these children had better social adjustment, were involved in more extracurricular activities and friendships than children subjected to various forms of abuse in the family and remaining in parental care. Participation in extracurricular activities provides the opportunity for positive encounters with peers and adult role models, provides the ability to feel appreciated and favors the acquisition of concepts such as safety, stability, and predictability [1].

Also, the post-traumatic development, namely the ability children and adolescents participating in the study to have greater confidence in personal resources and develop appropriate coping mechanisms maltreatment- trauma related was found to be better in institutions than children who remained in family.

Our hypothesis, that the placement of children in institutions care after abuse within the family may be associated with the emergence of psychopathological problems was confirmed. Thus, our results showed that these children had more emotional and behavioral problems compared with those who remained in the family, especially problems of anxiety, depression, social networking and aggressive behavior and that the risk of developing psychopathological disorders, such as affective disorders, ADHD and conduct disorders. This can be explained by the fact that although institutional placement is intended to provide a protective system to maltreated child, being placed in a safe environment does not induce immediately a security feeling of the child, behavioral adjustment problems may occur and inappropriate reactions to stress.

In our study no significant differences were found between the children problems depending on the type of abuse suffered, slightly higher scores being obtained however in sexually abused girls, the results being consistent with other data in the literature. Children from foster care as a result of sexual and physical abuse and neglect were found to have high levels of externalizing and internalizing problems.

Common diagnoses found in maltreated children were anxiety, depression, ADHD, behavioral disorders, attachment disorders. ([2], [7], [8], [9]). In his study, Lansford [10] concluded that the protective factors of resilience in children who have been physically abused (such as social skills) are related to preventing the occurrence of internalizing and externalizing problems as vulnerability factors (low social competence, low self esteem, low self-regulation capacity) lead to the development of these symptoms. Regarding children evolution after abuse within the family by gender, our results showed that girls from institution had both a lower posttraumatic growth, fewer skills and more emotional problems than boys, it probably because sexual abuse, with the biggest impact on the individual was present in girls. The results of other studies are conflicting regarding the resilience of abused children, by sex, some studies [4] show that girls are more affected than boys after physical / sexual abuse, showing more internalizing symptoms (anxiety depression), boys showing rather relationship problems and aggression, attention disorders; other studies show the opposite ([11], [12], [13]) that boys are more vulnerable to risk factors, often developing behavioral problems as a result of abuse, and relationship quality with peers is better in girls compared with boys who have more externalizing problems, peer acceptance level being considered a protective factor for them.

Finding in our study of numerous correlations between the degree of posttraumatic development, the level of social functioning and emotional and behavioral problems in children and adolescents from care institution after abuse and maltreatment, can lead to the conclusion that for the children and adolescents who have been abused within the family and were included in a protection service, social adjustment, participation in activities, friendship relations and post-traumatic development constitute protective factors of resilience following abuse.

Abstract

Foster children are often in search of affection and can, in some cases, demonstrate this search by violent behavior. These children are subject to mixed feelings toward both their natural and foster homes.

This study is exploratory. The purpose is to identify how growing up in an SOS Children's Village (VESOS) is experienced by children Togolese involved. The aim is to observe the peer pressure and the relationship issues with their foster mothers. A semi-structured interview has been conducted on a sample of 93 VESOS children and 69 ordinary children living with their natural families, aged 6 to 12. The majority of the VESOS children (64.52%) prefer to live in the SOS village rather than in their natural family or anywhere else. Knowing the main indicators of children's individual experiences at the VESOS will help determine the appropriate therapy required for these foster children in Togo.

Key-words: Children, fostering in VESOS, individual experience, resilience, Togo.

Introduction

Foster children have a feeling of loss or abandonment that often makes them constantly circumspect and reactive [1]. Their negative attitudes toward adult people, their feelings and aggressive behavior that they used in the past as a means of survival still exist in their new social environments [1,2,3]. Even if fostering is highly rated as a therapeutic measure, it is necessary to examine the approach to be adopted by their foster parents and its benefits on the child's development [1]. It is therefore quite interesting to take a careful look at the foster children's daily existence in the VESOS homes in Togo. (The VESOS are integrated components of the ''SOS Villages d'Enfants'' which is an International No-Governmental Organization. It is specialized in fostering orphans and abandoned children on a long-time basis.)

Context of child admission in foster homes in Africa and in Togo

From a traditional point of view, child admission in foster homes is interpreted as entrusting the child to the care of the extended family network. The admission rate in foster homes of children aged 10 to 14 in 20 African countries is approximately 20 percent, varying from 9 to 42 percent [4]. Child admission in foster homes is explained by the customary obligations for informal family solidarity, education, protection in case of the death of a parent, child labor contribution, economic reason, the fact that the child belongs rather to the ancestry lineage than to a couple [5,6]. Though this specific child fostering system has played a great protection role in the past, nowadays, it is, however, marred with serious drawbacks due child abuse and exploitation [5].

Individual and family background lives of foster children

Children in foster institutions suffer from a lack of affection due to the death of a parent, desertion, neglect, child abuse, accusation of witchcraft [7]. Previous traumas have a negative impact on their behavior and attitude in their new social environment [1,2,3,8,9].

Personal experiences and feelings of foster children

Foster children have a strong feeling of a great loss. They expect nothing good from adults. They are suspicious of others and, at times, feel torn between their foster and natural families [1]. They show great

emotional greed. They are aggressive, and test the limits of the foster parents' patience. They take the risk of being rejected and sometimes they put in check the foster family [2].

They may want to return to their original parents despite a deleterious life [3]. Nevertheless, foster parents are able to help them build up self-confidence, their efficiency and to develop their feelings of belonging to the same family [1].

Problems and hypothesis

This exploratory study aims to explore how growing-up in a VESOS is experienced by the foster children themselves. The issue is to observe the foster children's relationships with their peers and with their surrogate mothers and to analyze their personal experiences and feelings. Our hypothesis is that there is a significant difference between the VESOS children and their counterparts living in their natural family at their experiences in the following areas: their daily life, their feelings, their emotions and family relationships.

Methodology

This study is carried out on 93 foster children of the three VESOS of Togo and on 69 children living in natural family (control group), aged 6 to 12 years. VESOS children live in these villages for at least three years. These are orphans, children of parents suffering from mental sickness, children accused of witchcraft, abandoned children, neglected and abused children. A semi-structured interview explores their individual experiences, feelings and their family ties. Data from the semi-structured interview were classified thematically and analyzed statistically. Comparison of the two samples with the Z test has identified differences between the two groups of children.

Results

Indicators of children's experiences	VESOS Children	Focus group children
Feeling of well-being in family	45(47.87%)	58(77.34%)* p=0.0001
Feeling of uneasiness in family	39(41.49%)	16(21.33%)* p=0.0069
Positive image of foster mother/ natural mother	95(84.82%)	109(63.37%)* p=0.0016
Acceptance of the child by others and common games	69(62.16%)	79(45.16%)* P=0.0315
Child physical abuse	12(10.81%)	14(08.00%) P=0.5485
Child emotional abuse	11(09.91%)	12(06.86%) p=0.4938
Feeling of being loved by foster mother/natural mother	30(32.26%)	26(38.24%) p=0.4295

**significant difference; figures represent the total numbers or frequencies and corresponding percentages are in parenthesis*

According to these results, the majority of the VESOS children (64.52%) prefer to live in the SOS village rather than in their natural family or anywhere else. They justify their preference by the accommodation comfort, the protection and security (17.95%), the entertainment games and presents (15.38%), the feeling of being loved, and the quality of education (12.82%), the high schooling attendance (12.82%), and the good quality of food (12.26%). The control group children feel more at ease than their VESOS counterparts. However, the VESOS children have a more positive image of the SOS foster mother. Compared to the control group, children VESOS feel more accepted by their peers and prefer to play with them. Children VESOS explain their welfare family by physical conditions, emotional and relational dimensions: to play with other children (21.57%), to have the feeling of being surrounded by friends, to have a good surrogate mother and to be well fed (17.65%).

In contrast, among children who don't feel at ease, 13.73% of them point at the death of (a) parent/s or the fact of not knowing their parents, 07.84% report physical and emotional abuse in both the VESOS and natural family homes, 05.88% have frequent nightmares caused by past traumas. 83.08% of foster children appreciate the SOS foster mother's attitude. Approximately 6% denounces physical and emotional abuse, deprivation of food and leisure.

Discussion

The results of the current study are similar to those of the literature review. The daily experiences and the well-being of foster children are less influenced by material conditions than by human relationships [10]. As far as the foster children are concerned, these results highlight the importance of children, family and peer relationships. These children often entertain warm relationships with their SOS foster mothers, their natural family members, with the administrative and teaching staff, and with their peers at school. Relationships with peers [10,11] or with foster siblings [8], could play a protection role when relationships with parents are strained. These relationships could contribute to the psychological, psychosocial development and to children's resilience.

Conclusion

The knowledge of the main indicators of subjective and emotional experiences of the children in the VESOS homes and factors that influence these experiences should guide therapeutic interventions in favor of children in Togo. The VESOS homes provide an appreciable social protection to foster children. These children like the material comfort and the care of their foster mothers. Though they are safe from many dangerous situations to which they were exposed in their natural family homes or customary adoption situations, traumas they went through must be taken into account more.

Abstract

This doctoral project focuses on the study of resilience in cases of incest father-daughter and stepfather-daughter-in prepubertal and pubertal period. Based on an interactionist perspective building of resilience, this study takes support on the complementary psychological, intrapsychic and environmental factors. In this context, it attempts to clarify the possible features that could be associated with a clear postage trauma of incest.

Keywords: Resilience, incest, doctoral research, preliminary data

Esquisse du phénomène de la résilience

Depuis quelques années, dans le domaine de la santé, des sciences humaines et des études cliniques, on assiste à un développement important de la recherche portant sur le phénomène de la résilience. Pensons, entre autres, aux études d'Anthony [1] sur les enfants " invulnérables (ce terme ne fut pas retenu, car il suppose une carapace solide et impénétrable qui permettrait d'affronter toutes situations traumatisantes, ce qui va à l'encontre de la résilience qui stipule qu'on n'est pas résilient toute la vie ou devant toute situation d'adversité.), de Garmezy [2], [3], et de Rutter [4], [5] auprès d'enfants vivant en milieu défavorisé, de Baddoura [6] et de Manciaux et Tomkiewicz [7] portant sur les conflits du Rwanda et du Kosovo, sur les catastrophes naturelles et sur les enfants des rues, ainsi que les études faites auprès des enfants victimes de maltraitance, de négligence [8] et d'abus sexuels [9], [10], [11] et [12]. Au regard de ce qui précède, c'est un fait que le phénomène de la résilience a toujours existé, bien que son terme soit quant à lui récent. Il proviendrait notamment des études de Werner [13] faite auprès de 698 enfants vivant dans des milieux défavorisés dans les îles de Kauai à Hawaï. Alors qu'une abondante littérature fait un portrait pessimiste de ces enfants, ces mêmes études montrent l'existence de cas atypiques, de leur facilité à surmonter les agents stresseurs et les épreuves de la vie. Ces personnes dites " résilientes " parviendraient à se protéger des séquelles habituellement rattachées à des expériences traumatisantes.

Au fur et à mesure que la recherche se développe, on assiste à la production d'un nombre considérable portant sur la notion de résilience. Toutefois, à la lumière de l'ensemble des recherches produites au cours des dernières décennies, la possibilité d'une éventuelle absence de séquelle apparaît à priori sujette à caution. En effet, les auteurs qui s'intéressent au phénomène de la résilience s'entendent sur le fait qu'il ne doit pas être perçu comme un antidote [14] qui inhiberait la souffrance de l'individu, ni comme une force inconditionnelle et statique dans le temps [15], [16]. À titre d'exemple, l'étude de DuMont, Widom et Czaja [17] démontre que parmi les enfants qui ont été victimes d'abus physiques et sexuels et de négligence durant l'enfance, 48% d'entre eux étaient résilients à l'adolescence, tandis que 24% le demeuraient à l'âge adulte. Ainsi posé, le phénomène de la résilience réfère à un dépassement plus ou moins progressif des traumatismes associés à de la maltraitance, à de la négligence, à des abus physiques et/ou à des abus sexuels ou à toute autre forme d'expérience traumatisante.

L'analyse de l'ensemble des études permet d'avancer que la résilience est un phénomène étant le produit de la contribution simultanée de facteurs de protection individuels, qu'ils soient d'origine génétique ou issus de compétences acquises et interindividuelles comme qualité initiale de la relation mère/enfant ou de la présence de tuteurs d'attachement [18]. Toutefois, et bien que la littérature traite de plus en plus de ce phénomène, on en sait encore très peu sur la manière dont ces facteurs interagissent [19]. C'est particulièrement le cas dans le domaine de l'inceste, étant donné que jusqu'à récemment, il existait un consensus clinique sur l'impact à long terme d'un tel trauma [20]. La recension des écrits de Lapointe et Le Bossé [21] portant sur le

phénomène de l'inceste et de la résilience montre que, parmi les conséquences les plus observées, on retrouve la dépression, la perte d'estime de soi et la stigmatisation [22], les sentiments de honte et de culpabilité ainsi qu'une sexualisation traumatisante [23], de même que la revictimisation [24]. Il apparaît également que les effets possibles de l'inceste varieront considérablement selon que le parent non abuseur sera capable ou non de fournir un soutien à l'enfant [25], [26], [27], [28] et [29]. À l'ensemble de ces traumatismes, il faut finalement ajouter celui de la « perte » du parent incestueux, qui, dès lors, n'est plus en mesure de jouer véritablement son rôle auprès de l'enfant. En fait, la perte se rattache particulièrement aux liens et à la relation dont l'enfant a besoin dans son développement.

En dernière analyse, la notion de résilience oblige à repenser la théorie selon laquelle les personnes victimisées demeureraient dans un état de victimisation toute leur vie. Ceci est particulièrement vrai en ce qui concerne celles qui ont vécu l'inceste et qui sont considérées comme résilientes. Les études montrent de plus que la résilience est un phénomène complexe qui doit être appréhendé comme tel par les chercheurs intéressés par cette réalité [15]. Concrètement, cette complexité a conduit les chercheurs à adopter une perspective interactionniste du construit de la résilience, laquelle prend appui sur la complémentarité des facteurs intrapsychique, psychologique et environnemental [30]. Dans cette optique, la présente étude propose un « arbrésilient » comme modèle symbolique pour comprendre la trajectoire de la résilience chez les personnes victimes d'inceste. Ainsi, les racines symbolisent les facteurs intrapsychiques, le tronc les stratégies de *coping* qu'on peut observer et la sève le lien d'attachement nourrissant. (Le modèle de l'arbre avec la germination a été produit par l'auteure et il est décrite plus spécifiquement dans la recherche doctorale. Toutefois, il sera présenté lors de la communication au congrès.) Ces trois éléments sont interactionnels et se veulent essentiels au développement de l'arbre.

1.1 Méthodologie de recherche

À la lumière de ce qui précède, il est apparu pertinent de procéder à une étude du construit de la résilience auprès de personnes qui, tout en ayant en commun le fait d'avoir vécu une relation incestueuse, se distinguent sur le plan du tableau clinique. Pour répondre à cet objectif, une étude comparative à double volet a été réalisée auprès des femmes ayant vécu l'inceste durant la période de l'enfance et/ou de l'adolescence de la part de leur père ou de leur beau-père [30]. Le premier volet vise à identifier le profil des participantes avec impacts cliniques traditionnels (PICT) et le profil des participantes engagées dans un processus de résilience (PEPR). Le second consiste à opérationnaliser auprès des deux profils, les trois indicateurs théoriquement associés au phénomène de la résilience dans la documentation sur le sujet. Il s'agit : 1) des stratégies de *coping* ; 2) du lien d'attachement créé dans la relation mère-enfant ou avec un adulte important ; 3) de la capacité de mentalisation.

1.2 1^{e} partie : la constitution des deux profils

La première partie consiste à identifier dans un tableau clinique les deux profils suivants : le profil des participantes avec impacts cliniques traditionnels (PICT) et le profil des participantes engagées dans un processus de résilience (PEPR). Pour constituer les deux profils à l'étude, la démarche typologique et l'analyse de contenu ont été retenues. Dans cette optique, l'analyse typologique a permis d'établir la présence/absence d'éléments spécifiques (PICT *versus* PEPR) alors que l'analyse de contenu a donné une description qualitative et quantitative du contenu manifeste et latent [31]. Parmi les nombreuses méthodes d'analyse de contenu [32], l'analyse thématique est celle qui a été retenue, car elle permet le répérage des catégories conceptuelles prédéterminées à chacun des profils. C'est sur la base de l'ensemble de ces choix méthodologiques que nous avons élaboré la procédure de l'échantillon et des profils PICT et PEPR.

1.2.1 Le profil des participantes avec impacts cliniques traditionnels (PCCT)

Comme en témoignent les études, l'inceste est incontestablement un phénomène traumatique, et ce, malgré que les conséquences peuvent varier d'une personne à l'autre [33], [34]. Dans cet ordre d'idée, les personnes associées à ce profil réfèrent à celles présentant des symptômes cliniques étudiés dans la littérature portant sur le trauma de l'inceste. Elles se sentent sans défense et demeurent dans une position de soumission et de dépendance, comme au moment où elles ont vécu l'expérience incestueuse. Elles ont le sentiment de ne pas avoir de pouvoir sur elles-mêmes ni sur les autres. Plus précisément, elles croient n'avoir aucune influence sur les événements extérieurs, pas plus que de pouvoir les modifier. Dans les cas d'inceste, plusieurs conséquences peuvent en découler, telles qu'un état dépressif, une perte du sens de la vie, une image de soi négative, un sentiment d'impuissance et de désespoir, ainsi qu'une tendance à se blâmer pour l'abus [35], {36], [37]. On retrouve également la confusion dans les rôles et l'hostilité envers leurs mères, leur reprochant de ne pas les avoir protégées. Toutefois, il n'est pas rare de constater qu'elles adoptent la position reprochée à leurs mères, c'est-à-dire de ne pas protéger leurs propres enfants d'un éventuel abus. Les statistiques font état qu'elles

seraient plus susceptibles d'être revictimisées à l'âge adulte et que la revictimisation prendra des formes plus sévères. Tel que le mentionne Foward [38], un des effets pervers du sentiment de victimisation est " cette interminable quête de la clé magique qui ouvrira le coffre aux trésors, l'amour et l'approbation des parents "(p.116). Finalement, les victimes d'inceste se perçoivent négativement, et ce, malgré les réussites. Suite à l'analyse de la documentation sur le sujet, nous avons retenu qu'un état dépressif, une faible estime de soi, une tendance à se blâmer pour l'abus, une perte de sens, la revictimisation et la transmission intergénérationnelle de l'abus sont des impacts associés au profil PICT.

1.2.2 Le profil participantes engagées dans un processus de résilience (PEPR)

Ce profil correspond aux personnes qui auraient la capacité d'être peu perméables aux éventuelles séquelles rattachées à l'inceste [39], [40]. Tout en ne déniant pas l'abus vécu durant leur enfance, elles seraient capables de faire face à cette expérience traumatisante. Elles ne se laisseraient pas submerger par toutes les émotions liées à la situation incestueuse et parviendraient à lui donner un sens. En fait, elles appréhenderaient l'inceste au même titre que d'autres expériences traumatisantes [41]. Elles seraient conscientes qu'elles ont été victimes d'un acte sur lequel elles n'avaient pas d'emprise et prendraient les moyens nécessaires pour agir sur leur vie en utilisant leurs ressources personnelles et celles de leur milieu. La recension des écrits de Geninet et Marchand [42] portant sur la recherche de sens montre que les victimes d'inceste présentent moins de symptômes dépressifs et une meilleure estime de soi pour celles qui y attribuent un sens [43]. Enfin, ce qui distingue les deux profils à l'étude, « victime » et « résiliente », c'est que dans le profil « victime », la personne demeure dans une position de soumission à l'égard d'autrui, s'identifie comme une victime et demeure susceptible d'être revictimisée. Dans le profil « résiliente », la personne se prend en charge afin de se redonner du pouvoir sur sa vie. Elle utilise des ressources internes et externes durant et après l'inceste. Dans cette optique, les personnes résilientes présenteraient une structure égotique forte identifiée dans la littérature comme une « égo-résilience » [44]. Ainsi, l'affranchissement des symptômes, la protection de ses enfants d'un risque d'abus sexuel, l'attribution externe de l'abus et la capacité de donner un sens à l'expérience incestueuse ont les critères retenus pour le profil PEPR.

2e partie: évaluation de la résilience à l'aide des trois indicateurs dégagés de la documentation sur le sujet

Ce deuxième volet consiste à évaluer les trois indicateurs théoriques de la présence d'un processus de la résilience. De façon opérationnelle, cet aspect de la recherche a consisté à répondre à la question suivante : comment chaque participante des profils PICT et PEPR se situait-elle au plan 1) des stratégies de *coping*; 2) du lien d'attachement créé dans la relation avec sa mère; 3) de la capacité de mentalisation ? Dans un premier temps, abordons succinctement le contenu de ces trois indicateurs.

1.2.3 Les stratégies de coping

Créé par Lazarus et Launier en 1978 [45], le terme « *coping* » fait référence à un ensemble de stratégies cognitives, comportementales et affectives qu'un individu utilise pour faire face aux situations stressantes. Le *coping* nécessite l'existence d'une difficulté et d'une réponse permettant d'y faire face. Il exige également des prédispositions personnelles et des styles comportementaux. Ce dernier point amène à distinguer deux approches du *coping* : le modèle intra-individuel et le modèle interindividuel. Le *coping* intra-individuel est appréhendé comme un processus d'ajustement qui prend en compte les cognitions, les comportements, les facteurs biologiques et les variables environnementales. Autrement dit, c'est un processus influencé par les caractéristiques propres à la personne, telles que la capacité à gérer les événements difficiles et les caractéristiques environnementales, comme les ressources sociales. Le *coping* interindividuel est envisagé comme un trait stable de la personnalité qui prédisposerait l'individu à faire face à d'éventuelles situations de stress [46]. Étant donné que les recherches présentées dans la section théorique identifient les stratégies de *coping* comme un indicateur possible de la résilience, la présente étude postule que les PEPR devraient disposer de stratégies de *coping* adéquates pour faire face à leur expérience incestueuse

1.2.4 La qualité du lien d'attachement créé dans la relation mère-enfant

On connaît depuis Bowlby [47] l'importance des liens d'attachement dans le développement de l'enfant et les conséquences néfastes qui peuvent découler du manque de contact affectif. Les études classiques sur la théorie de l'attachement proposent que les premières expériences relationnelles ayant manifesté la figure d'attachement construisent des « modèles opérationnels internes » du soi de l'enfant et de son entourage. (Dans la plupart des cas, la mère représente la figure d'attachement, mais selon Bowlby (1969/2006), la figure d'attachement peut provenir du système familial ou du système social. En fait, c'est la disposition « maternelle »

d'une personne importante pour l'enfant.) Ces premiers schémas lui permettent d'interpréter, de moduler et d'anticiper son monde affectif et relationnel ainsi que celui de la figure d'attachement. Toutefois, la théorie de l'attachement a véritablement pris son essor à partir du paradigme de la « situation étrangère » élaboré par Mary Aisnworth et ses collaborateurs [48]. Ce modèle d'attachement se catégorise selon trois styles : l'attachement *sécure* (type B) ; l'attachement *insécure-évitant* (type A) et l'attachement *insécure-ambivalent* (type C). À la suite de ces études, un quatrième type d'attachement est introduit par Main et ses collaborateurs [49] sous le vocable *désorganisé-désorienté (Type D)*. Ce quatrième style se construit lors de relations dysfonctionnelles vécues comme menaçantes par l'enfant, telles que des problèmes de consommation d'alcool, de drogue et/ou de santé mentale du parent. Les recherches portant sur la résilience identifient la qualité du lien d'attachement instauré dans la relation mère-enfant ou auprès d'un adulte important, comme un indicateur possible de résilience. Nous pouvons penser que les PEPR auront créé un lien d'attachement sécuritaire avec leur mère.

1.2.5 La capacité de mentalisation

Tel qu'il a été mentionné précédemment, la mentalisation serait un facteur de la résilience [50]. Rappelons que la mentalisation réfère à un mécanisme de défense fonctionnel du développement précoce. Elle peut également être vue sous l'angle d'une *métacognition* envers soi et les autres. Selon Peter Fonagy, spécialiste de ce concept, la mentalisation [51] ou ce qu'il appelle « reflective self » (auto-réflexive) réfère à un processus qui permet de se représenter à la fois ses propres états cognitifs et affectifs et ceux des autres. Sur le plan psychique, cette capacité de mentalisation serait notamment fonction de l'autre indicateur potentiel de la résilience que constitue le lien d'attachement dans la relation mère-enfant ou envers un adulte important [52], [53]. En effet, la capacité de la figure d'attachement, habituellement en lien avec la mère, à donner des soins, à refléter ses émotions et celles des autres et surtout à aider l'enfant à reproduire cette capacité lui permettrait de réguler ses émotions et de transposer cette capacité dans la sphère sociale. En d'autres termes, le « reflet miroir » de la personne importante permettrait à l'enfant d'explorer son monde émotionnel, de se représenter ses états mentaux et, par conséquent, d'organiser son monde interne [54]. Cela lui permettrait également de comprendre que les autres ont des affects différents de soi, ce qui est nécessaire dans la négociation des relations au sein de la famille et à l'extérieur d'elle [52]. L'étude de Fonagy et Bateman [55] portant sur les mécanismes de changements, dans le cas du traitement des troubles de personnalités limites, montre que les expériences dysfonctionnelles précoces nuisent à la capacité de mentalisation. En contrepartie, la dysrégulation court-circuiterait quant à elle le processus de mentalisation. C'est notamment le cas lorsque l'enfant est confronté à des expériences précoces difficiles. Ainsi, Theunissen [56] stipule que, sur le plan psychanalytique, la transgression de l'interdit de l'inceste serait associée, entre autres, à la dysrégulation du Soi. Étant donné que les études identifient la capacité de mentalisation comme un indicateur possible de résilience, nous pouvons penser que les PEPR devraient disposer de ce mécanisme régulateur des affects.

En résumé, la présentation portera sur les données préliminaires des deux profils établis dans la première phase de l'étude et de l'analyse des indicateurs de la résilience établie précédemment. Ce dernier volet constitue la vérification des hypothèses de la recherche.

Conclusion

Le phénomène de la résilience est fréquemment constaté dans notre société et de plus en plus exposé dans les médias. Au cours des dernières décennies, il est devenu un sujet d'étude pour les chercheurs qui s'intéressent au fonctionnement considéré optimal des personnes qui ont été victimes de situations traumatisantes. Or, et bien que les recherches sur ce phénomène permettent de comprendre comment un enfant abusé ou négligé demeure dans un état fonctionnel, malgré le trauma auquel il a été confronté, on constate qu'il est difficile d'en faire une liste des déterminants. Afin d'en comprendre les mécanismes, la présente recherche a consisté, dans un premier temps, à classer un groupe de femmes ayant été victimes d'inceste durant l'enfance et/ou l'adolescence selon deux profils (PICT *versus* PEPR). À partir de ces profils les auteurs ont formulé trois hypothèses se rapportant aux facteurs régulièrement observés dans la littérature sur le sujet. C'est dans cette perspective que seront présentés les résultats préliminaires de la recherche doctorale.

Abstract

We propose a qualitative analysis of the impact of sexual abuse at the end of childhood, on access to maternity in two mothers, their investment of the child based on gender, and the place occupied by this child in their psyche.

After a critical review of studies on the prevalence of sexual abuse, reporting very conflicting statistics, we present a synthesis of psychoanalytic conceptualizations on psychic transmission of trauma.

The analysis of interview data collected from these two mothers, Anna and Olga allows us to retain the theoretical and clinical elements including: Anna and Olga have different degrees of resilience, due to levels of mental development of trauma consequences of abuse vary. Traumatic sequelae are expressed by a reactivation of trauma either during pregnancy or childbirth, either during interactions with the child, with differentions according to the sex of the child effects. Separation and individuation mother / child remains problematic, when the child is female because of fear of repetition of trauma, and a tendency to reject the male child remains when the abuser confusion fantasy / male continues. In contrast, our analyzes show that the possibility of a resilient rebound, involving partial or complete mental preparation of the initial trauma, requires that the young mother had previously been able to rely on a male / father figure positively invested enough attractive, to allow separation from the mother, and to counterbalance the image of the abuser, allowing the positive oedipal investment male.

Keywords: sexual abuse - Children - Maternity - transmission - sex of the baby - paternal model - maintenance - resilience - trauma

Introduction: prevalence de l'abus sexuel, des statistiques contradictoires

L'UNICEF (2009) recense 150 millions de filles et 73 millions de garçons de moins de 18 ans victimes de violences sexuelles.

En France, 8,8 % des femmes interrogées de plus de 40 ans déclarent avoir subi au moins un rapport ou une tentative de rapport sexuel forcé avant l'âge de 18 ans. Mais un pourcentage presque deux fois plus élevé est mentionné par Bayle (2006) (15% d'abus sexuels dans l'enfance et l'adolescence pour ce groupe de femmes.)

La recherche épidémiologique internationale comparative de Finkelhor (1994) dans les pays anglo-saxons montre que les taux de prévalence de l'abus sexuel dans 19 pays varient de 7 à 36% pour les femmes et de 3 à 29% pour les hommes.

Elements theoriques sur l'impact de l'abus sexuel sur la maternite et l'investissement du bebe

La grossesse et (ou) l'accouchement peuvent réactiver les traces du traumatisme sexuel passé non élaboré avec trois complications possibles : prématurité, dépression périnatale et (ou) un syndrome post traumatique.

Dans la littérature, on remarque également un impact sur l'investissement du bébé [33]. La petite fille peut renvoyer la mère à sa propre image et à son passé en réactivant potentiellement le traumatisme alors que le garçon peut renvoyer à l'image de l'abuseur. La fille peut donc risquer d'être traitée comme la mère l'a été dans son enfance et le garçon peut englober les caractéristiques de celui qui a abusé d'elle .

1.1 Rappel sur les modèles psychanalytiques de la transmission des traumatismes passés.

Pour Abraham & Török [1], il y a 3 concepts importants. Tout d'abord, l'introjection qui est l'élaboration psychique de l'expérience vécue.

L'inclusion, quand l'appropriation subjective de l'événement est impossible du fait des conflits entre le désir de savoir et de comprendre et au refus explicite ou inconscient de l'entourage d'assouvir ce désir.

Et enfin la crypte qui correspond à l'incapacité de partager le secret qui nous lie à l'autre ou de s'extraire de ce secret suite à la disparition de l'autre.

Les traumatismes non surmontés incorporés par le sujet feront ainsi partie de lui-même et sont susceptibles d'être transmis aux générations suivantes sous forme de « fantômes ». Quand un enfant est confronté à un parent porteur d'un secret (cas fréquent chez les parents abusés dans l'enfance) une identification à l'objet incorporé encrypté de son parent s'opère et cette identification se retrouve alors dépourvue de toute représentation verbale. L'évènement traumatique non élaboré qui a été « indicible » pour la mère, devient donc « innommable » pour l'enfant.

Ciccone [13] évoque le concept de transmission traumatique en expliquant que ce qui n'est pas transmis par un biais symbolisable, se transmet aux générations suivantes dans un état brut. L'identification est, pour Ciccone, la « voie royale de la transmission », en particulier l'identification projective. La transmission se réalise par l'inconscient, plus particulièrement l'infra verbal, par la manière de dire plus que le dire lui-même (attitude, geste, signe, timbre de la voix auxquels le jeune enfant est très sensible.)

Lebovici [35] développe le concept de mandat. Ainsi, pour se construire, l'enfant a besoin de s'inscrire principalement dans deux histoires : celle de sa mère et celle de son père. Les conflits infantiles des parents peuvent influencer le processus d'affiliation d'où l'hypothèse théorique générale de notre recherche : l'abus sexuel est par définition une situation traumatique et les séquelles traumatiques d'un abus sexuel précoce devraient, pour la femme en devenir, faire l'objet d'une transmission intergénérationnelle sauf si des processus résilients complets peuvent être mis en place.

1.2 Elaboration mentale du traumatisme et degré de résilience : esquisse d'un modèle théorique.

Qu'est-ce qu'être un adulte résilient après un abus sexuel dans l'enfance ?

Nous disposons de quelques critères élaborés à partir de la thèse de Lecomte (2002) sur le devenir adulte des enfants maltraités et de notre modèle psychanalytique de référence. Pour Lecomte (2002), être résilient dans des contextes d'abus sexuels dans l'enfance consiste à ne pas reproduire sur ses enfants ce que l'on a vécu par identification inconsciente

A partir de notre modèle psychanalytique, être résilient c'est avant tout réussir une élaboration mentale du traumatisme initial suffisante pour atteindre le stade génital et s'épanouir dans une sexualité génitale. Etre résilient implique donc l'investissement pérenne d'une sexualité non entravée par l'abus initial ainsi que le désir d'une une vie de couple en investissant un objet génital et en désirant s'engager dans la maternité sans difficulté majeure.

Ces éléments impliquent un niveau d'organisation œdipien de la personnalité avec une identification possible à sa propre mère et un investissement de l'autre sexe malgré le trauma.

Nos trois nouvelles hypothèses sont donc les suivantes:

H1: L'abus sexuel durant l'enfance ou l'adolescence chez la fille risque, par le canal de la transmission psychique, d'entrainer une non-élaboration du traumatisme. Elle va générer, lors de l'accès éventuel à la maternité, une réactivation du traumatisme soit durant la grossesse, soit lors de l'accouchement, soit lors des interactions avec l'enfant après sa naissance

H2: Du fait de la confusion bébé/agresseur lorsque l'enfant est de sexe masculin, l'investissement du bébé garçon doit être marqué par un rejet plus grand que lorsque le bébé est une fille. L'identification maternelle à sa fille devrait se doubler d'une non séparation-individuation pour la protéger d'une répétition traumatique.

H3: La possibilité de résilience, impliquant l'élaboration mentale partielle ou complète du traumatisme initial, requiert que la jeune femme ait pu s'appuyer sur une image masculine paternelle positivement investie . Celle-ci aura été suffisamment attractive pour permettre la séparation d'avec la mère, le désinvestissement de la figure maternelle et également faire contrepoids à l'image de l'agresseur, en faisant perdurer l'investissement œdipien positif du masculin.

Considerations methodologiques

Notre étude étant exploratoire, nous avons recours à la méthodologie des cas uniques contrastés (Widlöcher 1990,1999) dans le but de construire un modèle des conditions d'élaboration du traumatisme sexuel précoce lors de l'accès à la maternité.

Notre étude porte sur l'analyse de données cliniques concernant deux femmes biélorusses présentant respectivement un niveau faible et beaucoup plus conséquent d'élaboration du traumatisme.

L'outil utilisé est l'entretien clinique de recherche avec des entretiens enregistrés intégralement et réalisés au domicile de ces mères qui ont signé un consentement pour participer à cette recherche.

Anamnèses brèves et quelques données cliniques.

1.3 Anna

Anna a 25 ans. Elle présente un vécu avec un cumul de traumatismes : son père se suicide alors qu'elle a deux ans. Sa mère reconstruit un couple avec un homme alcoolique qui abuse d'elle sexuellement entre ses 10 et 11 ans. La révélation de l'abus aboutit à l'incarcération du beau-père et au retrait de l'autorité parentale à la mère qui battait Anna, l'accusant d'être responsable de l'incarcération du beau-père. Anna est alors placée dans un orphelinat.

À 16 ans, Anna est enceinte d'un garçon qu'elle abandonne à la maternité.

À 19 ans, deuxième grossesse, Anna accouche d'une une fille Maria dont elle a la garde exclusive.

À 22 ans, Anna donne naissance à un troisième bébé, un garçon qu'elle abandonne à la maternité comme le premier.

1.4 Olga

Olga est une femme mariée de 37 ans, mère de deux enfants : Sasha 16 ans et Lisa 12 ans.

À l'âge de 14 ans, Olga a subi une agression sexuelle de la part de son petit ami et d'un ami âgés de 17 ans.

Conclusion

Ces deux femmes présentent à la fois des points communs en matière de niveau d'élaboration mentale du traumatisme initial (séquelles lors de l'accouchement, interaction avec les enfants nés infléchie par le traumatisme initial et variable selon le sexe de l'enfant avec rejet, voire abandon de l'enfant de sexe masculin et lien anaclitique serré avec les enfants de sexe féminin par peur de la répétition du traumatisme.) et des différences (impact sur leur développement personnel et leur vie sexuelle ultérieure ainsi que leur investissement du partenaire de sexe masculin.)

Anna, contrairement à Olga, rejette tout objet de sexe masculin (confusion totale abuseur/Objet de sexe masculin) en lien avec deux images parentales toxiques, l'absence totale d'étayage externe de substitution et le cumul des traumatismes subis.

Olga présente le niveau de résilience le plus élevé (vie de couple et professionnelle stable même si le traumatisme impacte sa relation à sa fille.)

L'impact du traumatisme est moindre chez elle car le double traumatisme sexuel dont elle a été victime est unique, commis par un membre extérieur à la famille proche et à un âge un peu plus tardif que chez Anna.

Olga bénéficie d'une vie de couple stable sans confusion mari /abuseur et sans réactivation de la conflictualité œdipienne trop marquée et d'un appui possible sur une figure maternelle plus sécurisante. La force de l'attracteur œdipien paternel est plus marquée chez elle et perdure plus de vingt ans plus tard. Ces deux facteurs jouent donc un rôle important dans la construction d'un processus face à une situation traumatique d'abus sexuel dans l'enfance commis par un tiers.

Abstract

The paper aims at pointing out, through a longitudinal research, the changes in the life of 20 persons with psychotic troubles in remission living in Romania, Caraş-Severin (Reşiţa) and Serbia, Southern Banat (Vârsec), related to life quality, symptoms, global functioning, personal and social skills, following the use of an applied interventionist working pattern, generated within the services provided by a multidisciplinary intervention team, in a stable and familiar frame, also grounded on various theoretical and practical approached. On the other hand, each case study highlights the individual factors related to the "no commitment" situation. The global results indicated the improvement of life quality in the social, assistential and psychological plane, the decrease of the disease remission period, of anxiety, underlining the family and environmental factors intervening in the process underlying the building of individual resilience in the case of persons with psychotic troubles in remission. The research shows that the clinical and assistential intervention at the subjects' domicile constitutes a modality of conceiving an efficient customised intervention. We may include, as part of the research object, the integrative approach of psycho-pathological theories and of assistential intervention. By means of the focus group we sketched the impact of the "working model" on the beneficiaries' families, their expectations and the ways in which they can be resilient, identifying with more accuracy the diversity of the needs of persons suffering from psychotic troubles, the transformation of these needs depending on age and psychological development requiring the simultaneous or successive use of different intervention methods and techniques.

Keywords: psychotic troubles, life quality, "no commitment" approach, multidisciplinary intervention.

Introduction

A person's welfare is illustrated, beside social and economic status, by a benchmark called health condition, characterised by a variety of indicators, among which life quality index. A good life quality is an inherent condition of individual and collective wellbeing, in all its forms (psychic, physical and social). For conducting a sociologic analysis, the objective aspects should prevail on the subjective ones: people's life quality results from the combination of the action of living standard, life level (material conditions not measurable in money) and lifestyle (human subject's reaction to existence conditions, both autonomous and socially triggered), with the subjective reflex of such in the subjects' satisfaction degree related to their life [1]. By acting in isolation, neglecting or ignoring the aspects related to social pathology inherent to society (unemployment, poverty, high criminality, various family dyfunctionalities, alcoholism etc.), any health strategy can only partially reach its major goal, which is ensuring the population's health condition. Social and political disintegration, low social stability, public health system deterioration, high unemployment rate, migration boost, alcoholism, criminality, these are only some of the factors included in the notion of "social stress" [2] In the same authors' opinion, this concept synthetically refers to the negative psychosocial effects upon individuals, groups and societies undergoing rapid economic, social, and political changes. The connection between social change and biological response affecting the health condition is uncontested, and the evolution of the health status in the states of Central and Eastern Europe confirms this assertion [2].

C onceptual delimitations

The notion of health is considered by Rebeleanu-Bereczki [3],an evaluating concept, like disease, being "circumscribed by the development of biomedical knowledge, intellectual orientations of culture, society's value system" [2] apud [5] . Lalonde (1994) assigns health the following four factors: biologic, (heredity, population's demographic characteristics, chronic, degenerative, geriatric troubles); environmental (climate, pollutants, husbandry conditions, catching diseases, rapid social changes); lifestyle (aspects related to food, sedentarism, alcohol and tobacco use) and medical care organisation (quality and quantity of medical resources, access to medical services, relation between persons and medical care resources) [6].

The World Health Organisation concisely formulated the concept of health as being "the state of complete physical, mental and social wellbeing which is not reduced to the absence of disease or infirmity". Reaching the personal highest health condition is one of the fundamental human rights (Preamble to the WHO statute, 1946). In such a perspective health is understood both as individual and collective (national) status, both as need and right, both as goal to reach by each person and as political goal to be reached by any state. Health becomes a component of social development, and ensuring health is related not only to a strictly medical approach, but also to a social one, as part of the set of social-economic conditions of a nation's development. Health is a multisemantic concept, like disease in fact. The concept of health in Herzlich's [7] opinion comprises three dimensions: absence of disease, good genetic constitution and state of body equilibrium The state of equilibrium supposes the individual's capacity of adaptation to all that is related to his life environment: food, climate factors, affective relations, work conditions, stressful life events, integration and adhesion to different social groups (family, friends, professional group, social layer etc.).

The concept of health also refers to social life, more precisely to the existence of adaptive behaviour, normal social roles, autonomy, personal and salary satisfaction etc. We should underline, from the analysis of the health condition definitions encountered in the literature, its close connection to the notion of life quality. Ioan Mărginean defines life quality by the set of physical, economic, ecological, social, cultural, political, health condition and more, in which people live, the content and nature of activities they carry on, the features of social relations and processes they participate in, the goods and services they have access to, the consumption patterns adopted, the life style and manner, the assessment of the extent to which the results and achievements correspond to the population's expectations, the subjective states of satisfaction / dissatisfaction, happiness, frustration etc. [8]. Health should become the topic of a permanent research of the balance between the social life field, where difficulties of social inclusion and the forms of social exclusions coexist with the acquisition of behavioural pro-health knowledge and skills, spirit of solidarity, population's individual and collective involvement in any endeavour aiming at the promotion of health and of quality medical services [3]. Vulnerable populations with medical-social needs "often ask for the authorities' support and are at present the largest consumers of social and health services, as these vulnerable categories are coping with complex social and medical needs" [9]. The needs of various vulnerable population categories are continually changing and a series of elements concur to their meeting: evolution of health condition, age, access to medical, social and educational services for the prevention of diseases [10].

In our opinion, an indispensable constituent for a better life of persons with psychotic troubles in the agora of social reality is represented by resilience, which means the ability to rapidly and decisively respond to unpredicted changes or a chaotic functional interruption, by the improvement of life quality, both on the psychological, social and assistential planes, the decrease of the remission period and of anxiety, underlining the importance of family and environmental factors.

Applied research

The purpose of the applied research is to enhance the integration capacity of 20 persons suffering from psychotic troubles in remission from Romania, Caraş-Severin county (Reşiţa) and Serbia, Southern Banat (Vârsec) in their social environment, considering that these persons are at the borderline between marginalised and vulnerable groups. The specific goals referred to the delimitation of an applied interventionist working pattern, generated within the services provided by a multidisciplinary intervention team, in the presence of a stable and familiar frame, concomitantly grounded on various theoretical and practical approaches; increase of psycho-social adaptability; improvement of the content of medical and social support; increase of the family cohesion degree; identification and promotion of the needs of persons suffering from psychotic troubles in remission.

The aforementioned analysis frame starts from highlighting the characteristics related to life quality, disease symptoms, global functioning as well as personal and social abilities of persons with psychotic troubles in remission, the highlighting of the changes occurred in the life of 20 persons suffering from psychotic troubles in remission living in Reşiţa and Vârsec, during two years (2011-2012).

Elements of research methodology

During the applied research conducted in order to highlight the improvement of life quality in the social, assistential and psychological plane, the reduction of the remission period and of anxiety, we also highlighted the role of family and environmental factors intervening in the process underlying the shaping of individual resilience in the case of persons with psychotic troubles in remission. The methods of data collecting were: analysis of documents, which refers to the health condition of the analysed group, useful for the shaping of the clinical and assistential intervention at the subjects' domicile, which constitutes a modality of conceiving an efficient individualised intervention; case study, which underlines the importance of the individual factor from the perspective of the "without commitment" situation; the focus group, which sketches the impact of the "working pattern" on the beneficiaries' family, their expectations and the manner in which they can be resilient, identifying with better accuracy the diversity of the needs of persons with psychotic troubles, their turning into needs depending on age and psychological development, which makes it necessary to simultaneously and sequentially use various intervention methods and techniques

This working model at the beneficiaries' domicile, represented by social and medical support and individual counselling, allows the patient with psychotic troubles in remission to get socially inserted, to live a life as normal as possible, to benefit from the means and measures of re-adaptation: complementary and community services. The action having defined the social and medical support and the individual counselling consisted in: drug therapy adapted to the disease type and severity; development of skills correlated to concrete situations testing the patient's capacity of adaptation and independent operation, a range of supportive services helping the community life of the persons with psychical disabilities; psychotherapeutic counselling of the patients in remission in view of their family, professional and social insertion.

Results and discussions

By the contribution of the entire multidisciplinary team (social worker, psychologist, physiatrist, psychotherapist, medical nurse) we reached a life quality improvement of persons with psychic disabilities, which was reflected especially in a better relationship of these patients within the family and in the extra-family milieu. As regards the beneficiaries' life quality, of the four domains investigated, i.e. physical health, social relations, environment and psychological condition, only one exhibited statistically significant modifications, i.e. the psychological one, between the first and the second testing moment. The positive life quality modification on the psychological level occurred in the first 6 months of research implementation. This indicates the rapid impact of beneficiaries' involvement in group and individual counselling activities. The other fields, physical health, environment and social relations, exhibited some enhancement, but not high enough to be statistically significant. We may suppose that alterations occurred in the very psychological plane precisely because, grace to therapy as well as individual counselling, the subjects acquired skills of self-awareness and disease symptoms management, ability to cope with stress, emotions and difficult life situations, capacity of self-acceptance, communication and relationing with those around them; compliance with treatment was encouraged and maintained.

The symptom analysis of the target group persons points out the decrease of obsessive—compulsive behaviours, anxiety and psychotic symptoms experienced. We could also remark a drop of depression symptoms, as well as very slight sensitivity drops, not high enough to be statistically significant. The independent life skills (self-care, personal and social relations, socially useful activities, aggressive behaviour) and global functioning are evaluated by specialists (psychologists, psychiatrists, psychotherapists, social workers). During the period of project implementation significant differences were recorded. We remarked an improvement, for all tested domains, related to the ability of self-care, socialisation, home activities supporting, aggressiveness management, as well as global operation. Recovery took place gradually, each individual having his personal maximum to reach, depending on the degree of deterioration due to disease. When analysing the frequency of hospital admissions we found that the target group persons exhibited, during one year, no hospital admissions because of decompensation, the hospital admissions being caused by other medical issues in two cases. Thus, by reducing the number of hospital commitments, the benefits are both for the medical system, where the expenditure for hospital admission are reduced, as well as for the individual, who no longer experiences the often traumatising experience of commitment. The very low frequency of hospitalisation proves that the working pattern at the beneficiaries' domicile has a positive impact, and the target persons could better manage their existential problems.

Conclusions

We may conclude that the health condition evolution is conditioned by the impact of the supportive environment determinants, economic and social development, poverty, unemployment, income inequalities,

social exclusion etc. The final conclusions, as reflection moment on the health condition of the individual and of family, forwarded the idea that health is an inherent component of a quality life.

Social vulnerability leads to connected social phenomena, such as marginalisation, social exclusion, and stigmatisation, which place these persons on marginal positions, which is disadvantageous for the individuals and dysfunctional for the social system. Social intervention may be expressed in terms of influence and authority and supposes the existence of two elements: the person applying the intervention (in our case social workers) and the person subjected to the intervention (in this case the person with psychotic troubles, his family or the community). The intervention agent should posses a series of resources the client needs, real capacity of getting legitimacy from the client as regards his actions meant to achieve an intervention for the psychotic client and his relations with the environment. The intervention environment may be represented by the client (including all the client's characteristics and resources), his milieu (family, social, institutional – approach considering the client to be a system made of the set of relations he maintains with his environment). Thus, the specialist intervenes upon the psychotic client, considered as a singular entity, and on his environment (family , group, community).

We underline that the persons with psychotic troubles undergo a continual stress; living with a psychotic trouble involves, both for the individual and for the caring persons, a state of chronic tension, with major consequences for the family health. The social support is another aspect that should attract more attention, as the increased demands for such personnel, as a consequence of the increasingly strong pressure experiences, are more and more largely recognised. For the solution to the problems of persons with psychotic troubles a special importance is granted, beside family, to wider networks of extended family, friends and acquaintances, who can crucially intervene in offering the necessary support, the special treatment consisting in an infusion of optimism, good understanding and adequate communication among those who care for the patient.

Given the clients' heterogeneity, the extended duration of the project, the richness and diversity of the material collected, it is rather difficult to draw a unitary conclusion, if we think that we worked with psychiatry patients with severe diagnostics, such as affective, bipolar, psycho-affective, obsessive-delirious troubles, as well as paranoid schizophrenia, dementia, Alzheimer; we consider that notable progress was made in the direction of the initial symptoms remission, but especially for the integration into family, social or professional life. Counselling succeeded in opening gates toward understanding, tolerance and acceptance of the massive misbalance produced in the family, the family. Family rebalancing by the rebuilding the communication bridges among its members led to progress in the attitude toward the "weakest link". It is known that this can misbalance the system, perverting its homeostasis, but in order to maintain it, the patient needs to accept the current situation and to strengthen the viable connections meant to ensure the good functioning of the family in a difficult situation.

Are resilience questionnaires capable of predicting burnout risk?

Portzky M.

Psychiatric hospital PC Gent-Sleidinge, Ghent, (Belgium)
michael.portzky@pcgs.be

Abstract

The aim was to examine if resilience questionnaires can predict burnout risk. 80 teachers and 251 nursing staff members were asked to fill in resilience and burnout questionnaires, as well as questions regarding job demand, absenteeism, and/or intention to leave the job. A highly significant correlation was found between resilience and burnout. The lower the resilience score, the higher the risk for burnout. No correlation was found between the personal appraisal of job demand and resilience: participants with a higher resilience score did not consider the job to be less stressful or demanding. Participants with a higher resilience did however show a significant higher intention to leave the job if job satisfaction is low. Resilience also proved to be the statistical most powerful predictor of absenteeism. Those who were most frequently absent scored within the psychiatric norm range on their resilience questionnaire. These results suggest that resilience questionnaires are capable to determine who is most at risk of developing burnout, or show related behaviour like absenteeism.

Keywords: Resilience, burnout, RS-nl Resilience Scale.

Background

The ever increasing prevalence of burnout is causing a much needed shift toward screening and treatment of burnout. Whereas up until a few years ago, psychiatric journals often refused articles on burnout, stating that it was 'not a psychiatric topic since it is not mentioned in the DSM', recent prevalence numbers are so dramatic, as is the feedback from therapists, that no one can further deny the social relevance or even cost of these numbers. A recent study in Belgium stated that up to 38% of all days of absenteeism at work could be related to psychological problems [1]. Another study among anaesthetists revealed that no less than 41% scored positive on current burnout symptoms, with also over 50% showing 'high risk of developing burnout' [2]. These numbers were so high and concerning that the authors even asked if these numbers could identify a public health risk? Therefore, a screening tool to determine who is most at risk to develop burnout could offer great benefits in terms of prevention and diagnosis.

1.1 Why should burnout relate to resilience?

Burnout is often defined as: '*a syndrome of emotional exhaustion, depersonalization, and reduced personal accomplishment that can occur among individuals who do 'people work' of some kind*' [3]. When looked at typical behaviour and complaints during a burnout episode, we see frequent reports of symptoms like depressed mood, feelings of hopelessness, insufficient/reduced coping abilities, and a strong reduce in the frequency of (positive) palliative activities (= activities that reduce the stress levels) and often combined with an increase in harmful palliative activities (such as substance abuse or auto mutilation). During the normation of the 'RS-nl Resilience Scale' (Dutch version of the 25 Item RS from Wagnild and Young) and the more recent version 'VK+ Veerkrachtschaal Plus', we found very significant correlations between resilience and all of the abovementioned symptoms and behaviours [4,5], hence the willingness to further examine the relation between resilience and burnout.

Methodology

In two separate studies, we used (among others) questionnaires for resilience and burnout in 2 professions which are regarded as high risk jobs to develop burnout, namely teachers and nursing staff members. The questionnaire used for resilience was the 'RS-nl': the Dutch version of the 25-item Resilience Scale [4]. Most important differences with the original are the removal of al double negatives in the formulation of the

items, and a 4-point Likert scale instead of the 7-point scale of the original. Minimum score is 25, maximum score 100, with healthy controls scoring an average of 85, and the psychiatric norm group scoring an average 70. Normated on 4800 persons, this questionnaire remains as one of the very few resilience questionnaires with norms for each age and gender group [6,7]. The questionnaire used for potential burnout symptoms was the UBOS Utrecht Burnout Scale [8]: a Dutch version of the Maslach Burnout Inventory MBI by Maslach & Jackson, 1986. It measures three typical symptoms of an actual burnout: emotional exhaustion, depersonalization and reduced personal accomplishment. To diagnose a burnout, the first two mentioned symptoms must score high, and personal accomplishment must score low.

1.1 The Dutch Teacher study group

In total, 79 Dutch teachers between the age of 23 and 65 were asked to anonymously fill in a RS-nl Dutch Resilience Scale, a UBOS-L burnout scale (the L stands for 'teacher version'), and a VBBA 'Vragenlijst Beleving en Beoordeling van de Arbeid' (Van Veldhoven, Meijman, Broersen, & Fortuin, 2002); a questionnaire to examine the personal appraisal of job characteristics, somewhat based upon the 'Job-Demand-Control-Support' model by Karasek [9].

1.2 The Flemisch Nursing Staff study group

In this seperate study, 251 nursing staff members between the age of 21 and 61 anonymously filled in the RS-nl and UBOS. On the Informed Conscent form they also had to fill in questions regarding abseteeism and the intention to leave the job.

Results

Both the Dutch study group [10] and Flemisch group [11] revealed very signifiant correlations between resilience and all characteristics of a burnout as examined by the UBOS/MBI, as shown in table1.

Tabel 1: orrelation between Resilience and Burnout, measured by RS-nl and UBOS/MBI (study 1= Dutch group, study 2= Flemish group)

	Emotional Exhaustion study 1 / study 2	Depersonalization study 1/ study 2	Reduced Personal Accomplishment study 1 / study 2
RS-nl Total Score	-.58***/-.24***	-.50***/-.29***	.63***/.39***
Subscale Acceptation of Self and Life	-.57***/-.28***	-.33**/-.28***	.42***/.37***
Subscale Personal Competence	-.51***/-.19**	-.52***/-.27***	.62***/.37***

*Pearson correlaton=: *= p ≤.05, **= p≤.01, ***= p≤.001*

In many cases it was clear that participants with the lowest resilience scores showed burnout scores which indicated an actual presence of all burnout symptoms, thus allowing a current diagnosis of burnout. These results suggested that the lower the resilience score is, the higher the risk of having or developing a burnout is.

The comparison between the resilience scores and the other data and/of questionnaires revealed that there is no difference between participants with high of low resilience scores and their personal, subjective appraisal of the job demand characteristics: participants with a higher resilience score found the job as stressfull and/or demanding as the lower scoring group. There was however a significant correlation between resilience and 'intention to leave the job', as well as with absenteeism. Those who were most frequently absent even scored within the psychiatric norm range on their resilience questionnaire. Thus the higher the resilience score, the less frequent they will be absent from work, and also the more likely they will leave the job if job satisfaction is low. In fact, resilience proved to be the only statistical reliable predictor for both. This suggests that those who score low on resilience will often remain longer at a job they dislike, thereby possibly increasing the stress levels and in the end the possibility to develop a burnout. Hence perhaps the observed increased use by human resources departments and firms of the resilience scale as a standard diagnostical tool, as mentioned by the firm that distributes the RS-nl.

These data confirm what is often seen in therapeutic settings. However, therapeutic experience clearly dictates that a normal or even higher score on a resilience scale does not suggest invulnerability. Everybody does have a limit on what they can endure, and a prolonged period of functioning above these limits will inevitably cause mental and/of physical problems. But as both these results and clinical, therapeutic evidence/experience

seem to suggest: those personal limits do differ strongly among individuals, and the lower the resilience, the faster and more frequent these limitations will be reached or surpassed. In this regard, it is perhaps not surprising that we demonstrated in a recent study that for people with a lower resilience score, "positive stress" such as caused by a promotion at work is just additional stress, and therby an equal additional risk to surpass these limits [12].

Conclusion

Resilience does seem to correlate strongly with burnout, both present or future, and thereby could serve as a diagnostical tool to measure the vulnerability to develop a burnout. It also confirms our strong belief that resilience, and the measuring of resilience, is most certainly not something that is only useful in a psychiatric patient population, but also among professionals and/or (health care) volunteers, in order to detect and if possible support those who are most at risk. As additional correlation data suggested, this could also reduce absensteeism at work.

Institutional resilience of social economy entities: rethinking social profit in Romania

Stănescu S.M.[1], Cace S.[1], Nemțanu M.[3]

Abstract

The paper explores institutional resilience of social economy entities in Romania within the current economic context. Among questions that arise, one could wonder to what extend social enterprises should be supported in a competitive market? Alongside, what elements of social economy entity are to be improved especially but not exclusively in the case of employment of vulnerable groups? The paper is based on qualitative and quantitative research outputs including national samples focus on demand and offer of social economy.

The paper contributes to the increase of knowledge regarding efficiency of social economy entities as economic actors able to achieve labor market insertion and stability. The results foster national and international comparative research especially towards the development of social inclusion policies.

Keywords: institutional resilience, social economy, social enterprises, social profit.

Introduction

Based on psychological meaning of resilience as capacity to overcome difficult periods [1], within the paper, institutional resilience refers to capacity of social economy entities to successfully survive current economic challenges. As social economy is linked with employing vulnerable people, the societal resilience is understood within the paper due to „its capacity to engage in positive relationships and to endure and recover from life stressors and social isolation" [2]. From these perspectives the paper overviews the social policy and social economy state of art in Romania with a particular attention paid to recent dynamic and development within increasing public awareness.

Current design of social policy in Romania is shaped by post-communist challenges in terms of negotiation process towards accession to European Union (EU); current EU member state status as well as globalization process [1], [2], [3], [4]. The switch from welfare state paradigm focus on welfare provision to all citizens to workfare focus on individual responsibility to provision of personal well being redefined the relation between state, market, family, and community as key players. In terms of social protection, contributory benefits were focus on workers protection and lacked unemployment and means tested benefits. Slow development of non-contributory schemes exposed vulnerable people to risks of long term poverty [2]. The implementation of minimum income guarantee regulations positively answered to local design of social policy measures but its earlier implementation revealed opposite effects than expected ones [5].

The assessment of social assistance system shows the lack of a strategic vision on targeting social benefits towards the poor people. This conducted to a rather reactive character of social assistance measures adopted during the time [6]. The need for sharing a long terms perspective on social assistance follow up measures for vulnerable groups is supported by research outputs on Romanian Governmental Programs. These public policy documents contain more 60 identified vulnerable groups [3]. For some of these identified vulnerable groups social protection measures were not adopted o where adopted in a fragmentary way.

Social economy in Romania

As one response to current labor market challenges, social economy is perceived as an innovatory employment solution especially but not exclusively for vulnerable people. EU recommendations to member states emphasized the support to social economy entities in terms of adopting national frameworks in order to regulate their existence (if the case) as well as adoption of various supporting mechanisms (financial, legal, institutional) [7], [8]. Taking into account European recognized forms of social economy entities (cooperatives, mutual organizations, associations, foundations) and national regulations available in member states; we notice

that the only recognized social economy entity is the cooperative. The European status on cooperatives is available since 2003. Similar initiatives on other types of social economy entities were not agreed at EU level despite their significant national contribution to economy (i.g. mutual organizations) [9].

Increased potential role played by social enterprises in labour inclusion of the most vulnerable ones (i.g. young people, women) imposed their valorization at both EU and national level and consequent support mainly through domestic mechanisms [9]. In terms of public support for this EU public policy recommendation, the number of people working in the field of social economy is constantly growing. The ones sharing specific working principles of economic activities focus on social profit are concerned and challenged by both economic performance and achievement of their social goals. Recent data shows that the 6% of total Europeans were working in social economy in 2002-2003 while in 2012 the total number represented 6.5%. In other words, the sector included 11 millions jobs in 2002-2003 and 14.5 millions jobs in 2012 [10]. Most probably the number of Europeans involved in social economy is bigger as there is not EU agreed set of statistic indicators measuring performances of social enterprises. EU national exchanges of Belgian satellite accounts as best practice could improve this situation.

The lack of a commonly agreed meaning of social economy in the context of a growing attention for this economic and social sector exposes it to misunderstandings and even vulgarisation. One of the common confusions is between social economy and employment of vulnerable people as well as social economy and corporate social responsibility. Early 2002 and 2008 Romanian regulations reflected a misunderstanding of social economy [11]. Not clear mention of eligible social economy entities within guidelines for launching ESF finance for social economy influenced the low participation of specific entities such as credit cooperatives, mutual organizations or cooperatives. Further assessments of implemented projects will reflect the impact of ESF from the perspective of social economy entities as principal applicant.

Within the current paper we use the definition of social economy as the "type of economy efficiently combining individual and collective responsibility, with the goal of producing goods and/ or provision of services, focus on social and economic development of a community having as final goal the social benefit. Social economy is based on a private, voluntary and solidarity initiative, with a high degree of autonomy and responsibility; it includes an economic risk and a limited distribution of profit" [12]. This definition of social economy was included in the latest publicly available draft of social economy law [13], [14].

Institutional resilience of social economy entities in Romania

In terms of in-force national regulations in line with social economy internationally recognized principles (democratic control, autonomy, private character, one voice, one vote and so on) and European entities, the following social enterprises are identified in Romania: associations, foundations, mutual organizations for employees as well as for retired people, credit cooperatives and cooperatives of 1st degree [11].

A key element in supporting social economy entities is represented by European Social Fund (ESF) the EU financial tool co-financing the implementation of national projects focus on development of social economy. Romanian ESF projects had a direct impact on increasing public debates and academic research [12], [13]. Still, the concept of social economy is not well known by population and, similar with other East-European countries it is still influenced by communist largely spread terms such as cooperatives and voluntary work. Information campaigns especially financed by ESF projects increased the public awareness [16]. We refer particularly to Operational Sector Program for Development of Human Resources 2007-2013, priority axis 6 Promotion of social inclusion, intervention domain 6.1. Development of social economy. The majority of 107 identified Romanian volumes dedicated to social economy were elaborated within research activities of ESF co-financed projects [14].

Romania is among the pioneer European countries in regulating the social economy framework. First social economy entities were functioning in Romania half of the XIX century: the Phalanstery from Scăieni (1835). The project for Savings and Loan Associations was adopted in 1845. Trade Code regulating cooperatives was adopted in 1887. Due to ideological discrepancies between free market and communist ideology on share of property and benefits, many Romanian social economy entities were vanished [11].

Romanian networks representing the interest of social economy entities in Romania were established in 1851 (Central Cooperative Bank CREDITCOOP), 1951 (National Union of Handicraft Cooperatives UCECOM). UCECOM supported the development of International Cooperative Alliance in 1895. CREDITCOOP contributed to establishment of European Association of Cooperative Banks (1970) [14].

Transition from planned economy towards free market challenges economic strategies of social economy entities especially due to recent European focus on labour inclusion of vulnerable groups as well as outputs of European Social Funds financed projects in Romania.

Research on social economy entities reflects a constant concern for assuring jobs for people. It is the case of craftsman cooperatives in rural areas or credit cooperatives for low income people or farmers confronting cash flow problems [18]. Still, the number is rather small but with potential towards vulnerable people. Adopting

mainstream measures for social enterprises possibly followed by targeted measures for social insertion enterprises could better support labour insertion of vulnerable groups [14], [16]. Representatives of social economy entities consider that among labour insertion of vulnerable groups, people with disabilities are better supported [19].

The current legal and institutional frameworks with impact on social economy entities support the establishment and functioning of new social enterprise [9], [20], [16]. Comparatively, associations and foundations include „easier" administrative procedures while cooperatives can cover a larger number of activities. The establishment of a cooperative of 1st degree implies one member [21].

Different perceptions of legal and institutional frameworks are to be noticed among various representatives of social economy entities. Legal framework is perceived as generally efficient especially by representatives of mutual organisations with consistent modifications in the case of cooperatives of 1st degree [19]. From the profitability point of view, mutual organisations are the mutual organisations followed by non-governmental organisations and 1st degree cooperatives. Despite the constant success in conducting economic activities towards social profit, latest developments reflect a constant decrease in terms of number of social economy entities and allocated resources. Investment in entrepreneurs active in social economy rather than investment in entrepreneurship skills of vulnerable people as sustainable solutions for assuring stable jobs [21] could be financially better supported by incoming ESF projects.

Conclusions

The paper emphasized the institutional resilience of social economy entities in Romania as sustainable answer to unemployment situation. Redesign of social profit for people by social economy entities is challenged by low employment capacity, decreased number of social enterprises, and lack of public supporting measures dedicated to social enterprises. Recent development of social economy entities is partially supported by legal and institutional frameworks. The level of public support is still low but positively influenced by recent ESF co-financed information and awareness campaigns.

Assisted institutional resilience of social economy entities could valorize their success in identifying sustainable solutions to reinvest social profit in the benefit of members.

Alexithymia and resilience in women with depressive disorders

Tepei A.

(ROMANIA)
andrada.tepei@gmail.com

Abstract

Difficulties concerning emotion regulation play a major role in depressive disorders. The present study investigated 63 female subjects (35 outpatients, and 28 inpatients) psychiatrically diagnosed with depressive disorders and screened with Beck Depression Inventory for severe depression. Two aspects that are at core related to emotion regulation have been measured using self-report scales: alexithymia which deals mostly with deficits in identifying, describing, and expressing emotions, and resilience, as a possible protective factor, in maintainig emotional stability. Results indicate that higher scores for depression are associated with an increased degree of alexithymia, and by extension a lower level of resilience. Alexithymia and resilience have been observed to be inversely correlated. This all points towards a complex relationship between alexithymia, resilience and depressive disorders in women, which this paper discusses by exploring the underlying psychological mechanisms involved in the assessment of all three.

Keywords: depression; alexithymia; resilience.

Introduction

Depression has been extensively studied, and as such empirically proven cognitive models have been developed [1]. Within these models, the functioning of emotion regulation mechanisms takes centre stage [2], [3], [4]. On that note, this study has chosen two dimensions related to affect regulation, alexithymia and resilience.

Alexithymia specifically defined as the difficulty in identifying and describing emotions has been associated with depressive disorders [5], [6], [7]) and with increased symptom severity [8]). One study found alexithymia as a predictive factor of depression [9]. At a neurobiological level studies show that the anterior cingulate cortex plays an important part in alexithymic affect processing, and its neuroanatomical characteristics could even be considered predictive for the response to medication treatment with antidepressants [10], [11], [12].

Resilience has been defined as the individual's ability to adapt in the face of adversity, traumatic events and other stressful life factors [13]. It comprises coping mechanisms and personality aspects. Its mechanisms reappraise hardships in a positive way and turn experiences into valuable learnings [14]. It is the process and the result of good adjustment to difficult life experiences, especially to those involving high stress levels [15], [16]. It plays an important part in maintaining life quality [17], [18] and emotional balance [19]. As such resilience could be viewed as a potential protective factor for general mental health [20]. Recently researchers started investigating possible links between depression and resilience. While the influence of resilience on the severity of depression is not yet well determined, a few studies have actually established a correlation between depression and low resilience levels [21], [22], [23]. Studies have also started exploring which resilience mechanisms could be most significantly impaired in individuals with depressive disorders [24], [25]. At the neurobiological level, scientific investigation is still incipient. Studies found some shared characteristics for the biological mechanisms lying at the base of depression and low resilience [26].

If alexithymia and resilience have thus far been both studied separately on subjects diagnosed with depressive disorders, to the researcher's knowledge no studies have been yet conducted to observe the correlation between the two dimensions. A possible link between the two could point towards certain shared underlying mechanisms that are dysfunctional and to potential starting points in psychotherapy based interventions, aiming at improving resilience specifically for this target group.

Methodology

1.1 Participants

The study has been carried out on 63 female subjects psychiatrically diagnosed with depressive disorders and screened with Beck Depression Inventory (BDI) for severe depression (a score of over 25). They were inpatients (28) and outpatients (35) recruited from the Sighetu Marmației Psychiatric Hospital and the Integrated Outpatient Clinic, during a 3-month period between March and May of 2013. The study admitted patients based on the following criteria: good ability to read and write so that they were able to fill the self-report scales on their own; voluntary agreement to participate in the study; at least one month prior of psychiatric drug treatment; no secondary diagnosis pertaining to the psychosis spectrum or to mental retardation. The presence of anxiety has been tolerated, since its comorbidity with depression is extremely high [27]. The patients age varied between 26-65 years (mean 49.8 ± 8.98). They came from both urban (26) and rural (37) environments. The age of the psychiatric diagnosis within group varies between one month and two years (mean 9.7 ±7.00).

1.2 Procedure and assessment tools

The patient interviews were conducted individually, and took place in a separate room. Subjects were assured of the confidentiality of their results. Sociodemographic and clinical information were collected from both patients and their hospital records. The patients then completed the self-report scales by themselves after adequate instruction received from the researcher. The scales selected for this study were: BDI, the Toronto Alexithymia Scale – 20 (TAS-20) and the Connor Davidson Resilience scale (CD-RISC).

BDI, the 1961 version constructed by Beck, tends to measure the present depressive state, more than depressive features of an individual [28], but this also depends on the instruction used [29]. For this study the participants' depressive state was measured, since they were required to respond to the questions considering their general state during the current week. BDI has shown high consistency on clinical and control groups [29].

TAS-20, developed by Bagby, Parker and Taylor [30] is constructed around three factors: difficulty identifying feelings, difficulty describing feelings and externally oriented thinking. It has 20 self-report items, scored on a five-point likert scale (1: absolutely disagree, 2: somewhat disagree, 3: neutral, 4: somewhat agree, and 5: absolutely agree). The result can be expressed as a global score or as three scores for each separate subscale. It has shown good internal consistency (Cronbach's alpha = 0.81), test-retest reliability (0.77), as well as good convergent and discriminant validity [31].

CD-RISC was chosen specifically for being validated on the clinical population [32]. It consists of 25 items, with a five-point likert scale (ranging from 0-not true at all to 4-true nearly all the time). There is no specific standard, higher total scores indicate greater resilience. Studies that have been conducted on world-wide population with depression have recorded mean scores varying between 39.0 and 64.9 [22], [26], [33], [34], [35].

1.3 Statistical analysis

Statistical analysis was carried out with SPSS for Windows v.16.0. Prior to hypothesis testing, data were examined to ensure that the assumptions of parametric testing were met. All three variables measured are numerical, and are normally distributed (tested with Shapiro-Wilk, $p>0.05$. There were no outliers. The Pearson coefficient was used for correlation analysis. Statistical significance was set at $p<0.01$, all tests were two-tailed.

Results

1.1 Correlation between measured depression scores and alexithymia scores in women diagnosed with depressive disorders

Results showed a strong positive correlation ($p<0.01$; $r(63)=0.730$) between measured depression scores and alexithymia scores in women diagnosed with depressive disorders. Measured alexithymia scores statistically explained 53% (r^2) of the variability in measured depression scores.

1.2 Correlation between measured depression scores and resilience scores for women diagnosed with depressive disorders.

A strong negative correlation ($p<0.01$; $r(63)= - 0.659$) was observed between measured depression scores and resilience scores in women diagnosed with depressive disorders. Measured resilience scores statistically explained 43% (r^2) of the variability in measured depression scores.

1.3 Correlation between measured alexithymia scores and resilience scores for women with depressive disorder.

Results pointed to a strong negative correlation ($p<0.01$; $r(63)= - 0.578$) between measured alexithymia scores and resilience scores in women diagnosed with depressive disorders.

Discussion

In the present study of women diagnosed with depressive disorders, we investigated the relationship between depression, alexithymia and resilience. Statistical results obtained point to a correlation between all three variables.

Increased levels of depression were linked to an increased degree of alexithymia, as has also been confirmed by recent research [5], [6], [7], [8], [9]. On the other hand studies have found associations between alexithymia and a large number of .psychiatric and psychosomatic disorders [7], so it is by no means exclusive to depressive disorders. Due to the nature of the study, a causality relationship between the two cannot be yet established. It remains uncertain if the degree of alexithymia was already present before the depression, or increased after the onset of depression. Whichever the case, alexithymia hinders the ability of identifying internal emotional experiences, and the process of communicating them to other people. These deficits could potentially play an important part in the perpetuation of maladaptive beliefs about self and others that are present in individuals with depression. It would be interesting to further investigate if alexithymia could be a factor that delays seeking help in the incipient phase of the depressive disorder, due to a lower ability of introspection of emotions, and a more externally oriented thinking. The results justify further study to test alexithymia as a possible risk factor for depressive disorders due to the fact that individuals are overwhelmed by somatic correlates of emotion that they cannot translate into meaningful language [9]. Such a deficit will probably hinder emotional regulation and disrupt successful adaptation to stressful life events, which have already been shown to be prevalent in people who develop depressive disorder [4]. The high alexithymia prevalence (>80%) registered in the group might be explained by the contribution of the third factor, externally oriented thinking, which considers emotion expression and introspection as less important. These types of attitudes might be due to lower degrees of education (6% have graduated elementary school and 59% graduated from secondary school) and could also be a reflection of specific cultural attitudes from the rural areas in which the subjects reside.

Increased levels of depression were also associated with a lower degree of resilience. Only in recent years (since 2005) has resilience been studied in groups with depressive disorders. Resilience includes positive coping mechanisms, oriented towards actions and active identification of solutions [32]). These types of mechanisms are less developed in individuals with depression, which are more oriented towards emotion centred coping mechanisms such as self-blame and avoidance [1], [25]. Another positive coping mechanism included in resilience is active search of social support, which can again be less developed in individuals with depression due to negative beliefs about interpersonal relationships, and possibly due to less efficient abilities in solving social related problems [1]. One other crucial aspect to resilience is having a positive outlook on life, and even a positive attitude towards challenging life events, whereas in depressive disorders negative thoughts about the future and feelings of hopelessness are more predominant [36]. Results could be partly explained by the way in which the two constructs of depression and resilience have been assessed. On closer inspection, certain items in the CD-RISC could constitute opposites of items from the BDI, such as those investigating self-image. Moreover while a positive self-image is central to resilience, a negative self-image and feelings of worthlessness are symptomatic of depression.

Higher levels of alexithymia were linked to low resilience in women with depressive disorders. A current conceptual model suggests that efficient affect regulation allows the individual to influence the way in which he lives and expresses emotions [37]. So alexithymia might disrupt the person's ability to efficiently regulate emotion and by that, interfere with some of the positive coping mechanisms found in resilience. One such form of meaning-based emotion regulating strategy that lies at the core of resilience is cognitive reappraisal, the adaptive process through which stressful events are reconstructed as benign, valuable or beneficial, by reinterpreting the meaning of the emotional stimulus [38]. It is an active coping strategy, which also relies on abilities such as introspection, identifying and expressing feelings, abilities deficient in individuals with high levels of alexithymia. One study has found cognitive reappraisal to be one of the most important predictors of resilience in patients with depression and anxiety disorders [25]. The link identified between the two dimensions would point to the importance of further study in order to determine specific psychotherapeutic interventions targeted on emotion regulation strategies contributing to the increase of resilience and the lowering of alexithymia in patients with depression.

1.1 Limits

A few factors that could have skewed the results of the study are: the small number of subjects; the effects of medication on the subjects (especially for those who have unedergone a longer treatment period); different types and dosages for medication; lack of a control group and of groups for moderate and mild depression; self-administered scales could potentially be a problem for the individuals with lower education levels.

Conclusion

This study's usefulness lies in establishing a link between depression, alexithymia and resilience in female subjects, and serves as a good starting point for further research that should aim to better define this link, determine causality, and pinpoint the exact factors of resilience and alexithymia that contribute to depression, so as to facilitate future psychotherapeutic interventions for this target group.

Abstract

BACKGROUND

Numerous studies have established that chronic illness is a sufficiently significant risk to allow the introduction of the concept of family resilience and have set hypotheses relating to the emergence of such resilience.

METHODS

Using John Rolland's integrative psychosocial model about Families, Illness and Disability and the Mc Cubbin's Resiliency Model of Family Stress, Adjustement and Adaptation, we describe and explain the construct of resilience among 38 French families with children suffering from severe chronic illness. The methodology included quantitative and qualitative evaluations. Standardized questionnaires (Impact on Family Scale, Family Relationship Index, Family Index of Regenerativity and Adaptation General) and projective tests (Family Apperception Test, Draw-a-Family) have been assessed. Semi-structured clinical interviews conducted with a small number of families illustrate some of the findings.

RESULTS

The first results of this study will be available at the beginning of 2014 and could be presented at the congress.

DISCUSSION

This descriptive study helps to understand the mechanisms present in the resilience processes of these families. The ultimate goal is to propose perspectives for psychologists and social workers, in order to create prevention and protection measures to support families raising a child suffering from a chronic disease.

Key words: resilience; family; children; rare chronic illness

Introduction

Family has been studied primarily as a psychosocial risk factor, but has been considered more and more as a resource over the last three decades (Nichols & Schwartz, 2000 [1]). It has been described as a system capable of resilience for itself [2], [3]; [4] as well as for its members [5]. Risk and protection factors have been identified [6]; [5].

The chronic illness of a child is considered as a "significant risk" in the life of a family [7] and has been established as a factor of early chromosome aging, especially impacting the mothers [8].

Risk factors impacting the family after the diagnosis of the chronic illness of a child are, among others:

- the weakening of the family members individual balances [9];
- the growing complexity of interactions [10];
- the strains of the illness itself [11];
- the conflict roles, financial worries, care necessities and loss of independence for the parents [12].

Rare children chronic diseases add to the context of a chronic illness a specific impact on the family. Rare diseases concern less than one person on 2000 in Europe, and 6000 to 8000 diseases are considered as rare. In total, it represents more patients than those suffering from cancer. Most rare diseases are chronic, severe and incapacitating. The issue of the disease is often fatal (the mortality rate goes from 5 to 30%). Among these rare diseases, some of them are orphan, which means that there is no efficient cure available right now. In some countries, national plans against rare diseases have been developed (source: orphanet.fr [13]).

Rare children chronic diseases demand that families adapt themselves to an experience that is almost impossible to share, to difficulties to obtain a rapid and certain diagnosis, to heaviness of daily care, and to the

financial impact due to the lack of common treatments [14]. A feeling of incompetence has also been described, especially among fathers [15].

Nevertheless, the chronic illness of a child may bring the opportunity to develop new resources within the family [16]; [17], [18], [19].

Objectives and hypotheses

Using an integrative psychosocial model, the Families, Illness and Disability model [20] and the Resiliency Model of Family Stress, Adjustment and Adaptation [21], [2], [3]; [22], our exploratory study aims to describe and explain the emergence of family resilience in the context of the rare chronic illness of a child, among a French population. The ultimate goal is to propose perspectives for psychologists and social workers, in order to create prevention and protection measures to support families raising a child suffering from a rare chronic disease in France.

Our first hypothesis is methodological: our study aims to verify the applicability of the North American psychosocial and systemic models quoted above to help understand the construct of resilience among French families with children suffering from a rare chronic illness.

Our clinical hypotheses set that:

- there are differences in terms of impact of the disease between members of the family;
- some factors have a significant influence on the outcome for the family and its members: the specific psychosocial typology of the disease (Rolland, 1994 [20]), the support of the social network of the family and of the health care team, and the importance of the belief and values system of the family.

Methodology

Resilience is more and more approached by specialized authors as a process rather than a competency [23]. Our study relies on the integrative concept of resilience [24] and uses a « non – normalized philosophy » of family resilience [25].

To address family process of resilience in its complex and multidimensional aspects, our study is based on the exploratory use, in a French population, of the North American systemic models of Family Adjustment and Adaptation Response [21], [2], [3]; [22] and Family System Illness Model [20]. For this purpose, standardized tools derived from some of these models have been translated into French for the first time, to our knowledge, following a process of « back translation » with a professional translator.

The studied population comprises families living in France and raising one child or more suffering from a rare chronic disease and not older than 18 years old. Our population includes different diseases, which has already been the case in numerous researches about chronic illness [26]; [27]; [25].

To be included, the diseases had nevertheless to share a comparable degree of severity, either in terms of actual income, or in terms of possible outcome. Separated, divorced or monoparental families have also been included. To avoid the period of intense psychological shock consecutive to the diagnosis [28], all families must have received the diagnostic disclosure more than six months ago.

The families have been recruited through associations supporting specific rare chronic diseases and through one reference center. All families have been contacted and have responded to the research by mail and post, and a few of them, willing to participate further, have been interviewed at their home, all members of the family being present.

The general procedure of the study was the following:

- one of the parents (the choice being free) responded to a detailed form elaborated in function of the major themes of the Family System Illness Model (type of the disease, time since diagnosis and first symptoms, impact on life span, day-to-day risks, incapacities, existence of crises, symptoms visibility, treatments and regimens, secondary effects, illness phase, …);
- both parents (if possible) responded to a standardized questionnaire measuring various types of impacts of the child disease on the family, the Impact on Family Scale [26];
- all members of the family above 12 years old responded to a standardized questionnaire, the Family Index of Regenerativity and Adaptation General [29];
- all members of the family above 12 years old responded to the Family Relationship Index [30], French version [31];
- the youngest children could send a Drawing of their family intended for the researcher if they wanted to participate.

The Impact on Family Scale was designed to measure the effect of the child's condition on the family. The scale used in our study is the shorter version with 15 items, which has better psychometric properties [32].

This scale measures the total impact on family, as reported by parents, but also other subscores: the subjective general impact on the respondent, the financial impact on the family, the social impact on the family, the coping efficiency of the family, and finally the impact on the siblings.

The Family Index of Regenerativity and Adaptation General belongs to the composite measures for resiliency research developed by Hamilton McCubbin. It is a self-report family system assessment measure which can be used to assess the major dimensions of the Resiliency Model of Family Stress Adjustment and Adaptation. The aim of this tool is to facilitate research in the study of family systems, their transitions, adjustment and adaptation, as well as their impact on family members.

It is designed to obtain 7 indices of family functioning: Family Stressors, Family Strains, Relative and Friend Support, Social Support, Family Coping Coherence, Family Hardiness, and Family Distress. Most of these subscales have good psychometric properties and validity coefficients and have been used separately in numerous North American studies, to the exception of the Family Hardiness Index and the Family Distress Index, whose validity coefficients are more limited. However, as a whole, this composite measure can be seen as a reliable and valid picture of the resiliency process operating in a family at some point of its history.

The Family Relationship Index has been originally proposed as an auto-measure of the quality of the family environment 2009 [30] but it has also been used as a means of identifying families at risk of a maladaptive outcome in some situations presenting a threat [33] and has been shown as very sensitive to the presence of family dysfunction, depression and anxiety in families of patients with cancer [34].

It is made of three scales, Family Cohesion, Family Expressiveness and Family Conflict, and can be used as a total composite of the three subscales, with Family Conflict negatively weighted in the formula. The French validation study of the questionnaire has shown that the French translation, used in our research, has interesting psychometric qualities [31].

Our methodology also included a Draw-a-Family possibility for the youngest children [35], and within the families that we have met at their home, an optional projective systemic test [36] for children who were too young to respond to the standardized tests but who did not want to draw their family. This qualitative part of the study will provide a rich material that could be used later on in order to illustrate specific parts of our findings.

Results

1.1 Description of the population

Our population is constituted of 39 families, in which 92 individuals above 12 years old have responded.

80% of the families live in the French Regions and 20% in Paris. 4 families are single-parent families, 5 are recomposed families. The average number of children per family is of 1,9. 6 families had more than one child suffering of a rare chronic illness with severe consequences or possible outcome.

The diseases present in our research are the following: Doose syndrome, Severe hemophilia (A or B), Williams syndrome, Rett and / or West syndrome, Prader Willi syndrome, Moebius syndrome, Sotos syndrome, Ectodermic anhidrotic dysplasia, MeCP2 gene duplication, Histiocytosis, Interstitial respiratory disease, Phenylketonuria.

Our respondents are 37 mothers, 27 fathers, 3 others (stepfather, grand-mother implicated in the day-to-day care), 25 children, among which 11 ill children and 14 brothers and sisters. The average age of mothers is 40,16 years old, and of fathers, 42,35 years old.

Socio-professional categories and education level means are higher than in the general population, which indicates a possible bias in the fact that people have been contacted through associations, which can be considered as affordable only to people having a certain level of education and the possibility to ask for help.

1.2 Quantitative results

The quantitative results of the study are currently being processed and will be precisely presented at the conference.

We will present general results and also results showing a comparison between 3 groups of families, depending on some specificities of the child's condition:

- diseases without incapacities and with no impact on the life span (17 families),
- diseases with incapacities but no impact on the life span (9 families),
- diseases with incapacities and an impact on the life span (13 families).

However, our first analysis seems to show that there are good correlations between the parents' scores to the Family Relationship Index, which has already been validated on a French population, and their scores to the Impact on Family Scale (especially the Cohesion dimension and the total score) and to the Family Index of

Regenerativity and Adaptation General, especially to the subscores Family Strains, Social Support and Family Hardiness.

Significant differences in the perception of the disease impact on the family have been found between fathers and mothers. Also, some specificities of the disease, such as its psychosocial typology, as defined by the Family System Illness Model, or else the support from relatives or the social network, seem to play a significant role in shaping the perceived impact of the illness on the family. The system of values and beliefs, to the contrary, does not seem to be correlated to this impact, according to our first results on a French population.

When compared to normative data if available, the results of our sample to the Family Relationship Index show levels of cohesion and expression above the normative sample, and levels of conflict lower than the normative sample, which will be interesting to discuss in the light of the literature about families with a chronically ill child.

Conclusion

One of the key interests of our study is to observe the applicability of some standardized North American models and scales to explain and describe family resiliency processes on a French population, the majority of these scales having been translated into French for the first time for that purpose.

Another aim of this study is to create an interest for further investigations using the same models and tools, if possible on larger populations and with other sources of recruitment than supporting associations.

As said earlier, after the results of our research are available, we intend as well to propose clinical and social interventions or measures able to foster the resiliency of families who raise one child (or more) suffering from a rare chronic illness.

Resilience in living with an (acquired) physical disability

Vrabete A., Băban A.

Department of Psychology, Babeş-Bolyai University, Cluj-Napoca (ROMANIA)
anavrabete@psychology.ro, adrianababan@psychology.ro

Abstract

In spite of multiple obstacles and adversity, some people with physical disability manage not only to survive, but to bounce back, or even sustain personal development following the acquirement of disability. Although the concept of resilience has been intensively documented in the literature, less has been said about specific factors associated with resilience, personal development and positive growth in the presence of acquired physical disability.

This paper presents a systematic review summarizing current findings in the literature in an attempt to identify and describe the factors related to resilience and positive growth in the lives of people with an acquired disability. Individual, social, cultural, and environmental factors regarding resilience and positive growth are presented and possible relationships between these factors are pointed out. Although demographical factors and the severity of disability play an important role in each individual's life, these factors seem to account for only a small amount of variation regarding resilience. Individual factors, such as cognitive appraisals, beliefs about self and disability, acceptance, finding meaning, hope, behavioral responses and selection of coping strategies, together with social and cultural factors such as social support, stereotypes and stigma, and environmental factors such as accessibility and environmental barriers, seem to play a much bigger part in fostering resilience and positive growth.

The importance of these factors is highlighted in relation to developing interventions that target the individual, the community and the environment, and can help to build adjustment, resilience, and in some cases, positive growth in relation to acquired physical development.

Keywords: disability, adjustment, coping, resilience, well-being, quality of life

Introduction

The process of adjusting to an acquired disability has common features across different individuals, such as a time of "crisis", when a person may experience a variety of negative emotions, and a time of adjustment [1], [2], [3]. However, the various outcomes regarding the quality of life and well-being of people with disability may be better understood by looking at the individual differences in coping with disability.

The use of engaging coping strategies such as information seeking, planning, problem solving, and seeking social support have generally been associated with a higher level of well-being and a better adjustment to disability [3], [4]. Still, there are individuals that not only adjust successfully to an acquired disability, but experience positive growth following it. This paper aims to describe the present findings in the literature regarding the factors that foster resilience in the process of living with a disability.

Adjustment versus Resilience

After acquiring a disability, individuals often face a large number of changes regarding body integrity and function, self-image, independence, economic status, fulfilling various social and professional roles, and perception of the future [5]. Feelings of loss and grief, anger and hostility, denial, depression and anxiety are common both in the acute, post-injury phase, and in the rehabilitation phase [1], [2], [3], [4]. Suicidal behavior, whether direct or through self-neglect, appears to be more probable in the first few years after the acquirement of the disability [4]. Higher levels of pain catastrophizing, pain anxiety and perceived illness unpredictability are associated with ineffective coping with, and poorer adjustment to disability [4].

Adjustment to disability is a life-long process, and generally encompasses a cognitive acknowledgement of it, of its permanent nature, as well as its impact on the person's life. Adjustment also implies an emotional acceptance of disability and its integration in the person's self-concept. In addition, renewed personal values, a

search for new meanings, and a successful negotiation of obstacles in the process of pursuing new goals are key elements of the adjustment process [3].

Studies regarding adjustment to spinal cord injury suggest that individuals that use active, goal-directed activities in coping with their disability are likely to report lower depressive and anxiety symptoms [6], [7], [3], [4], [8]. The use of engaging coping strategies is also associated with better adjustment to disability, and higher levels of overall life satisfaction [6], [7], [3], [4], [8]. Additionally, having an internal health locus of control, and the use of acceptance and positive reappraisal as coping strategies are also associated with better psychosocial adjustment to disability [4].

Studies on well-being and quality of life consistently show that on average, people with disabilities score lower on well-being and quality of life measures, as compared to people with no disability [9]. This has led some researchers to argue that in many cases, full adjustment, in terms of "bouncing back" from a severe rupture in one's health condition, may not be achievable [9]. Nevertheless, demographic characteristics such as age, gender, race or socioeconomic status and disability characteristics are only weakly related to measures of adjustment to disability [10]. Furthermore, examples of resilience and well-being in people with disabilities invite to a closer look into the factors that foster such outcomes.

Resilience has been defined in the literature as the ability to bounce back when experiencing negative events and/or to adjust successfully despite the presence of substantial adversity, as well as using positive emotions to cope [11], [12]. Resilience also implies successful emotion regulation, as well as an awareness and fructification of one's resources [13]. Resilience, thus, coincides with the presence of adjustment, yet exceeds it, by incorporating the presence of success and personal growth, in spite of adversity [14].

Evidence of Resilience in Living with an Acquired Disability

Some models of well-being have successfully been applied to the case of living with a physical disability, supporting the idea that it is unnecessary to develop a distinct model of well-being for people with disabilities [15]. However, when constructing specific interventions it is necessary that the factors that foster resilience in the face of acquired physical disability specifically, to be considered.

The appraisal of one's disability may represent the core element of adjustment and resilience [10]. It is demonstrated that persons that reinterpret their situation in search for positive meaning and that seek opportunities for personal growth after acquiring a disability show positive adjustment (resilience) to it [10], [2]. Finding positive meaning, dispositional optimism and high levels of perceived control over one's disability have been associated with lower depressive symptoms and higher levels of well-being [16], [15]. Central roles in resilience are also played by the acceptance of disability, and preserving self-worth regardless of disability or appearance [10], [2]. In maintaining self-worth, accounts of resilience stress the importance of incorporating disability in the self-concept, without defining the self by the disability [10], [2].

Other elements associated with resilience in living with a disability are a heightened sense of priorities, a greater appreciation for life and valued activities, along with developing a more thoughtful approach to life [10]. Additionally, having higher levels of extraversion, good social problem-solving abilities and the presence of assertiveness are likely to foster positive adjustment to disability [10], [17].

Positive adjustment in living with a disability is also favored by having supportive relationships within the family, friends circle and/or other people with disability [10], [18], as well as valuing time spent with close ones [10]. Beneficial social interactions, hope, optimism and self-efficacy have been linked with low pain catastrophizing [19], [20]. Emotional support and encouragement from family were even found to be linked to higher training self-efficacy for a group of female athletes with disabilities [21]. Moreover, perceived social support was linked to higher levels of hope in adults with visual impairment [22].

While developing better social skills and seeking social support are efficient strategies for improving adjustment to disability, it is reminded that not all social support is beneficial [10]. Intrusive and over-protective forms of social support from close ones may encourage dependence on the sick-role, thus leading to poor adjustment, by fostering low tolerance and anxiety [10].

Another element associated with resilience and receiving social support is spirituality [23]. Religious attendance is likely to encourage the development of a social and instrumental support network with fellow worshipers [23]. Spirituality has also been associated with the presence of positive affect and better health perceptions in persons with rheumatoid arthritis [24]. Both religious service attendance and private religious involvement were associated with better physical functioning and lower levels of depression among elderly men and women with various physical disabilities [23]. However, while religious coping is associated with higher levels of hope and life satisfaction in the case of people with disabilities, it is only so when spirituality stands as an important value to the individual [23].

Optimism is consistently linked with the concept of resilience [10]. Optimistic outcome expectancies are both directly and indirectly, through the mediation of emotional coping, associated with lower depressive symptoms in the case of multiple sclerosis, and efficacy expectancies are related to depression through mediation

by emotional coping [25]. Moreover, the presence optimism may also foster more efficient coping with chronic pain [17].

Along with optimism, fostering hope in the process of adjusting to an acquired disability may lead to the selection of more efficient coping strategies. Hope is associated with positive adjustment and resilience in living with a disability, especially due to its goal-oriented nature [10]. Hope encompasses the ability to identify meaningful goals and to find ways to pursue them [10]. Higher levels of hope are associated with the use of more sociable and engaging coping strategies, as well as greater functional ability in the case of visually-impaired adults [26]. Moreover, individuals with visual impairment that score high on goal-directed coping and goal-directed planning also tend to use more social and confident coping strategies [26]. Hope is also associated with lower scores on depression and lower reported impairment in various traumatically acquired severe disabilities [27]. It was also identified as being an element of main importance of coping with disability by persons with spinal cord injury [28].

Conclusions

Resilience encompasses adjustment, yet exceeds it, by the presence of high levels of well-being and quality of life, and personal growth in the presence of substantial adversity.

The fact that in most cases, people with disabilities report a lower quality of life and lower levels of well-being than people without disabilities has led some researchers to infer that full adjustment to a previous state where disability had not yet occurred is not generally attainable. However, examples that exceed these expectations and the fact that demographic and disability characteristics are only weakly related to adjustment call for a closer investigation of the factors that may foster resilience in dealing with an acquired disability.

The perception of disability is outlined as a central process in relation to adjustment and resilience. Finding optimism, hope, positive meaning and healthy social support in the experience of integrating disability into one's life is then elementary to fostering resilience. Additionally, positive reinterpretation, the preservation of self-worth, and seeking personal growth after the onset of disability, together with cultivating better social problem-solving skills represent coping strategies that encourage positive adjustment to an acquired disability.

A better knowledge of the individual characteristics and external factors that foster resilience in living with an acquired disability may prove useful in guiding interventions that encourage positive adjustment. Such interventions may help the individual in identifying and using their available resources and promoting flexibility, or they may target the family and close ones for providing appropriate support. Moreover, interventions may target communities, with the goal of building social, educational and instrumental support networks.

Abstract

We propose to present the protocol for innovative research that connects our interest for extreme situations in our practices family psychotherapists. The study, submitted in 2012 at the French Paul-Emile Victor Polar Institute (ENPI) and accepted six months later in 2013, brings us to follow longitudinally reports that unfold between polar wintering base Dumont D'Urville Adélie Land (Antarctica) and their families before, during and returning from their polar lasting 12 to 16 months mission. This study began in September 2013. It raises the question of the relationship between geographic distance and psychic separation work in quite particular voluntary separation context. It opens the broader interest which may relate to other situations also under voluntary separation (submariners, astronauts, workers oil rigs field ... Beyond the presentation of the characteristics of this protocol and assumptions that underlie them; we propose to present the first data from the first clinical encounters (individual and family).

Keywords: voluntary separation, family myth, work psychic separation, identity and belonging, systemic approach

Présentation de la recherche

L'intérêt de plus en plus important accordé, en France, à l'études des facteurs humains dans les situations extrêmes, a été impulsé par Jean Rivolier, une figure des Expéditions Polaires Françaises. Aux Expéditions Polaires Françaises, en tant que responsable du « Bureau médico-physiologique », il a dirigé le contrôle d'aptitude des candidats aux expéditions et contribue à l'amélioration des conditions de vie en hivernage. Il a élaboré et fait évoluer les méthodes de sélection et de suivi psychologiques des hivernants. En 1969, devenu médecin-chef des Terres Australes et Antarctiques Françaises (TAAF). Il est responsable de l'ensemble des problèmes sanitaires pour les quatre districts. Il organise alors le Service Médical TAAF en structure pérenne et efficace. Les expéditions sont des laboratoires qui explorent et testent tous les sujets touchant à l'adaptation de l'homme : médecine, biologie, psychologie, sociologie, adaptation au froid, sommeil, bioclimatologie

Jean Rivolier a été aussi professeur en psychologie, fondateur et directeur du Laboratoire de Psychologie Appliquée (LPA) de l'URCA. Ce travail de recherche puise une partie large de ses racines dans cet ancrage originaire [1,2,3].

Au sein du LPA, après nous être consacrés, en amont de l'hivernage, au processus de sélection psychologique des candidats hivernants aux campagnes concernant autant les Terres antarctiques que sub-antarctiques - c'est à dire Australes - françaises, nous avons été amenés à nous intéresser au retour d'hivernage, en aval de celui-ci.

Il est, en effet, essentiel, pour les institutions impliquées dans ces missions en environnements extrêmes ou inhabituels, de mieux connaître le devenir des personnels qui y séjournent. Ceci pour mieux préparer le retour des équipes, mais aussi pour affiner les méthodes de sélection et les critères d'aptitude psychologique requis pour des individus amenés à participer – *ou reparticiper* – à d'autres missions du même type [4].

Première recherche sur le retour des hivernants polaires

Un premier travail de recherche pour le doctorat en psychologie a été mené par Amaury Solignac sur *Les enjeux psychologiques du retour de missions isolées. Le cas des hivernants polaires français.*

La méthodologie a reposé sur des questionnaires et des entretiens de recherche explorant les pratiques, les représentations et les émotions de ce groupe d'individus au cours d'une séparation volontaire d'une durée inhabituelle.

Les questionnaires quantitatifs et qualitatifs se sont inspirés de ceux élaborés lors d'études précédentes [5,6]. Les entretiens ont été réalisés en métropole, mais aussi sur le terrain en début et en fin de mission (entretiens de debriefing). La fin de l'hivernage, en effet, est une fenêtre ouverte sur le déroulement de la mission, et ce qui interviendra après c'est à dire la fin du séjour polaire, le retour chez soi, les retrouvailles avec les proches, et la reprise d'une activité professionnelle en dehors de la mission [5,7,8].

Le texte complet de la thèse ainsi que plusieurs résumés sont disponibles à cette adresse : http://asolignac.free.fr

Recherche en cours: le suivi des liens des hivernants polaires avec leurs proche

L'étude que nous menons à présent, qui arrive dans la dynamique de la précédente, s'intéresse à présent aux liens qui unissent l'hivernant polaire et ses proches, avant, pendant et au retour de l'hivernage polaire.

L'aspect innovant de notre projet concerne la conjonction de deux dimensions : celle des situations extrêmes et celle des approches systémiques. Le corps des recherches portant sur les situations extrêmes a développé les notions de *stress* et de *mécanismes de coping* face aux conditions extrêmes .Progressivement, à côté des des théories portant sur les stratégies de coping, sont venus s'ajouter les notions de soutien social, la théorie de la *résilience*

Comme thérapeutes familiaux, nous voyons à l'oeuvre la *résilience familiale* dans la diversité des situations que nous rencontrons dans notre travail clinique avec les familles. Ce travail nous permet d'explorer les deux dimensions de l'Identité et l'appartenance de chaque situation clinique d'enfant ou d'adolescent rencontrés dans le champ de la pédopsychiatrie. Dans ce double aspect d'une même réalité, nous rencontrons, en effet, à la fois l'aspect concernant la spécificité du fonctionnement mental, qui relève de l'identité, d'une part, et d'autre part, l'aspect concernant la place, les fonctions de cet enfant ou de cet adolescent dans son milieu naturel, qui relève, quant à lui, de son appartenance.

En tant que systémiciens, pour penser ces deux dimensions de l'Identité et l'appartenance à l'oeuvre au sein de la famille, nous nous appuyons volontiers sur la notion de mythe familial d'Antonio Ferreira qui le définit «comme un ensemble de croyances bien intégrées les unes aux autres et partagées par tous les membres d'une même famille. Cet ensemble de croyances concerne chaque membre de la famille et les positions de chacun dans la vie familiale. Elles ne sont remises en cause par personne malgré les évidentes distorsions que souvent elles font subir à la réalité » [9]. Dans ce contexte, notre réflexion porte plus spécifiquement sur les rapports entre mythe familial et travail de séparation psychique [10,11].

Sur la base de cette experience systémique des familles, notre présente démarche de recherche a pour objectif de "parler avec les hivernants polaires et leurs proches" à propos de leur expérience polaire : comment cette expérience s'est elle décidée, comment s'est elle mise en place, comment est elle en train de commencer, comment est elle en train de se dérouler, puis de s'achever. Et aussi comment l'hivernant est-t-il revenu à sa vie au retour de son hivernage après une période d'éloignement géographique d'une durée allant de 12 à 16 mois ?

Nous utilisons le terme de "proche" plutôt que de famille car il s'agit de pouvoir laisser une place, dans le protocole, à tous ceux qui sont impliqués dans le départ, durant l'absence et lors du retour de l'hivernant polaire.

Les différentes étapes du déroulement de la recherche

- Avant son départ, un entretien avec l'hivernant et ses proches se déroulera à leur domicile. Il s'agit d'un entretien semi- directif (série de questions avec réponses libres) portant sur les relations entre l'hivernant et ses proches. L'entretien étant enregistré à l'aide d'une caméra pour permettre une analyse ultérieure.
- Un questionnaire d'évaluation familiale, proposé à chaque membre de la famille (FACES III validé en français)
- Durant l'hivernage, des questionnaires (séries de questions avec réponses fermées) seront proposés aux proches durant l'été métropolitain. En parallèle, d'autres questionnaires seront proposés aux hivernants à DDU, et un membre de l'équipe de recherche les rencontrera à deux reprises sur place (février 2014 et novembre 2014) pour un entretien semi-structuré et la passation des échelles du CAMIR (échelle d'attachement Blaise Pierrehumbert) et de la RSA *Resilence Scale for Adults* [12,13].

- Quelques mois après le retour d'hivernage, un autre entretien avec l'hivernant et ses proches se déroulera à nouveau à leur domicile. Le moment de la rencontre sera fixé en fonction des disponibilités de l'hivernant polaire et de ses proches et de celles du clinicien-chercheur.
- Un questionnaire sera à nouveau proposé à chaque membre de la famille.
- Les données de l'évaluation psychologique individuelle sont recueillies par le membre de l'équipe psychologue clinicien non-systémicien qui a déjà utilisé pour la sélection initiale elle-même la passation du Rorschach et deux épreuves d'inventaire de la personnalité: le Gordon et l'IP9. Ainsi qu'un questionnaire biographique.

Au moment où nous rédigeons ces lignes, Amaury Solignac est en train de réaliser à la base DDU les entretiens programmés de début d'hivernage.

Nous espérons pouvoir analyser les données des premiers entretiens familiaux (octobre-novembre 2013) et celles des entretiens individuels (février 2014) pour notre communication au Deuxième congrès mondiale sur la résilience de mai 2014.

Mais, pour l'instant, après les premiers entretiens familiaux, un constat se dégage qui est une réponse à notre travail initial d'hypothétisation. Un constat qui tiendrait dans une formule lapidaire : «Partir par fidélité». Ou encore: «S'éloigner de la famille par fidélité à ses valeurs.» Et qui se résumerait par un message émanant de la famille – et que l'on suppose de l'ordre inconscient comme le sont les mythes familiaux - un message paradoxal: «Pars, si tu veux rester des nôtres».

Ce qui nous fera reprendre une fois de plus une des dernières considérations de Freud dans le final de son ouvrage *Malaise dans la civilisation*: «La famille ne lâche pas l'individu ». Même quand il a l'air de vouloir s'en éloigner spectaculairement, pourrait ajouter pour conclure.

The resilience and the development of the human resources from education

Andone L.

The National Institute of Economic Research Costin. C. Kiriţescu" Bucureşti
andoneluminita@yahoo.com

Abstract

The sustainable development is an economic, social and even political process. The main objective is to achieve the standard of living adequate to the human resources through their contribution to achieving the objective.

The initial and continuous training of the teachers in the school education requires an understanding of the need for change in order to be able to meet and resist the changes that appear like rollers at the level of society.

Health engages resilience as it involves a dualistic complex of the human reasoning and, that is why, I suggest introducing a „movement for health" hour for the human resources from education.

Supporting the human resources financially and materially with a view to maintaining and training continuously, assuring the stability of the personnel in the school unit, raising the salaries to a motivating level, providing human resources on the basis set out in the school unit are to be found in the results obtained by the students.

The decentralization of the units from the budgetary sector with regard to education leads to hesitation regarding the recruitment, the selection as well as the professional training of the teachers which are partially coordinated by the school unit and the school inspectorates of the counties which, in their turn, obey the orders and the organization from the centre that is directed by the Ministry of National Education. The recruitment, selection and the training of the teachers at the level of school unit leads to performance and to achieving quality education due to the fact that those teachers would be selected who have skills in the speciality and the field in which they are to be hired. Testing the skills should be done at the future job place.

Key words: resilience, human resources, development, continuous training, efficiency

Resilience- concept and definitions

The concept of *resilience* is associated with scientific, social, economic, political fields. Thus, we can refer to a multitude of constructive formats, namely: psychologic *resilience*, biological *resilience, urban resilience*, organizational *resilience*, institutional *resilience*, business *resilience*, economic *resilience*, financial *resilience*, political *resilience*, informational *resilience*, social *resilience*, etc. (http://rezilienta.ro/rezilienta/descriere-rezilienta) [1].

The concept of resilience is one of the concepts that Boris Cyrulnik is preoccupied with – the capacity of being able to overcome the mental traumas and the most severe emotional injuries: disease, mourning, rape, torture, bomb attempt, deportation, war **...** (http://www.ceruldinnoi.ro/pages/Boris_Cyrulnik_Murmur _fantome.htm) [2].

The development of the human resources from the school education

Many authors consider the adaptive capacity as being actually influenced by resilience and denoting the ability to achieve some plans of intervention and implementation of technical measures before, during and after the manifestation of extreme events; adaptive capacity is, thus, considered to be influenced by resilience (Klein ş.a. 2003, http://riscurinaturale.blogspot.ro/2011/01/rezilienta.html) [3].

The sustainable development is an economic, social and even political process. The main objective is to achieve the living standard adequate to the human resouces through their contribution to achieving the proposed objective.

The development aims to increase the efficiency of the activities from all sectors of activity and also the increase of the material, financial as well as human capital.

The development of the human resources from school education through initial and continuous training of the teachers from the school education requires the understanding of a need for change in order to be able to meet and resist to the changes that appear like rollers at the level of society.

Permanent education is seen as a continuous investment in order to develop the human resources. All the learning activities have as purpose improving the knowledge, the skills and adapting to the new.

The training is seen as a continuous investment.

The law of national education has provided clearly the criteria and the purpose of continuous training for the teachers.

The efficiency of the human resources from education is given by a number of factors like:

- pecuniary factors (the salary, the prizes, the distinctions, etc);
- social factors (the reputation in society);
- professional satisfaction that is reflected in the school performance;
- health.

The balance of the qualified teching staff

Following an analysis it has been found that, at the level of preschool education, the balance of the qualified teachers continues the increasing trend from the previous school year, reaching 95,4%. On the whole, the growth is of 0,8 percentage points, and, in case of rural areas, it is of 1,5 percentage points. Nevertheless, the preschool education represents the level that has the highest percentage of unqualified teachers. Also regarding the preschool education differences still exist between the percentage of the qualified teachers from the urban areas and of those from the rural ones, even if the percentage has decreased from 5 to 3,8 percentage points.

The percentage of the qualified teachers has increased in the current school year both in primary and lower secondary education with 0,8 percentage points. The growth is more significant in the rural environment, in both primary and lower secondary education.

In secondary, post-secondary and primary education the percentage of the qualified teachers is almost 100%.

In the educational system, the percentage of the qualified teachers follows an increasing trend. For the current school year, only the post-secondary education registers a decrease of 0,1 percentage points concerning the qualified teachers.

An analysis on residence environments indicates that in the rural environment the biggest percentage of unqualified teachers is to be found in the pre-school and lower secondary education, levels where it can be noted also the biggest difference regarding the residence environments to the detriment of the rural areas (3,8 percentage points, 2,9 percentage points respectively), these differences are yet decreasing from the previous school year (approximately 5 percentage points).

This indicator reprezents the number of qualified teachers, as a percentage expression from the total number of teachers.

The indicator determines the human resources potential from the educational system and reflects the quality of the educational process.

Depending on the recorded values, it can be evaluated the opportunity of initiating new personnel policies or corrective policies at the level of the system.

The number of students per teacher

The ratio pupils/students per teacher/professor has registered relatively constant values compared to the previous school year. At the undergraduate level, the lowest ratio (11 students/teacher) continues to exist in the lower secondary education, while in the pre-school and primary schools the ratio has the highest value (17 students /teacher).

The largest discrepancies are found in the pre-school education, where the average is higher in the rural environment (19 pupils/teacher, versus 16) and in the primary education, where the ratio is reversed in favour of the urban environment (19 pupils/teacher versus 15).

In the lower school education, the lowest ratio pupil/teacher continues to be registered, especially in the rural environment where the ratio is of only 10 pupils to one teacher. It is expected that the recent measures to rationalize the school network by dissolving/ emerging school units that function having a reduced school population to change the values of this indicator. Although such initiatives were taken in the previous years too, the value of this indicator has not changed, thing which demonstrates that a systemic problem exists.

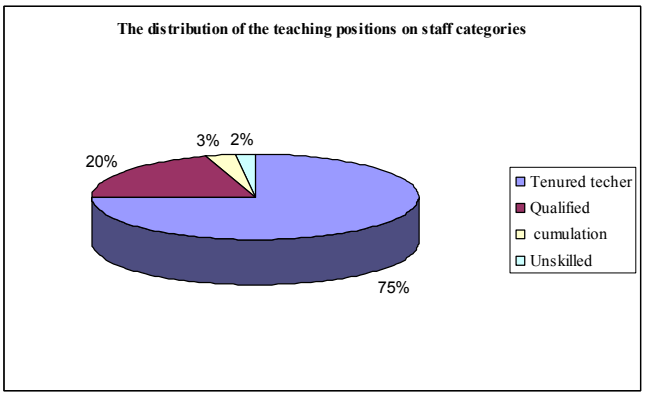
European guiding marks

The number of preschool pupils/students per teacher has had a decreasing trend in most of the European states in the last years, situation determined in the first place by the demographic evolutions and by the growth of the number of specialized/ support teachers.

At European level, there are 14 pupils/ teacher in the primary education and 10 pupils/teacher in the lower school education. Greece, Lithuania, Portugal continue to have ratios lower than 10 pupils/teacher in both primary and lower secondary education.

Romania registers a ratio close to the European average in both primary and high school education.

Providing qualified teachers for school units



The distribution of the teaching positions on staff categories (tenured teacher, qualified, cumulation)
The unqualified teachers are to be found in disadvantaged areas.

Aspects that must be remedied:

Applying the legislation concerning the employment of the personnel in school units.
The participation of the teachers in professional reconversion and training courses.

Conclusions

The decentralization of the budgetary institutions requires the acquisition of some principles of human resources management so that the conditions of an involvment and participation in the activity of the institution should be created, provided that we want to live in a society in which the fundamental values are creativity, freedom, pluralism and tolerance.

Providing quality educational services depends largely on the quality of the professional training of the teachers.

Performance represents a person's good result obtained in a competition. Achieving performances constitutes the reason for the teachers' entire activity in a school unit and indicates the level of individual or collective achievements.

The on-going projects aim at:

- increasing the atractiveness of the teaching career through improving the systems of recruiting and maintaining in the post the best university graduates;
- special reconversion programs on guidance and counselling activities, extracurricular activities as well as geographical and occupational mobility of the teachers.

Proposals

Health engages resilience as it involves a dualistic complex of the human reasoning and, that is why, I suggest introducing a „movement for health" hour for the human resources from education.

Supporting the human resources financially and materially with a view to maintaining and training continuously, assuring the stability of the personnel in the school unit, raising the salaries to a motivating level, providing human resources on the basis set out in the school unit are to be found in the results obtained by the students.

The decentralization of the units from the budgetary sector with regard to education leads to hesitation regarding the recruitment, the selection as well as the professional training of the teachers which are partially coordinated by the school unit and the school inspectorates of the counties which, in their turn, obey the orders and the organization from the centre that is directed by the Ministry of National Education. The recruitment, selection and the training of the teachers at the level of school unit lead to performance and to achieving quality education due to the fact that those teachers would be selected who have skills in the speciality and the field in which they are to be hired. Testing the skills should be done at the future job place.

Trico-tisser sa resilience: elaboration de processus mnesiques resilients auto-tutorants au service du rapport au savoir chez un etre detruit

Boulard F.

CREN, Doctorante en 3e année, Université de Nantes (France)
boulard.felicie@gmail.com

Abstract

This research studies the course of these victims who refuse to remain prisoners of their trauma, anticipating a "sustainable" future, despite the social discourse that condemns them. One goal is to develop the unique light, the unique history and so "being in contrast" with a fatalistic reading of goals. It helps to develop favorable conditions to help child victims of a heavy societal trauma - six victims of incest from 10 years to 74 years - and is part of a qualitative axis where the encounter with the subject will lead to a narrative training, through its singular lived in pre-professional and professionalizing training. The narrators are all retained engaged in a common axis of acquisition, accession, recognition, a place in society by the profession. Their personal is trauma intra-familial. In order to "knitting their life" [1], they are intimately and mentally fight against societal impressions that fit into statistical life prospects doomed to fail. They thus develop self-tutorants memory resilient processes that it studies through four axes:

- Educational: the knitting-weaving in training
- Social: the knitting-weaving that form with the various protagonists more or less emotional that gravitate around the victims
- Conative: illustrating the "self." It calls for understanding the psychological processes of adaptation and defense that the victims of incest put in place, consciously or unconsciously, through their environment
- Cognitive: which is based on actual neurobiological capabilities, acquired, developed or blocked

Keywords: education, professionalization, trauma and schooling, incest, symptoms, emotions, resilience, resilient self-representations tutorantes, security.

L'inscription du trauma incestueux dans notre société.

Toutes les sociétés actuelles prohibent l'inceste et le condamnent sévèrement. L'interdiction pour un homme, d'avoir des relations sexuelles avec de proches parents, apparait comme une loi universelle, et par conséquent liée à la nature humaine elle-même [2].

Juridiquement, médicalement et socialement condamnable, la reconnaissance officielle de cet acte est une phase possible qui peut permettre aux victimes de se reconstituer, de rebondir suites aux symptomatologies liées à l'agonie psychique dont elles témoignent, lorsqu'elles peuvent y mettre des mots.

1.1 Représentations générales théoriques

Il sera rappelé le cadre de cet interdit d'un point de vue législatif et psycho-social, ainsi que l'inscription psychopathologique des symptomatologies à court, moyen et long terme. Ce sont toutes les connaissances de ces symptômes liés à l'inceste qui ont conduit des chercheurs, dans de études, littéraires, empiriques, statistiques… à conclure à un trauma enfermant l'individu victime dans un fatalisme social…

1.2 Représentations individuelles méthodologiques

En répondant à l'invitation de participer à cette recherche, les entretiens cliniques-dialogiques que j'ai menés ont permis à chacun de mes sujets de faire l'histoire de leurs positionnements actuels et passés, de prendre conscience de leur cheminement et de tenter de l'observer.

Les six sujets entendus ont trouvé une position sociale : Théo est collégien, Howard en préformation professionnelle, Amélie est diplômée et enseignante, Caroline est responsable d'un groupe sécurité, Thalis vient d'obtenir son premier emploi à quarante-trois ans, et Julia retrace son récit de formation jusqu'à sa retraite.

Chacun s'est ainsi construit avec son histoire et ses ressources singulières, opérant un tissage qui leur ayant permis de traverser un nœud sociétal, puisant en lui des ressources auto-tutorantes pour «évoluer».

Un «être» dynamique

De sa conception aux années de sa croissance physique, l'individu s'inscrit dans un développement neurologique, physiologique, social, culturel, amical… Son développement s'ancre dans un univers mnésique qui lui permet d'être en équilibre face aux différentes stimulations de son environnement.

1.1 La mémoire

En appui sur les travaux menés par Eric Kandel [3], cette étude prend sa base sur la capacité de développement mnésique qui repose sur le fonctionnement du cerveau, centre gestion de l'activité.

Celui-ci reçoit l'information sensorielle et adapte sa réponse à son environnement, même celle-ci ne correspond pas toujours aux attentes.

1.2 Le sujet, victime des représentations mnésiques sociétales ?

Après avoir posé la toile de fond des concepts de mémoire et de mnésie, intéressons-nous à l'individu confronté trauma de l'inceste. A travers le récit de mes narrateurs, ils relèvent d'eux même leurs manières de se verticaliser de nouveau, d'exister, de donner un sens à leur vie.

La résilience se définit

Le concept de résilience s'inscrit dans un cadre international, c'est pourquoi il a été nécessaire d'en préciser le contenu, lors du 1e congrès mondial sur la résilience de juin 2012 à Paris, sous la direction de Boris Cyrulnik et Serban Ionescu.

Emmy Werner [4] et Michaël Rutter [5] défendaient la thèse selon laquelle un enfant, après un fracas psychotraumatique certain, serait capable de nous apprendre certaines choses à travers un nouveau développement de bonne qualité. C'est grâce à ce nouveau regard posé sur ces jeunes victimes de la vie, soulevé dès les années 1980, que nous fûmes invités à comprendre que tout individu positionné face à un traumatisme n'est pas forcément condamné. Ainsi, en 1998, Mickaël Rutter définit la résilience comme étant la capacité de bien fonctionner malgré le stress, l'adversité, les situations défavorables [5].

Michel Manciaux [6], en appelant à une définition « humaniste » de la résilience, énonce que « la résilience est la capacité d'une personne ou d'un groupe à se développer bien, à continuer à se projeter dans l'avenir, en présence d'événements déstabilisants, de conditions de vie difficiles, de traumatismes parfois sévères».

Pour Michel Manciaux et Tomkiewicz [7], « résilier c'est reprendre, aller de l'avant après une maladie, un traumatisme, un stress. C'est surmonter les épreuves et les risques de l'existence, c'est-à-dire résister, puis les dépasser pour continuer à vivre le mieux possible. C'est résilier un contrat avec l'adversité. »

En France, c'est principalement Boris Cyrulnik qui a développé ce concept de résilience à travers ses ouvrages, ses publications, profitant de son statut de Professeur, d'éthologue, de neurologue et de psychiatre pour enrichir le concept.

1.1 Tricoter résilient sa vie et aboutir à des trico-tissages résilients

Lorsqu'une société dit la norme, elle la crée. Le sujet victime d'un traumatisme garde l'empreinte du trauma en mémoire(s) dans son corps, à travers une blessure, une trace douloureuse! «Le tricot inclut la répétition nœuds par nœuds » [8]. C'est à partir de cette définition du **tricot résilient** que s'initie cette recherche: c'est une stratégie de survie, un processus naturel qui se tricote tout au long des années avec mille déterminants que nous essayons d'analyser (sentiment de soi, discours social, contexte culturel, etc….) » [9].

Ni le tricotage résilient, ni le tissage résilient ne peuvent être suffisants pour bien comprendre comment l'individu traverse une «épreuve» avec ses «nœuds» intra-personnels traumatiques. Les nœuds, qu'ils soient traumatiques, environnementaux, familiaux, sociétaux ne peuvent, à terme, que prendre un volume qui ne peut se résoudre. Un nœud entraînant un autre nœud entraînant lui-même un autre nœud qui entraine finalement le blocage d'une situation. Or, le sujet peut avancer sur une situation. C'est là où nous pensons qu'il peut tricoter, tisser, mais en aucun cas il ne peut tenir sur du long terme en équilibre sans courir un très grand risque de passage à l'acte fatal, s'il n'utilise pas les processus plus fins analysés dans ce travail.

«*Trico-tisser*» représente ainsi la capacité, pour un sujet, de lier le concept de tricoter au concept de tisser. C'est lui permettre de passer le nœud, de contourner le nœud, mais de créer un lien lui permettant de passer «d'avant le nœud à après le nœud».

Tissage résilient: «Le tissage résilient prend sens dans son tissage de liens éco-environnementaux. C'est l'adaptation à la situation immédiate du tricot résilient (fructueux ou infructueux) à travers un lien unique (tel le lien simple qui définit ce point de couture basique) instantané, modifiable, adaptable à chacune des situations auxquelles est confronté l'individu et qu'il utilise pour faire face [10].

Elaboration en cours de la définition du **trico-tissage résilient**: «c'est une stratégie d'adaptation et/ou de défense à la situation immédiate, ou à plus long terme, qui s'établit à travers les représentations résilientes auto-tutorantes.

Le trico-tissage est dès lors «une stratégie basique en construction singulière qui peut se complexifier par la multiplication des rencontres et adaptations menées, relevées et constatées dans l'après-coup» [10].

1.2 Les représentations mnésiques résilientes auto-tutorantes

«Les représentations résilientes auto-tutorantes sont des processus psychiques d'adaptations et/ou de défenses mises en place par une victime de trauma dans un rapport matériel et/ou immatériel, avec une manifestation du conscient et de l'inconscient, à visée objective et/ou subjective, dans un monde réel ou fantasmé. Ces dimensions peuvent interagir entre elles, se compléter pour certaines pour être plus efficientes vis à vis de l'objectif visé; celles-ci prôneraient souvent un positionnement positif identitaire du sujet» [10].

Ces représentations résilientes – que Jean-Pierre Pourtois, Bruno Humbeeck et Huguette Desmet nomment ressources – pourront être utilisées ou non dans une immédiateté, dans un temps proche ou au contraire à plus long terme. Ces liens chargés de ressources sont mémorisés, ils ont été réalisés momentanément par un acteur proche de la victime qui a observé la mise en scène. Comme pourrait le dire un biologiste, cette ressource mise en scène, est «mise en culture». Elle est consciemment ou inconsciemment mémorisée, elle pourra de fait être reprise et remise en scène par notre sujet. C'est ce processus dynamique que je nomme auto-tutorant. Cette représentation que le sujet aura pris chez l'autre, il va l'utiliser pour son propre compte afin de se sortir d'une situation «x».

Ainsi le sujet se trouve face à une situation qu'il souhaite surmonter, passer, dépasser. Dans ses souvenirs, une de ses connaissances a utilisé une technique d'approche qui lui avait permis de passer l'épreuve, il s'en souvient car il l'a mémorisée. Avec sa personnalité, le sujet "blessé" va alors s'approprier la technique précédemment utilisée. A cette occasion, il s'approprie cette méthode à travers ses filtres, ses représentations, sa façon d'être, et son identité. C'est ce que je nomme ici l'utilisation d'une représentation mnésique résiliente auto-tutorante. Il a pris appui sur ses souvenirs de la situation et de la réponse de l'Autre. Il est dans une action, un mouvement, une dynamique. Le terme auto-tutorant fait référence à cette action et le participe présent a toute sa place dans cette dénomination "auto-tutorant". Il ne peut être auto-tutoré par un évènement figé, passé, dépassé.

Ce point de jonction consiste pour l'individu blessé en la mise en action du trico-tissage résilient, à travers une représentation résiliente auto-tutorante qui peut être illustrée par la photographie suivante. La traversée de ce nœud sociétal à dépasser peut être représentée par la technique du tissage, c'est à dire, la mise en contact de deux fils, un fil de chaine et un fil de traine.

Prolongement

La résilience a sa spécificité. Elle est une possibilité pour une victime qui s'est vécue à travers une «mort» psychique, une agonie psychique de reprendre sa «formation». Boris Cyrulnik développe la notion de tricotage résilient pour les personnes qui tentent d'avancer avec leur nœud traumatique.

Je prends appui sur la nature animale et moléculaire capable de tisser, pour en faire un lien avec les travaux de Boris Cyrulnik.

Ce lien prend sens dans le trait d'union de ces deux concepts donnant naissance au «trico-tissage» résilient. La formation de l'individu par ses rencontres interactionnelles ne peut s'établir qu'à travers des ressources, ici nommées des représentations résilientes auto-tutorantes cognitives, conatives, environnementales et sociales.

C'est à travers le récit que cette structure naissante prend son sens: le récit, partage expérientiel authentique, parole d'échange entre celui qui reconstitue sa vérité communicable par un discours social et l'autre, qui a une posture de «recueilleur» de l'expression proposée.

Cette étude est bien avancée dans la transcription fidèle des entretiens, les relectures et l'accord de mes narrateurs de ces transcriptions analysables. L'analyse des données recueillies donne sens à la problématique d'un trico-tissage résilient, qui s'opère à travers des processus résilients auto-tutorants au service du rapport au savoir chez un être détruit.

L'étude va prendre fin prochainement, mais j'espère qu'elle se poursuivra dans un cadre autre que le doctorat, j'espère qu'elle prendra sens dans des travaux universitaires collaboratifs, co-constructifs.

Abstract

Throughout this study we investigated 90 primary school and kindergarden teachers' knowledge of resilience and of resilient children. The teachers had to give a definition of resilience, list the characteristics of resilient children and give practical examples.

This study showed that the teachers have a partial knowledge of resilience. The descriptions of the characteristics of resilient children are relevant but differ from one teacher to an other. The characteristics pointed out are heterogeneous and there is very little consensus opinion. The teachers tend to describe the difficulties or traumatic situations or events children go through rather than describing a resilient process. Resilience should be studied during the training modules for teachers and become an efficient tool for day to day practice.

Keywords: resilience, classroom practice, characteristics of resilient student, teachers

Objectifs

Our study is based on Russo and Boman's work [1] which explored the ability of australian primary school teachers to recognize resilient children.Their results showed that the concept of resilience is well known but that the teachers have difficulty in identifying the different levels of resilience. Along the same lines, the purpose of our exploratory study is to have a clear vision of the french teachers' knowledge of resilience and of what the characteristics of resilient children are, according to them.

Theoretical background

"The link between resilience and school is generally considered through two main aspects. On one hand, school system can reveal resilience by pointing out students who do well at school despite lacking family environment [2] on the other hand, school can provide support thus overcoming family educational failings" [3]

Studies on teachers' knowledge of the concept of resilience [4] show large disparities. In general, teachers consider that school can play an important role in the development of the resilience of vulnerable children mainly when they are young. In contrast, the older the children are, the more the teachers believe that it is the personality of the child and his family's background that play the most important role.

Other studies report that teachers attribute resilience more to the children's personal characteristics than to their environment [5] [6]. This amounts to resilience being considered as an innate ability in the same way that students are considered to be responsible of their motivation to learn and of their academic failure.

According to these authors [6] teachers would designate children being resilient when they are good communicators, when they have a strong emotional attachment with at least one adult, when they believe that the children have the capacity to accomplish a task successfully and when they demonstrate a sense of responsibility. These results are confirmed by Oswald, Johnson and Howard [4] who point out that teachers ascribe resilient capacity to personal qualities and family environment.

Furthermore, these authors also underline the fact that teachers underestimate their own role and the educational institution's influence in the development of the resilience process. In the study by Green, Oswald and Spears [6], teachers describe children as resilient on the basis of their ability to cope academically but without considering the exposure to harmful circumstances. There is certainly confusion between competent child and resilient child. Russo & Boman [1] conclude their article by noting that, although their research has shown that teachers have some knowledge of resilience, it does not mean they recognize the resilient students. Theoretical

knowledge of resilience has no implication in professional practice. In other words, students do not benefit from this supposed knowledge. A link may be missing between theoretical understanding of resilience and the ability to implement this knowledge in the classroom.

Methodology

1.1 Procedure

The collection of data was obtained from an online anonymous questionnaire, created for the study. It was made available by several teachers' associations via their website. This questionnaire was designed to identify the profile of the teachers, to collect a definition of resilience and the characteristics of a resilient student.

To obtain a better understanding of their knowledge, a list of terms taken from the definition of resilience has been established. This list was created from the definitions proposed by eight international specialists of the resilience. This list is divided into the following four dimensions: individual processes; trauma reconstruction process; recovery of a suitable development. The point is to find these terms in the definitions provided by the teachers. Concerning the characteristics of a resilient student, they had to tell the story of a student they considered resilient. The characteristics used to describe this student were selected. They will be compared to the list of characteristics given by Groberg [7].

1.2 Sample

90 questionnaires were collected. Women are the most numerous (83, 33%). The largest age group is the 40-50 (36.67%). Teachers aged under 30 account for 4.4%, those aged 30-40, 26%, and those over 50 years old represent 32.89%. Teachers of elementary school represent three quarters of the set.

Presentation of results

11. Ability to define resilience

Table 1: Number of terms included in the definition of resilience cited by teachers

Number of terms included in the definition of resilience	Number and percentage teachers
≤ 1	19 (21,11%)
2	32 (35,55%)
≥ 3	39 (43,33%)

Table 1 shows that 43.33% of the teachers cite at least three expected words to define resilience. 35.56% of the teachers mentioned two words and 21.11% of the teachers give up to one word. It should be noted that among these 21.11%, 13.33% give none, explaining that they didn't know the concept. Concerning the allocation of the terms employed, it appears that the dimension "individual process" is illustrated by 38 occurrences, that of "trauma" by 37, that of "reconstruction process" by 15 and that of "resumption of the development adapted "by 13.

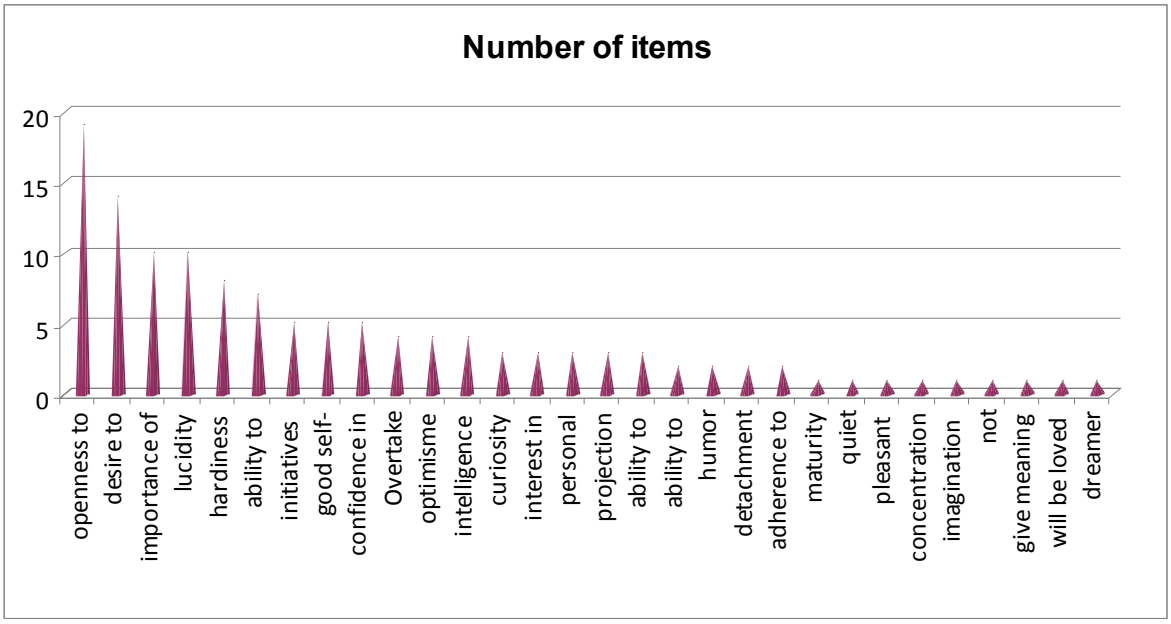
12. Characteristics of resilient students

Table 2: Number of terms specified to characterize the resilient student

Resilient student characteristics	Number and percentage teachers
≤ 2	76 (84,44%)
3	10 (11,11%)
≥ 4	4 (4,44%)

As shown in Table 2, 4.44% of the teachers give at least four characteristics of the resilient child. The vast majority of teachers (84.44%) cite no more than two characteristics of the resilient child.

Figure 1: Proposed atributes



As shown in Fig. 1, the proposed attributes are numerous. Contact with others is the predominant characteristic, followed by lucidity, the desire to succeed and the importance of education and culture as a means of opening to the world. Compared to the list of Groberg [7] most of the characteristics are present. However the facts of being loved by at least one person, of having an adult as a reference or a model, of believing that things will work out are lacking.

Discussion

On a theoretical level, this study is an extension of Russo & Boman's one [1] as it also explores the teachers' perceptions of resilience. It is different in its methodology regarding the fact that it is based on the exploration of representations whereas Russo & Boman's is based on proposals submitted to the subjects. It is applied to a French population, which has never been done before. Finally, this study compares these representations to the theoretical definitions, but also to their implementation via the description of a situation involving a resilient student.

To some extent, our results are consistent with those of Green *et al*. [6] which show that the mastery of the resilience concept is too limited to be useful in professional practice. The definition of resilience is often incomplete and a certain number of teachers are not acquainted with that concept. The variability of the knowledge creates inequal situations from a teacher to another, as Oswald, Johnson, Howard [4] have already pointed out.

Despite this, asking teachers to relate the situation of a resilient student resulted in the identification of characteristics. These are numerous, correct but scanty. The stories highlight essentially the child's difficulties rather than emphasizing their resilience. The representation of a resilient student is overwhelmed by the trauma or difficulties he is confronted to. This representation is partially fueled by the media: Resilience is the ability to overcome trauma. Although this definition is not false, it is however imprecise and has no operational benefit. Indeed, no information is given on how to recognize resilient children. This definition does not inform teachers about children who need help to promote the emergence of a resilient process. One will also note specific characteristics directly related to school. Thus we find, for example: being calm, focused, adherence to standards. Questions arise from these choices: is it the description of a resilient student or the description of a suitable student for the school universe? To what extent do these characteristics have to be taken into account in the resilience of children in general and in academic resilience in particular?

The teachers' point of view concerning resilient student, and in return, on the non-resilient student is essential because it can influence their practice. The students often spend more time with their teachers than they do with their own family. The impact they can have on the mental development of children is often determinant [8].

Conclusion

The objectives of this study were to identify the teachers' knowledge of the concept of resilience, study which had never been done in France before. The Aim was also to identify the characteristics attributed to the resilient students. Our results are consistent with those reported in the literature indicating that teachers working on different continents master only partially a concept that could be of great use in their professional practice.

Despite this, the testimonies concerning students identified as resilient highlights the attention given to the difficult situations or traumas suffered by children. It appears highly necessary that the concept of resilience should be integrated into the training courses for kindergarten and elementary school teachers

Academic resilience and academic adjustment for the first year university students

Cazan A.-M.

Transilvania University of Brasov, Faculty of Psychology and Education Sciences (ROMANIA)
ana.cazan@unitbv.ro

Abstract

Recent research shows that there are significant differences between resilient and non-resilient students on a variety of background characteristics and personal attributes (learning motivation, perceived learning environment, academic stress). The present study aims to investigate the associations between resilience, perceived stress and academic adjustment. The results showed that the Romanian version of The Adolescent Resilience Scale, the main measure used in this study, has good psychometric properties. The results confirmed that resilient personality traits mediate the relationship between academic stress and academic adjustment. The results indicate the need for further exploration about the relationship between resilience and academic stress and negative life events in order to make clearer predictions of academic adjustment.

Keywords: Academic adjustment, academic resilience, academic performances, stress, negative events.

Introduction

Kumpfer [6] shows that the studies on resilience focus on several aspects such as the operationalization of the concept of resilience, the self-characteristics of a resilient person, the difficulties of separating cause and effect or locating good measures for resiliency variables. Resilience can be understood as a process, or as a feature of an individual. As a process, resilience must be viewed as interplay between certain characteristics of the individual and the environment, a balance between stress and the ability to cope [12]. Resilience is a developmental process, an "ordinary magic", resilience is not a fixed attribute but a set of processes that can be fostered and cultivated [10]. As a psychological characteristic, resilience means a set of trait of individuals with strong mental health and who show adaptive recovery from adverse conditions [13].

First year at the university is a time of transition, challenges and demands. The combination between these demands and the individual adaptive resources determine a high level of academic stress and a low level of academic adjustment and resilience. Recent research shows that there are significant differences between resilient and non-resilient students on a variety of background characteristics and personal attributes (learning motivation, perceived learning environment, academic stress). Learning engagement and learning motivation can also be considered factors which can explain academic resilience [8]. Academic resilience is positively related to academic self-efficacy, mastery orientation, self-regulation of learning, academic achievement [16]; and it is negatively related to self-handicapping, anxiety, procrastination, lack of regulation and failure avoidance [9].

Recent studies in the field seek to better understand the construct of resilience and provide a context for how it can be further studied in academic settings. Recent studies showed that two groups of factors explain the variance in students' ability to deal with academic setback and adversity: individual characteristics and supportive school community. In terms of individual characteristics, the most important factors are locus of control, academic engagement, and self-efficacy. In terms of the supportive school community, the most important factor refers to positive teacher – student relationships [2]. Positive relationships with students maintain and create a positive academic environment and a sense of belonging, promote positive expectations and provide opportunities for participation and academic engagement.

As Martin and Marsh noted [11], the studies that deal with academic resilience tend to be focused on ethnic groups situated in adverse conditions and situations, chronic underachievers or resilience in the academic setting for students with learning disabilities. More frequently, academic resilience is studied in association with academic stress or negative life events. Resilience is often used to suggest an ability to recover from stressors and the relative degree of resilience depends on the stressor in question [5].

Purpose of study

The present study aims to investigate the associations between resilience, perceived stress and academic adjustment. Our hypothesis is that resilient personality mediates the relationship between academic stress and academic adjustment.

Methods

1.1 Participants

The participants were 340 first year students at various faculties at Transylvania University of Brasov. The sample was composed of 82 men and 259 women, with a mean age of 20 years.

1.2 Measures

Several questionnaires were administered: The Adolescent Resilience Scale [15], Student-life Stress Inventory [4] and The Academic Adjustment Questionnaire [3].

The Adolescent Resilience Scale [15] consists of 21 items and three factors: Novelty Seeking, Emotional Regulation, and Positive Future Orientation. Novelty seeking refers to the ability to show interest in and concern about a wide variety of events. Emotional regulation is a trait of individuals who exhibit composure and control their internal emotions. Positive future orientation concerns approach to goals in the future [13].The scale was translated and adapted for the Romanian population and the psychometric analysis revealed high reliability coefficients for all the dimensions: .76 for Novelty Seeking, .70 for Emotional Regulation, .82 for Positive Future Orientation and .81 for the entire scale.

Gadzella's [4] Student-life Stress Inventory (SSI) offers good measurements for academic stressors and reactions to stressors. The academic stressors dimension yields scores from five stress categories: frustrations, conflicts, pressures, changes, and self-imposed. Reactions to stressors yield scores from five categories describing reactions to physiological, emotional, behavioral, and cognitive stressors. The 51 items require a 5-point Likert-type response format. The Alfa Cronbach coefficient shows good psychometric properties, ranging between .70 and .84.

The Academic Adjustment Questionnaire [3] is a self-report instrument scored with 0 and 1, designed to assess the student's adjustment to the academic learning process. The 24 items measure two dimensions: Neuroticism and Procrastination. The reliability is very high for the entire AAQ scale (.86), but also for Neuroticism (.84, respectively), and for Procrastination, although slightly smaller (.77). High scores on AAQ are not measuring the adjustment, but the academic maladjustment and provides a specific expression to the emotional adaptive reaction (through Neuroticism) and to the efficiency of the academic adaptation (through Procrastination).

Findings and results

Results showed moderate but significant correlations coefficients between resilient personality, academic stress dimensions and academic adjustment. In order to test the mediation hypothesis we tested various alternative structural models: the first model included as endogenous variable the overall score of the Resilience scale, the second model included all three resilience scales, but both models had unsatisfactory fit indexes. The third model included also previous academic performance (school grades at the end of high school) as predictor for academic adjustment. The inclusion of previous academic performance led to a more appropriate model fit (Table 1).

Table 1. Fit indexes for the selected model

Model	χ2	df	p	RMSEA	CFI	NFI
	168,94	8	>.001	.157	.827	.823

Note. RMSEA: Root Mean Square Error of Approximation; CFI: Comparative Fit Index, NFI: Normed Fit Index

The path analysis revealed that both stressors and reactions to stress have direct negative effects on two of the resilient personality traits: emotion regulation and positive future orientation. High school grades have positive direct effect on positive future orientation. Both emotion regulation and positive future orientation have negative direct effects on academic maladjustment. Novelty seeking does not have significant effects. The results

showed indirect significant effects of stressors and reactions to stress on academic adjustment, which prove that resilient personality traits mediate the relationship between academic stress and academic maladjustment (Table 2). Although previous findings suggest that academic achievement is a prerequisite of resilience [1], the present study did not confirm this hypothesis, previous academic achievement (high school grades) has not a significant effect on resilience.

Table 2. Direct, indirect and total effects (Standardized estimates) for the structural model

Exogenous/Exogenous variables	Novelty seeking	Emotion regulation	Positive future orientation	Academic (mal) adjustment		
EFFECTS	Direct/Total	Direct/Total	Direct/Total	Direct	Indirect	Total
Stresssors	.02	-.33**	-.08		.17**	.17**
Reaction to stress	-.15*	-.18**	-.13*		.12*	.12*
High school GPA	.05	.12*	.03	-.01	-.06	-.07
Novelty seeking				-.02		-.02
Emotion regulation				-.44**		-.44**
Positive future orientation				-.28**		-.28**

* p<.05, ** p<.01.

The total variance explained of academic (mal) adjustment is 30%.The most important traits of the resilient personality seem to be emotion regulation and positive orientation to future, while novelty seeking has no influence on academic adjustment (Figure 1). Resilient students are able to cope with stressful situation and to regulate their reaction to stress in order to achieve a higher level of adjustment. Resilience is a mediator in the process of overcoming and adapting to stressful events generated by the academic life.

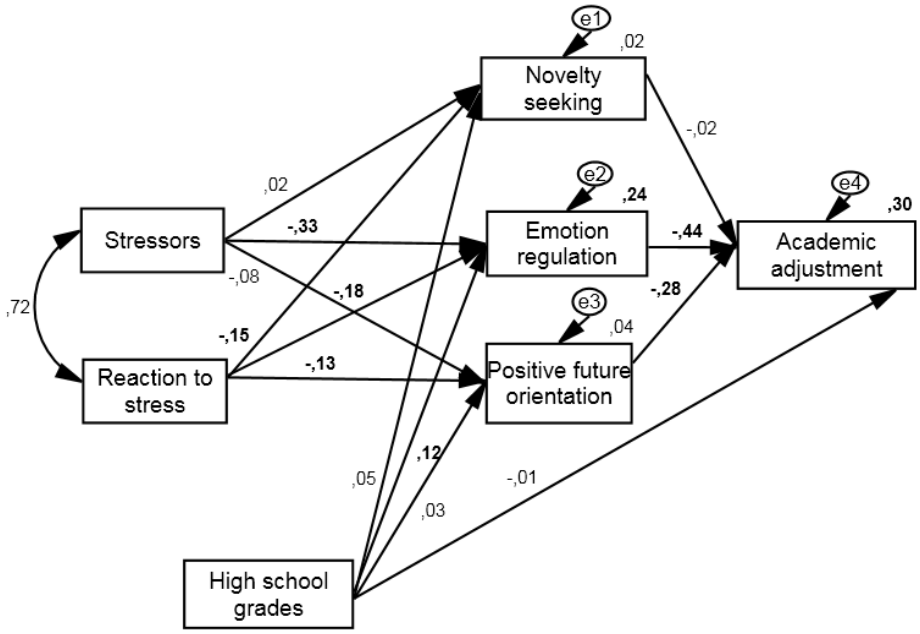

Figure. 1. Structural regression model of academic (mal) adjustment (standardized estimates)

The results highlights that the more important aspect of resilience is emotion regulation, confirming the fact that emotion regulation contributes to academic adjustment. Emotion regulation has been linked to many different types of adjustment: cultural, interpersonal or educational adjustment. A mediation model was also proposed by [17], suggesting that emotion regulation has a mediating role between family communication pattern and academic adjustment.

Academic stress is a risk factor that may lead students to negative health outcomes [18]. Individuals who are highly resilient exhibit adaptive skills to convert stressors into opportunities for learning and development, thus leading to a higher level of academic adjustment. A student's level of resilience and the manifestations of that resilience are related to effective adaptive strategies to academic stress [20]. Stressful situations can be considered from this point of view as antecedents which occur and impose the necessity to regulate emotions and to change the future orientation [19]. The mediation effect explains the fact that

individuals may have adequate reserves to recover from moderate stressors yet lack sufficient resilience to recover from severe stressors [5]. Resilience refers to good adaptations despite stressful (common) experiences. The results indicate the need for further exploration about the relationship between resilience and academic stress and negative life events in order to make clearer predictions on the benefits to academic adjustment.

Conclusion

The review of the resilience literature reveals numerous relevant constructs linked with academic resilience, like depression, stress, vulnerability, mental illness. These factors are indicative for positive adaptation and they are counterbalanced by efficient psychological adjustment, ability to develop new coping strategies, high self-efficacy and positive self-esteem.

The results showed that the Romanian version of The Adolescent Resilience Scale has good psychometric properties. Further studies will test also the factorial structure of the instrument after its translation. The most important finding is the mediation model, proving that resilient individuals can perceive stressful circumstances to be less threatening (emotion regulation), they can identify the positive outcomes of events and they view difficult situations as challenges (positive future orientation), they are more likely to complete tasks in creative ways rather than in routine ways (novelty seeking), thus leading to effective academic adjustment.

Further research in the field must take into account also other aspects such as, achievement motivation, academic self-efficacy, anxiety and coping strategy. Social support and parental styles were also reported in the literature [14]. Academic resilience is not static [7], thus students who are academically resilient at one point in their lives may begin to struggle academically under the influence of risk factors. In order to test this hypothesis, a further study with a longitudinal design would appropriate. Given the fact that this study was conducted at university level, in order to validate the mediation model in and examine how stress and resilience affect academic adjustment, we intend to conduct further researches on various age groups and educational levels.

The need for mentoring as a resilience factor for adapting to school workplace

Crasovan M., Predescu M.

West University of Timisoara, Educational Sciences Department
mali.crasovan@gmail.com, mfpredescu@gmail.com

Abstract

The professional development of teachers is a never-ending story. The teacher has to learn new skills, new didactical approaches and to adapt them to new cohorts of students with different characteristic. One major step in the professional career of teacher is the start of practice in teaching. In this period the stress is double. On the one hand there are certain expected didactical performances required in practice. On the other hand there is a need to adapt to specific job requirements, organizational culture and values. The most effective method is mentoring the new teachers and to coach them during the process of accommodation to job. Romanian education system is starting to adopt mentoring practices in schools.

The studies show that the first year of teaching is critical for the debutant, making him choose if he continues his activity as a teacher and, on the other hand it predicts the type of teacher he will become regarding his beliefs, attitudes and his practices. The debutants overcome some enormous difficulties when they start their career and many of them fail and do not make it through the accommodation period. 30% of them do not teach for more than 2 years, 40-50% of them leave the system in the first five years of teaching [1]. For the diminution of these difficulties, the specialists have proposed solutions that aim at the practice extended to the workplace and induction/ mentoring programs

Our study goal is twofold. We are trying to find out the main needs for mentoring of the debutant teachers. For this purpose we will conduct a focus group with teachers that have been working in schools for maximum 2 years. We will collect two categories of data: stressors in job adaptation and needs for mentoring. The second goal is to design a scale of stress and mentoring resources in teaching career. The scale will be pretested and tested on a different sample of novice teachers.

Key words: difficulties, opportunities, induction, mentoring, novice teachers, stressors

Theoretical background

The first workplace and starting the teaching career as a full time job as a teacher is a period of time that everybody remembered very well. This is a stressful period, with plenty of emotions, challenges and uncertainties. Teachers came back to schools, changing the role of student with the role of teacher and make the transitions from learning to learning others. After the time spending in universities and schools as learner, the novice teacher often has an idyllic image about teaching profession.

The studies show that the first year of teaching is critical for novice teacher, making him choose if he continues his activity as a teacher and, on the other hand it predicts the type of teacher he will become regarding his beliefs, attitudes and his practices. The debutants overcome some enormous difficulties when they start their career and many of them fail and do not make it through the accommodation period. 30% of them do not teach for more than 2 years, 40-50% of them leave the system in the first five years of teaching [1].

Wanzare [2] makes an inventory of ways of describing the first year of teaching:

- Critical in beginning teachers' decision to make a commitment to teaching and to remain in the profession (Gold, 1996: Hope, 1999);
- Critical in developing novice teachers' confidence in themselves as maturing professionals (Weasmer and Wood, 1998);
- A period during each NQTs shape their attitudes, beliefs and practices(Michael at al., 2002);
- A ritual bridge that NQTs have to cross to enter the teachers' world (Britzman, 1986; Roy at al., 1998);
- Most challenging, exhilarating, and often most traumatic to beginning teachers (Cole at al., 1995; Kottler et al., 1998);
- A period during which NQTs face unique problems (Huling-Austin et al., 1989).

In the same time, the novice teacher experiments emotional, social and professional isolation [3], having few opportunities for professional debates or cooperation with other teachers. This culture of "closed doors" could determine a non-involvement attitude [4]. The novice teachers are oriented on their own needs; the first and only preoccupation is the content and the silence of the classroom. During this stage, they don't have total control of class, don't have clear rules, they react to different situations and aren't able to anticipate the possible problems that could appear. As any other teacher, they have a lot of responsibilities and tasks in schools; they have to teach well, to evaluate the students correct, to discuss with parents, to find solutions to different problems and the list can continue.

Kessel [5] divided novice teachers in two categories: first of them have authoritative attitudes, with strategies of domination and the second one there are the laissez-faire attitude, with strategies of fraternizing. For the diminution of these difficulties, the specialists have proposed solutions that aim at the practice extended to the workplace and induction/ mentoring programs. The aim of these programs is to offer assistance, guidance, counselling, support for the debutant teachers in order to facilitate the integration of the theoretical knowledge with the practical ones and to adjust better to the specific atmosfere and school micropolitics (the term was introduced by Kelchtermans, Ballet, 2002) [6]. When the debutant benefits from the support of a more experienced person is called induction, and the one offering his expertise and experience in domain is called mentor.

The induction period reffers to a period, between 1 and 3 years, untill the obtainance of a form of certification for the didactic profession. In many educational systems, going through this period, under the guidance and assistance of an experienced teacher, called mentor for the professional debut or induction mentor, is mandatory. The aim of this induction period is to be sure that all new qualified teachers are being helped during the first years of teaching through a program that assumes two elements: an individual developing program, support and dialogue with a mentor, and on the other hand, the monitoring and assesment element of the debutant's performance, be reporting to a set of special standards. This period is usually finalised with a complex evaluation and the further path of the teacher depends on its result (continuing as a teacher, loosing the right to teach, extra guidance program) [7].

The objectives of the study

The relation between resilience and professional debut has a great value. The teaching debut is a typical adverse situation, not because teaching is stressful in itself, but because it implies a time of great changes and challenges for the novice teacher. First of all, it is the need to adjust to the new workplace, not only in term of teaching competences, but also in terms of meeting the schools standards, habits, needs and requirements. Secondly, the typical novice teacher is a graduate student. For most of the novice teacher this is the first full time workplace. In this respect, they switch from a social group of peer students to a more diverse (at least in terms of age distribution) group of coworkers, hierarchically structured and functioning according to some particular rules. Thirdly, teaching is a job that involves social responsibilities. They have to prove that they meet the standards of quality in educating children. In this case, the pressures are both top down (local education authorities, managers) and bottom up (from children and their families).

The first purpose of our study was to find which are the most and least stressful situations for the teachers and if they could be categorized in patterns. The second purpose was to find which type of resources the teachers need in order to overcome the main difficulties in the beginning of teaching profession. Our assumptions were that teachers have difficulties in several key areas of teaching, namely didactics, classroom management, curricular approaches and adapting to school culture. Basically, we made the assumption that the most stressful situations involve maladjustment of novice teacher to the teaching environment with an internal locus of control. We also made the assumption that novice teachers will search for resources that increase their teaching skills in the form of mentoring, trainings and opportunities to share teaching experiences.

Subjects and instruments

For our study we searched for novice teachers, both in mainstream and special schools, with an experience less than three years. Due to the fact that there were exclusionary criteria and a limited number of schools (from Timisoara city) our sample is not random but a convenience one. The number of novice teacher is small (N=20) due to the small number of new teachers that entered the teaching profession following the changing rules for admission in teaching.

For the purpose of the study we developed two instruments, one is a scale of stressors and the other is a list of resources for novice teachers. The two instruments were developed following 2 focus groups, with two groups of eight novice teachers each. From the first focus group we obtained a list of 20 resources that were available to at least one of them in the schools. Four of them were versions of previously named resources. Finally we keep for our list of resources 16 different provisions for novice teacher. This list is consistently with

the literature in the field of mentoring. The subject had to classify them hierarchically from the most useful (ranked 1) to the least useful (ranked16).

From the other focus group we get a list of 19 stressful categories. We reduce them to ten general categories and then, for each of them, we designed four typical situations. That led to a list of 40 typical stressful situations. Our subjects assessed each situation on a Likert like scale in five points; from *I am confronted very rarely with this situation* to *I am confronted very often with this situation.*

Results

In order to analyze the result of *The Scale of Stressors for Novice Teachers (SSNT)* we will refer to two operations. First, we will see what are the most stressful situation and the least stressful ones. This analysis will allow seeing if the stressful situations have a similar input or require a similar set of skills to overcome. The second analysis is if there are some patterns of stressful situation. We will accomplish this by factoring the forty stressful situations.

The descriptive data of the scales revealed that SSNT has a good internal consistency (α=.893). The mean of the scale is 87.16 with a standard deviation of 18.55. The lowest mean for an item was 1.44 (s=.61) and the greatest 3.72 (s=1.56). The range for items on a five point scale indicates that all the stressful situations are relevant. 15 items ranged from 1 to 3, that means weak stressful situations, 8 items ranged 1 to four and 17 items ranged 1 to 5 which indicates that the situations are strongly stressful for at least some of the subjects.

The items with the lowest means were:

The children doesn't respect me (mean= 1.44, s=.61)
The children with slow pace disturb my activities (mean=1.55, s=.85)
I found difficult to adapt the curricula to the level of the class (mean=1.55, s=.61)
I lose a lot of time due to schedule (mean=1.55, s=.70)
The children don't obey as they should (mean=1.61, s=0.77)

All the items suggest that these situations aren't typical for a stressful situation. Some novice teachers have sometimes difficulties with behavioral management or curricular adaptation, but most of them don't find this situation as stressful. All items are related with personal competence of the teachers or the relation between teachers and pupils.

In contrast, the most stressful situations are:

The family needs to motivate stronger their children (mean=3.72, s=1.56)
Parents participate only in small numbers to our meetings and don't involve in activities (mean=3.27, s=1.40)
The today's pupils aren't motivate to learn (mean=3.11, s=1.45)
The resources of the classroom are not proper and affects my activities (mean=2.88, s=1.45)
Today's pupils are insolent (mean=2.88, s=1.45)

As we can see, our assumptions were wrong. The items above show that teachers are not stressed by personal performance but by external factors. Two of them involve the parents that are not motivating the children enough for school activities and are not participating in classroom activities and meetings with teacher. That means that the novice teachers share responsibilities for children performance with parents in a teaching paradigm which requires close supervision of pupils outside school. Two statements refer to motivation as a factor of poor activities. It seems that novice teacher have difficulties in motivating pupils or they don't assume the role of motivating them. Two statements are general statements about the characteristic of *today's pupil* using an idealized image of a former, "golden age" children different from the actual students that behaved well and was motivated to learn. Such an approach reveals a specific attitude toward school and school role.

We performed a principal component analysis on the SSNT, and we used Varimax rotation in order to minimize the correlations between factors. The rotated solution consists in twelve factors that explain 93.44 of total variance; each factor has a explaining power between 12.00% and 4.77% from total variance. Some factors are composite and have a greater number of items that are loading significantly, other are described by just one statement. We will present only those with composite structure.

The first factor consists in 7 items, with a loading value between .854 and .635 and explains 12% of total variance. We named this factor adjustment due to the fact that has items describing diverse situation which involve adjustment to requirements. Some of the items are: *it is difficult to adapt to school habits, I feel that I am monitored closely, the experience teachers are reluctant with me, and it is hard to teach because children are different.*

The second factor explains 10.48% of total variance and we name it children issues. It has 5 items loading between.804 and .636. Four of five items are directly referring to children as being insolent, fidgety or lacking motivation. The fifth item is about the stress of completing documents about children.

The third factor is time pressure. It consists in four items and explains 10% of total variance. On this factor some items are negatively load, but all four are connected to time, even it is a loss of time (for example to participate in trainings or to do paperwork) or it is not a loss of time (to observe other teachers or to manage the discipline problem).

The fourth factor is about parents and resources. It is not surprising that the two separate issues are related because parents are good providers of resources in Romanian schools. The factor consists in five items and explains 9.92% of variance. This factor is loaded by teachers who externalize the cause of the stressful situation, blaming the parents or the lack of resources for lack of performance.

The fifth factor consists in four items related with lack of knowledge and the sixth consists in four items related with the overloading of the novice teacher. The last two composite factors are related with discipline issues and inefficiency.

Our second goal was to see what type of resources the novice teachers are finding useful. We ask our subjects to rank the 16 type of resources. All the resources were found useful at least by some of them (all of them have a range of 12). The results showed that the most desired resources are:

Emotional support (mean=6.22, s=3.81)
In service training on different subjects (mean=7.33, s=3.74)
Being assisted in classroom by a more experienced teacher (mean=7.56, s=4.47)
Mentoring (mean=7.67, s=6.42)
Team teaching with a more experienced teacher (mean=7.89, s=5.50)

We have to notice that all the support is at school level, involving a more experienced teacher. That could support the idea that the novice teachers perceive the mastery in teaching as a handcraft that could be learned in close relation of an experienced teacher. They want "to steal the skills" of being a good teacher from a role model one.

In contrast the least useful resources are in our subject's opinion:

Access to teaching literature (mean=10.28, s=3.89)
Participating to conferences, symposiums, workshops and debates (mean=10.17, s=3.80)
Practical courses delivered by university (mean=9, s=4.48)
Clear expectations from the school manager (mean=8.72, s=4.40)
Group discussions with other novice teachers (mean=8.61, s=3.84).

The conclusion from the items listed above emphasize the fact that external sources for professional development or the self-development activities are disregarded when compared with school based resources. Theoretical and practical updates of knowledge and skills are not as important as learning by doing and learning routines. This type of procedural learning has, nevertheless its strong point but disregarding sharing experiences, learning new skills and self-development leads to executive teachers that are applying learned routines and ways of teaching. Unfortunately this contradicts the contemporary model of critical teacher, focused on discovering new way of teaching and self-developing.

Discussions and conclusions

Our study reinforces the idea of guidance, support and mentoring programs for novice teachers. During the first year of teaching they balance between school expectation, pupils, parents, community, their own teaching philosophy, their own system of beliefs, trying to find their own way. It is a difficult and stressful situation.

As we can see from the results mentioned above, the novice teacher inventory as stressors only aspects that are not depending on them directly. They mentioned adjustment, children, time pressure, parents and resources. They aren't able yet to analyse the complex teaching context and focus only on themselves and others doesn't function well. They are overwhelmed by the multitude of tasks and new and challenging situations and often they don't ask for help to expert teachers. Even the teaching profession is one of the most sociable one, the teachers are solitary, alone in their classes.

Regarding the useful resources, they mentioned emotional support, mentoring, observing the experienced teachers and discussions with them. They need direct information with instant impact and efficiency. Even in Romania is stipulated in official documents the concept of mentoring for induction period, but this isn't implemented yet because the lack of money and the lack of resources. In some schools there are some informal mentoring programs, for a short period of time.

The teacher activities and responsibilities become more and more complex and teachers' activities are not longer conducted strictly in the classroom. They have to work with community, with pupils with special needs and must assume active roles in terms of their own learning and development.

Specific and efficient in the strategy to increase resilience in university environment

Danciu E.L.

West University of Timisoara, Romania, Faculty of Sociology and Psychology, Department of Educational Sciences

Abstract

Explained as the ability of individuals to bear stressors without manifesting psychological dysfunction, mental illnesses or a persistent negative disposition, "of surviving adversities, traumas and threats and to go on with his life with a feeling of control, competence and capacity, the concept of resiliency (in the psychological field) was created by Boris Cyrulnik one of ethology French pioneers, neuropsychiatries, psychoanalysts, psychologist and author of numerous works.

He means more than the simple adaptation to adverse conditions or simple survival. Under the conditions in which problematic social life is more and more complicated and families can no longer fully maintain their children at universities, when many students are forced to find a job to handle the demands but the problems that life interposed in their path, it is increasingly necessary to form those capabilities that will help them cope with success of major and continuous changes; to find a new way to work, and to live when the old is no longer possible to exceed arguments, to recover quickly after failures.

The manner in which a team of experts have used a whole series of natural techniques and innovative, specific therapeutic procedures first aid psycho physiologic and therapy self help students traumatized your to steady himself and monitoring necessary for them to work in harmony in the relationship with their environment, the results obtained and the manner by which the time limit has been exceeded inherent blockage is the subject of article.

Key words: resiliency, risks, natural techniques, assisted programs of resiliency, self therapy, first aid psycho-physiological

Introduction

Under the conditions in which problematic social life is more and more complicated and families can no longer fully maintain their children at universities, when many students are forced to find a job to handle the demands but the problems that life interposed in their path, it is increasingly necessary to form those capabilities that will help them cope with success of major and continuous changes; to find a new way to work, and to live when the old is no longer possible to exceed arguments, to recover quickly after failures, especially because the traumas affect the brain, ultimately influencing their learning and behaviour.

Some students, leaving home for the first time in their life, adjust themselves quite difficult, frustrations are high in the absence of family and close friends offering needed affection to overcome problematic situations. [10]

This capacity of being able to overcome the most serious mental traumas and emotional wounds – illness, loss of loved ones, rape, torture, attempt, deportation or war, is termed resilience and represents the materialization of human dignity and power in their absolute form.

Introduced by american psychologist – Prof. Dr. Al Siebert, the term of resilience, as human ability, refers to “aspect that helps us to survive adversities, traumas, tragedies, threats or other acute or chronic stressors (poverty, violence, chronic desease, death of loved ones, physical or emotional abuse) without manifesting psychological dysfunctions, mental illnesses or a persistent negative humor and allows us to continuing our life with a feeling of control, competency and capacity”.

Resilience assumes that you have the capacity of maintaining your health and energy when you are under constant pressure, to rapidly recover after failures and to overcome adversities, to successfully cope with continuous and major changes, and to find other opportunities to work and to live, when all other options become impossible, in a manner as less dysfunctional or destructive as possible, not letting yourself overwhelmed by the negativity of the feelings and to turn to good account the life lessons received. [1] [4]

Positive psychological adaptation in front of a significant stressor factor affecting development and even survival [3] ***resilience*** assumes a range of personality traits serving as resistance sources when we are confronted with a stress situation. The existence of more than one term associated with resilience in order to describe its characteristics or being used as "synonymes" like: *adaptative coping, emotional intelligence* [5], *learned optimism* [12] *resources discovery*, *life orientation, self respect, self-efficacy, self-confidence, self-healing personality,* all created confusions and slowed down research on this topic. Concepts related to the feeling of coherence (Sco) as the "sixth sense" for survival, with a global orientation, also known and mentioned by Antonovsky as *"stress hardiness, "the sense of permanence"* , *the importance of "social climate" "the construction of family reality"*, all emphasized on the *„search for meaning"*.

From the perspective of salutogenesis, is essential to maintain health, against the stress and germs, and the concepts preponderently vehiculated are *„flow*", „*learned resourcefulness*", *life control*" „*self-efficacy*", *general resistance resources*" and they fulfilled the wide range of the concepts in this field.

In resilience building, the core process is represented by the ability to cope, and the basic model is represented by the scheme:

The stressor X (potential stress source) induces a cognitive representation with the decision determining if X is an event that can be quickly managed, or is representing a stress factor because can overcome the person's coping possibilities. If the stressor is identified as dangerous, then the coping responses are activated.

Resilience also assumes a range of personality traits serving as resistance resources when we are confronted with distress situations. [6]

It also assumes o range of personality traits serving as resistance resources when we are confronted with stress situations. [13]

Methods

The longitudinal research initiated by a team of psychologists, educators, social workers, sociologists, therapists, doctors, was held for a period of 48 months, with required sequential adjustments and evaluations every six months or any time it was necessary, correlated with the seriousness of the cases.

The main research objectives were:

- *Developing young adults' resilience, in such way that, when seeking to develop themselves against oppressive adversity, to experience a state of wellbeing*
- *Using a composite methodology for collecting and interpreting research data of both qualitative and quantitative character, methodology taking into account multiple realities*
- *Identifying the relationship between adapting capacity through humor and the effect of social pressure sources on physical and mental health*

Hypotheses

Using certain methods adequate to each set of issues and each personality, it will have as effect a real resilience.

Primary, secondary and tertiary methods, individual techniques and anti-stress strategies have been used, anti-stress, pro-eustress, sanogenetic behaviours targeting the enhancement of anti-stress filters efficiency have been exerted. The coping categories used (avoidant and vigilant coping, relational coping, anticipatory coping, preventive coping, practical/dynamic) have been focused upon issues and emotion.

The instruments

The instruments used have been the Adaptive Scale through Humor, the Panas scale, the ASSET test, the Resiliency Scale for Students [6] and the Resiliency Scale [14], Individual Semi-structured Interviews, the Interview Guide that was made the topic of both focus-group sessions, and individual semi-structured interviews.

The two sample groups, **the control group and the** experimental one, that became enriched, both as casuistry, but also numerically during the 4 years, included the following categories of subjects

- **Coming from families within which domestic violence is commonly manifested**
- **Having serious health issues – breast cancer, brain surgery due to head trauma, multiple surgery due to genetic deficiencies**
- **Having financial issues and unable to cover tuition expenses due to:**

- *broken pledges made by family or financial supporters*
- *constraint of not leaving far from family, to other areas/locations*
- *hard financial situation*

- **Having both parents deceased and no financial supporters**
- **Having adjustment problems due to lack of parenting – their parents working abroad**

The majority of the subjects are introverted and having difficulties in personal attachment, [8] they prefer solitude and their issue is the keeping of a secret. They do not accept to exhibit their problems in public, nor their emotional status, and they behave as having no problems at all. In order to gain their confidence and to determine them to accept the offered aid, a long period of exercising empathy and communication was needed [11] – even the group therapy meetings were very discreet, never within the university premises, and in favorable circumstances for relationship. [9]

The subgroups of sample group included subjects with both developed and underdeveloped sense of humor.

The stages of research comprised the selection of experimental and control groups, training the team partners, manipulating the variables and post-experiment testing.

Results

Apart from the methods and instruments used, important was the communication, the high level of empathy and trust, either in therapist or in teacher, inter-personal relationship teacher-therapist that went even to visiting them in hospital, counseling them and their families, actions taken for their admission in hospital, their surgery, exams given in hospital in order not to loose the year of study, and all these in order to increase their self confidence, self respect, and not allow themselves to be defeated by the persistence of adversities.

The interactional model of stressors, coping and results was focused upon highlighting the impact of various stress factors, of coping and interpersonal relationships established within family and group of friends, enhancing the level of self esteem and respect, upon students' operation and adjusting to university life.

The provocative methods being used determined a pleasant, stimulating atmosphere that allowed subjects a direct and spontaneous expression of their own ideas and feelings.

The teachers and students' answers to individual semi-structured interviews on the topic of applied resilience had a correlation of $r=0.32$, $p<0.01$, the value of concordance between the answers of the two sample groups being 58%. The scores obtained for assessments of behavioural reactions and levels of affectivity demonstrated a more significant impact of anti stress strategies $|t| = 2.57$ respectively $|t| = 2.62$ ($p<0,02$) compared to relational ones.

Correlations between humor coping and social pressure of external group were extremely significant – $r = .121$; $p< 0.01$, as were those between the manner of stress adjustment and the lack of organizational support $r = .128$; $p<0.01$. Also significant was the relationship between humor coping and the pressure of current stress specific to academic instructional activities $r = .102$; $p<0.05$.

A possible increased efficiency of humor as coping strategy has been found, and in correlation with the stress specific to academic environment, all the three stress types have an extremely significant correlation – $r = .128/176/232$; $p<0.01$, which entails the need for a more active involvement of the group in overcoming stressful situations.

Aggressive humor correlated the most with the stress types specific to academic environment, even if the sarcastic and manipulating humor is specific to male gender $r = .126\text{-}128$; $p<0.01$.

Humor for insinuating or self defeating, for self deprecation, have significant direct correlations with stressful situations ($r = .126$; $r=.145$; $p<0.01$) when pressures emerge within the tasks.

Per total sample group was obtained a $r=0,34$ $p<0.01$ correlation between students' estimation and that obtained through objective methods. The concordance value between methods of intervention was 52%, a quite low value, due to parents' proclivity to exaggerate the seriousness of the impairment.

Regarding the psychological impact of the illness on the students' lives, the results revealed the fact that subjects being included in the category of those with a serious diagnostic obtained questionnaire scores showing a more significant impact of the illness $|t| = 2,57$ respectively $|t| = 2,67$ ($p<0.02$) compared to those in the moderate category.

Related to the objective criterion, no significant relationship between seriousness of desease and its psychological impact has been found. Separately analysing just the exacerbation criterion, a higher questionnaire score was obtained, meaning a more important impact, as the number of exacerbations grows ($p<0.05$).

The specific therapeutical procedures of „psycho-physiological first aid" and „self adjustment therapy" proved themselves to be easy to implement, both within group activities and in the consulting room, and demonstrated that behind unexpected reactions of „difficult students" there often is an unidentified trauma.

The writing activities carried on with subject destabilized by the destructuring violence of traumatic shock took different shapes (diaries, essays, correspondence, notes, fragments, graffitties) and determined *the elevation of „ I" defying pain and terror*.

Apart from used methods and instruments, important were communication, the high level of empathy and trust, either in therapist or in teacher, interpersonal relationship teacher-therapist that went even to visiting them in hospital, counselling them and their families, actions taken for their admission in hospital, their surgery, exams given in hospital in order not to loose the year of study, and all these in order to increase their self confidence, self respect, and not allow themselves to be defeated by the persistence of adversities.

Conclusions

The relevance of the results obtained following investigations, the sequential adjustments carried on in order to gain a real resilience that is not just an external process at community level, but also an internal one, a personal transformation making us more flexible, robust/sturdy and qualified/skilled, demonstrated the efectiveness of undertaken interventions. Coordinate action, behavioural expression of the inner world through images or words, securing attachment build step by step helped students to become again masters of their own emotions and to create around them what they intended to see.

In most of cases, the effort exerted during this process, discovering the strenghts of their own personality that they weren't aware of, achieving things they did not believe they could, and transposing in a posture of co-therapist for the others after crisis, were all more important than efficacy of obtained results.

Positive inter-relationship, high socio-affectivity, confidence that they have the power to continue against all obstacles, openness to others, all as effects of implemented therapeutical interventions demonstrated the validity of original hypothesis.

The problems will never absolutely disappear, but the courage to overcome them will last. With the same discretion, because nobody likes to see one's life advertised, the interventions on the topic of resilience continue. But now we consider that we have more numerous and effective solutions to solve the others' problems.

Une analyse des relations entre le bien-être pédagogique et la résilience des enseignants du secondaire

Dobrica-Tudor V. , Théorêt M.

Université de Montréal (Québec, Canada)
viorica.dobrica@umontreal.ca, *manon*.theoret@umontreal.ca

Abstract

When we study the importance of resilience of teachers' work, we think to the positive impacts of this state both their own emotional and professional well-being and the success of students: a resilient teacher reflected on professional practices and trusts to its ability to adopt new teaching strategies [1]; [2].

From a mainly qualitative exploratory research conducted with ten teachers, we want to describe and understand how teachers adopt work practices reflected and shown a high level of educational well-being, they also perceived as resilient.

To do this, we developed a method that uses the technique of Q-sort. We ask participants to rank statements developed from the model proposed by thinking about Korthagen and Vasalos [3] practice. Depending on the degree of agreement between these statements and practices, they are asked to think aloud, to their classifying.

In this research, we investigate how difficult emotions related to pedagogical relationships with students lead teachers to adaptive behavior, manifested by reflections on what changes to make. For the implementation of these changes, teachers live feelings of self-efficacy and satisfaction, feelings that we associate with educational welfare and educational resilience.

Keywords: welfare educational, emotional, professional practices, resilience, Q-sort.

Le cadre théorique

Notre recherche se penche sur deux concepts : le bien-être pédagogique et la résilience.

Klusmann et al. [2] associent le bien-être professionnel des enseignants à la réussite de leurs pratiques professionnelles: une gestion de classe efficace qui favorise l'apprentissage dans un environnement sécuritaire, la création d'un environnement d'apprentissage basé sur le respect et le soutien affectif des élèves et la motivation de ceux-ci. Selon Soini, Pyhältö et Pietarinen [4], le bien-être pédagogique des enseignants se développe pendant des interactions professionnelles à plusieurs niveaux: avec les élèves, les collègues, les familles et d'autres membres de la communauté scolaire. Des dimensions qui pourraient caractériser le bien-être professionnel des enseignants, nous nous concentrerons sur trois : le sentiment d'efficacité, l'engagement professionnel et la satisfaction au travail. En concevant le bien-être comme un processus soutenu par l'engagement et la satisfaction au travail et renforcé par le sentiment d'efficacité de pratiques professionnelles, nous nous inscrivons dans l'approche sociocognitive.

La résilience, le deuxième concept de la recherche, représente une qualité dynamique que l'individu mobilise pour répondre aux besoins d'adaptation positive aux circonstances difficiles; elle est orientée vers un but et entraîne l'engagement dans des actions significatives [1]. Pour Fredrickson [5], la résilience représente un construit psychologique soutenu par des émotions positives; les émotions difficiles seraient associées aux problèmes de santé mentale: troubles anxieux, agressivité, dépression, épuisement, etc. La résilience professionnelle des enseignants reflète la réaction personnelle que l'individu développe face à une demande reliée au travail et se caractérise par l'habileté de faire face à un échec, de prendre une distanciation affective face au travail et de garder sa santé mentale [2].

Dans notre recherche, la résilience est définie comme « multidimensional, socially constructed concept that is relative, dynamic and developmental in nature » ([1], p.1302) est analysée á partir des interactions pédagogiques enseignant-élèves. L'adaptation positive réfère á l'amélioration de la qualité des relations sociales, comme celles avec les élèves, et á la mobilisation des compétences professionnelles [6]; [7] pour contrecarrer l'effet des émotions négatives liées au contexte du travail. D'autre part, vue comme une ressource personnelle

qui atténue des défis spécifiques á la profession enseignante, la résilience apporte sa contribution au développement du processus de bien-être pédagogique [8].

À la suite de notre cadre théorique la question qui se détache est: « à partir des émotions difficiles issues des pratiques des enseignants du secondaire, il y a des relations entre le bien-être pédagogique et la résilience? »

La méthode de recherche

Dans cette section, nous développerons la démarche méthodologique afin de répondre à la question de recherche: type de recherche, critères d'échantillonnage et profils professionnels des sujets, procédures et outils de collecte des données.

1.1 Type de recherche

Le désir de comprendre plus en profondeur la perception de leur résilience chez les enseignants qui adoptent des pratiques professionnelles réfléchies et montrent un niveau élevé de bien-être pédagogique, nous a orientée vers une recherche de type exploratoire, menée par des stratégies mixtes de collecte et d'analyse des données. En prenant en considération que c'est la recherche qualitative qui cherche à comprendre de l'intérieur des phénomènes humains (comme le développement du bien-être pédagogique et de la résilience) et sociaux [9], l'approche dominante est qualitative. Au cours de la recherche, nous avons respecté les règles d'éthique qui s'appliquent á une recherche qualitative.

1.2 L'échantillon

Notre échantillon est un échantillon non-probabiliste composé de dix enseignants œuvrant dans des écoles secondaires publiques situées dans la grande région de Montréal et qui se sont portés volontaires. Hormis le genre féminin prédominant, on constate la richesse relative de l'échantillon, par les variations des profils, tous des enseignants du même ordre scolaire ayant complété leur insertion.

Une synthèse des profils professionnels des enseignants participants est enregistrée dans le tableau suivant (Tableau 1) :

Variable	Genre		Expérience professionnelle (nombre d'années)			Contexte d'enseignement (selon la nature de l'école)		Nature de la classe	
Description variable	Femme	Homme	3 - 5	5 - 10	10 +	Privée et publique	Publique	Ordinaire	Adaptation scolaire
Valeur	9	1	2	3	5	3	7	8	2

Tableau 1: Profil professionnel des enseignants participants

1.3 Procédures et outils de collecte de données

Nous avons privilégié, pour la collecte des données, la méthodologie Q (appelée aussi la technique Q-sort) « considered particularly suitable for researching the range and diversity of subjective experiences, perspectives, and beliefs » ([10], p. 94]). La technique issue de cette méthodologie consiste à proposer à des individus ou à un groupe le classement, selon une échelle imposée, d'une série d'énoncés élaborés par le chercheur dont l'analyse dévoile une représentation hiérarchisée des attitudes individuelles [11].

Conçue par Stephenson (1953) pour l'étude de la subjectivité humaine, la méthodologie Q s'avère une méthode de recherche particulièrement pertinente pour l'identification et l'évaluation du monde perceptif des sujets [12]. En combinant les analyses qualitatives et quantitatives, elle met en évidence la subjectivité des participants à la recherche, d'une part, et les éléments communs et les différences entre ceux-ci, d'autre part [13]; en d'autres termes, elle permet aux chercheurs d'étudier á la fois la divergence et le consensus des points de vue d'un groupe des participants á une recherche [14].

Pour comprendre quels liens font les enseignants qui vivent des émotions difficiles avec leurs élèves et leur bien-être pédagogique, nous avons conçu 14 énoncés. Chaque énoncé, théoriquement appuyé sur le modèle de Korthagen et Vasalos [3], révèle un aspect de la pratique professionnelle des enseignants, considérée par nous la source potentielle d'émotions ; de plus, il a été mis en relation avec une des trois dimensions du bien-être pédagogique des enseignants.

Pour cette étude, nous avons retenu seulement les énoncés qui faisaient référence aux relations pédagogiques enseignant – élèves : soit des aspects qui réfèrent au rôle professionnel des enseignants auprès des élèves (mettre en œuvre des compétences qui favorisent l'apprentissage scolaire et la gestion des comportements inappropriés) soit des aspects qui mettent en relief des attitudes développés par les enseignants par rapport aux relations avec les élèves et aux changements à faire.

Selon la structure de la fiche de réponses, les enseignants ont dû situer les énoncés sur une échelle de cinq préférences : en commençant avec la valeur -2, les énoncés avec lesquels ils sont le moins d'accord, jusqu'à celle de +2, le plus d'accord. En faisant "des choix forcés", les enseignants priorisent certains aspects de leurs pratiques au détriment des autres, en réduisant, sans l'éliminer, le risque de biais de déclaration [15]. En nous inspirant de Shinebourne [10] qui suggère que la méthodologie Q soit conclue par un entretien, nous avons demandé aux enseignants d'argumenter à haute voix le rangement de chaque énoncé sur la fiche des réponses. Cette double technique nous a permis de mieux comprendre les raisons qui soutiennent le classement chez chaque enseignant: plus précisément, elle nous ont permis d'explorer les réflexions qui se cachent derrière les perspectives représentées par chaque sorte [16].

Résultats et interprétations

Sept énoncés sont le sujet de la présente communication: ils mettent en évidence les réflexions relatives aux relations pédagogiques que les enseignants entretiennent avec les élèves et aux facteurs qui peuvent influencer leur réussite scolaire. Plus précisément, ces énoncés visent : (1) l'intérêt des enseignants pour des facteurs d'ordre social et affectif (santé, pauvreté, émotions, statut de la famille, etc.) qui peuvent influencer la réussite scolaire, (2) le bien-être chez les élèves, (3) la compétence à motiver les élèves ; (4) l'impact des pairs sur la réussite scolaire ; (5) la perception qu'ont les enseignants de leur rôle professionnel sur la réussite scolaire et (6) du rôle du questionnement dans l'apprentissage des contenus et (7) la gestion des comportements inappropriés.

Les valeurs issues de **l'analyse des fréquences** des données obtenues par la technique Q-sort montrent que les enseignants participants s'intéressent au bien-être et á d'autres facteurs qui pourraient jouer sur la réussite scolaire de leurs élèves, ils évaluent positivement leurs compétences de gestion de classe et de conception de stratégies d'apprentissage qui favorisent le questionnement et la motivation des élèves et leur permettent de contrebalancer certaines influences des pairs sur leur réussite scolaire.

Voici deux conclusions qui se dégagent **de l'analyse qualitative de données** issues des argumentations faites par les enseignants á l'occasion du classement des énoncés:

Les enseignants qui vivent des émotions négatives seraient caractérisés par un niveau modéré de satisfaction relative aux relations avec leurs élèves et un manque d'engagement professionnel. Ils ne se perçoivent pas comme efficaces, manifestent un faible désir de changer quoi que ce soit dans leur milieu de travail. Ils éprouvent un intérêt modéré autant pour le vécu émotionnel, affectif et social des élèves que pour leur l'apprentissage, ce qui expliquerait qu'ils offrent peu d'activités favorisant le questionnement des élèves et la compréhension.

Ces tendances montrent que les émotions difficiles associées au travail enseignant influencent autant l'état de bien-être pédagogique des enseignants que leurs pratiques professionnelles. Les réflexions des enseignants qui vivent de manière prédominante ce genre d'émotions mettent en évidence que la source de satisfaction professionnelle, même faiblement valorisée, demeure la réussite scolaire de leurs élèves.

En exprimant leur désir de garder les choses comme telles, ils expriment une certaine tendance au cynisme, spécifique aux personnes souffrant d'épuisement professionnel [17]. Ces tendances sont en concordance avec les résultats des recherches menées par Blasé, Blasé et Du [18] et Näring, Briët et Brouwers [19] qui concluent que la persistance des émotions difficiles a des effets négatifs sur le niveau de motivation et de créativité et sur la santé mentale des enseignants qui peuvent développer des symptômes de stress, de crainte, etc.

Les enseignants de notre recherche qui vivent plus d'émotions positives que négatives sont disposés à faire des changements dans leur milieu de travail et s'adaptent facilement aux particularités des élèves ; ils s'intéressent au bien-être de leurs élèves et à leur réussite scolaire, encouragent leur questionnement, réfléchissent à des démarches qui favorisent leur motivation et gèrent leurs comportements inappropriés par des règles négociées au début de l'année scolaire et des réflexions sur ces comportements et leurs conséquences sur eux-mêmes et sur les autres. Le niveau élevé du bien-être de ces enseignants reposerait sur leur sentiment d'efficacité, le niveau élevé d'engament professionnel et sur la satisfaction reliée aux relations avec les élèves. L'analyse des réflexions de ces enseignants porte vers la conclusion que, au cours des pratiques professionnelles, le bien-être pédagogique et la résilience des enseignants s'influencent réciproquement.

Les tendances qui se dégagent de l'analyse des argumentations de nos enseignants sont appuyées par des résultats d'autres recherches. Tout d'abord, Fredrickson [5] affirme que la persistance des émotions positives devrait avoir un effet positif sur le bien-être psychologique des individus : elles orientent l'attention et la pensée des individus. Les enseignants de notre échantillon qui vivent plus d'émotions positives que négatives et se déclarent satisfaits de leurs relations avec les élèves, se perçoivent efficaces et engagés dans la réussite de leurs élèves : ils mettent en pratique des stratégies qui favorisent la motivation et la réflexion des élèves sur les contenus á apprendre et leurs

comportements. Brièvement, ces enseignants s'intéressent aux stratégies actives d'enseignement et d'apprentissage et deviennent plus efficaces; leur degré d'autonomie quant aux décisions professionnelles et l'estime de soi s'améliorent, ce qui influence positivement leur bien-être au travail [2]; [4]; [20]; [21].

L'intérêt de ces enseignants pour le bien-être de leurs élèves et l'attitude positive face aux changements concernant le contexte de travail (milieu et pratique) pourrait être interprété comme une adaptation positive au contexte du travail, donc une forme de manifestation de la résilience. Dans ce sens, Fredrickson [5] affirme que les émotions positives représentent l'essence de la résilience psychologique et de l'engagement dans l'activité et «des marqueurs du bien-être optimal ».

Discussions et conClusion

Dans cette section, nous cherchons une réponse á notre question de recherche. Pour ce faire, nous présentons la synthèse des principales tendances qui se dégagent de l'analyse des récits des enseignants participants.

La première tendance vise les relations entre la nature des émotions et les dimensions de la pratique professionnelle.

Les pratiques professionnelles des enseignants qui vivent des émotions positives au cours des relations avec leurs élèves sont plus riches que celles des enseignants qui rapportent que ces relations sont plutôt sources d'émotions difficiles. Ainsi, seuls les enseignants de la première catégorie mettraient en pratique des stratégies de gestion des comportements inappropriés des élèves. Plusieurs recherches, dont celle de Daniels, Bradley et Hays [22] ont identifié ce genre de comportements comme une des sources importantes de l'épuisement professionnel chez les enseignants, le côté opposé du bien-être [23].

La deuxième tendance fait référence aux relations entre les émotions et le bien-être pédagogique des enseignants. À partir de l'affirmation de Steinberg [24] qui considère que les émotions reflètent la manière individuelle d'évaluer une situation externe et dévoilent la relation que le sujet entretient avec la situation, il nous semble significatif que les enseignants dont les émotions négatives s'associent au doute sur leur efficacité, montrent un faible engagement et un manque d'intérêt face aux changements. Cela pourrait indiquer que l'état de bien-être de ces enseignants est faible et qu'il peut changer seulement par des démarches personnelles. Une telle démarche est suggérée par Leung, Mak, Chui, Chiang et Lee [25] et suppose la prise en charge de la gestion des émotions difficiles : chercher et accepter l'appui social et développer des ressources rationnelles/cognitives qui favorisent et soutiennent l'engagement professionnel. Nous envisageons cette prise en charge comme une adaptation positive, donc une forme de manifestation de la résilience.

La figure suivante *(Figure 1)* illustre des liens entre les concepts analysés que notre recherche a mis en évidence : on y retrouve des liens entre les dimensions du bien-être pédagogique et des pratiques professionnelles et les émotions qui les ont générées et/ou les entretiennent. L'analyse de la figure suggère qu'une gestion appropriée des émotions aurait des conséquences positives sur l'état de bien-être (plus de ses dimensions seraient activées) et sur l'ouverture face aux changements des pratiques professionnelles.

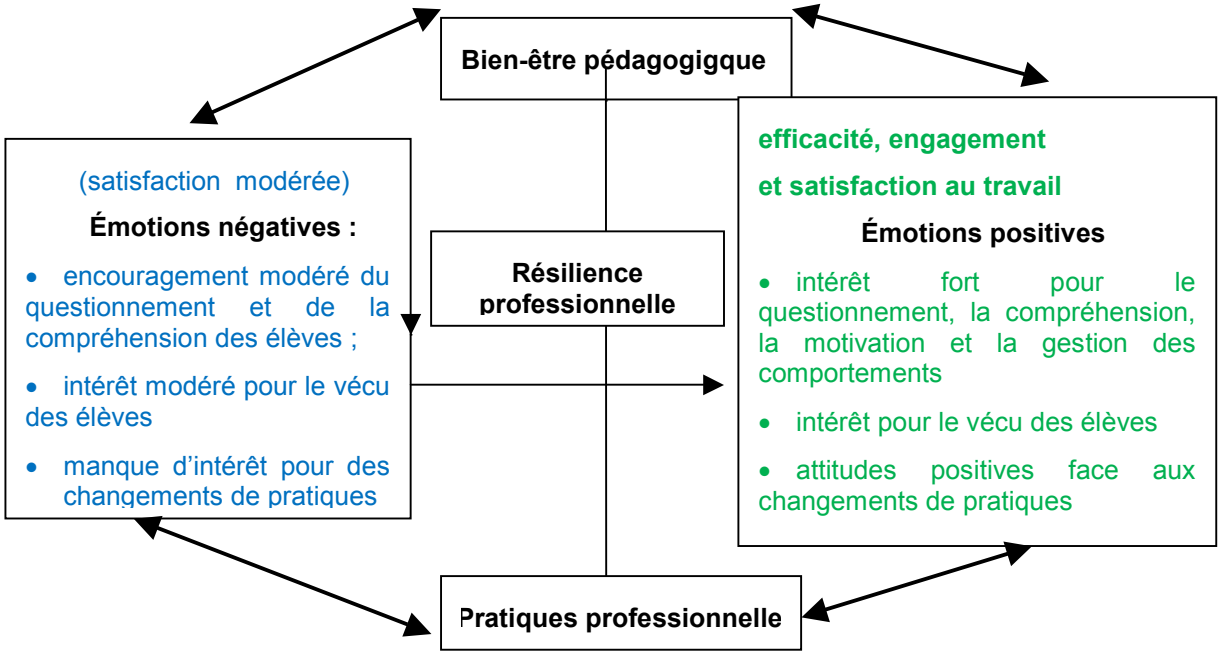

Figure 1: Analyse des tendances mises en évidence par la recherche.

En conclusion, sans pouvoir indiquer le sens des relations, des liens semblent apparaitre entre le bien-être et la résilience des enseignants du secondaire. Cette étude comporte certaines limites dont la plus évidente est que nous nous sommes penchées sur des relations entre le bien-être et la résilience issues des relations enseignant – élèves, en ignorant, ou presque, l'effet que d'autres aspects qui caractérisent la pratique professionnelle des enseignantes pourraient avoir sur ces relations.

Six or seven: when is a child resilient enough to start school and to cope with the transition stress? Czech and polish experience: social policy and research outcomes

Hoskovcová S., Sikorska Iwona M.

Abstract

A debate on when to start school has continued in the Polish education system for four years now. Until recently, children started school at the age of seven. However, the comparison of the Polish education system with those of other European countries provoked wide public discussion on the necessity to amend the existing regulations. In the Czech Republic, the contrary idea is under discussion, namely whether to change the school starting age from six to seven years, which is due to a growing number of school postponement cases and maladaptation to school life.

In favour of the change in Poland, psychologists have put forward several main arguments, including intense natural cognitive interest demonstrated in early childhood, the effectiveness of involuntary (unintentional) learning and memory and small children's interest in writing and reading. The main arguments against the change emphasise that six-year-old children are not socially and emotionally mature to start school: they show insufficient emotional and behavioural self-regulation levels and have not developed strategies for coping with stress. Current trends in the Polish and Czech educational systems will be discussed in the light of research on resilience with the emphasis on the outcomes that demonstrate how resilience develops.

Keywords: school age, school postponement, transition stress, resilience, self-control, Polish education system, Czech education system.

Mature to start education

Children that start school enter a new period in their lives. The transition from preschool to primary school brings about change in several basic areas of their functioning. Firstly, play is supplanted with learning as children's main activity. Secondly, involuntary learning is gradually superseded with voluntary learning, which is carried out according to instructions and requires self-discipline. Thirdly, the basic skill that brings children's success at school is the appropriate level of their emotional intelligence with regard to interpersonal and social relations as well as stress resilience.

Factors that help children become mature enough to start school are individual in character, including both physical properties of a child's body, intelligence and his or her motivation levels, inclinations and goals. The environmental factors include the financial situation in children's family, the social and cultural assets of their families as well as the family structure and atmosphere, i.e. community factors as educational models and styles.

It has been found that lower social economic status predicts the school achievements of the children in a negative way, compared to children with a higher economic status [1]. Lower social economic status is related to more stressful life circumstances. Also there has been found that traumatic experiences have influenced the school achievements of children negatively. And therefore it can be said that stress influences the school achievement of children. There have been some attempts to try to minimize these stress factors in several school programs.

Constantine et al. [2] have put forward a resilience development model that can also elucidate on the role of external influences, including not only children's family and peers, but also the education system and local communities. Resilience in children is developed through caring relationships and support at school, high expectations from adults supported with their trust in children's capabilities and children's participation in

competitions and socially significant activities. Finally the research of Leer, Loke, Wu, & Ho [3] showed that primary school students have the need for health and psychosocial wellbeing education. Intervention programs or early identification of needs are needed.

We did see in our previous research ([4], [5]), that children at the age of six and seven do want autonomy. On this fact focused also Cooper, Nye, Lindsay [6], who did find out, that the support of autonomy by the parents results in better outcomes of tests, better grades and finishing of homework. Parents and teachers have to motivate and support the child in autonomy. Children at the age of six are commonly believed to be physically and cognitively mature to start education. Polish parents, educators and psychologists have revealed a number of potential emotional and social difficulties that children may experience in the process [7]. Social concern stems from the fact that six-year-old children develop in an inharmonious way: their cognitive abilities often match those of a seven- or eight-year old, but their manual or social competences and their self-regulation levels are more akin to those of a five-year-old.

Study of polish six-year-olds

The major outcomes of Polish pilot studies (carried out in 2012–2013 prior to the decision to make education compulsory for six-year-olds) have demonstrated the following [8]:

1. Six-year-old children in form one attained the same level of mathematical skills at the end of a school year as their seven-year-old counterparts in form one. This also means that, as regards mathematical skills, six-year-olds in form one have benefited the most.
2. As regards children involved in the study, it was the weakest group, namely children that had the lowest results in the autumn measurement, that demonstrated the highest development rate regarding the three types of skills.
3. Six-year-old children in form one demonstrated the highest development rate with regard to reading.
4. The competence level demonstrated by children in form one was higher than that of children in reception-class and lower than that of seven-year-old children in form two, that is children that started education at the age of six. In a nutshell, it is not the age that proves decisive, but skills that children acquire.
5. Seven-year-olds in form two, namely children that attended form one as six-year-olds, demonstrated a higher competence level than their seven-year-old counterparts in form one.

The opponents of the idea to send six-year-old-children to school are particularly concerned with the fact that children are insufficiently mature in terms of their realistic self-perception, emotional self-regulation, social skills, problem-solving abilities and coping with stress. This opinion is based more on parents' own observations or feelings. The outcomes of relevant research fail to demonstrate any significant difference in these competences between six- and seven-year-olds ([9], [10]). However, the claim that the education system is not suitably prepared for the needs of small children, is difficult to refute.

Situation in Czech Republic and school maturity

Compulsory education starts at the beginning of the school year following the date on which the child turns six years of age. A postponement of the school education is possible on base of the request of the parents and expertise by a pediatrician or psychologist. A child which turns six years of age between the beginning of the school year and the end of the calendar year may be accepted for the compulsory schooling, if physically and mentally ready and if this is requested by his legal representative (§36, 561/2004 Sb. Zákon o předškolním, základním, středním, vyšším odborném a jiném vzdělávání: school law).

Of the six year-olds, the postponement of the start of compulsory schooling is allowed to around 17.5 - 18% of them. In 7-year-olds and older children, it is only about 1% of postponements. Less than 1% of children entering compulsory schooling are in the age of 5 years. There is a difference between boys and girls. While roughly more than 83% of the girls newly enrolled in primary schools are 6-year old and only about 15% 7 years old, more than a quarter of boys are 7 years old and only about 72.5% of boys are enrolled at the age of 6. The discussion about the school start at 7 years is motivated by the quite high rate of postponements. The main reason for the postponement is lack of attention and social immaturity at children. We personally do not agree with this interpretation.

For the decision about the beginning of the school education we use the criteria of “school maturity”. There was no big research on this topic, but we provide now a project on transitory moments in education. The term “school maturity” is traditional in Czech pedagogy and psychology. School maturity is defined in different ways, but according to Mertin [11] over the past 20 years the view of the child's entry to compulsory education and the concept of school maturity changes. There is a move away from a medical approach in pedagogy and psychology and psychologist begin to promote an ecological systematic approach to psychic phenomena. In practice, this means that almost every child at the age of 6 years is able adapt to the conditions of education and

accordingly the school has to adjust the content and form of education. We should not look just on the maturity of the child, but also on the preparedness of the school on children with different abilities and specifities.

Discussion

Environmental factors play an important role in the process of resilience development. Thus, as Urie Bronnfenbrenner's ecological psychology [12] suggests, there is a necessity to create a harmonious combination of the systems that have an impact on children's development. As regards children's successful start at school and their educational achievements, it is not only their family homes' microsystem (one that motivates them to learn) that matters, but also their mesosystem, that is, their parents' friendly or hostile relationships with educational institutions. Of importance is also the subsequent strata of children's environment, such as the exosystem, e.g. a direct impact that parents' salaries have on the family life in children's homes. And finally, the macro system, that is, sets of beliefs, norms and opinions prevalent in a given culture of society (e.g. children should enjoy blissful childhood as long as possible, instead of starting school already at the age of six) The last strata is known as the chronosystem, and it describes the influence of events that modify the process of developing maturity and taking up developmental tasks (e.g. poverty or loss in a family).

The answer to the question posed in the paper's title as to when children are mature enough to start school is a complex one, and it cannot be considered only in terms of children's competences. In order to be resilient, children cannot just rely on their own resources, but they also require support from the education system and family environment. This is because general social, economic and political dynamics and structures have an influence on their development.

The paper is supported by the grant GACR 13-28254S „Transient moments in the life path of the child and adolescent.“

The bullying phenomenon: victims point of view

Lazăr T.-A.

West University of Timişoara (ROMANIA)
lazar.theofild@gmail.com

Abstract

The investigation of the bullying phenomenon in Romanian schools is a topic of small interest among our researchers, being, at the same time, an extremely demanding process due to the general population view that there is no real danger in typical bullying acts. Numerous studies worldwide indicate that there is a strong connection between bullying and some very dangerous social situations for teens: delinquency, drug abuse, depression and even suicide. The articles objectives aim to identify the bullying victim rate in Timis counties schools, the most frequent bullying acts that students experiment as bullying victims and the characteristics of the students that are most likely to become bullying victims. The research, involved quantitative methods (questionnaire based investigation), and it was conducted in representative schools from Timis county, on a representative sample of 998 mid-school and high-school students. The recommendations are adapted to the Romanian realities, comprising concrete and adapted actions for reducing the rate of bullying victims in schools

Keywords: bullying, victims, antisocial behaviour.

Bullying – definitions and statistics

The bullying phenomenon in schools represents an important social problem worldwide, due to its associated potential negative outcomes that include development of anti-social behaviour, drug use, and depression, self-harm and even suicidal events.

The bullying phenomenon consists in „continual physical, psychological, social, verbal or emotional methods of intimidation by an individual or group. Bullying is any action such as hitting or name-calling that makes you feel angry, hurt or upset" [1]. Dan Olweus, referring to bullying in schools, defines the phenomenon as a situation in which the student „is exposed, repeatedly and over time, to negative actions on the part of one or more other students" [2].

Every bullying act has a series of common elements: a desire to hurt, a harmful action, a power imbalance, repetition, an unjust use of power, evident enjoyment by the aggressor and generally a sense of being oppressed on the part of the victim [3].

Bullying in schools can shape in many forms of manifestation. Direct bullying acts are easy to identify and consist in either physical action (hitting, kicking, pushing, biting) or psychological-emotional ones (name calling, threatening, gossiping). The indirect bullying acts are harder to identify and consist mostly in psychological-emotional and social acts (social isolation, intentional exclusion).

The bullying phenomenon worldwide is presented in an extended report of the United Nations published in 2006 [5]. According to UN, Africa Region has the largest frequency of the bullying phenomenon. In Zambia, 67% of the female and 63% of the male students investigated have been bullied within the two months previous the survey. South America region seconds, with values around 50%. On Asia continent the reports shows low rates of the phenomenon all over the region. In Europe, the bullying phenomenon shows great differences between countries, European countries presenting both very high rates (in Lithuania 64% of the female and 65% of the male students have been bullied in the past couple of month similar with Africa region and in Portugal - 44% of the female and 56% of the male respondents reported bullying rates similar to South America region) and very low rates (Czech Republic and Sweden only 15% of both male and female students have been bullied, less than Asia's lowest rates). According to the data, we can draw some tendencies regarding bullying in the world: Africa Region has the largest frequency of the bullying phenomenon and South America region seconds. North America region keeps constant moderate rates of the phenomenon and European countries presents both very high rates and very low rates without being able to determine a specific tendency of the region. Finally Asia region reports the lowest rates of the phenomenon all over.

From a recent sociological survey undertaken in Timisoara in 2013 [5] results that the occurrence of bullying actions in Timisoara's schools has a high rate (more than 80% of the subjects investigated had bullied

or had been bullied), an important percent of 14,94% considering bullying actions as normal interaction between students.

Victims of the bullying phenomenon

1.1 Types of victims and characteristics

The bullying victims can be categorized into two types: the passive victims and the active victims [2].

From a psychological point of view, the passive victims are fragile and unsecure in their relations with their peers and have weak abilities to control their anxiety. They are usually sensitive, calm and cautious individuals, but have low self-esteem. Because of their low self-esteem they tend to under evaluate their own capacities, to isolate themselves from social groups, making them this way even more vulnerable to bullying acts. In most of the cases, this type of victims do not have any friends in their class and for this reason the colleagues do not intervene when they are aggressed.

Also as a characteristic is the lack of the aggressiveness, meaning that the bullying acts on them are not resulted as reaction to their behaviour. If they are boys, usually are physically weaker than the average.

The passive victims usually do not share with parents, teachers or other people their negative experience, making intervention difficult. This characteristic silence is probably derived from the shame of admitting that they are in a submissive position and the fear that if they tell, the aggressor will react more violently.

The active victim type is also called provocative or victim-aggressor. This type is described as hot-tempered and anxious, and it is likely to react under threat. They alternate their status from bully to being bullied [6]. This category has difficulties to control their emotions and over-react to aggressions. The provocative victims show emotional instability, are easily irritated and seek revenge when they are aggressed, sometimes bullying weaker peers. Their self-esteem is even lower than the passive victims have.

The victim-aggressor type is usually highly unpopular in school, being nor popular as some of the aggressors are, nor demanding sympathy, as some of the victims are [8]. This fact results in social isolation and makes them unable to develop health peer to peer relations.

1.2 Study on bullying in Timis county schools, Romania – a victims point of view analysis

An extensive study on the bullying phenomenon in schools was undertaken in 2013 in Timis County, Romania [5]. The sociological survey was applied on a representative sample of 998 students (54,9% female and 45,1% males) from Timis county middle and high schools. The questionnaire was structured on 25 items, 8 of them referring to types of bullying actions, from the victims' point of view.

One of the main objectives of the study was to highlight the types of bullying actions experimented by students by the victims perspective. Regarding to this objective, two work hypothesis were released: (1) in school, the physical type of bullying actions are more likely to be recognised by the victims than those of psychological-emotional types; (2) girls are more likely to be victims of the bullying actions than boys.

From the data analysis resulted the following frequencies regarding the type of bullying acts from the victims point of view:

Bullying acts – from the victims point of view								
	Physical actions				Psychological and emotional actions			
	Pushed	Slapped	Kicked	Bitten, scratched	Threatened	Isolated	Laughed at	Gossiped
Very often	6,53%	2,51%	1,91%	3,61%	2,81%	3,71%	6,22%	12,45%
Often	13,25%	4,82%	3,81%	9,24%	8,23%	10,04%	11,75%	17,67%
Rarely	34,34%	22,19%	18,67%	22,29%	21,99%	18,17%	21,39%	24,80%
Hardly ever	17,77%	13,96%	15,46%	17,57%	18,07%	17,67%	26,41%	20,48%
Never	23,29%	52,31%	55,72%	43,17%	44,28%	46,39%	29,92%	2%
NR	4,82%	4,22%	4,41%	4,12%	4,62%	4,02%	4,32%	4,32%

Table no.1. Bullying acts – from the victims point of view

As shown in the table above, the hypothesis that the physical type of bullying actions are more likely to be identified by the victims than the psychological-emotional one is invalidated. The study reveals that, from the victims point of view, the students are more likely to identify the psychological-emotional ones (laughing at –

75%, gossiping – 75%, threatening - 51%, social isolation – 50%), than the physical ones (pushing – 71%, biting, scratching – 52%, slapping – 43%, kicking – 40%).

The analysis by gender of the bullying actions frequency from the victims' point of view was studied by type of action: physical and psychological-emotional.

The analysis of the physical acts revealed the following: (1) in the case of pushing bullying actions shows small differences: 21% of the female subjects declare that experimented pushing very often and often, compared with 18% of the male subjects; (2) slapping actions analysis shows significant differences by gender: a double percentage of male respondents experimented slapping very often and often (10% of the boys, compared with only 5% of the girls. Continuing, the study reveals that 69% of the female respondents declare that never experimented slapping in school, compared with only 39% percent of the male respondents. (3) the victims of kicking actions are also more likely to be boys than girls, the study revealing that only 33 percent of the girls and a 57 percent of the boys admitted that they experimented kicking actions from school peers; (4) the analysis of biting actions by gender shows significant differences related to the victims experiences point of view: 50% of the female respondents never experimented biting actions on themselves, compared with only 35% of the male respondents.

Regarding to the psychological-emotional actions, resulted: (1) threatening is also a bullying specific action experimented mostly by boys from the victims point of view, the study showing that 66% of them declare that on some extent they were threatened in school, compared to only 48% of the girls; (2) referring to social isolation, the gender distribution does not show significant differences between boys and girls as victims of this type of bullying action. Nevertheless there are some differences from the frequency point of view, 60% of the boys experimenting this type of action often compared to only 48% of the girls; (3) the analysis of laughing at type of bullying actions does not reveal significant differences between boys and girls (65% of the female respondents and 68% of the male respondents were laughed at at least once by their peers in school). The difference appear again on the frequency of the action: 21 percent of the girls experimented laughing actions often and very often, compared with only 14 percent of the boys; (4) in the cases of gossip type bullying actions the differences are obvious, female respondents experimenting in higher percentages and more often this type of action than male respondents. 79% of the girls compared with 72% of the boys were gossiped at least once in school and 39% of the girls compared with only 18% percent of the boys declare that they are often and very often gossiped by their peers in school.

The hypothesis that states that females are more likely to be victims of bullying actions in schools than males is refuted also. The analysis shows that, from the victims' point of view, male subjects identify themselves as victims in a higher degree than female subjects. On 7 of the 8 types of bullying actions analysed from the victims' point of view, the percentages are higher in the males' category, exception being the gossiping section, where the females are more frequently self-identified as victims.

1.3 The effect of bullying on victims

Children which are victims of bullying acts can be negatively affected emotionally and socially, determining low self-esteem, social exclusion, aggressive behaviour, depression and even attempted suicide. Numerous international studies concluded that children that are victims of bullying acts are more likely to develop depression and commit suicide than other adolescents [8, 9, 10, 11, 12]. Students which are being bullied for a long period of time can develop "comparatively low levels of psychological well-being and social adjustment and to high levels of psychological distress and adverse physical health symptoms" [13].

It is logical to assume that victims of bullying would be fearful and anxious in the environment in which the bullying took place. These victims might respond with avoidance/withdrawn/escape behaviours (skipping school, avoiding places at school, running away/suicide), more aggressive behaviours (such as bringing a weapon to school for self-defence or retaliation), and poor academic performance.

Studies show that there is a connection between academic performances and bullying, in the sense that the victims of bullying acts will develop fear and anxiety feelings toward school, being more likely to skip school and avoid school-related activities. Some studies demonstrate that 90% of students who were bullying victims experienced a drop in school grades [14]. Others show the link between victims and grades [2], or between the level of intelligence and the level of victimization [15] .A major study made in USA showed that around 160,000 students miss school every day due to fear of attack or intimidation by a bully [16] and that approximately 20 percent of students report being scared throughout much of the school day [17]. All of this without early identification and intervention can lead to isolation, depression and even suicide. A more recent study undertaken in UK on a representative sample of students followed the possible relationship between self-harming and bullying victims. From the total sample of children who had self-harmed (2.9% of the total sample), more than half were victims of frequent bullying. Exposure to frequent bullying predicted higher rates of self-harm even after children's pre-morbid emotional and behavioural problems, low IQ, and family environmental risks were taken into account. Compared with bullied children who did not self-harm, bullied children who self-

harmed were distinguished by a family history of attempted/completed suicide, concurrent mental health problems, and a history of physical maltreatment by an adult [18].

Conclusions

In order to reduce the number of school bullying victims, one of the main actions is prevention. Preventing bullying means creating specific policies addressed directly to bullying acts, creating and applying a set of sanctions to aggressors and offering education to potential victims, in order to enable them to confront and succeed in bullying situations. The steps for preventing bullying can be undertaken from multiple directions. Prevention actions can be directed towards creating social environments in witch bullying is not tolerated or by educating aggressors in order for them to be able to find constructive ways of channelling their anger.

A clear definition of the bullying phenomenon and specific policies of banning this type of behaviour, that includes also clear sanctions, can be the first step for preparing schools to deal with the phenomenon. These policies should address clearly all the types of bullying, including physical, psychological, emotional and social acts. Completing this policies, a set of clear and specific sanctions, adapted to the gravity of the acts, should be elaborated. This way the potential aggressors can assume the consequences of their acts before they choose to act.

The social perception of the bullying has changed greatly in time, and, even if proper politics can influence organisations, such as schools, it is hard for them to produce effects in the general community. People (teachers, students or parents) that are part of families in witch bullying acts are accepted as normal need explicit models regarding the alternative ways of reacting to those thoughts and feelings that usually conduct them to exercise bullying acts. They need support to learn new behaviours in order to part from their old ways of coping with the challenges.

Community education is hard and takes time: many people feel like all the things that happen in the privacy of their home, regard only them and therefore they reject most of the change suggestions. But if a father exercises bullying acts toward a mother and the children learn this behaviour in the process, what was a private matter, becomes a community interest one, because the negative behaviour splips into the community by the future acts of the children.

The prevention and reduction of the bullying phenomenon can be addressed in four steps: (1) Detecting the bullying situations – one of the most problematic aspects of the phenomenon is the difficulty to identify/recognise the bullying acts by the adults. In order to efficiently fight the phenomenon first of all it is necessary to know, identify and measure it. The measurement can be made, for example, by sociological surveys undertaken in schools. (2) Awareness and education – after measurement, the data should be disseminated, in order to show to the involved parties the extent of the phenomenon. It is important to organise meetings with all the parties involved: at school level debates regarding bullying can be organised with teachers, parents and students. The meeting should be channelled on finding intervention methods for the problems identified. Also, within this step, trainings for the teachers should be organised in order to develop new skills regarding socio-affective communication, active listening and conflict management. (3) Communication – the best way to find efficient solution regarding reduction of bullying acts in schools is to strengthen the communication between victims, school and parents. But, the problem usually is that the victims have difficulties in relating their experiences because of shame or fear of being blamed. It is important for example to create ways of securely permit victims and victims parents to relate their stories: a dedicated telephone line, or a counselling service. (4) Supervision and control – most of the bullying acts take place within school premises, in moments when the teachers' supervision is missing, or in places where adults are not present. For this reason it is important to program and sustain a more complete supervision program of the adults, especially in the places with high risk (during break periods, during lunch periods, at the school exits). If the adults' presence is more obvious and they intervene promptly in cases of bullying, the victims will feel more protected and the bullies will know that their behaviour is not accepted. Only the supervision and control is not enough though, a strong communication between the adults that participate is important in order to have a cohesive and efficient intervention.

Abstract

The Dominican Republic is a country with a very low public investment in education and an education system that has a high rate of school desertion. In addition, school education is not valued by Dominican families following a traditional design. These circumstances and other social and economic make the school dropout rate increases, especially in eighth grade at the end of primary schooling. It is to analyze the role of family related variables (family and family social climate communication) relative to resilience in the case of students who, despite all these difficulties, continue to study in the Dominican education system.

Keywords: Dominican Republic, permanence school, family dynamics, resilience

Introduction

1.1 L'éducation en République Dominicaine

La République Dominicaine a un faible investissement public dans l'éducation (il n´atteint pas le 2% du PIB en 2011) et des indices de succès scolaire insuffisants selon les indicateurs internationaux. Les principaux problèmes qui découlent de ces conditions d'enseignement précaires peuvent être résumés en ces trois: a) des déficiences dans la salle de classe, ainsi que dans le nombre et dans la formation des enseignants, b) un grand nombre d'élèves par classe c) un grand niveau de désertion scolaire [3].

Le taux si élevé de désertion scolaire se doit, entre d´autres raisons, au grand nombre d'enfants et d'adolescents (âgés de 5 à 17 ans) qui travaillent, et qui selon les statistiques officielles cela suppose presque le 17 % de la population totale (NCLS, 2000, 2002). Pour comprendre ces chiffres on doit tenir compte que dans le cadre dominicaine le travail des enfants est considéré avec naturalité, car il a été traditionnellement considérée par les parents une manière de leur apprendre un métier, ainsi que d'internaliser la responsabilité, sans oublier que cela suppose aussi une contribution économique au foyer. Tout ceci, bien sûr, a des implications évidentes dans la façon ou l'éducation est valorisée par les familles. En outre, le nombre de mères célibataires qui élèvent leurs enfants à cause de divorces ou de l´abandon du père a considérablement augmenté [11].Ceci a fait que les difficultés économiques soient très grandes, sans oublier l´existence d´un certain laisser-aller dans l'éducation des enfants.

Cependant, malgré ces conditions socio-économiques et éducatives défavorables, qui font prévoir une véritable incapacité à poursuivre les études, tous les étudiants dominicains ne se comportent pas de la même façon. Il est vrai que les familles ayant une situation économique qui leur permet de payer une bonne éducation surpassent ceux qui ont des difficultés, mais il est vrai aussi que dans des contextes socio-économiques défavorisés il y a aussi des étudiants qui continuent leurs études contre vents et marées. Dans cette étude, nous allons nous intéresser à explorer les caractéristiques de ce dernier type d'étudiants.

1.2 Permanence dans le système éducatif et la résilience. La résilience de la famille

En raison de l'absence de normes d'éducation dans le cadre familial et, par conséquence, de la manque d'intérêt pour le développement des enfants et des adolescents, autant de la part des familles, que de la société, on pourrait s'attendre à ce que l'étude des caractéristiques de la dynamique de la famille, pourrait nous aider à faire une prédiction sur la continuité des élèves dans le système éducatif. Il suffit de se rappeler que dans des études antérieures la communication de la famille est un indicateur de l'existence d'un environnement familial

sain, et que cela, à son tour, est un important facilitateur du processus de socialisation et de la construction des valeurs [4] et donc, dans le processus d'adaptation des enfants et des adolescents [12].Tout cela a une relation directe sur le maintien des étudiants dans le système éducatif.

Cependant, cette étude vise également à explorer le potentiel explicatif de la résilience des élèves concernés, puisque l'inclusion de cette variable pourrait signifier la possibilité de rompre ces prévisions, permettant ainsi de faire face aux difficultés avec succès et même de s´en sortir renforcé [6],continuant dans le système éducatif dans des circonstances tellement défavorables. Des études récentes expliquent la résilience au-delà de certaines qualités personnelles et soulignent l´importance de l'environnement et, en particulier, l´importance de la famille. Cela a mené à développer des recherches systémiques de la résilience familiale [7] dans lesquelles la famille est considérée comme une source de résilience même dans le cas où il y aient certains troubles [16]. Ce processus dynamique qui semble exister entre les influences réciproques de l'environnement et de l'individu permettent une meilleure adaptation à l'environnement et peut donc être considéré comme caractéristiques pertinentes cadre familier [8].En ce sens, il y a des recherches qui ont mis en relation la famille et la résilience à l'adolescence, de sorte que l´on a montré des comportements plus ou moins résilients sur la base de ce domaine [5], et d'autres ont établi des relations entre la fonctionnalité de la famille et la résilience [10].

Par conséquent, dans cette étude, nous avons cherché à analyser les caractéristiques de la dynamique de la famille des étudiants dominicains, leur résilience et la corrélation entre ces deux variables, autant parmi les étudiants qui poursuivent leurs études en première année du baccalauréat, qu´entre ceux qui les abandonnent en 8ème, la dernière année de l´éducation primaire.

Méthodologie

1.1 Les participants

411 étudiants dominicains scolarisés dans quatre écoles dont le taux élevé d'abandon scolaire de la 8ème année de l'enseignement primaire est très important (étudiants entre 12 et 18 ans), ont participé dans cette étude. Dans la deuxième année académique, c´est à dire la première année du baccalauréat, cette étude n´a pas pu être menée que sur 114 étudiants, parce que le reste (297) n´a pas poursuivi les études.

1.2 Variables et instruments de mesure

1.2.1 Résilience

Pour évaluer le niveau de résilience on a utilisé l´échelle Wagnild et Young (1993) qui se compose de deux facteurs:

a) la compétence personnelle, considérée comme la reconnaissance de facteurs tels que la confiance en soi, l'indépendance, la décision, l'invincibilité, la force, l'esprit et la persévérance.
b) l'acceptation de soi-même et de la vie, représenté par des facteurs tels que la capacité d'adaptation, l'équilibre, la flexibilité et la perspective de vie stable. Ses propriétés psychométriques sont acceptables (alpha de Cronbach = 0,94 pour la pleine échelle et de 0,91 et 0,81 pour les deux facteurs signalés).

1.2.2 Climat de la Famille

L´évaluation du climat de la famille a été effectuée par l´escale du même nom de Moos et Moos [9], dans son adaptation en espagnol (Fernández et Sierra, 1989) dont la dimension des Relations Internationales qui a été utilisée ici, a les suivantes trois sous-échelles: la cohésion, l'expressivité et les conflits familiaux. Les indices de fiabilité des sous-échelles sont acceptables et sont situés entre 0,52 et 0,82.

1.2.3 Communication de la famille

La variable communication de la famille a été évaluée au moyen de l´escale de communication parents-adolescents de Barnes et Olson [2] dans son adaptation en espagnol par l'équipe de recherche de l'Université de Valencia (Lisis). Elle dispose deux échelles se rapportant au père et à la mère, avec trois échelles relatives à une communication ouverte, offensive et d'évitement. Leurs taux de fiabilité sont acceptables. Ils vont entre 0,64 à 0,91.

Résultats

1.1 Résultats référés à la communication et au climat de la famille

Les résultats obtenus dans les variables relatives à la communication et le climat de la famille dans les années scolaires analysés ont été :

Tableau 1. Types de communication de la famille selon l´année scolaire

Communication	Minimum		Maximum		Moyenne	
Ouverte	1	1,27	5	6	3,62	3,66
Offensive	1	1	5	7,5	2,05	1,99
Évitante	1	1	5	6	3,05	3,15

Remarque. Dans chaque colonne la première partie correspond aux étudiants de 8ème degré et la seconde à ceux de la première année du baccalauréat.

En ce qui concerne le milieu familial on a obtenu des résultats très similaires dans les deux années scolaires, en ce qui concerne le score total (1,13 et 1,12 en 8 et 1 respectivement) ainsi que dans les trois dimensions: la cohésion, l'expressivité et de conflit.

1.2 Analyse de la résilience

Les résultats obtenus en ce qui concerne le niveau de résilience dans les deux années scolaires ont été les suivants:

Tableau 2. Résilience totale

Année scolaire	N	Minimum	Maximum	Moyenne
8ème	411	43	121	83,2
1ère année du baccalauréat	114	56	139	86,3

1.3 Corrélations entre résilience et cadre familier

Les résultats obtenus dans les différentes corrélations indiquent qu´en 8ème année il y a une corrélation faible et significative de la résilience, en ce qui concerne la communication familiale ($r = 0,119$, $p = 0,01$) et le milieu familial ($r = -0,21$, $p = 0,000$), tandis que dans le second cas la corrélation est inverse. Cependant, dans la 1ère année du baccalauréat les corrélations sont faibles et pas significatives.

Conclusions

Les résultats, concernant la dynamique de la famille (la communication et le climat de la famille), indiquent que le niveau de communication ouverte, dans le groupe étudiants du 1er degré de baccalauréat, même s´il reste dans des niveaux faibles augmente légèrement Par contre, la communication offensive diminue les niveaux et se maintient dans des niveaux moyens. Ces résultats semblent montrer que les caractéristiques de la communication de la famille des étudiants qui continuent à étudier sont un peu meilleures, tenant compte que l´on parle toujours des conditions défavorables. Ces résultats sont cohérents avec la situation familière décrite dans l'introduction et cela suggère la nécessité d'intervenir autant que possible dans l'amélioration de ces conditions, en particulier avec des campagnes de sensibilisation qui signalent l'importance de l'éducation dans le développement des enfants et des jeunes et le soutien économique pour fournir un accès à une telle éducation.

En outre, tel que l´on peut le voir dans le tableau 2, les niveaux de résilience sont mieux en 1ère année du baccalauréat, bien que dans les deux cas, les élèves sont places dans des niveaux qui sont considérés des niveaux de résilience de bas niveau. Il n´y a que deux étudiants de la première année du baccalauréat qui sont déjà placés dans un niveau modéré de résilience et personne de la 8ème année. Ces résultats nous portent à croire que les étudiants qui continuent à étudier sont ceux qui ont les meilleurs niveaux de résilience, malgré les conditions si défavorables et avec si peu de soutien dans le tissu social et familial. Dans ce cas, on pourrait promouvoir le tuteur de résilience afin qu´il puisse aider dans leur développement secondaire.

Enfin, on a pu vérifier, avec les étudiants de 8ème année lorsque l´on analysé encore l'échantillon total, qu´il semble y avoir peu de corrélation entre la résilience et la dynamique de la famille qui est significative, mais quand on analyse ceux qui ont été capables de continuer avec le baccalauréat, malgré les difficultés rencontrées il n'y a plus de corrélation significative. Ces résultats pourraient indiquer que l'influence qu´un environnement

familial si défavorable a dans la résilience, pourrait diminuer dans le cas des étudiants qui continuent les études de baccalauréat jusqu´au point de leur permettre y continuer. En tout cas, il est très important de noter que nous avons travaillé avec de très faibles niveaux dans toutes les variables testées, probablement en raison des conditions défavorables dans lesquelles la recherche a lieu, qui nous fait voir la nécessité d' une autre étude qualitative qui nous approche un peu plus aux variables qui nous aident à expliquer mieux la continuité des élèves dans le système éducatif.

The issue of resilience in the context of small age children education

Stan L.

"Al. I. Cuza" University of Iaşi, Romania
lstan@psih.uaic.ro

Abstract

The training of early age children is currently recognised as an especially important intervention for a person's normal existential course. The adults (parents and teaching staff) involved in the shaping of minors' personality hold a set of attributes with stakes for both present and future. The current study is aimed at pointing out which are the conditions within the institution of preschool education that can expose children to delicate/ difficult/ risk situations that could induce mental discomfort or stress, as well as at highlighting a number of aspects of specialised paideic intervention with clear potential to determine the occurrence and development of a natural process of resilience in the child confronted with such circumstances. The study focuses on two complementary aspects: the manner in which kindergartens face the issues of trauma and children's resilience, and the structural characteristics of the educational activity in kindergartens that favour the process of resilience among minors (the specific features of the education's general purposes during the first years in one's life – global development/ socio-emotional development, the use of kindergarten space in relation to children's needs, the primary group of pre-school children, the kindergarten teacher as a significant person in the child's life).

Key words: trauma, resilience, small-age children, early education, development, educational outcomes.

Prolegomena

Until almost 200 years ago, an institution for small children appeared, even to the most optimistic persons, a daring idea or an idealistic project; yet currently, its reality (throughout the world after 1840 – the year of the first experience in Germany), the valuable experiences that have been accumulated and the ample debates around the issue of optimising its functioning within the complex framework of early education demonstrates the practical value of daring ideas. From a historical perspective, the organisation of educational institutions for early age children, especially of kindergartens, was motivated by invoking numerous aspects: the need to shape the children's personality in particular directions (perceived as end-goals of the functioning of the respective structures); the need to train children from an early stage to identify appropriate responses to the challenges that they will face in the future in societies (increasingly) different from traditional ones; supporting and helping parents (first, the mother and/ or, subsequently, the father) to perform their professional roles; protecting the persons in a process of becoming (as well as the social group) from potential future failure; materialising the values and principles of human living in the relationship between the adult and the young generations; respecting the rights of human beings in general, and respecting children and their rights in particular etc.

Issues connected to trauma, and respectively to resilience in the case of small children, constitute a topic which cannot be encountered in works on small age pedagogy, although the education practice integrates numerous special situations experienced by small children and upon whose successful resolution the normality of their life depends. Theoretical approaches to education assimilate trauma to special situations experienced by the child and recommend that it should be dealt with through the lenses of special psycho-pedagogy [1]. We believe that a thorough and updated analysis of the field undoubtedly highlights the possibility to integrate the above mentioned issues, in their essential aspects, within the training offer for kindergarten teachers. The current study argues below that formal educational activity for pre-school children is inevitably connected to the issue of trauma in their lives (when such trauma exists) and, through certain structural characteristics, it determines the emergence and development of a natural process of resilience in small children confronted with difficult circumstances. Since we accept the idea that "the resilience of individuals exposed to risks or adversities *should represent the goal of all interventions"* (highlighted by L. S.) that target human beings [2], we support the need to raise the awareness of the kindergarten's potential in achieving normal development for all children, including of those marked by problematic situations.

Kindergartens and children's trauma

The trauma experienced and felt by small children, due to circumstances related to life in the family that they belong to, generates effects that accompany them in kindergartens as well. Under these circumstances, it becomes imperative that teachers recognise the presence of the difficult situation, so that it would not aggravate and, especially, so that it would not be associated with other negative events within the pre-school institution. Nevertheless, educational experience and specialised literature indicate that, unfortunately, there are numerous situations with negative impact on pre-school children as a result of inappropriate/ wrong approaches in the teacher – small child relationship. The "ingenious violence" [2] that children can experience in their interaction with certain teachers may occur under subtle forms: the expression of tasks using an inappropriate tonality and/ or as a "pretention" towards children, the obsession for accomplishing an activity within a short time frame, respectively pressuring children to complete a task, inappropriate assessments in relation to children's age and needs for personal affirmation, strict/ severe evaluation of children's activity and products (focusing mainly or exclusively on finite products, rather than on how to capitalise on the process of obtaining results and on the intentionality accompanying an activity), the exaggerated control over children, blocking children's tendency towards autonomy (keeping them in a state of dependency via permanent fear, perfectionism, high level of exigency), labelling children, insulting them, administering inappropriate sanctions (bodily punishments, isolation, non-communication etc.). Within the time frame from birth up to the age of 7, children signal their confrontation with dangerous situations by structuring characteristics connected to development: helplessness, passivity, generalised fear, lack of responsiveness, high arousal, state of confusion (including at a cognitive level), lack of verbalisation, difficulties in talking about the event, in identifying emotions, sleep disorders, nightmares, separation anxiety, pain/ psychological mourning connected to children's abandonment by the reference adult, clinging to significant persons, somatic pains (stomach ache, headache), unrest, excessive crying, sudden "freezing" of the entire body, avoidance reactions, alarm responses to visual stimuli or physical sensations connected to trauma etc. [3].

Structural characteristics of kindergarten educational activity that facilitate the children's resilience process

The facilitation of the process of children's resilience in pre-school educational institutions is highlighted by a few land marks: the end goals of kindergarten education, the valorisation of institutional space, the pre-school group, the kindergarten teacher.

1.1 The end-goals of pre-school educational institutions; global development and socio-emotional development

Institutions of children and of childhood, post-1990 kindergartens (the year of the Conference in Jomtien/ Thailand that introduced the idea of *lifelong learning* and imposed the reconsideration of the importance of education after birth) explicitly undertake, as a marker of their identity, the goal of developing small children, irrespective of the existential background and origin (family, socio-economic, religious, cultural background etc.) and independent of children's particular conditions (normal/ abnormal from a certain point of view [4]. Everywhere in the world, during the first years of their life, children are perceived in a relational and holistic perspective; "the children is regarded as a whole, with its body, mind, emotions and creativity, as well as with its personal history as social identity. (...) As Mihaela Ionescu [5] notices, research draws attention to the correlation between children's development and the quality of nutrition, care, education and, implicitly, to the children's vulnerability during this formative period considered critical or sensitive".

Based on such conception with respect to children, Romanian kindergartens undertake development as an end-goal in its global dimension: physical, health and personal hygiene development, socio-emotional development, development of learning abilities and attitudes, development of language, communication and of the premises for reading and writing, cognitive development and knowledge of the world [4], [5], [6]. The very content of the *Law of Education* in Romania (2011), under article 67 [7], mentions that early education focuses on children's physical, cognitive, emotional and social development, respectively on the early remedy of potential development deficiencies.

The fact that curricula documents explicitly invoke the emotional components as a dimension of formative interest at the level of pre-school education constitutes a significant step towards the emergence of an appropriate conception on early education and towards the re-balancing of the relationship between general scopes centred on intellectual development and socio-emotional development. At the same time, they highlight the option, at political level, for *developmentally appropriate practices-DAP,* also known as the "social-emotional orientation" in education), set in equilibrium with didactic or academic practices [8]. The option for the abovementioned idea valorises in an adequate manner the truth that "children's intellectual functions are

developed and actualised in the constant interaction with affective and social development" [9]. If trauma constitutes the expression of an imbalance in development, with visible effects over the emotional component, the kindergarten's activity is called upon to make its presence noticed and to intervene, with its instruments, for the purpose of normalisation. From this perspective, all end-goals assumed by pre-school educational institutions become general purposes subordinated to the imperative of global development; in this valorising register, the children's autonomization, socialisation, disciplining and preparation for primary school must be re-signified.

1.2 Kindergarten space and children's needs

From a pedagogical perspective, the kindergarten's space is perceived as a material frame of children's life which must be subordinated to the formative intentions assumed by the institution and, in particular, it must be used to the maximum in the process of learning (in response to the principle of intuition, of the link between theory and practice, respectively to the correlation between education and life). However, over the past years, one relates to kindergarten inner and outer space by taking into account all children's needs, not only the needs connected to intellectual stimulation; the institution of children education thus assimilates, in a beneficial manner, the message that minors "who present a high level of chronic anxiety produce high quantities of stress hormones, cortisol, which hinder the exercise of cognitive capacities and the functioning of the immune system" [5]. Resorting to kindergarten characteristic material facilities, in conjunction with and as a continuation of the positive attitudes of the educating adult, contributes to pre-school children's mental comfort [10]. Kindergartens' spatial and object-based materiality tends to assimilate elements encountered in family life: a quiet space (a small room), a cosy sofa, a comfortable armchair, attractive toys that stimulate research etc., a friendly and intimate atmosphere (created by warm colours, balanced forms, openings towards the elements of nature or their valorisation, music etc.). Such objects are a concrete and material way in which kindergartens support children's well-being [11], especially when children feel in danger (as, for instance, when they separate from the parent who brings them to the kindergarten). They allow children the control over space, to explore it in various perspectives (according to the available equipment), to individualise/ personalise the actual living environment while they are in the kindergarten, to protect themselves, to impose their own security boundaries etc. The spaces of pre-school educational institutions constitutes one of the most visible and direct indicators of the adults' vision towards the child, childhood and education during the first years of life.

1.3 The kindergarten – the living environment of the primary pre-school children group

Kindergartens are structured as institutions for every child, and, equally, also for the group of pre-school children. No matter how generous it might be, the space of pre-school educational institutions is limited to a few square meters, a surface that facilitates, in itself, the production of interpersonal contacts, including physical ones. The mere repeated exposure of a child to the other children in the kindergarten induces mutual acceptance (irrespective of the dysfunctionalities that might emerge during this process), various interactions and the generalisation of these states in an environment that is different from the family. The physical proximity involved by the space of the kindergarten involves closeness, "direct contact between persons and social groups, engaging a multitude of psycho-social processes and effects" [12]. Kindergartens not only enables and but also constructs, explicitly, frequent occasions to situate children (among themselves) at intimate distances (up to half a meter), at personal distances (75 centimetres), but they also facilitate public distances (more than 3.50 meters) between children themselves (in certain circumstances), or children – teachers, children – parents of other children, children – persons involved in care giving and educational activities in pre-school educational institutions. The pre-school group is stimulated to be and is assisted by teachers in becoming a group of games, of interaction and controlled/ self-controlled communication by resorting to the rules of the game; such groups affirms its characteristic features as a primary group within the sense ascribed to such term by Cooley [13], [14].

1.4 Kindergarten teacher –persons of significance in children's life

Early education programmes are associated with the advantage of putting children in contact with professionals in the field of minors' upbringing and education. During their initial institutional training and throughout their career, teaching staff assimilate the necessary competences for the efficient interaction with pre-schoolers: the competence to know children's personality, to organise and run kindergarten activities, to construct the curriculum (objectives – contents –communication and assessment strategies) correlated with pre-schoolers' global needs for communication and optimal interaction with children, parents, other categories of specialists, to establish the partnerships necessary to optimise activities that shape children's personality and, especially, the competence to use games and stories as essential means to perform kindergarten activities.

Beyond the shown competences, teachers activate certain moral values (kindness, tolerance, sympathy, generosity etc. [15]) and different instrumental attitudes (accepting the child, love for the child, availability for

his or her problems etc. [16]) which kindergarten teachers, during the state of early-education, assimilate as unconditional professional imperatives, as elements constitutive of professional deontology. Kindergarten teachers are the only teachers in the educational systems which are being required, as a matter of professional imperativeness, to offer affection in an exemplary and unconditioned way. Because "the affective character of the family environment is, undoubtedly, its greatest force" [17], one can reach very far away, only by benefiting from their mother's love. Everything starts from love and trust, argue Thompson, O'Neill and Cohen [18]: a child's mother and father must trust their children; they must not be always scared, critical, or nag them ceaselessly. The stake of affection offered by parents to their own children constitutes a fact that kindergarten teachers internalise and actualise during the time when their professional role turns them into the temporary substitutes of parents. Teachers who accompany children in the kindergarten perform emotional work *par excellence*; they demonstrate closeness, sensitiveness, tenderness, express encouraging and motivating messages to involve minors in attractive and pleasant activities, strive to be (at least temporarily and for a limited interest which must not be neglected) a substitute of a family member, of the family, a symbol. Ultimately, in their relationship with pre-schoolers, teachers must actually strive to be as careful, as devoted and unconditionally affectionate as a good parent; and knowledge of this truth must be accompanied by the understanding of the type of relation between each child and his/her parents [19].

Conclusion

Because kindergarten shave significant leverages to support children resilience, the issues of trauma and resilience of small age children can become a topic of interest within pre-school education pedagogy.

A teaching model for preventing the educational failure at university level

Țîru C.M.

West University of Timișoara, Teacher Training Department, (Romania)
tiru.carmen@yahoo.com

Abstract

Because of the educational failure phenomena's complexity, it is very important for professors to determine and use in the teaching process some specific strategies which will prevent or remove many related specific issues. The first step in this way is the deep study of the educational context, followed by the design of a strategy centred on the educational success. Any strategy for preventing educational failure must ensure the success of the entire educational process which is oriented on students' personal needs.

In this respect, the aim of this study is to identify some particularities of an educational process which assures students' success in the educational process, as a basis for designing a teaching model for preventing the educational failure at university level. In order to attend this aim, 119 students at the West University of Timisoara were surveyed, analysing the characteristics of the teaching process of their course and seminary professors, for the academic year 2013-2014, semester I. The research tool was constructed on the characteristics of the Functional (pentagonal) Model for Educational Contexts. The obtained responses represent the basis for building up the guidelines for educational failure prevention strategy at university level. Also, the results of the research, although realised on a small sample, can be used for the optimization of the educational process at university level.

Keywords: educational success, educational failure, strategy for prevention.

Introduction

Any educational activity initiated at university level supposes to create and to organize such educational contexts which provide an ideal framework for teaching and learning activities. It is a real difference between an idealistic design and the educational reality of teaching activities. In order to implement good practices for the teaching process at university level, in accordance with the classic and modern educational principles, the professors need to use general models which will be particularized on the specificity of the educational context. In other words, modelling the educational situations assumes to offer such guidelines which are based on the expression of a constant repetitiveness in their challenging, successiveness and organization. This will avoid such issues which should determine students' educational failure at university level and assure success in their activities.

In this respect, in the scientific literature, draws our attention two models described by V. Ionel [6]: The Structural (Triadic) Model for Educational Contexts and The Functional (pentagonal) Model for Educational Contexts. Hereinafter, we try to adapt them to the particularity of the educational process at university level.

The first one takes into account the approach of the educational contexts through three components of it. This model can be considered a general pattern for the educational contexts, but must be adapted to the specific manifestations of the three elements in the educational process.

1. The educative factors meaning the professors and teachers, which are stabile elements (because represent sine qua non elements for the educational process), but also have their uniqueness and individuality (assured by personal knowledge, representations, opinions, judgments, values etc.).

2. The educative relations representing the multidimensional rapports between the two educational factors, settled up on a cooperative and communicative educational context. The professors and students are co-participants in the teaching process, they empathies and assume commune responsibilities for maximize the educational value of it.

3. The educative influences or the extern factors of the educative contexts are related to the characteristics of the educational environment, the educational finalities, the principles and the applied rules in the educational process, the teaching and the evaluation strategy. Also, the educative influences are materialized in social and cultural influences from the family, the community or other membership groups in which are

involved the two actors. The educative influences offered by the educational process at the university level must have a real valence in the student's educational training, but cannot ignore the external influences, previously mentioned.

The *Functional (pentagonal) Model for Educational Contexts* not excludes the first model, but tries to develop more specifically each elements and offers some recipes for avoiding or preventing the educational failure of the students. The elements of this model are the following [6, pp.135-141]:

1. The educative challenge refers to the influence of the educative factors on provoking and supporting the students' transformational process. According to J. Dewey, the role of the educational institutions is to coordinate all the educative influences through valorising the natural or artificial contexts, in order to provoke a response activity from students [4]. So, the characteristic of the educational provoking context are: a teacher that is less centred on his knowledge and beliefs than others, much opened for listening and knowing his students, for offering feedback to the students and for changing himself in the educational process. The students are invited to assume responsibilities, to reflect, to solve problems and to use self-evaluation.

2. *The permissiveness* is used by the author as a behavioural dimension of the professor, which facilitate the students' evolution in the learning process. According to the model proposed by J. Wittmer and R. Myrick, the facilitative professor is: carefully, genuine, understanding, respectfully, pedagogically and scientifically documented, opened to communication [10]. These teachers' qualities are very important in the educational process which prevents students' failure and assure success.

3. *The permeability* refers to the students' availability for receiving and internalizing educational influences and for involving in some specific educational issues. So, the permeable learning is not only refers to the knowledge assessing process, but will become an adaptive process, with real value in the transformation of the student and his authentic learning.

4. *The educative influences* (previously mentioned) are discussed in this model from the perspective of their customising by the professors (the teaching style, the managerial competence, the teaching and evaluating strategies etc.) and the students (the personal characteristics and educational choices, the co-participation in the educational process, the personal values etc.).

5. *The pulse* of the educative contexts is related to the dynamic and the continuous changes of each dimensions previously mentioned. The educational process must be structured and coherent, but also flexible and adaptable to the change.

This model highlights the interdependence between the teaching and the learning processes in order to assure educational success and prevent students' failure through all educational dimensions previously mentioned in this article.

At university level, the model for prevention the students' educational failure must be a starting point for the resiliency model, which should be used for students who are engaged in such educational situations. In the resiliency literature, an important place is given to the protective factors which will prepare the people for negotiating successfully the risk [7] or to the relation between these factors and the situation of resilience in which these people are involved [8]. In any educational process, teachers should provide and model three protective factors: caring relationships, high expectations and opportunities to participate and contribute. These factors are related with students' basic needs for safety, love and belonging, respect, power, and accomplishment and learning [2].

J. Brooks points of that schools can strengthen resilience by developing social competence, increasing bonding between students and caring adults, communicating high expectations for students' academic and social performance, maximizing opportunities for meaningful participation of students in the school environment and creating partnerships with families and community resources [3].

Z. Barley, H. Apthorp, H., and B. Goodwin concludes that a high level of students achievement is assured by creating a "safe and orderly" school environment and classrooms with "clear goals" and effective feedback [1].

There is a moment when the individuals become persons at risk for academic failure and it is very important for teachers to involve and to understand which and how many factors contribute to the poor outcomes. Because the school-related factors appear to be among the many factors that have a significantly impact on the academic success or failure [9], teachers must develop and implement an educational process which is focused on the following characteristics: academic engagement, expectations and self-efficacy, individual study completion, curricular relevance, safety and communication in relation with students (positive relationship). Not every professor at university level has developed during his own career an educational process settled on these particularities. The foundation of this type of relationship with students begins with educators who have a resiliency-building attitude [5].

Methods and instruments of the research

The previously mentioned studies were centred mostly on factors which determine educational failure or assure a base for students at risk and them resilience process. Because any resilience process starts with identifying the causes or the factors which determine the educational failure, it is very useful for professors at university level to apply a teaching model for preventing the failure of students.

The hypothesis from which we started our research was: the educational process in the higher education system functions by a teaching model for preventing the students' educational failure and anticipate the need for the students' resilience process.

Settled up on a *survey based investigation* (a questionnaire with 28 items), our research goal was to establish the characteristics of the four dimensions of The *Functional (pentagonal) Model for Educational Contexts* (considered a possible teaching model for prevent students' failure) in the educational process at university level: the educative challenge, the permissiveness, the permeability and the pulse, previously presented in this article. Identifying the main characteristics of the teaching process as prevention from failure, we may offer guidelines for providing support in the professors' teaching activity and students' learning activity. In this respect, we surveyed a number of 119 students from the West University of Timişoara (year 1 of study) that analyzed in generally their professors' teaching activity for the courses and seminaries in the first semester of the year 2013-2014.

The objectives *of the research* were:

O1. To settled up the characteristics of the teaching process (for course and seminary activities) as a model for preventing students' failure at university level.
O2. To identify the differences between the course professors and seminary assistant-professors, following the model of preventing students' failure in the educational process, on each dimension of the model.
O3. To offer some suggestions for a better strategy to prevent educational failure at university level.

Discussions about the results *of the research:*

In order to analyse the obtained results, we made an analysis on the following dimensions:

1. The score averages for each characteristics of the model for seminary and course activities.
2. The score averages for each dimension of the model for seminary and course activities.
3. The t test on independent samples (course professors and seminary professors), to establish the significant differences between the averages of the scores obtained by the course and the seminary professors on each dimension of the preventing model.

In the following, we present the analysis of data on each mentioned dimension:

For the course activities the highest average has obtained by the following characteristics: he is well prepared in his teaching field (4,54); he is respectful in the relation with the student, considering each student as a unique person (3,66) and the teaching process is dynamic, but with a rhythm adapted to the students (3,62).

The lowest average was obtained by the course professors at the following characteristics: he modifies the teaching strategy by the students' personal particularities (2,82), he looks for meanings behind of words, observing the facial expression of the students and orients the students to their colleagues through encouraging being sensitive to others problems (2,87).

For the seminary activities the highest average has obtained by the following characteristics: he is well prepared in his teaching field (4,65), assures the co-ordination of all activities in order to provoke students for answering to the issues (4,20) and the teaching process is dynamic, but with a rhythm adapted to the students (4,09).

The lowest average was obtained by the seminary professors at the following characteristics: he orients the students on colleagues through encouraging them to be sensitive to others problems (3,14), he looks for meanings behind of words, observing the facial expression of the students (3,22) and he knows the students feeling, allocating attention for relating to them (3,24).

Analyzing these score averages, we observe that the professors give a higher importance to the curricular aspects of teaching: the contents are very important and as well as the dynamicity of the process. For the seminary activities is very important to interact with students and to involve them in the educational process. But, the sensitive part of the teaching process (the meaning of the words, the personality of the students, their feelings and their desires to help colleagues) obtained lowest averages, more in the course activities than in the seminary activities, but in other cases in lower than other characteristics.

Relating to the four dimensions of the preventive model, we analyze the score average of the course and seminary activities. The results obtained for course activities is higher on *the permissiveness* (3,49) *and the pulse* of the educative contexts (3,43) dimensions. At the seminary level, the higher average was obtained also on *the permissiveness* dimension (3,80) *and the pulse* of the educative contexts (3,82) dimensions. The two dimensions not exclude students' involvement in the educational process and the teacher orientation on their needs, but

according with the previously mentioned scores on each characteristics, it is more important the process, than the person.

The t test on independent samples (the course professors and seminary professors), to establish the significant differences between the averages of the scores obtained by the course and the seminary professors on each dimension of the prevention model renders the following:

-for the educative challenge dimension there are significant differences between course professors and seminary professors;
-for the permissiveness dimension there are significant differences between course professors and seminary professors;
-for the permeability dimension there are significant differences between course professors and seminary professors;
-for the pulse dimension there are significant differences between course professors and seminary professors.

Table. 1 T test for the significant differences between course-seminar professors

Dimension of the model	Sample	Score averages	T	Sig. (2-tailed)
The educative challenge	Course professors Seminary professors	3.2772 3.7286	t= -5.446	p<0,01
The permissiveness	Course professors Seminary professors	3.4947 3.8003	t= -3.643	p<0,01
The permeability	Course professors Seminary professors	3.2756 3.6387	t=-3.960	p<0,01
The pulse	Course professors Seminary professors	3.4369 3.8205	t= -3.985	p<0,01

Conclusions

Although, the mentioned results of this study demonstrates that the teaching activity has some characteristics which indicate that professors are interested in applying and developing the chosen dimensions of a teaching model for preventing the educational failure at university level. The educational process is a structured on, settled up on various strategies which use the students as co-participant and develop their personality. At the seminary activities, each dimension of the model is more emphasized than in the course activities, because in this context is much easy to establish a relation with students and to encourage their formative evolution. But, it is required the optimization of each dimension, mostly on the sensitive aspects of the teaching process. The students need to be in deeply observed, known, listened and supported in their personal problems by teachers and colleagues, because these personal life issues have a very strong influence on their learning process.

At the beginning of this article, we mentioned that a teaching process that is settled up on the principle of The Functional (pentagonal) Model for Educational Contexts, not only prevent failure, but should be a model for a resilience model at university level. In this respect, we offer some suggestions for teachers to implement a better strategy for preventing the educational failure of their students:

-The contents are not only used as a way to achieve the educational objectives, but are resources for provoke students to manifest their real educational potential and personality. Of course, most of the time, professors at university level have great expectations from their students and include them into a pattern of the perfect student. In this situation, professors forget that students should have various problems, determined by various factors and are interested only on attending the established objectives.

- The educational finalities, materialized in the specific competencies must assure a support for students to overcome the real life problems and to adapt to every change which can appear. In order to set up such finalities, professors must be connected to the real life issues of the students, to know and to support them in their educational evolution or resilience process (when it is necessary).

-The used teaching strategies must create educational situations, connected to the specificity of the adult life, because it is important to help students to assume the responsibilities that come with it. Also, it is necessary that these strategies assure an educational climate which determines the students to be opened and supportive with their colleagues' problems.

-The evaluative strategies are not only instruments for establish the students' educational evolution, but must demonstrate how good was their decision regarding the learning process in different educational contexts, how well they know himself and how will be manage possible future issues.

For attending these characteristics, professors must use the educational time not only for teaching, but for feeling and modelling personalities.

Abstract

In the study of resilience, the danger would be to observe the phenomenon externally while the inner experiences of people may be more fragile and unstable. All the resilient are not equal. Self-perception and its resources but also optimism makes all the difference. A certain kind of optimism characterizes the most resilient. They tolerate and include difficulties in the evaluation of events. It joined the benefit of psychological flexibility in the process of resilience as well as self-determined motivation also linked.

Starting with the compilation of the results of several analyzes with teachers of large school boards in the Greater Montreal and Saguenay (N = 534) around the notions of resilience, mental health and motivation, we propose to design the resilience from inside. In fact, more eudémonique vision of life in the workplace promotes resilience and psychological health. This seems to us a more complete vision of a more stable resilience.

Keywords: Resilience, Psychological Health, motivation, internal adaptation, resistance, development

Mise en contexte

La résilience, comme « adaptation positive dans un contexte d'adversité, une tendance à se ressaisir après des événements stressant et à reprendre ses activités habituelles avec succès et même à développer une moindre vulnérabilité face à de futurs facteurs de risque » [4]offre la possibilité de l'entrevoir comme processus.

1.1 *Résilience et personnes résilientes*

Afin de permettre le processus de résilience, il est avantageux d'avoir des caractéristiques résilientes telles que le sens de l'humour, par exemple, afin de réagir aux événements. Une estime de soi, la croyance en ses ressources, une certaine confiance offrent une vision de soi permettant d'évaluer les événements et d'établir aussi des rapports sociaux avantageux. Pour envisager la résilience, la manière d'observer les événements a donc toute son importance. Il s'agit d'être optimiste, mais pas simplement. Le réalisme dans ce positivisme importe beaucoup. De fait, il faut distinguer *l'optimisme situationnel* de *l'optimisme dispositionnel* où le premier serait spécifique à un événement en particulier tandis que le second s'applique quelque soit la situation [27]. On le nomme aussi *optimisme réaliste* [21]. La personne résiliente a en effet une faculté de voir les événements tels qu'ils sont, de manière réaliste, mais sans toutefois y perdre sa vision positive. Ainsi, tout va mal, mais ça va s'arranger. Cet optimisme réaliste peut être nommé également flexibilité psychologique (Kashdan & Rottenberg, 2010) où l'individu accepte la situation telle qu'elle est, ce qui lui permet de tolérer l'anxiété associée. Cette notion de flexibilité et/ou de réalisme dans le positivisme est très intéressante car elle permet aux individus de ne pas être victimes des situations. Toutes ces caractéristiques permettent des résultats résilients, « avoir de bons résultats malgré la menace à l'adaptation et au développement (Masten, 2001). Dans ce cas, on observe de bonnes formes de réalisation au travail, un engagement dans les relations amoureuses, la capacité d'entretenir des relations amicales, de développer une famille, d'avoir des enfants.

1.2 Résilience et santé psychologique

L'adaptation en résilience comprend deux notions importantes dont l'une d'elle est souvent négligée. En résilience il faut concevoir une adaptation externe visible par un comportement attendu normal au travail, dans la société. Mais elle comprend également un volet interne de maturité, de santé et de bien-être psychologique. Mais actuellement encore, la recherche se focalise essentiellement sur l'adaptation externe [7] [10], ce qui ne permet pas de voir que la personne contrôle son existence tout en négligeant son corps, sa physiologie, ses limites [9]. Et de fait, l'important devient avant tout l'adaptation sociale mais la personne renonce à une partie d'elle-même [20]. Pourtant, la résilience c'est aussi la capacité de maintenir ou retrouver un

haut bien-être face aux adversités de la vie [23]. Il est vrai que la plupart du temps, résilience rime avec bien-être. [26] [30] [34]

Tout le monde n'est pourtant pas du même avis. La santé psychologique n'est pas forcément liée à la résilience [6] [14] [32]. Des enfants dits résilients sont dépressifs [3] [8], ont des difficultés relationnelles [16] [35]. Les relations interpersonnelles des adultes résilients sont parfois difficiles [20] [35].

Pour mieux comprendre la résilience, il faut l'entrevoir de manière processuelle. Dans la définition même de la résilience se trouve un certain mouvement. En effet, il s'agit de résister avant tout aux événements difficiles, voire traumatiques, mais ensuite il faut pouvoir se développer normalement dans la société, sans trouble de santé. Et c'est bien autour de la notion de développement que se trouve probablement notre clé de bonne santé psychologique parce que cette notion est alimentée par la motivation autonome.

1.3 Résilience et motivation

1.3.1 Motivation autodéterminée

Le concept de motivation autonome, ou autodéterminée, est issu de la théorie de l'évaluation cognitive mise en place par Deci et Ryan (1985) *in* Deci & Ryan [10] et se base sur la satisfaction de trois besoins psychologiques fondamentaux: compétence, autonomie, relation. Lorsque ces besoins sont satisfaits, la motivation est dite intrinsèque et l'individu agit par intérêt, plaisir et satisfaction [10]. Autrement, la motivation est dite extrinsèque avec 4 styles de régulation (externe, introjecté, identifié, intégré). Dans les recherches, les styles identifié et intégré sont souvent fusionnés parce que trop difficiles à distinguer. Ces motivations sont également réparties en motivation autonome (identifié, intégré, intrinsèque) et contrôlée (externe, introjecté). La personne en régulation externe dépend de son milieu et agit pour éviter les punitions et acquérir les récompenses. En régulation introjectée, la personne contrôle elle-même la situation, c'est elle qui juge si elle doit faire ou ne pas faire en fonction de la valeur qu'elle s'accorde à l'action en cause, afin d'éviter notamment de la culpabilité. En régulation identifiée, la personne est consciente de ce qui lui convient, lui plait ou lui déplait, mais choisit de faire les choses pour son développement. De fait elle est en mesure d'accepter une situation non agréable, elle estime que cela lui permettra de grandir vers autre chose. En régulation intrinsèque, la question de l'importance de supporter certaines choses pour son développement ne se pose plus, elle a un plaisir inhérent à l'action. Les nombreuses études se concentrant sur la motivation autodéterminée montrent un lien positif avec le bien-être [11].

1.3.2 Caractéristiques motivationnelles en résilience

Les descriptifs des personnes résilientes appartiennent également à la motivation. En effet, les personnes résilientes sont indépendantes [36], autonomes [20], ont une bonne estime d'elles-mêmes [5] [17] [20] [21] [25] [28], une certaine confiance [2] [20] [25] un sentiment de compétence [2] [20] [21] [25] [28], d'auto-efficacité [20][21][25][28]. Elles sont aussi capables d'établir des liens sociaux [19]. Les personnes résilientes ont un amour de leur travail, du plaisir [2] [21] [33].

1.3.3 Hypothèses

Toutes ces descriptions et cette adaptation interne peu évidente nous amène à poser les hypothèses qu'il devrait y avoir des individus différents pour ce qui est du bien-être et de la détresse, les deux volets de la santé psychologique [24], mais différents également en résilience, puisque certains vont vivre une résilience avec de la dépression tandis que d'autres la vivront en bien-être. Au-delà du lien, nous pensons que la motivation a un effet sur la relation même entre résilience et santé psychologique, que nous pensons de l'ordre de la médiation. C'est-à-dire que c'est parce que les personnes sont motivées de manière autonome, qu'elles peuvent vivre une meilleure santé psychologique en étant résilientes.

Expérimentation

1. Participants et questionnaires

Des enseignants du primaire et du secondaire issus d'écoles des grandes commissions scolaires de la région de Montréal et du Saguenay (N=534), ont participé à une étude élargie réalisée par l'équipe de psychologie du monde du travail et des organisations de l'Université de Montréal. Les instruments de mesure ont été distribués lors de journées pédagogiques.

Le questionnaire de motivation [12] comprend 4 facteurs (externe, introjectée, identifiée, intrinsèque) de 5 items chacun, sur une échelle en 6 points (1 = tout à fait en désaccord et 6 = tout à fait en accord). Les alphas de Cronbach varient entre .84 et .93.

La résilience a été mesurée via l'échelle de Hardiesse/Résilience (ÉHR) développée par Brien, Brunet, Boudrias, Savoie, & Desrumaux [4]. Elle comprend 3 facteurs : l'auto-efficacité (12 items), la croissance (5 items) et l'optimisme (6 items), pour un total de 23 items sur une échelle en 5 points (1 = presque jamais et 5 = presque toujours). Les alphas de Cronbach varient entre .86 et .91.

Le bien-être est mesuré via le questionnaire de bien-être au travail [13]. Il comprend 4 facteurs (engagement, ouverture à l'environnement, bien-être par rapport à soi, équilibre) pour un total de 25 items sur une échelle en 5 points (1 = presque jamais et 5 = presque toujours). Les alphas de Cronbach varient entre .75 et .85.

La détresse est mesurée via le questionnaire de détresse psychologique au travail [13]. Il comprend 4 facteurs (dépression, détresse par rapport à soi, détresse par rapport aux relations sociales, rapport à soi) pour un total de 23 items sur une échelle en 5 points (1 = presque jamais et 5 = presque toujours). Les alphas de Cronbach varient entre 0,79 et 0,93.

2. *Résultats*

Nos résultats sont multiples et ont fait l'objet d'autres présentations et publications antérieures. Nous visons ici à offrir une compréhension générale à partir de l'ensemble de ces résultats. Des analyses de profils ont été réalisées pour obtenir des différences d'individus sur les facteurs des variables de bien-être, détresse et résilience. Ils ne sont pas présentés ici. Nous avons ensuite comparés ces groupes sur les variables globales. Des analyses de médiation selon Baron & Kenny (1986) ont également été entreprises pour découvrir les liens médiateurs entre résilience, santé psychologique et motivation. Les analyses préliminaires respectent les assomptions de base.Nous analyses montrent qu'il y a des résilients en excellente santé psychologique et d'autres peu résilients et ayant une santé psychologique très moyenne, c'est-à-dire qu'autant la détresse que le bien-être sont à la moyenne arithmétique de l'échelle de mesure. Ceci nous confirme le lien positif entre résilience et santé psychologique. De plus, la motivation autodéterminée suit cette même logique. Les plus résilients sont aussi ceux qui vivent le plus de motivation autonome et satisfont le mieux leurs besoins, tout en ayant toutefois autant de motivations contrôlées (externe et introjectée) quelque soit leur niveau de résilience. Il n'y a pas de différence statistiquement significative pour ce qui est des motivations contrôlées. Pour les groupes intermédiaires, il n'y a pas de différence de résilience statistiquement significative. Par contre, ces groupes diffèrent en santé psychologique. Par exemple, le groupe 3, pourtant aussi résilient que le groupe 2 a de biens meilleurs niveaux de santé psychologique que ce dernier, ainsi que des motivations autonomes plus élevées. Les données visuelles sont rapportées à la figure 1.

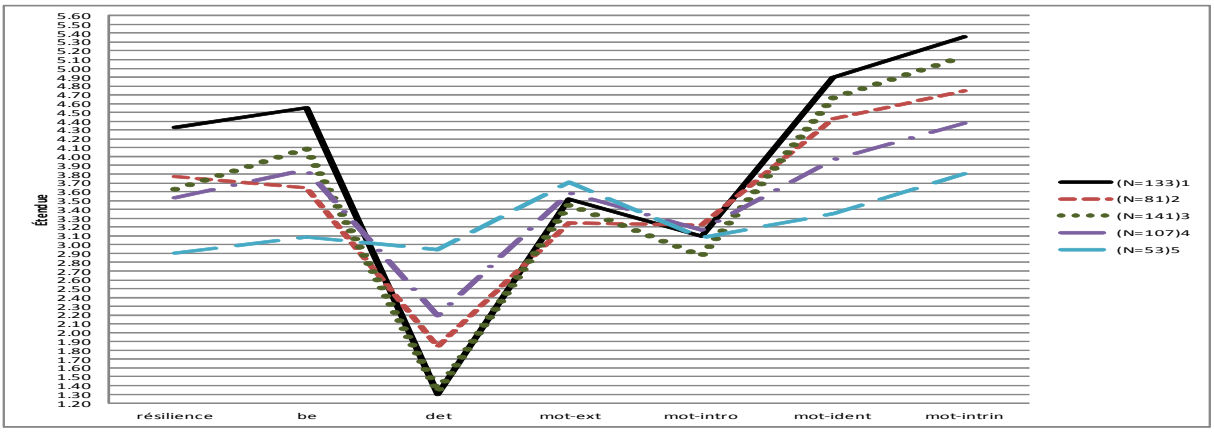

Figure 1. Distribution des moyennes de résilience, de santé psychologique et de motivation au temps 1 (N=534)

Ce lien linéaire est également confirmé par nos analyses de médiation puisque nous observons des prédictions de la résilience sur la santé psychologique (R^2 = 0.45 ; $F_{(1,520)}$ = 430.15, p < 0,001 bien-être; R^2 = 0.28 ; $F_{(1,513)}$ = 203.67, p < 0,001 détresse), de la motivation sur la santé psychologique (R^2 = 0.31 ; $F_{(1,523)}$ = 240.47, p < 0,001 intrinsèque sur bien-être; R^2 = 0.24 ; $F_{(1,516)}$ = 165.84, p < 0,001 intrinsèque sur détresse; R^2 = 0.17 ; $F_{(1,521)}$ = 109.58, p < 0,001 identifiée sur bien-être; R^2 = 0.15 ; $F_{(1,517)}$ = 95.12, p < 0,001 identifiée sur détresse), de résilience sur la motivation (R^2 = 0.20 ; $F_{(1,519)}$ = 130.25, p < 0,001 intrinsèque; R^2 = 0.13 ; $F_{(1,518)}$ = 79.35, p < 0,001 identifiée). Les pourcentages de prédiction sont compilés aux tableaux 1 et 2. Les prédictions

sont nettement améliorées pour prédire la santé psychologique lorsque les motivations sont ajoutées à la résilience.

Tableau 1 :
Prédictions du bien-être totales et partielles en pourcentage

Type de médiateur	prédiction totale	résilience	médiateur	portion patagée
motivation intrinsèque	54	22	8.4	24
motivation identifiée	49	31.3	3.6	14

Tableau 2 :
Prédictions de la détresse totales et partielles en pourcentage

Type de médiateur	prédiction totale	résilience	médiateur	portion patagée
motivation intrinsèque	37	8.4	12.3	16
motivation identifiée	33	16.8	4.8	11

Discussion

Les résultats présentés sont sommaires mais d'emblée ils permettent de saisir que la résilience, tout en étant en lien linéaire avec la santé psychologique, ne peut à elle seule suffire. D'ordre général, être plus résilient c'est être aussi en meilleure santé psychologique ainsi que les nombreuses études l'ont déjà montré [26][30][34].Cette recherche ajoute cependant d'autres éléments. Nous pouvons assumer que la motivation aurait une part de responsabilité du fait de son apport de médiation. Au-delà de la résilience, avoir des motivations autonomes apporte un atout supplémentaire pour assurer une bonne santé psychologique. Et ce n'est pas une évidence qu'être résilient soit synonyme de motivation autonome (13% de prédiction identifiée, 20% intrinsèque). De plus il n'est pas essentiel d'avoir moins de motivation contrôlée, en fait les plus résilients en ont tout autant que les moins résilients. Par contre, il semble nécessaire de vivre plus de motivation autonome.

Lorsque la personne entretient des motivations autonomes, identifiées, elle conçoit que les choses ne soient pas idéales ni même plaisantes en tout temps. La personne tolère. On peut supposer alors qu'elle puisse être flexible avec les événements de la vie. Tout n'est pas toujours rose. Cela se confirme avec les résultats de régression entre flexibilité psychologique et santé psychologique. En effet, la résilience peut expliquer 24% de la flexibilité psychologique qui elle-même explique 27% du bien-être au travail selon les résultats de Théorêt et collègues (2014). La vision que l'individu a des événements, sa manière de les appréhender fera toute la différence. La résilience est d'ailleurs également décrite comme le fait de s'adapter et de trouver du sens dans les événements stressants, une forme motivationnelle qui pousse à poursuivre une sagesse, une auto-actualisation, un altruisme et d'être en harmonie avec une force à la source spirituelle [22]. Il s'agit non pas de résister, ce ne serait qu'un début, mais bien de s'y développer malgré tout. Voilà toute une forme d'optimisme et de flexibilité de l'esprit capable d'envisager les événements à son avantage.

Par contre, Il y a probablement une distinction à faire entre flexibilité psychologique et résignation, ce qui ferait toute la différence. Si l'on conçoit la résilience selon la résistance et le développement, nous pensons que se résigner amènerait la personne à rester en résistance, à puiser dans ses ressources et à les épuiser, sans pouvoir s'y renouveler et s'y développer, ce qui amènerait des résiliences partielles nommées aussi désiliences ou désistance [20]. La personne avance mais y a perdu un peu en cours de route.

Conclusion

Nos résultats montrent l'importance d'observer ce que l'individu vit à l'intérieur de lui, comment il se perçoit, quelles motivations il entretient. Ce que nous voulons retenir ici est notamment l'apport indéniable, supplémentaire et non d'évidence de la vision des choses. Aristote prônait une vie eudémonique où le bonheur n'était pas dans l'immédiateté mais dans la manière de concevoir son existence dans ses actions bénéfiques et non dans ses acquis matérialistes ainsi qu'il est possible de nos jours. La motivation intrinsèque, la flexibilité psychologique sont des concepts représentant très bien cette vision de la vie. Et cela dépend de la personne, et non de son contexte. Bien sûr que l'environnement, les tuteurs affectifs ou les traumatismes divers auront un impact. Par contre, si la personne ne peut être responsable de ce qui lui arrive, il lui revient de choisir ce qu'elle en fait. Et le fait de voir les obligations et désagréments comme un tout permettant aussi de se développer ainsi que le conçoit la motivation autonome est justement une manière de se responsabiliser en tant qu'individu en

plus d'agir pour améliorer un environnement trop souvent éloigné de nos besoins humains. Cela évite également le risque d'être victime d'une situation extérieure à soi car après tout, il est possible de développer de la résilience aux moments où l'on s'y attend le moins, comme dans l'ajout d'événements traumatiques par-dessus certains non digérés encore et ne provoquant pas de processus de résilience au premier abord. Le développement intervient quand la vision des événements change et qu'il est possible de les entrevoir comme une possibilité d'avancement plutôt que de recul [20]. Et cela personne ne peut mieux le faire que la personne elle-même.

The elderly - a person that needs more attention

Breaz M.A.

University of Aurel Vlaicu Arad Romania
maria_breaz@yahoo.com

Abstract

Resuming in a few words the clinical nature of the elder patient, it can be said that he is a person of whose enormous functional reserves during his development and maturity are in great measure lost. In spite of the reduced reserves, most of the systems continue to work pretty exact although in a considerably slowed rhythm. Rarely does it require prohibiting the elder from doing some activities. The condition is that the activities that he develops should not necessitate strength or unusual agility. The only necessary limit at this affirmation is that the elder should be warned that many activities request from now on more time to execute and he should be encouraged to accept this thing and not try to rush.

Keywords: old person, ageing, disease.

Senior monitoring

The elder patient always imposes a certain specific situation putting the doctor in a different situation like when examining a young or adult patient and that is by differencing the normal from the pathological.

This particularity diverts from the fact that the normal of an adult is different from what we consider normal at an elder person, because the ageing process (the natural process, physiologic) attracts changes of the morphological and functional parameters of the organism, changes that are considerate physiological for a certain age. In other words, it is important to establish whether we find ourselves in front of an elder with changes of "ageing of the physiological scenery" or in front of an "elderly ill person". With all this, the differencing is often difficult whereas the two processes can coexist tightly bounded, being hard to separate, which influences negatively the proper evaluation of the elder and the development of the therapeutic measures.

Starting from this difficulty, in practice can be met two aspects:

- Either are considerate pathological some aspects of normal ageing, situation that doctor Constantin Bogdan considers with certainty to be the most frequent one;
- Either some pathological aspect is being considered normal, belonging to the physiological ageing. Roland appreciates that this second situation is frequently found also because of the elder's entourage (relatives, friends) that are trying to convince him that he has to comfort himself with the idea that full health is in the past and that he has to confine himself at being ill and weak, expecting to feel even worse before the end. As long as the elder and even the doctor accepts the continue pains, the dizziness, the weakness, the fatigue and other symptoms as an integrating part of the advanced age, many diseases will remain undiagnosed and untreated.(2003)[1]

That is why the elderly patients must be encouraged to relate the new and upsetting symptoms right at it appears. The elderly will appreciate the interest that his doctor or his caretaker has, they will trust each other and will be able to stay calm when the situations when the accuses regarding their physiological involution should not alarm them (it is possible that even at a very advanced age a man will hardly accept the decrease of his physical strength or eyesight, which are normal phenomena).[4]

Although the morbidity and mortality are constantly increasing with age, a lot of elder persons can enjoy a full and active life; the proportion of these decreases slowly from 95% at the age of 65 to 85% at the age of 80 and to 70% or less at the age of 90. This means that the older age should not inspire fear in most of the cases; it is a period that permits the individual to fully enjoy every moment, a period when unfulfilled ambitions can be reached.

Few studies have examined the health of some random elderly lots living in their own houses. This kind of study was realized in three districts at SV Ontario and provides estimations of the elderly proportions of different ages that have lost a part or all their independence.

Based on a simple activities analyze (walk, climbing stairs, washing, dressing), this study has found that most of the elderly are keeping their life style completely independent until the end. Between the age of 65 and

70 the incidence of significant disabilities slowly increases from 5 to 10%. Only after the age of 80 this enhancement of losing independency reaches 20-30% at the risk population.

The importance of this simple study is that it draws attention about the false nature of the idea that older age is mandatory the time of debility and losing health. Most of the elder, but not all of them, rely very much on health, more than on any other aspect of life and that is why is important that this message should be sent all over and of course, accepted. It will encourage the elderly to have hopes for his health, understanding that it can be accepted that the disabilities could not necessarily occur.

The elderly usually imagine a picture of chronic and continuous disease with the reduction of its capacities and with disabilities. However, there must be emphasized that the chronic disease and the age don't always go hand in hand. Shapiro finds that more than half the patients with internment longer than 6 months are persons under the age of 65, fact confirmed by the studies made in the hospitals of London and Ontario.(1983) [3]

Therefore, it is important to make the difference between the patients suffering of a chronic disease and elderly persons. This might have many health problems, typical to the elderly being the pathology but in relatively few cases it conducts to the continuation of complex disabilities to have as a result the loss of independence. In the other cases, the hope to obtain a satisfying recovery to independence is good.

The elder patients appear from many chronic state of disease (remarkable being the atherosclerotic disease, the vascular, bronchopneumonia chronic obstructive, the late diabetes, chronic arthritis). The first and the most common of these – atherosclerosis- appears usually as a series of acute episodes of heart attack, gangrene because of the peripheral vascular disease etc.

Although a part of the individuals become chronic ill in these conditions, the majority continues to maintain a dependent way of life, besides de occasional acute episodes.

Chronicity does not mean that the treatment can't be applied to reduce the problems and to maintain the independency. Ronald Cape appreciates that at an elderly the effect of a chronic disease falls, in big lines, in one of the three possibilities:

- First is that of the proven terminal disease and the patient dies in two-three weeks
- Second is that of the disease that responds to treatment and it properly rehabilitates and the patient is recovering it's full independence
- Third possibility is that the disease has as a result a significant loss of functional ability so that the individual becomes dependent of the surrounding persons support.

The American geriatrician considers that the elderly are afraid of the third possibility, so the management of the elderly diseases should avoid this situation if possible. (2003)[1] This objective can be realized having the elderly patient in a continuous rehabilitation program at home or if necessary in a day center with provision of community services, in order to encourage and maintain independency, be it only partially. Another problem related to the elderly pathology, that we consider is worth mentioning, is that of a surgical condition with a risk of dying, for example the discovery of an asymptomatic abdominal aortic aneurysm at an 80 years old person, situation possibly lethal because the rupture of the aneurysm will be most certain the cause of death. A surgery would remove the aneurysm and his lethal risk but, on the other side, this kind of intervention performed at a healthy octogenarian is encumbered by a pretty high mortality (approximately 19%) and can determine, through the operatory stress and by possible adverse effects of the drugs, the deterioration of mental capacity and of the independency of the individual. The experience shows that most of the elderly, if they are being given the possibility to choose, prefer a shorter and independent life instead of a long period of invalidity, when they are dependent of the care of others.

Another aspect of the elderly pathology, which we believe that deserves to be mentioned here, is the special role it may have the preventive geriatric medicine. And in this sense can be given many examples.

Thus, osteoporosis, considered somewhat universal at elderly women because of hormonal deprivation at menopause, have a high risk of fracture at the age of 75-80.

In the world, annually, there are hundreds of thousands of serious bone fractures attributed to osteoporosis. [4] The diet analysis of middle-aged women shows that, for many of them, the diet does not contain enough calcium, although negative calcium balance may be only a secondary factor of this multi factorial disease, it plays an important role and is certainly a remediable factor . It can act preventively also on other etiologic factors, of osteoporosis, by hormonal correction and physical activity, particularly important being the preservation of an even modest physical activity.

The elderly Digression on Mentality

To make a minimum assessment of what the old age means in the history of mentalities, we need, if not a trans disciplinary approach, at least multifaces vision.[2] Entering the maze of the mechanisms of history on the path of mentalities, we are obliged to consider the statement of Fr. Scheling from his mythology philosophy

course as a determinant factor of history: "Not because people's history receives its mythology, but rather mythology determines its history or rather, it does not determine, but it constitutes the fate that was destined from the beginning ".

How man realizes the differentiation of animal world by symbolist mediation, there were made through the argument of the assumption above several meanings and references of the symbol "old".

"If old age is a symbol of wisdom and virtue (elders are old at the origins, meaning wise and guides) if the China (1993)[4] the elders have always enjoyed respect, it is because they are a foreshadowing of longevity , a treasure of experience and reflection , which is only an image of immortality. Per se, according to tradition, Lao- tzi was born with white hair, has an old man's face, hence his name which means old teacher. Taoism during the Han dynasty knows a supreme deity called Huang Iajun, meaning Senior Old Yellow, a purely symbolic expression that H. Maspero likened to the Ancient of days, we'd have to add the "old man on the mountain" of Druids.

In Revelation, the Logos is depicted with white hair, which is once again the sign of immortality. But to escape from the confines of time refers to both, to the past and future, to be old refers to existing before and after the birth of the world even after it will no longer be. Thus Buddha calls himself "the firstborn of the world". Shiva is worshiped at times (especially in anakorian Cambodia) under the name "the old Senior". The secret society Tiandlhui is sometimes designated as "the True Ancestor Society" (for example, in the edict of its condemning given by the Emperor Gia Long). This ancestor is the sky, at least for the Real Man, the son of heaven and earth (BHABI ElimGraoGuet Mast).

Considering ole age, in the archaic and traditional mentality in terms of violent behavior, we have to note that the elderly enjoy in archaic and traditional communities the exceeding of authority and respect and thus protection. It can be said, of course, that in some tribes found still in archaic community, there is the customary stoning (killing) rituals of the elders and it is brought as main argument of this behavior the economic motivation (they are "a burden on the community and can't be fed without jeopardizing the community resources").

This argument is rather the argument through which a society in crisis is chasing two rabbits: shown as being very understanding concerning the archaic tribal behavior, justifying them a behavior as being normal; based on a typical reasoning for the communities found in crisis and founds excuses for his actual behavior by discovering "its historical roots".

The reality is totally different. In support of this affirmation the arguments are numerous:

- The average age of archaic and even traditional communities is very low which means that the number of elderly in the true sense of the word is very small [1]. However, in a community that includes several hundred individuals, they were just rulers, doctors, the council of elders without whose opinion the community didn't do anything important.
- Given the previously reported, the ritual of killing of the elderly must have another explanation : perhaps a ritual self- offering for a sacrifice which the community members were obliged to execute or even a perversion of sacrificial rituals of a community in times of crisis , which could lead including to a deletion of the essential differences (e.g. "own foreign" when an old man, through his limitations of driving opportunities belongs to the community), which would allow their passage into the register of sacrificed victims. They were recruited from strangers, incomplete members or without family in the community that unleashes the chain of revenge, of indiscriminate violence (if the case of tribe's elders we can't discuss the lack of relatives in the community, they being usually related to almost the entire community), and between the individuals infected by the sacred distinction(the elderly were usually holders of secrets and rituals of 'differentiation of the sacred , of the attracting of willingness over the community"), and under the circumstances, the aggression of the elderly would have drawn the wrath of sacred over the community .
- Although the documents we currently have refer more to the awe and respect enjoyed by male elders is hard to believe that the old women did not enjoy the same respect, being the holders of the secrets of feminine rituals and initiations and which commonly identified themselves the "Great Mother "with Gea, with the earth, in its feminine state and with lunar grace. Even acute awareness of the impossibility for them to become mothers would not be sufficient for battering during the archaic and traditional period. We know, for example, that in previous centuries, inside the house, at the father's death occurs a rotation: "If the mother survived her husband she was forced to remain a widow, to leave her bed to her son and daughter-in-law and move to another room or mostly with her unmarried daughters or even granddaughters .At the father's death, the son inherits household management together with the best place for sleep." This means that only because of the death of her husband, losing the moral capacity of procreation, she loses her position of queen in the hive, the mother of the family, in favor of the one having the moral right to procreate and perpetuate, and by no means does not mean that she is abandoned: she switches in the position of forming future mothers for the family.

• It can accept the idea that during the archaic and traditional mindsets, the limited right to verbal aggression or loose of the elderly belonged only to the children. In their case, we can talk rather of a greater permissiveness among adults in some communities, based on the grounds that they do not fully belong to the group and not even to human category ,not being passed through initiation rites led by adults (usually even by the elder). We do not believe that they were allowed to exceed a certain limit.

Based on the research that was made in the last half century, nowadays is possible to use some intervention strategies that facilitate the development of resilience also on people exposed to the risk of developing psychical disorders due to their life experience. In this case we talk about an assisted resilience, built with the help of specialists. [5]

Conclusions

As a final conclusion of those found, I want to emphasize the society's special care for vulnerable groups, as well as the perspective to enable older people within certain legal actions and beneficial for active functions. In Romania the cult of ancestors and forefathers represents a true cult extended until today under the guise of Christianity popular type (should be enough to remember "the elders of cabbage" and days about the cult of the dead, who are still called " elderly " to which may be added the mythical toponymy of ancestors and old women). From this perspective it is more difficult to understand the western " implant " of institutionalization of elders or elders abandoned and alone. In addition, the Christian imagery is also populated mostly by elders: based on ancient God figure ,besides of a whole series of saints belonging to this category , it should be noted that all the Fathers of the Church are elders. Without a more complex treatment of old age problems from an anthropological perspective , from these reported until now, we can remark that in the archaic and traditional mentality elders enjoy respect and protection in the traditional archaic authority communities.

A strategic approach based on resilience

Casula C.C.

Società Italiana di Ipnosi (SII), Italy,European Society of Hypnosis
consuelocasula@gmail.com

Abstract

The workshop will describe a strategic approach based on resilience to help patients who suffer from unresolved traumas and are constrained by limiting beliefs and toxic emotions to open their hearts, minds and souls, and so find the courage to imagine a better future and conceive different options that favor change in sensations, feelings, thoughts, attitudes and behavior.

The workshop overviews a model of resilience which helps patients transform destiny into choice, obstacles into challenges, chaos and rigidity into harmony, resignation into active hope, pessimism into doubt, and problems into searching for solutions. This model plays an important role in eliciting empowering emotions and transforming limiting beliefs into permissive and exploring attitudes. It is essential for finding the patient's hidden physiological, remedial and evolutive resources and for enriching his/her vulnerability with curiosity, compassion and connection.

This workshop will provide clinical examples and practical exercises to demonstrate how to strengthen the therapeutic alliance by awakening the patient's flexibility, creativity, and resilience, how to draw his/her despair and unwillingness to live into the openness and explore new options in a world of infinite possibilities.

During the workshop participants will learn a set of therapeutic strategies – physiological, emotional, cognitive and behavioral - for treating unresolved traumas. These will provide therapists with the means to help their patients face the future with the awareness that they are alive and life is full of surprises, so that they discover new paths in a fertile land, and they accept being guided by passion for the possible.

Keywords: doubt, analysis, learning, challenge, relations, choice, harmony

A Strategic Approach Based on Resilience

The strategic approach proposed here is based on a sequence of Seven Steps to help patients to bounce back stronger than before from normal or extraordinary adversities, utilizing their vulnerability as a resource to live a full and meaningful life.

This approach is based on twofold premises. The first one comes from Antonosky's (1) *salutogenic* approach that asserts:

1) each of us is exposed to traumatic experiences and is able to overcome them;
2) each of us lives in a network of relationships which sustains and defines us;
3) each of us can reflect upon what happened, learn from experience and develop new talents and potentialities.

The second premise comes from Dan Siegel's (2) definition of wellbeing from the perspective of the emotional brain and neurobiology. According to Siegel, wellbeing is a product of three mutually reinforcing components, such as a coherent mind, empathic relationships and neural integration. To reach such ~~a~~ wellbeing, it is important to calm our minds, to heal emotional trauma, to feel more secure and safe in our intimate relationships, developing more empathy for significant others and ourselves and reaching neural integration.

Emotion is a central integrating process in the brain that links the internal and interpersonal worlds of the mind. The ability to organize emotions helps to integrate experience and adapt to stressors, and promotes affect regulation. Integrated minds have the characteristics summarized by Siegel's acronym, "F.A.C.E.S.": Flexible, Adaptive, Coherent, Energized and Stable (2). When there is integration, coherence is achieved and the brain is used in a most effective way. Unresolved trauma or recurrent stress can cause us to have deficits in processing information in an overly rigid or chaotic way, without any flexibility. He who processes information in a rigid way has difficulty adapting to new situations and events. He who processes information in a chaotic way is unable to tolerate stressful situations without becoming overly anxious or emotionally activated in dysfunctional ways.

During the therapeutic process based on resilience, the therapist calls up new reflections on the trauma, offering a new representation of what happened, and a better awareness of the patients' ability to overcome

stressful events. The aim of the therapeutic process is to develop patients' ability for utilizing old and new resources to live a meaningful life.

Based on these premises, the *Seven Steps Strategic Approach* aims at helping patients to find their own resilience during a synchronic and diachronic process, which faces past traumas and diverts energy from what cannot be modified to changes that can be promoted in the future (2). Synchronic integration involves the elements which create a cohesive mental state at any given moment in time, while diachronic integration involves the mind flow across time in a manner that facilitates flexible and adaptive functioning. The double integration serves as a mechanism of self-regulation, as a way to organize the coherent flows of states, offering a new representation of the wound and of the patients' ability to heal the memory of the trauma.

The *Seven Strategic Steps* are seen as a systemic whole where each ingredient influences and is influenced by the others, so that changing one enhances the potential effect of the others.

Let us start by defining resilience.

Resilience is the ability to rebound again and again, to react to threats imposed by destiny, and to reframe difficulties into growth opportunities. Being resilient helps us to appreciate the extension of life as a gift, to discover new talents and strengths by considering life as a creative act, and to recover and recuperate one's own energy as soon as possible. Resilience de-emphasizes suffering through the use of positive emotions, and turning adversity into the development of one's own potential, thus strengthening ones character (3) .

Resilience proposes ways to govern emotions in order to be stronger than despair, to recognize suffering as an agent of change, to detach from what happened and concentrate on finding effective strategies, focusing attention on the resources, determined to achieve healthy objectives.

As a synchronic and diachronic representation of the wound, resilience awakens, enhances and combines personal, social, cognitive and spiritual resources, giving an ethical sense to pain: suffering helps us to understand the true meaning of life and leads to readiness to change. Patients find the resilient balance between stressful events, the force of reality and interpersonal skills.

Let us now examine the *Seven Therapeutic Steps.* Each step describes a passage from one state to another, each of them represents a portion of a mental and emotional pathway to help patients to enhance their own resilience.

From despair to doubt

The strategic approach starts by helping patients to recognize, hold and accept their despair and, at the same time, seed some doubts in their negative beliefs and perceptions. If patients have lost their ability to see the light at the end of the tunnel, the therapist helps them to visualize a more luminous future. Putting aside despair, and welcoming the epistemic emotion of doubt calms the soul and recognizes that the future is unknown: thus catastrophic certainty is put aside, and life's ambiguity and mysteries are embraced with serenity.

Patients discover that the compulsion to repeat the past is not an obligation: in human events there is no determinism that makes us confident that the future will be a black and white photocopy of the past.

A wound becomes destiny if only we think that nothing could change, while we know from our experience that a spark is enough to rekindle the flame of life from the resilient ashes (4).

From confusion to analyzing risk and protection factors

After recognizing that they cannot predict the future, patients are ready for the second step which brings them to self-regulation based on searching for information helpful to contextualize what happened, and the selection of logical memories and significant episodes, neglecting what might disturb and postpone the healing process. This step aims at enhancing patients' ability to evaluate risk and to utilize protection factors. There are risk factors, such as difficulty in establishing and maintaining positive relationships, high levels of anger and aggression, inappropriate expectations toward self and others, and destructive behavior. There are also protective factors, such as open temperament, good intelligence, autonomy, problem solving ability, and commitment to reach pursuable goals. Through the search for useful information, patients enhance control, commitment and challenge, the three components of hardiness (5), and achieve a global orientation that gives them a widespread, enduring, and dynamic feeling of trust based on the belief that external stimuli are structured, understandable and predictable, and that events are comprehensible, manageable and meaningful. It also indicates that resources are available and sufficient to meet the demands posed by the stimuli.

From regret to learning from mistakes

Patients who narrate their story to the therapist are helped to reconstruct their past, change the emotional representation of the trauma, and engage themselves in a constructive way. After narration, the events change meaning and patients are ready to resurface some memories to consciousness, feeling freed from

repeating the same mistakes. At this point the therapy process aims at recognizing that negative emotions, such as remorse, regret, shame and guilt, keep them locked in the past, while active emotions invite them to go towards the future with confidence, hope, curiosity and trust, so that they are open to looking for new options of what they have to do to become what they want to become (6).

This step aims at reframing mistakes as a learning opportunity, contextualizing what happened as it happened, separating intentions from actions, differentiating patients' responsibility from others, distinguishing accidents from "destiny".

At this point, patients are ready to recognize what they have learned that otherwise could not have been learned. This step helps patients to go back to the past from the present, knowing what happened after the trauma, recognizing their own value and merits as well as their own limits.

From avoiding obstacles to challenging them

After seeing the past trauma with the eyes of the present and gaining better knowledge of their resources, and after reframing past mistakes into learning opportunities, patients are ready to adopt an optimistic style of coping that transforms stressful events into less threatening ones, into a challenge worthy of investment, commitment and engagement. They stop seeing difficulties as insurmountable, and start looking towards the future with curiosity as well as transforming adversity into the development of their own potentialities (7) (8). At the cognitive level this involves setting events into a broader perspective in which patients believe they can influence them. At the level of action, they see themselves as reacting to stressful events by increasing their ability to control and interact with them, trying to turn them into an advantage and an opportunity for growth, and achieve greater understanding. When pain is transformed into challenge, patients feel that resilience is a second skin which bounces off the blows of life and transforms vulnerability into strength (9). Resilience is the ability to get up stronger than before after a fall, appreciating the extension of life: the final moment has not yet arrived.

From isolation to relationships

After gaining self-confidence in their ability to regulate post traumatic emotion and to cope with stress, patients are also ready to understand that recognizing their vulnerability can bring a sharpened appreciation of new relationships that give new meaning to life. As it is possible to learn how to love after having suffered emotional deprivation, it is also possible to love again after a loss or a death of a loved ones, developing a secure attachment (10).

Even when the starting point was lacking the emotional basis of security offered by a caregiver, the affective constellation of an adult or elder, as well as the way in which this affective constellation is perceived, can be changed by new relations that initiate evolutionary development. When patients are prone to raise their heads and pay attention to the people who helped them during their most difficult period, they are also ready to find a way to facilitate the nurturing of the best in themselves.

As a result of the growth of their resilience, patients discover that they are more comfortable with intimacy and become more compassionate with themselves and with others who suffer. They comprehend the value of close and caring relationships and the importance of altruism, devotion towards others, benevolence, gratitude and generosity.

From blaming destiny to accepting it

After the discovery of the importance of the safety net of relationships, patients may be ready to transform what has happened into choice. This passage gives power back to patients who have felt that destiny had been unfair and bitter in their regard, making them suffer or taking away what was most dear. Accepting what cannot be changed allows them to enjoy what is left, the importance of still being alive and of living in the present, discovering talents, virtues, strengths and resources that were neglected because they were not needed (11).

Transforming destiny into choice means embracing what happened and recognizing that they are different persons with new options to explore what was unthinkable before because it was not necessary since their life followed a regular path. This helps patients to acknowledge a sense of impermanence, transitions and transcendence, accepting natural laws and their changes, differences, and mysteries. At this point patients are ready to be different persons at different levels, and become future and solution oriented.

From chaos and rigidity to harmony

Accepting their own destiny and transforming it into choice makes patients ready to find harmony between chaos and rigidity (2).

Patients who find their own harmony are better able to recognize that their resilience is made of **H**ope, **A**wareness, **R**ealization, **M**orality, **O**pportunity, **N**iceness, and **Y**earning (11). **H**ope keeps repeating the mantra: "yes you can", "you have all the resources you need to become what you want to become".

Awareness keeps patients alert in recognizing and using their talents, virtues and strengths.

Realization of resources combines motivation and commitment to achieve own goals.

Morality is the determination to live by values and virtues.

Opportunity keeps the wise mind and heart open to receive what life offers.

Niceness reminds patients of the importance of being noble, kind, gentle, generous, equanimous, and magnanimous.

Yearning is the call to achieve what they want to achieve, not letting the pain win over the desire to live a meaningful life.

1.1 Post Traumatic Growth

The Seven Steps proposed as a therapeutic strategy to enhance resilience after a trauma helps lead patients from the land of suffering to the domain of 'Post-Traumatic Growth' (PTG), eliciting the positive psychological change experienced as a result of the struggle with highly challenging life circumstances (12). In particular, as a result of the Seven Steps, patients recognize that, as a consequence of the trauma, they have changed for the better in some significant ways.

They have developed a reconfiguration of how to make meaningful sense of the world, deepening intimate relationships, gaining better recognition of personal and social resources, developing or mastering new skills, and giving different priorities to goals or setting different ones.

Following the *Seven Steps Strategic Approach* leads patients to modulate their emotion and to awaken the profoundly spiritual belief in their connection to something greater.

Resilience of women and elders survivors of domestic violence

Dinu A.I.

Romania
adela_dinu@yahoo.com

Abstract

The joy of having a family can not be ignored even in the most dysfunctional families. The family is considered to be "the most active center of aggression" [4], family members being exposed to much greater risks, as victims of domestic violence than as potential victims in any other type of violence [5]. Since 1980 Straus, Gelles and Steinmetz claimed that it is more likely for a person to be hit or killed in his/her own family by another family member than anyone else on the street. However, building a family which ensures a secure and protective space is a major hope of life for each of us. At the time we are children, satisfied or dissatisfied with our own family, hope to build a family in which we can give and receive love and affection, as future adults. At the time we are adults, happy or hurt due to dysfunctional family relationships, we are proud of our family or we assign blame for its failures. Concerned about the mental health rather than identifying the causes and treatments for mental disorders, I developed an approach for assessing the characteristics of "survivor personality", which is a resilience personality that continues to live despite adverse conditions. The approach of assessment was applied to adult victims of domestic violence: women and elders. Women endure suffering and humiliation for the sake of children and family. Elders forgive children nonsense and hope that children would remember fondly their parents, after death. Capacity of resilience develops as there are increased educational benefits that the external environment has on the individual. The proposed assessment approach valorises principles of participatory practice, non-formal education and outcome evaluation in the single systems.

Keywords: family, domestic violence, resilience, mental health, participatory practice, outcome evaluation

Social services for women and elders survivors of domestic violence

1.1 Domestic violence, a process of “illness”

Survivors of domestic violence are any of the family members like children, adults and elders who were directly or indirectly affected by various forms of emotional, physical, sexual, social and/or financial abuse. They go through a process similar to "illness" and recovery is difficult, but not impossible. Faced with situations of humiliation, despair and often of helplessness, domestic violence survivors learn various strategies to endure suffering, communicate through silence, look for support and find solutions in hostile conditions without resources like money, housing, clothes, identity documents, etc. Sometimes the survivor finds an extreme solution of killing the aggressor. The next challenge he/she faces is the punishment given by justice and by the whole society up to the end. Inner struggle of the human being is similar to fight of the body against an outside virus. Resilience is our ability to cope with continuous pressures and disturbing failures during life. Negative emotions like fear, anger, anxiety, despair, helplessness could weaken resilience if those who have these feelings allow them to become permanent. Fear and daily cares weaken the immune system and increase vulnerability to diseases. Tranquilizers or other harmful substances are short-term solutions. We become more resilient when we accept our feelings of sadness, anger, loss and confusion and struggle to not let them be permanent. As a consequence people recover and become stronger than before, as Wilhelm Nietzsche said "What does not kill me, makes me stronger".

If domestic violence is like a process of “illness”, recovery based on resilience, is a “healing” process. Supportive factors are friends, relatives, well-known people but also specialists who offer positive answers to people`s attempts to cope with abuse, to stop and prevent the abuse (social worker, psychologist, lawyer, policeman, priest, doctor, etc.). Working with survivors of domestic violence, specialists need to assess the impact they have on the resilience capacity of their clients.

1.2 SEISS model, an innovative system to assess resilience capacity

In order to assess social services impact I built SEISS model, an innovative system that brings important information about competences acquired by domestic violence survivors. This model fulfils the following requirements:

1. to assess competencies related to resilience capacity: self-esteem, communication, expression, conflict resolution, orientation towards change, participation, etc.
2. to assess each competence in relation to three dimensions: behaviour, affectivity and knowledge
3. to use a five-level scale of rating for the results obtained
4. to adapt to client`s needs and particular intervention
5. to use specialist`s experience and client`s feedback
6. to allow clear measurements that can be periodically repeated
7. to allow visualization of the assessment results

We will take the example of one competence that is relevant for adult survivors of domestic violence: women and elders. Since people are wonder themselves and survivors are asked usually "why do not you leave? Why do you stay with the abuser? ", we will exemplify the competence of orientation towards change.

At the cognitive level knowledge has different degrees of complexity that will enable the client to relate effectively to different life situations. In order to have a reference, I chose an ordinal scale. This scale shows a hierarchy of the competence levels, from lower to higher ones. It is a scale similar to the metric scale of intelligence that allows "a hierarchical ranking between different intelligences; and for practical purpose this ranking is equivalent to a measurement" [2].

The lowest level on the cognitive dimension is the category named *knows-that*. When abuse happens, the survivor can not explain it. In most cases, the survivor accepts the situation as it is because has no other environment to compare with. *What happens to me? Do I am a victim? What is domestic violence? A simple argument or more than that?*

The next level is *know-how.* The survivor has some ideas about what others have done in similar situations of abuse and compares their situations to own situation requiring change. Often he/she listens to what others say. *What would happen if I leave? What risks do I have? How can I manage to find a place to stay and take care of myself (and of my children)?. It is not easy, I already know some people in my situation.*

Distant understanding is the next level over the previous ones. The survivor reflects on the benefits and risks given by the current situation and compares them with a new situation after assuming changes in life. *If I leave, I have to stay together with my kids at my mother's place. I will not have enough money, have to find also some work from home, borrow some money if necessary, and manage to send my children to school.. Why he can not stop being violent? I can not endure beating and humiliation! What if I stay in a shelter..*

The fourth level is *implicit understanding* and survivors reach this level after some attempts to get out of the situation of abuse. It involves direct experience of a life change and understanding of what to do in that situation. Survivor identifies possible resources to overcome the difficulties caused by change. *It takes a few days for the police to start investigation of my case, evidences will be checked, lawyer will represent me in court, I will protect myself and my children from other abuses of my husband and I will complain to the police. It will not be easy but after all this going, I will regain my independence.*

The highest level of competence on cognitive dimension is *intuitive acting*. The survivor knows how to act in own situation but is able also to identify solutions in an abusive situation faced by other victims. *I have passed through this entire situation, but I do not want other people to suffer as I did. I will talk about what happened to me and I will advise victims not to accept the terror that I experienced myself. I will direct them toward the institutions in charge and let them know step by step what to do..*

Behavioral dimension (acting) is similar to the cognitive dimension and is based on multi-levels rising from lower to higher depending on the type of behavior displayed for this competence (orientation towards change). First level is *remembering*. The survivor recognizes a behavior that was taught through his/her interaction with other people. *Every time something bad happened in our house, my mother went to church.*

I remember that I often quarreled with my wife because of our child. He was spoiling everything I bought and was never satisfied. Once the police detained him and I was silent because he was my son. First time he hit his mother. He was replying back and insulted her. I did not take it into account. I've always said that he will appreciate us when we will not be alive.

The next level is *imitating /applying*. Imitation is an individual behavior similar to behavior of another person. We apply what we learned in interaction with others. The victim goes to church, just like her mother when facing the abuse.

The third level on behavioral dimension is *deciding/selecting.* The survivor is able to compare different acting behaviors, in the same way as for the cognitive dimension. He/she selects the behaviors that fit better with the situation encountered and decides to use them. The survivor will experience the first attempts to produce change.

I do not feel like a man in the house. I ended up being hit by my own child. I try in vain, nothing changes… Now I'm thinking of moving to one of my sisters that offered me a place to stay in her flat. I need nothing from what I had before excepting my pension money and to be left in peace..

The fourth level is *discovering/acting independently*. The survivor has a higher degree of autonomy compared to previous levels. He behaves in his own style, being adapted to the situations encountered.

My sister visited me few times, then I moved my things to her place and I told my son that I`d go. I will change property of the house to my son`s name and do everything that should be done as a parent.. I do not want to be ashamed.. A good parent is expected to leave something for his child and then do what he wants..

The highest level on behavioral dimension is *developing /building.* The survivor is able to continuously improve own behavior in order to adapt to complex situations.

As long as I can, I'll take care of everything I need, and when I am not able anymore, I will use the savings I made. I'll stay at asylum, if needed, but never come back where I left from.

SEISS model takes into account also the affective dimension, which has another five levels of competence. The lower level of the scale corresponds to the category named *is irrelevant*. We may include in this category affective states indicating the absence of emotional reactions, lack of enthusiasm or lack of interest to produce a change. The survivor feels safe only in own living environment. He/she is indifferent to produce any change. He/she does not empathize with people who are in similar situations and want to change their lifestyle. *I'm not going to change anything. I take life as it is. I'm overwhelmed, I do not want to bother with this thought anymore...*

The second level on affective dimension is named *taking attitude/reacting*. The survivor has certain emotional reactions that help him/her to adapt to a situation considering also the affective reactions of others. He/she expresses ambivalent feelings when it comes to change. Sometimes he/she is very determined to produce change, and then feels fear, indecision, anxiety and irritation. *When somebody tells me to produce a life change, I get angry, I struggle with myself and I cry a lot if I am overwhelmed...*

The third level introduces the concept of *empathic care*. In social psychology "empathic concern" is more than "empathy". Thus, if "empathy" means to feel what the other person feels, “empathic concern” creates "altruistic motivation" [1] to help the other when needed. The survivor expresses empathy and altruism toward people in similar situations of abuse that led to life change. He/she accepts experiences of other persons, without blaming them and provides support when they need it. *When I met this person and she told me that she wants to start it over again, I felt like we were living the same drama…*

The fourth level is *affective equilibrium* meaning capacity of affective self-adjusting. The survivor initiates, maintains and adjusts its internal emotional states and behaviors that express emotions in order to achieve own goals. *I wait for the most appropriate time. I have patience and do not let myself be overwhelmed by fear. I am optimistic that my life will change in better.*

The highest level of competence on affective dimension is named *affective harmonization with others*. The survivor is aware of own feelings and accepts also the feelings of others. He/she is able to influence others, in their way of thinking and feeling. The survivors become good examples for other victims that intend to change something in their life. *I saw how they were looking at me. I felt proud I could go to an end my abusive life. It is not easy to have this fate..*

1.3 Case studies

Case C.A. was evaluated as having the following cognitive levels for the competence *orientation towards change: knows-that, knows-how,* has *distant understanding* but has not *implicit understanding.* She agrees that family abuse is a repetitive problem and affects health. She accessed medical services to get out of depression. Family violence made her suffer and be isolated by friends and relatives. She started thinking of going to doctor rather than commit suicide. The doctor prescribed a medical treatment but advised her to access also social services for victims. The social worker helped her to identify personal resources in order to assume change and to contact other institutions in charge to provide additional support. If she does not reach the level of *implicit understanding*, could re-enter in the abusive cycle of violence.

There are also exceptional cases like F.A. The woman was able to reach the cognitive level of *implicit understanding,* but she was not assessed positively for the previous level of *distant understanding*. The woman had prior attempts to escape from violence, but she was not successful. The specialist noticed in the *registration case form* that F.A has the occupation of medical registrar. In this context, he understood the context that helped his client to get the optimal knowledge for reaching the level of *implicit understanding.* Even if she had sufficient knowledge about institutions and domestic violence phenomenon, could not act independently to produce change. In this case, the specialist should be more interested to help the client to assume and plan change for herself rather than focusing on discontinuity into her cognitive evolution.

Conclusions

Adult victims like women and elders have similar forms of abuse, in terms of vulnerabilities such as: less physical force, financial dependence, low self-esteem, isolation and fear of change. Emotional feelings are intense, both women and elders being strongly affected by the abuse. The need for social services becomes increasingly urgent. In order to have impact through the services provided, specialists should consider the educational outcomes of their work. They should support the client to pass from one level of competence to another, as exemplified for the competence *orientation towards change.* Client will assume change depending on a number of conditions like: his/her knowledge of abuse, types of families he/she knows, learned behaviors in own family, emotional reactions to abuse, relationship between the client and the specialist that provides services, educational approaches followed by the specialist, methods and tools used by the specialist to monitor and assess the impact of his work on the client health, solutions identified together with client for his/her safe. Intervention takes time, but results obtained need to be visualized at every step.

Resilient components in group geronto-psychotherapy. A case study.

Draghici R.

"Ana Aslan" National Institute of Gerontology and Geriatrics Bucharest (ROMANIA),
rozetadraghici@yahoo.com

Abstract

Resilience has been defined as a dynamic, ever-changing process. Four fundamental research directions have been described in the literature. The first three consider resilience only as a reaction to life traumas, whereas the fourth takes into account the patients' wish to enrich their life, to experience new things and to open themselves towards new relationships so that they feel they have used their full interrelation abilities and achieved all that they could. In this last interpretation, resilience can be defined as a mindset that urges the elderly to be more open, to live new experiences and to consider life as a continuous and uninterrupted progress: a life with a widened horizon and fulfilled human relations.

The main targets of the experiential therapy are the reinterpretation of negative events as valuable sources of expertise and the integration of the design of polarities, thus meeting the needs of the elderly with depressive-anxiety disorders. My study applied in geriatric clinic has demonstrated the effectiveness of a psychotherapeutic model that uses expressive-creative techniques, more specifically the effects it may have on restoring a more appropriate and adaptive behavior by the resizing and the revaluation of their own resources.

Keywords: resilience, the elderly, group psychotherapy, depression, anxiety

Introduction

Resilience is seldom associated with old age because older people experience the decline and the loss of normality. Resilience is a regenerative capacity that maintains a person functional and adapted in the face of losses, chronic illness or disability. Resilience thinking in the elderly gives them the ability to recover from difficulties, to thrive with a sustained purpose, to develop in a changing and cloudy world. Actually, older people have a higher level of subjective well-being than people in any other age group. [4]

As any other adults, resilient old people also use flexibility and adaptation to bounce back without any difficulty. They seem to be champions of giving up previously held physical and mental abilities and, in this respect, continually redefine themselves and adapt to what is their "new normality". Resilient qualities that improve as a result of the interventions include self-esteem, locus-control, purpose of life and interpersonal relations. Resilience may represent an important target for prevention and treatment in anxiety, depression, and abnormal stress reactions due to aging. [5]

Nowadays, therapeutic interventions are specifically designed to promote the wellbeing of older people, whereas the psychologist is there only to assist them strengthen their feeling of control over their own existence and the events that affect them, favoring their personal growth so that they accept themselves as they are, in harmony with others, but keeping them autonomously. [1] [4]

Different expressive and creative therapies may help elderly people to rediscover and express their Self. [6] Such psychotherapeutic methods may give them the possibility to live a new life and give them a sense of well-being. [8] Considering the relational disorders of the elderly, group therapy is often suggested, because it puts face to face the aging process and the reality, creating a miniature society, a micro-cosmos with a very operational role. [2]

Geriatric patients with depressive and anxious disorders are difficult to treat as their psychological problems are accompanied by physical and social troubles. The group therapy presents financial benefits, but it also offers patients support and understanding that allow elderly people to strengthen their coping mechanisms and resolve their conflicts. [2] [3] [7]

Methodology

1.1 Purpose, objectives and hypotheses

Purpose of research: to see whether creative and visual-plastic methods of experimental psychotherapy can yield a positive response in the treatment of geriatric patients diagnosed with depressive and anxious disorders involved in group therapy.

The practical-applied objectives were centered on the improvement of depressive-anxious symptoms, the decrease of personal and relational difficulties and on improving the global functioning and resilience of the patients.

*General hypothesis: that g*roup therapy, using experiential techniques with creative-visual support, is indeed efficient in depressive-anxious disorders of elderly people.

1.2 The formal setting of the group gerontotherapeutic intervention

The general criteria of selection were applied from the first contact with the patient and the observation sheet. The psycho-gerontological assessment consisted of interview, direct observation and psychometric testing. An important selection aspect was the patient's interest in and agreement for group therapy.

The two-month experiment took place during eight 150 minutes weekly therapeutic sessions. I used Gestalt and expressive-creative methods (collage, drawing, painting, metaphors) in four working groups composed by 30 patients aged between 65 and 79, suffering from depressive-anxious disorders, admitted at the N.I.G.G..

For baseline testing and retesting I used the Hamilton Depression Evaluation Scale (HDRS), the Hamilton Anxiety Evaluation Scale (HARS), the General Health Evaluation Scale (GHQ-12), and the Social Dysfunctions Subscale (SDS).

1.3 The therapeutic process

1.3.1 The structure of the therapeutic process:

a) the initial gerontopsychological evaluation of each subject;
b) identifying the symptoms and describing their effects (on the emotional, cognitive and behavioral levels);
c) establishing the hypothesis and the psychotherapeutic objectives;
d) establishing and implementing the therapeutic plan;
e) the final evaluation and catamnesis.

The purpose of the therapeutic process undergone is to increase the client's integrity (congruence between the internal experience and the external behavior): more freedom of choice, less dependence, a widened experience.

1.3.2 The experiential psychotherapeutic plan:

a) symbolic analysis of the symptom (decryption) with the noticeable symptom (evaluation according to the nature, duration, intensity, frequency, conditions in which it appears or reappears) and the masked symptom (mediated most of the times through drawing);
b) the analysis of the existential plane (context) followed on the temporal dimension from present to the past with identifying the disturbances occurred and the consequences in the social, couple and parent-child planes;
c) the analysis of the transgenerational plane with the key themes, the myths and secrets of the family unconscious can show what the symptom solves in the present existential plane.

Results and discussions

Comparing the test-retest scores averages of the t-test for paired samples it emerged that the difference is statistically significant between the two averages; during the initial testing, before the beginning of the therapeutic process and during retesting, at the end of the therapy.

The analysis of the tests' results showed that the therapy was more effective on the following parameters: depressive mood, self esteem and self blame, activity and interests, tension and irritability.

More general effects were: a better self clarification, a reduction of the anxiety and of the depressive symptoms. There was an increased interest in and enjoyment of different activities, and an increased ability to make decisions.

The subjects became more open to themselves and their inner world. The increase of self-esteem was in a reverse relation with self-blame. The subjects realized the way in which the attitude towards one's self affects the relations with the others.

Conclusions

The reduction of the self-evaluated and hetero-evaluated anxious-depressive symptoms showed the changes that occurred following the therapeutic process. The observations of the behavior are enough to allow a satisfactory level of significance of the therapeutic process.

We can notice four resilience components that can help those less-resilient elderly to achieve:

a. *The sense of belonging.* Old people desire to be a part of something, to feel they belong to a group of people with common interests and goals.

b. *Creating meaning through personal memories*. Elderly people who pursue personal growth as they age tend to be more resilient to changes. Creating meaning and purpose around the events of one's life is an effective way to promote growth and, for older people, this can be accomplished through the use of life reviews.

c. *Self-efficacy.* Through personal connections, older adults learn about their own potential, which increases their ability to handle their own problems, their flexibility and adaptability.

The meaningful relationships they have with friends and family help them adapt and their engagement in meaningful activities gives them a purpose and motivates them.

d. *Openness.* This refers to the ability to change and adapt – to be open to new ideas, values, and experiences. Helping the elderly to reframe loss and change as a means of redefining oneself may assist in generating more openness.

In conclusion, the experiential therapeutic group serves as a multiple mirror for each of the participants, but also as a support source and confirmation of their own therapeutic experience, of personal efforts and of discovered and practiced resources.

La resilience des femmes agees

Gal D. , Rușitoru M.

Abstract

We currently live in an aging society that is aging more. As part of this process, women are the most marked by a certain population growth (aging and feminist society).

The aging is experienced differently by women and by men. During aging, gender differences affect both the general health and life expectancy, the differences related to socio-economic status. Being elderly woman means, in most cases, to confront widowhood, divorce and loneliness on the one hand, and undergo physical deterioration, impotence, weakness and pain, on the other hand. As part of this presentation to try to identify and understand what are the internal and external resources (family, community, society) supplying the resilience of women in adulthood. At the same time, I have some questions and I want answers about the ways through which society is able or not to respond adequately to the adversities that older women face.

Keywords: aging, elderly woman, resilience, human development, assisted resilience

Les concepts “résilience” et “résilience assisté”

Si la résilience serait un processus à signification mineure, particulière et dépourvue d’ampleur théorique, la recherche scientifique lui aurait attribué tout simplement le statut de „terme”. Pourtant, la documentation sur son historicité et évolution indique la transcendance disciplinaire et la force éclaircissante/explicative, ce qui fait que „la résilience” a acquis, dans le temps, le statut de „concept”. En vérité, de l’utilisation initiale dans la physique des matériaux pour décrire la résistance et la capacité de certaines structures à faire face aux choques, le concept de „résilience” a été adopté par différents domaines, ayant des sens enrichissants, mais pas nécessairement très précis. Il en découle la difficulté qu’au-delà de la reconnaissance de l’importance du concept, il s’impose d’adopter une définition rigoureuse mais aussi exhaustive. L’adoption du concept dans la littérature, la jurisprudence, la médecine, l’économie, la politique et les sciences socio-humaines a constitué et constitue toujours l’élargissement de l’extension du concept (sphère de compréhension), mais aussi l’accentuation et l’enrichissement de son intension (sens et signification). Dans le plan de l’action, nous gardons à l’esprit une large variété de constructions autour du concept de résilience” : résilience phycologique, résilience biologique, résilience urbaine, résilience organisationnelle, résilience institutionnelle, résilience des affaires, résilience financière, résilience politique, résilience informationnelle, résilience sociale. Dans cette condition, nous pouvons affirmer le caractère transdisciplinaire, voire paradigmatique j’oserais dire, du concept en question: il s’applique à l’étude de la matière inanimée, mais aussi à l’être humain et, en tant que processus se retrouve sous différentes formes de manifestation dans des structures complexes, possédant des capacités adaptative et de développement, génériquement décrites comme étant biopsychosociales et spirituelles.

Les tentatives de définition d’ordre général retiennent pour noyau la caractéristique de processus adaptatif de la résilience, intrinsèquement relié aux systèmes, comme réponse aux situations d’adversité et/ou de trauma, la différence spécifique, par rapport aux autres réponses adaptatives étant donnée par le potentiel de développement et d’apprentissage, dans le registre de la normalité, entraîné par la résilience, qu’il s’agisse de systèmes individuels ou sociaux.

“La résilience assistée”[1] est le concept qui “va plus loin”: de la résilience naturelle, intrinsèque, comprise comme ressource individuelle, à la résilience anticipée, préparé et stimulée par la participation des professionnels qui accompagnent la personne potentiellement résilient, dans le contexte élargi de milieu familial, communautaire ou social, censé à être, à son tour, résilient.

Perspectives d’aborder le concept

La perspective démographique. À l’heure actuelle, la population de la planète traverse un processus accéléré de vieillissement. Il s’agit d’une notoriété reconnue, et en grande partie, assumée par la plupart des États du monde entier, par les organisations internationales telles que l’ONU, l’OMS, UE, etc. mais aussi par d’autres

instances (à base des études démographiques). L'accroissement du taux de la population âgée dans le total de la population présente des conséquences, considérées généralement comme étant alarmantes, notamment parce que jusqu'à présent la société humaine ne s'est jamais confrontée à un tel phénomène, et par conséquence, elle n'est pas prête à y faire face. À travers une sélection des données Eurostat, le processus de vieillissement démographique, sous l'aspect des différences de genre, peut être décrit comme suit:

"Dans les 50 dernières années, l'espérance de vie à la naissance a connu une augmentation, en moyenne, de 10 ans dans l'UE. En 2010, dans l'UE(27), en somme, l'espérance de vie à la naissance était en moyenne, de 82,9 pour les femmes et de 77,0 pour les homes.

La caractéristique la plus évidente est représentée par l'espérance de vie, considérablement moins élevée, chez les homes par rapport aux femmes.

Pour les hommes, l'espérance de vie à la naissance atteignait le sommet de 74,0 ans en 2011 dans la plupart des pays d'Europe de l'Est. Quant aux femmes, la valeur la plus élevée de l'espérance de vie à la naissance a été enregistrée dans la région placée en second rang quant à l'espérance de vie des hommes, à savoir Comunidad de Madrid (86,7 ans en 2011), talonnée de près par l'Île de France et Rhône-Alpes (les deux avec une moyenne de 86,6 ans).

En 2011, les différences les plus significatives entre ces valeurs ont été enregistrées dans les États baltiques, où les femmes peuvent vivre de 11,2 ans (Lituanie) şi 10,1 ans (Estonie) plus que les hommes." [2]

Si dans le langage ordinaire nous parlions d'un âge avancé après 60-65 ans, considéré comme le troisième âge, à présent se profile une nouvelle catégorie d'âge, celle du „quatrième âge", de plus de 80 ans, considérée comme „une deuxième évolution populationnelle majeure" [3], catégorie d'âge prépondérant représentée par les femmes.

La perspective du développement humain et du cycle de vie. Le viellissement individuel physiologique (non-pathologique) est considéré comme étant une étape normale de la vie. Même si le viellissement est une étape d'involution et diminution de toutes les capacités biopsychosociales, il est reconnu, d'autre part, la possibilité de mentionner un bon tonus fonctionnel, susceptible d'être conservé, voire amélioré jusqu'à la fin de la vie. Autrement dit, le développement humain est possible tout au long de la vie, y compris au troisième et quatrième âge. Si les différences individuelles jouent un rôle décisif dans le développement tout au long de la vie, on ne peut guère éloigner l'hypothèse que le milieu familial et la communauté peuvent favoriser un vieillissement bon ou réussi [4]. Même dans ces conditions portant sur cette ouverture optimiste, le vieillissement est aussi un processus accompagnant le développement tout au long de la vie et qui s'installe à un moment donné, comme étant signifiant: vivre avec moins de forces, avec une apparence physique changée, et, dans la plupart des cas, avec l'incapacité, la maladie, la solitude, les relations sociales et les revenus diminués. Pour cette raison, le viellissement comme processus et l'âge des aînés comme état peuvent être considérés adversités chroniques qui, en même temps, peuvent recevoir des accents traumatiques ou être perçus comme situations de perte dramatiques. Toutefois, nous savons que face à l'adversité, au trauma et à la perte, la réponse résiliente (individuelle, familiale ou du milieu social et culturel) peut signifier en même temps: sagesse, maturité morale (dignité, pardon, réconciliation), sélection des relations, milieu familial chaleureux et apportant du soutien, communautés et institutions offrant des services et empreignes par la sollicitude.

La perspective de la philosophie féministe et post-féministe. Dans son acception radicale et profonde, l'orientation féministe met en exergue des caractéristiques et expériences appartenant, à différents degrés, aux femmes: une première catégorie est celle des expériences exclusivement féminines : grossesse, allaitement, règles mensuelles, ménopause); des expériences prépondérant féminines (l'éducation des enfants et le soin des personnes âgées, le ménage au foyer – „management domestique", l'infériorité et la marginalisation dans les pratiques religieuses et civiles, le viol, la pornographie, la prostitution, l'harcèlement sexuel, le veuvage); d'autres expériences, généralement nommées expériences de l'oppression et de l'anonymisation, communes à toutes les catégories de marginaux: races, classes sociales, ethnies, sociétés [5]. Bien-entendu, en parallèle avec les catégories d'expériences féminines individualisées s'opèrent les différences socioculturelles: dans les sociétés avancées, démocratiques, les expériences féminines positives demeurent des sources du développement de soi, de la construction de l'identité et de l'intégrité personnelle, alors que dans les sociétés de type traditionnaliste empreignes par les conceptions ancillaires de la femme, les expériences négatives sont dominantes. Tout au long de la période de vieillissement, même les expériences positives féminines de l'affirmation de soi tendent à diminuer ou sont détériorées, perdues, converties en expériences négatives: la maternité devient l'expérience du nid vide, la biopsychologie féminine est marquée par le climatère, l'image et l'estime de soi modifiées peuvent devenir source de la détérioration voire de la perte de l'identité, l'autonomie perdue devient dépendance de types variés. Les statut social des femmes veuves est marqué par le divorce, le veuvage, les chances réduites de mariage/remariage. Autrement dit, à travers l'interaction des facteurs individuels de la femme, le processus de viellissement détermine un profile distinct du vieillissement féminin, ce qui signifie, une fois de plus, l'affirmation de l'hétérogénéité de la catégorie des „personnes âgées". Je trouve importante la réitération de la caractéristique de l'hétérogénéité par rapport à la catégorie „personnes âgées" et avec la sous-catégorie des

femmes âgées, parce que l'hétérogénéité, dans ce contexte, constitue la prémisse de l'attitude éthique qui, à son tour, est favorable à la société résiliente.

Les femmes âgées et la société résiliente

La féminisation du vieillissement (espérance de vie plus grande pour les femmes que pour les hommes, le taux plus élevé des femmes dans le total de la population des personnes âgées), le fait que les soins accordés aux aînés (femmes et hommes) appartiennent d'habitude majoritairement aux femmes, elles-mêmes âgées, le statut social et financier en règle générale moins élevé que celui des hommes, le problème de la solitude, mais aussi les situations d'adversité quotidienne engendrées par le viellissement, tous ces éléments justifient qu'il faut prêter une attention particulière à la population féminine vieillissante [6] [7]. L'attention prêtée par la société aux femmes âgées ne peut être séparée du contexte général de la responsabilité qu'elle doit assumer et manifester par rapport à d'autres catégories vieillissantes dans leur hétérogénéité. Évidemment, je ne propose pas la discrimination à base de genre, mais le respect pour les différences et leur valorisation, sans aucune transformation en hiérarchies. Assumer éthiquement la responsabilité sociale peut transformer une société indifférente, discriminatoire et marquée par l'adversité vis-à-vis des personnes âgées, en une société réceptive et résiliente.

La responsabilité sociale commence par l'adoption d'une attitude éthique (éthique gérontologique), c'est-à-dire une attitude subordonnée à la culture du détail et de l'anticipation (dans le cadre des politiques, de la législation, des services et des recherches destinées aux aînés), culture attribuant une place à l'historicité personnelle, au contexte du développement et de l'existence individuelle, à la diversité et au respect pour la dignité humaine. Une société éthique possède tous les atouts à devenir une bonne société pour un bon vieillissement.

Conclusions

L'analyse conceptuelle, méthode déductive et approche interdisciplinaire nous ont permis de saisir la relation entre le vieillissement démographique (différences spécifiques entre les sexes), d'une part, et de la résilience féminine aussi que de la société de l'autre part. Nous avons vu que la longévité et l'espérance de vie, plus élevé pour la population feminine, coexiste avec les expériences de résilience des femmes tout au long de la vie, y compris, à la vieillesse. De l'analyse que nous avons fait on ne peut pas déduire des relations de causalité entre la longévité des femmes et la résilience des femmes, dans le sens d'explications déterministes, mais on laisse cette question ouverte pour des nouvelles recherché, peut-être de facture empirique. Nous ne pouvons pas dire que le vieillissement de succès des femmes est causé et s' explique par la prédisposition native et/ou par l'attitude appris et développé au cours de la vie, mais nous pouvons commencer à supposer qu'une société éthique et résiliente peut être une réponse en mesure de soutenir le vieillissement réussi pour les femmes et pour les homes aussi .

Resilience in successful aging

Abstract

Aging successfully represents a goal for many older people but at the same time, they also experience various types of loss as they age, which at most times results in increasing stress. Besides functional decline, many of them have to face pain, weakness, sleep problems, depression, anxiety, cognitive deficits, physical illnesses and personal or financial loss.

One quality that can be fostered or strengthened, in order to help seniors to cope with adversity in aging and achieve greater happiness, is resilience. Although there is no consensus about what resilience is and how to define it, it is commonly understood as the ability of people to resist and effectively overcome adversity. In late life, resilience can be defined as the maintenance of physical and psychological health in the face of risks or threats.

There is a paradox of old age concerning the concept of resilience in late life. This means that in spite of losses, cognitive and physical declines experienced in later life, older adults report wellbeing and content with life. Resilience allows seniors to accept the process of aging, while dealing with problems and crises.

The aim of this paper is to identify the key elements of resilience in elder people and the ways they are making meanings confronting events specific to this age. Understanding this phenomenon can lead to new health promotion strategies which should be incorporated in programs aimed to facilitate the process of successful aging.

Keywords: Successful aging, resilience, health promotion.

Introduction

In the latest decades the field of gerontology has gained a better understanding and developed

more interdisciplinary depth, allowing researchers to make progress in investigating and understanding concepts and theories of aging, making sense of what the experience of getting old means and how all this can be shaped as a process [1].

Research exploring positive views of old age and the aging process has drawn the concept of resilience into this field. Although progress has been made until now, there is no common understanding of what might be different about late life resilience and how the concept should be employed in fields like gerontology. Is resilience in later life an internal quality or a process? Can it be defined as a single trait or as a part of a larger equation of personal characteristics? Does it stay constant over time?

Resilience can be seen as the ability to incorporate both vulnerabilities and strength over a great range of time frames and areas. In this paper we argue that being resilient in old age helps one cope with various types of loss, such as: functional decline, chronic illness, mental problems, financial loss.

Concept Delimitation

Although the concept of successful aging has become better understood and developed more over the last decade, it is not yet fully known how individuals get there. It seems that a number of individual characteristics and personality traits contribute to how one adapts with success to challenges. Apart from the individual's characteristics and personality traits, there seems to be another factor that can contribute to the process of successful aging. This factor is represented by the resources that one has in order to meet the demands of every new challenge. When these resources are available and sufficient in order to meet these demands, we can talk about resilience.

The concept of resilience has evolved over time, from the initial studies that were limited to childhood to being applied across lifespan, framed as a resource to all people at all stages of life [2].

1.1 Successful Aging

Successful aging is defined as an adaptation process to multifaceted challenges that maximize an individual's capacity to reach his or her own goals [3]. This adaptation process occurs over the lifespan and can be described as active aging, defined by the World Health Organization as „the process of optimizing opportunities for health, participation and security in order to enhance quality of life as people age" [4]. Taking this into consideration, we name successful aging, when the results of adaptation enable individuals to ideally reach his or her goals.

The concept of successful aging appeared in the early 1990s as a reaction to the loss-focused geriatric and gerontological research that preceded the concept. In the first article that mentioned this concept, the authors stated that cognitive and physiological losses documented in the literature so far as age-related changes were mischaracterizations of the natural aging process. Rowe and Kahn, 1987 [5] described normal aging as a continuum that extended from usual aging to successful aging. This continuum represents the variability that appears in performance differences between younger and older people without pathological conditions. One can argue that a group of older adults may not perform as well as a group of younger adults, but that does not mean that the older group cannot perform at all. Within the older adult group there might be individuals that can perform similar or even better than individuals from the younger group. In the model presented by Rowe and Kahn in 1987 [5], this particular aspect was considered evidence of successful aging.

There are many other models that describe the process of successful aging as including the following themes: successful aging happens across lifespan; it can incorporate many domains, including health, social relations, and psychological state; it occurs in response to challenges and is defined for each individual to the degree that individual's goals and preferences differ [6], [7], [8].

However, the general description of this model of successful aging as it is represented in the literature appears to match older adults' perception regarding it. Elders define this process as an ongoing multidimensional aspect that is different from chronological age [9].

A few characteristics of the successful aging process as described by older people are: having a positive attitude, coping with change, accepting limitations that cannot be overcome, practicing spiritual beliefs and staying engaged both socially and cognitively. Other important aspects reported as valuable by older adults are: maintaining basic physical functioning, being free of major life-threating disease, engaging in social and recreational activities and feeling independent [10].

1.2 Resilience

Some people manage to face different problems and recover fully even after suffering traumatic conditions of extreme deprivation, serious threat and major stress. This unique ability manifested by them has been named resilience.

The concept of resilience has been derived both from social and health sciences [11]. Due to its ambiguities in what concerns definitions and terminology, the term resilience, used now widely has very often been criticized [12]. It is not yet clearly defined and understood because it involves many factors and has developed in diverse disciplines including psychology, education, social work, medicine and others.

One definition of this concept was made by Rutter, 2007 [13] who defined it as it follows: the discovering that some individuals have a good psychological state despite suffering risk experiences. This means that not necessary individual's immunity to trauma matters in the case of resilience, but their ability to recover after adverse experiences.

In response to this definition other authors [14] stated that the important fact is not just the resistance to adverse experiences but also the ability to grow and develop oneself in difficult conditions. Earvolino-Ramirez, 2008 [15] also agrees with this conceptual framework, describing resilience as a bouncing back activity, rebounding after loss and reintegration in the society. The author argues that what is unique about resilience in relation to other similar concepts is that we can associate it with positive growth while exceeding a specific problem.

A series of characteristics related to resilience are described by Harvey, 1996 [16]. These characteristics indicate one's resilient capacity: control over the process of remembering traumatic experiences, integration of memory and emotion, regulation of emotion related to trauma, control of symptoms, self-esteem, internal cohesion (thoughts, emotions and actions), establishment of secure links, understanding the impact of the trauma and developing a positive meaning.

More recent, a three-dimensional construct for understanding resilience was proposed by Knight, 2007 [17]. This model underlines resilience as a state, a condition and a form of practice. As a state, resilience incorporates emotional and social competence and orientation towards the future. As a condition it states what can be done about it and as a practice is important to identify how individuals can develop and use resilience.

Another important aspect when discussing resilience at a conceptual level is to distinguish the mechanisms of being resilient: the one against aversive or stressful events themselves, the one against adverse

outcome in terms of transformation of adaptive response and health-promotion processes to maladaptive ones and, the one against development of a disorder in the face of aversive events [18].

Resilience and successful aging

Resilience may vary according to age, with modifications happening over life-time at both individual and cultural level. As we noted earlier, although the initial studies of resilience were limited to childhood, there is now a great concern in the research field regarding resilience and old age and more specific, how can resilience contribute to the process of successful aging.

Studies have shown that there are factors related to resilience and old age. In order to describe these factors, Hardy, 2002, [19] proposed the concept of resilience repertoire. This repertoire is represented by a supply of skills and resources that can be used to face the aversive experiences that elders cross in their lifetime in order to reduce or attenuate the negative consequences of those events. In some cases, this resilience repertoire can even lead to a positive growth and development. There can be a variety of factors and elements in the repertoire of an old person and he/she can use them in different ways and at different times in order to get through aversive experiences.

Concerning the relation between successful aging and resilience we need to focus on several aspects of health that are relevant to this topic. The first one is health status; studies have shown that the way health is defined and viewed by the individual is more important rather than the actual level of health status or absence of the health problems [20]. The second one is represented by health promotion and its relationship with reducing risk and increasing resilience in older adults [21]. The third relevant aspect is represented by physical activity and its benefits for older adults. Research on this theme states that physical activity levels are associated with great benefits for older adults, as cognitive resilience, faster reaction time, improved psychological well-being and reduced risk of cognitive decline and dementia [22]. Other research suggests that reduced levels of perceived stress and a lower risk of depression and anxiety were reported as benefits of physical activity in a study of older individuals [23]. Nutrition represents the forth aspect relevant to health in this topic because a balanced diet and activity patterns are associated with a reduction of mortality and cognitive decline among the elderly [24]. The last factor is represented by medication compliance. Many elders have to deal with chronic diseases and adherence to a complex medication regime which is very important in order to recover or stabilize from disease symptoms and gain a state of well-being [25].

Some other important aspects relevant to the link between successful aging and resilience are represented by social support, activities and finances. Studies show that social support received before and during adverse experiences was an important factor in resilient individuals [26]. Elders with high resilient outcomes reported twice as much involvement in leisure or household activities than the ones with low resilient outcome [27]. Higher levels of self-reported successful aging were associated with a higher level of daily activity [28]. Concerning finances, studies [29] show that low income might not be as threatening and high income may not be as protective as other aspects, as social support.

In relation to old age and successful aging there seems to be one more key dimension. Meaning in life has been identified as being important in several studies. In 2008, Heisel and Flett [30] not only found that meaning in life is a factor related to resilience, but also, it explained a significant variation in suicide ideation over and above physical and mental health problems. In another study, having meaning and meaningful relationships was identified as a central theme in an exploratory study of resilience among older adults who have been experiencing mental illness [31].

Interventions which promote health and well-being across the older adults' population should be widely implemented and recommended. These programs might lead to an enhanced quality of life among elders. As a consequence of a continuous growing emphasis in the literature on stress and coping in what concerns resilience and older adults, interventions to promote it in this population were proposed. There is a need of understanding the key elements of resilience in older people in order for practitioners to develop and implement efficient types of interventions. There are some programs which promote resilience through creative engagement, because it is argued that this component is an integral part of successful aging [32].

Everyday interventions and interventions in response to specific challenges represent other ways in which practitioners might promote successful aging through resilience. The first type targets to improve the overall health status and to reduce perceive stress in order to increase the elders' readiness for adapting to psychological challenges. The second one refers to specific timely programs aimed for the moment when challenges do occur.

Conclusion

Resilience is very important to aging and the aging process, because adversity is inevitable throughout lifetime and as we age. Although there are individuals that do not necessary need to face chronic illnesses or

other health events, even for them there will be physical and psychosocial challenges common to elderlies such as role loss, loss of a friend or a family member.

Even though defining the concept of resilience and its connection to successful aging is quite challenging, it still remains a unique ability that represents a positive response to life stressors. When the result produced by one's resilience are conclusive for a better functioning in any domain that he or she values as important, we can say that resilience can lead to successful aging. There are a number of individual characteristics that make an older person resilient. Physical, psychological, social, and environmental characteristics can either facilitate or impede resilient responses. All these characteristics should be targeted when designing health care interventions that aim to foster optimal functioning.

Loss of life whilst still alive: improving resilience and attachment with older people and people with dementia through the application of 'Neuro-Dramatic Play'

Sue J.

Leeds Metropolitan University United Kingdom, Taiwan University of the Arts
drsuejennings@hotmail.com

Abstract

Much is known about attachment and resilience with children and teenagers. However the loss of attachments and decrease in resilience in later life has less research and implementation of policies and funding. Dementia is on the increase and many care homes and carers implement a system of benign dependency, with medication for 'difficult' individuals, rather than paying attention to the personal and social fabric in the individual's history and current difficulties. This presentation illustrates how a programme of Neuro - Dramatic - Play with people with dementia can improve well being, slow down deterioration, improve social relationships and influence independence. The presentation will be illustrated with Power Point slides.

Introduction:

Ever since the pioneering work of Bowlby (1965), who was ostracized by the psycho-analytic movement, greater attention is being paid to the effect on children of early disrupted or disorganized attachment relationships.

Following 'hard upon' was the emergence of a greater understanding of resilience with the outstanding contributions from one of our key speakers, Boris Cyrulnik (2005, 2009), whom I honour and appreciate with this presentation.

These powerful influences from attachment and resilience led me to re-consider early infant development in relation to the importance of 'playfulness'. As I asked a colleague, 'What is the 'ness' in being playful?'. Can we also suggest there is a concept of playfulless? There is now limitless literature on play, play therapy, attachment but the writing is still not joined up. Then came the first research project.

An intensive programme was planned for 9 children aged between 8 and 11 who have been excluded from school, or who have severe behavioral and emotional difficulties. Volunteers meant that each child had a significant adult within the group as a whole. The six days were divided in to 2 days of physical and rhythmic activities (embodiment), 2 days of painting and modelling, (projection) and 2 days of drama and stories, (role), based on the EPR developmental paradigm (embodiment-projection-role), [5], [6], [7], [8], [9]. Also, through the pairing with an adult, each child was able to explore risky actions, such as standing on each other's backs or shoulders, within the safe containment, of being 'held', rocked or cradled, or working in a circle with a large parachute that connected everyone together.

The sessions did not progress as planned as any attempt to introduce any drama work or masks was immediately rejected and the children became very disruptive. They did not want to engage in any role activities. However a return to the physical and sensory sessions immediately calmed everyone down.

There was one role that all the children coveted, that was preparing and serving food and dressing up in a chef's hat and apron. I reflected and then shared with staff what could be happening.

It was very significant that the children *in particular* wanted to stay with the rhythm and drumming work

1. They requested repeats of the face and hand massage
2. They enjoyed taking physical risks when supported by their adult partner
3. They enjoyed 'messy play' with finger paints and clay.
4. They wanted to be a part of the food preparation, serving and also sharing. They enjoyed sitting with the adults and talking

I suggest that sensory and rhythmic play belong to the very early stages of child development, and that 'playing at chef' is dramatic play rather than sustained role play or drama. Being involved with food is also one way of satisfying emotional hunger.

Having closely observed the children's behaviour for the remainder of the programme, they thrived on the physical, sensory and rhythmic play, with some dramatic play. I suggest that these children were all functioning at an emotional age of 18 months - 2 years. It made complete sense that they *could* not play roles, (not that they *would* not).

This led to detailed observation of the earliest stages of development, before and immediately after birth, in relation to 'embodiment' – the first stage of the EPR paradigm. This evolved into a more detailed analysis of mother-infant playfulness and culminated in a second paradigm 'Neuro-Dramatic-Play', which takes place 6 months before birth and six months after birth. Now that more is understood through neuroscience in relation to attachment, playfulness and the function of the mirror neurons [2], [11], one can see the importance of the attachment process from conception rather than developing by the end of the first year. Neuro-Dramatic-Play is composed of: sensory play, rhythmic play and dramatic play, and is navigated through the 'dramatic response' (DR) or 'as if' stage which occurs within a few hours of birth. The DR is the imitation by the new born infant of the expression on the mother's face. The infant is engaged in an act of drama, usually before he or she experiments with sounds.

Understanding Neuro-Dramatic-Play at the start of life led me into consideration of its relevance towards the end of life. As an anthropologist I had saturated myself in the life of the Temiar tribe in the Malaysian rain-forest. Although I was looking at the role of the arts and culture in child-rearing, that led to non-competitive adults, [6], I was looking at the context of the life-span. The stage of 'wisdom' rather than the stage of 'fertility' is marked by change of name, relaxation of food restrictions, and senior roles in the community. The Temiars traditionally show great respect towards children and older people. Older people are seen as a source of wisdom and experience. Their comment to me about young teachers was 'How can they teach others? They have not lived long enough themselves!'

The prevalent attitude towards older people in the west is one of indulgent care, with the expectations that they wish to sit still, listen to music, and have decisions made on their behalf. We rarely consult older people, (apart from the judiciary and House of Lords), and older people have few opportunities to make their own choices.

In NDP terms, older people are almost working in reverse of the developmental processes of small children: there are fewer opportunities for sensory stimulus and creativity, a weakening of thought processes, loss of attachments and relationships, (home, pets, interests); there are also fears of dependency, falling, loneliness, intruders, isolation, forgetting; deterioration of hearing, sight and memory.

'The Tempest in my mind doth from my senses take all feeling else' (Shakespeare: *King Lear*)

Medication is seen as the first treatment rather than the last. If people are confused they are deemed to be not capable, whereas the use of the arts and storytelling, especially in dementia care have shown that memories can be retrieved and lucidity can improve. The application of NDP in ageing can help the loss and grieving process, encourage new attachments, enhance sensory integration, and promote existing skills and experience. But most importantly, if resilience is strengthened, then everything else will follow. Resilience is often mistaken for being 'difficult' or 'challenging'; older people who are feisty or contrary or original can suffer sarcasm or be ignored.

I include 'Theatre of Resilience' as a culmination of a synthesis of NDP and EPR, where theatre is perceived as a social and collaborative activity around a script, story, ritual or traditional or cultural celebration. It involves movement and music, image making, rhythm and drumming, dramatization of stories.

Scene 1: A multi-cultural production (with Israeli Arabs, Jews and Brits) of Lysistrata toured small theatre in Israel including a performance in a day-centre for people with dementia. The staff were worried that people would not 'behave' and might disrupt the play, and we reassured them that whatever happened was fine. There was an extraordinary piece of interactive theatre when a woman in the front row started to call out at Lysistrata, especially when she was confronting the Magistrate; the woman egged her on, 'Go on Lysistrata, you just tell him – go on, you tell him'!

When the play finished she said 'I want to talk to that Magistrate!' We set up the scene and all the outpourings of her anger were directed to this very authoritarian actor, as she attacked him with her handbag, but in role as Lysistrata and he stayed in role as the Magistrate.

The next day I had a 'phone call from the manager of the day-centre. She said that there were two things that she thought I would like to know. Everyone had arrived at the day-centre, and for the very first time, everyone had remembered what they did the day before. As we know it is usually the short term memory that is affected first in dementia. Then because of the sexual nature of the play, it enabled people to talk about sex. She went on to say that many of the carers were young and found any reference to sex by older people difficult to handle. However because the subject had been 'distanced' in the play, and there was a lot of humour around sexual politics, and bawdy innuendo, it had enabled a transition from their own lives, loves and struggles.

Scene 2: In a residential care home with a large number of people with dementia we have put in place a weekly dramatherapist who works in the dementia unit using themed material, creative movement and stories. From time to time there is an intensive input to further extend her work. This session was bringing a holiday to the group since they were unable to go away on holiday. We planned a trip to the sea-side and set off by train, singing traditional songs; we played with sand and shells, created billowing waves with big pieces of blue fabric. There was a Punch and Judy show, a Magician and a fancy hat competition, enjoyed by 20 staff and the same number of residents. Then we caught the train home and then enjoyed potato chips in screws of paper, and some ice-cream. The residents participated fully and remembered other holidays and activities.

Reflections:

Intensive play and arts activities, as well as regular inputs to reinforce learning, contribute to an innovative approach for Creative Care of older people, especially those with dementia. Brains need stimulation or they will atrophy, absence of a familiar landscape often leads to depression.

However it is often politically expedient to keep older people in a state of dependency, to blunt their senses through medication and to treat them as children who need to be indulged. Providing they are kept clean and fed what else is required? In some institutions even cleanliness and food are not achieved. Scandals in care homes are widespread and increasing.

Perhaps we need to consider attitudes towards old age, before implementing new forms of activity and therapy. We need to decide whether older people can be respected for their age and wisdom, rather than deciding they are not productive and there are at the bottom of the heap for resources.

A Story for Resilience - Pele the Fire Child

Many years ago in a village somewhere near Hawaii, there is a young girl called Pele who loves lighting fires. She loves the smell of the wood smoke, and the sound of the crackling twigs, and her eyes light up at the glowing embers and she can see all sorts of pictures and stories in the dancing flames. Soon the other children join her and together they roast vegetables and dance round the fire singing songs.

The other parents come and visit Pele's mother to complain at the bad influence Pele is having on their children. And Pele's mother has to say to her daughter, 'Pele, you are making our life very difficult here; people are complaining so you have to stop lighting fires'. Pele finds this very difficult but she really does try and it lasts for some days. But then the feeling is so strong that she goes off to find another place where perhaps they could light fires. She goes for a long walk and reaches a huge field, far away from the village. 'Ideal for us' she thinks, and she runs back to the village to tell the other children.

They plan a picnic and go off for the day; drag logs and branches to make a fire and cook their meal. They told stories and sang songs and soon it is time to pack up. Just as they were putting out the fire, a man appears waving his arms and shouting. It is the farmer who owns the field and they all run as fast as they can back home. The farmer follows and starts knocking on the doors of the houses asking for the children who lit the fire in his field. The adults tell him to go to Pele's house, which he does, and he speaks very angrily to her mother.

Her mother talks to her again and says that this time is her last chance otherwise she will have to leave home. Pele is really sorry and tries very hard not do other things instead. But she still longs for her magical fires and keeps wondering whether there is another place. She and just some of the children decide to go off for the day, (the others were too scared of perhaps meeting another angry farmer). They walk for a very long way and find a place the other side of the forest on a piece of rough ground that does not appear to belong to anybody. They light their fire and sing and dance, but most especially they tell stories. They cook vegetables which especially sweet that day, little did they know that this might be the last time they had this adventure. Or maybe they did know and were determined to make it the best they had done.

They go home happily and are not aware that the smoke is drifting upwards across the top of the forest towards the village. People open their windows and sniff: hm - wood smoke – Pele. Her mother is waiting for her and tells her that she has had her last chance and that she must leave. Pele packs a bundle, ties it to a stick, puts it on her shoulder and walks away.

She looks after herself, cooking her food as she goes and soon she comes to the seashore. She lights a fire from driftwood and sits gazing out to sea, wondering what she will do next. A water sprite called Nimusha comes to speak with her and says that she does not like Pele lighting fires and that anyway she is stronger than she is. Pele challenges her to a trial of strength, knowing that she will win but since when has fire survived the strength of water! Nimusha creates a tidal wave that come towards the shore, Pele immediately turn it into a twenty-foot high jet of steam and laughs in triumph.

She discovers it is rather nice making explosions under the sea and she causes all sorts of islands to form and some of them are volcanic. Soon she decides that she has created enough explosions and that it is time

to make her own island. She creates the biggest explosion she has ever done and makes the volcano her home. She rides her chariot across the flames laughing as she goes and the young men of the village create games of prowess on the rim. The older people of the village decide to protect themselves and they make offerings of white sweet smelling hibiscus flowers and throw them into the crater.

Meanwhile Pele is becoming calmer and is less angry and spends more time curled up asleep at the edge of the volcano having wonderful fiery dreams.

And now, if you are visiting there, you may see a little old woman with gray hair and a tattered red shawl. And she may just come to you and ask you for matches and a candle. Pele still keeps her fire and if pressed, may even tell you a story or two. And her eyes will still light up at the memories of her fiery life.

Abstract

Teenagers go through a stage of life in which they live affectivity and sexuality with great intensity of a point of view as well as relational identity. Ways to design, understand and see the emotional and sexual relationships are determined by various factors such as culture, social context and home environment, among others. The promotion of emotional and sexual health (SAS) includes the development of a positive vision of affective relationships in which sexuality translates into satisfying experiences, safe, free of coercion, discrimination and violence. Following the model of determinants of health Dahlgren and Whitehead [1], we can observe that there is some risk factors and protective influence of direct and indirect health of people, as well as sexual emotional health of young people.

Traditionally, the study of sexuality has been specifically focused on risk factors, placing the intervention since the risk (risk approach).

In this communication the results found in qualitative research was carried out by order of the Department of Health of the Generalitat of Catalonia are presented. The technique of data collection was used in the focus groups. Participation in the research was 72 teenagers total. Specifically, we present the perception of adolescents in relation to their own emotional and sexual health and that of their peers, from the resilience perspective. It focuses attention on the factors that contribute to living sexuality in a responsible way.

In conclusion, it should be noted that among the younger population wchich is in a situation of vulnerability, the emotional, affective and social variables are crucial in sexual risk behaviors.

Keywords: emotional and sexual health; adolescents; resilience; vulnerability; social risk; affective and sexual education

Introduction

La santé affective et sexuelle (SAS) est un droit de l'adolescent, et la promotion d'une sexualité responsable est un devoir des institutions publiques. L'adolescence est une étape de la vie où l'affectivité et la sexualité est vécue avec une grande intensité.

L'identité sexuelle est formée avec le passage du temps et permet à la personne de formuler un concept de lui-même sur la base du sexe, le genre et l'orientation sexuelle, et développer socialement en fonction de la perception d'avoir leurs capacités sexuelles

C'est dans cette étape que l'orientation sexuelle est définie et requiert le respect de l'autre pour que l'adolescent développe un concept positif de soi-même et se manifeste avec sécurité et liberté. La situation de vulnérabilité ou de risque social chez les adolescents peut être accompagnée des déficits affectifs importants, par la situation familiale, par la différence culturelle ou par le contexte social. La santé affective et sexuelle implique une vision positive vers les relations affectives et, donc, des expériences satisfaisantes, rapports sexuels protégés, libre de toute coercition, discrimination et violence.

La promotion de la santé affective, sexuelle et reproductive inclut l'intégration de quelques facteurs de base définis par la World Association for Sexual Health [2]: reconnaître, promouvoir, garantir et protéger les droits sexuels de tous et les situer dans le contexte des droits humains ; avancer vers l'égalité et l'équité de genre; condamner, combattre et réduire toutes les formes de violence sexuelles; promouvoir l'accès universel a l'information complète et l'éducation intégrale de la sexualité; assurer que les programmes de santé reproductive reconnaissent le rôle central de la santé sexuelle; arrêter la diffusion de l'infection du HIV et d'autres STI; identifier, aborder et s'occuper des préoccupations, des dysfonctions et des problèmes sexuels ; aboutir à la reconnaissance du plaisir sexuel comme l'une des composantes essentielles de la santé et du bien-être global.

Cette perspective multidimensionnelle et écologique de la SAS intègre les aspects émotifs, affectifs et sociaux, particulièrement importants chez les adolescents puisqu'ils sont en plein processus de construction de sa

propre identité sexuelle, d'établissement de relations sociales et affectives, de construction du concept qu'ils ont d'eux-mêmes et de leur autoestime.

En suivant cette ligne, l'OPS [3] remarque que l'affectivité, les émotions et le fait de tomber amoureux sont des éléments particulièrement importants à aborder pendant l'adolescence, à cause de l'intensité avec laquelle les adolescents vivent ces expériences. Le but final serait de promouvoir une sexualité responsable chez les jeunes. Dans les collectivités de jeunes en situation de vulnérabilité ou de risque social, cette nécessité est encore plus latente car dans ces collectivités l'existence de déficits affectifs importants est plus probable à cause de la situation familiale dans laquelle les jeunes peuvent se trouver à vivre et aussi de la différence culturelle ou de contexte social [4] .

En ce qui concerne la dimension sociale, l'UNICEF [5] remarque l'importance de la dimension sociale de la sexualité, spécialement chez la population en situation de vulnérabilité, car une grossesse d'adolescente non planifiée peut produire des effets sur les conditions de vie (l'éducation, le projet d'avenir, des conditions convenables de logement, etc.). Lorsque les jeunes ont une perspective d'avenir positive, une grossesse qui n'était pas prévue peut avoir des conséquences négatives sur leur bien-être et sur leur avenir en retardant ou en arrêtant leur projet d'avenir.

Selon le modèle des déterminants de la santé de Dahlgren et Whitehead [1], on peut remarquer que différents facteurs influencent de manière directe et indirecte la santé et aussi la SAS des jeunes. Quelques uns de ces facteurs peuvent avoir un lien avec : les *conditions politiques, socioéconomiques, culturelles et environnementales*, comme par exemple le lien avec l'école et les perspectives de travail [6] ; les conditions matérielles et les ressources limitées et les faibles perspectives et aspirations pour l'avenir [7] ; *la communauté*, comme par exemple, vivre dans des quartiers pauvres avec des taux de chômage et/ou de criminalité élevés [8]; *la culture d'origine et la religion* [9] [10] *; les facteurs en relation avec les réseaux sociaux et communautaires*, comme par exemple la structure familiale et l'éducation familiale [11], la pression du partenaire et des amis [12]; l'absentéisme écolier [6] ; *les facteurs en relation avec les traits personnels et les styles de vie* [12], comme par exemple des croyances concernant la sexualité et la consommation de substances psychoactives ; etc.

Afin de promouvoir la SAS dans une perspective écologique et de favoriser des relations affectives et sexuelles mûres, responsables et sûres il faut renforcer les facteurs de protection qui peuvent favoriser une perception positive et responsable de la sexualité et, par conséquent, prévenir des conduites à risque spécialement dans les collectivités en situation de vulnérabilité ou de risque social.

Nous allons présenter les résultats liés aux perceptions qu'ont les jeunes en situation de risque social de leur propre santé affective et sexuelle et de celle de leurs pairs.

Méthodologie

L'étude présentée ici est une recherche participée, à caractère qualitatif, de mode cooperatif.

2.1. Participants

Ont participé à la recherche 72 jeunes, dont 65% de filles et 37,5% de garçons. 18,1% d'entre eux avaient un âge compris entre 12 et 14 ans, 40,3% avaient de 15 à 17 ans et 41,7% de 18 à 20 ans, de 15 origines différentes. L'origine la plus représentée est la marocaine dans 34,7% des cas, suivie de l'espagnole dans 20% et de l'équatorienne dans 12,5%. Le groupe de jeunes présente des caractéristiques communes, parce que beaucoup de jeunes des quartiers défavorisés sont issus de l'immigration.

2.2. Instruments

L'information a été rassemblée par le biais de groupes de discussion, selon les âges (da 12 à 14 ans ; de 15 à 17 ans ; de 18 à 20 ans) ; ensuite on a élaboré les questionnaires correspondants, la fiche d'identification du profil de base des participants ; la fiche résumant les principales contributions du groupe, le processus de dynamisation et le climat créé.

2.3 Procédé

On a créé 10 groupes de discussion (5 groupes composés de jeunes immigrants, 3 de quartiers défavorisés et 2 de jeunes sous tutelle).

Les groupes de discussion ont été conduits par deux chercheurs selon les questionnaires élaborés. Les contributions de chaque groupe ont été enregistrées en version audio avec le consentement des participants et avec l'accord de confidentialité.

2.4 Analyse des données

L'information des groupes de discussion a été enregistrée en version audio et a été transcrite de manière littérale par la suite. À partir des données trouvées on a effectué l'analyse du contenu, avec le support du logiciel Atlas ti v.5.0. Les codes d'analyses élaborées ont été validés par des juges.

Résultats

Nous allons présenter les résultats relatifs aux perceptions qu'ont certains adolescents de leur propre santé affective et sexuelle et de celle de leurs pairs, en focalisant l'attention sur les conduites à risque.

En analysant les données on trouve des différences par sexe dans quelques conduites à risque. Dans le cas des filles, ces conduites à risque sont associées à des relations sexuelles impulsives, des relations après avoir consommé de l'alcool (cela démontre une perte de contrôle sur ses propres décisions et une vulnérabilité majeure) et à l'induction d'avortements.

<<Il y a une pilule pour avorter qui est vendue dans la rue ; elle est illégale>> P1, filles de 12 à 14 ans, groupe CRAE.

Dans le cas des garçons, on trouve des commentaires sur les conduites observées chez d'autres jeunes en relation avec la non-utilisation du préservatif, des croyances autour de la sexualité et des infections à transmission sexuelle.

<<Parfois ils n'ont pas de capote… S'ils n'en ont pas, ils utilisent la méthode du retrait. Nous connaissons beaucoup de filles qui n'utilisent pas de préservatif. Elles pratiquent le retrait.>> P10, filles de 15 à 17 ans, groupe des quartiers défavorisés.

<<Les gens disent que quand tu es soûle c'est mieux parce que tu es plus décontractée, bon je crois que quand quelqu'un est soûl il sait quand même ce qu'il fait...>> P11, filles de 15 à 17 ans, groupe des quartiers défavorisés.

<<Beaucoup de jeunes n'utilisent pas de préservatif. Il y a beaucoup de garçons qui ont le SIDA et n'utilisent pas de préservatif, j'en connais...>> P2, garçons de 18 à 20 ans, groupe d'immigrants.

Le groupe cible de jeunes entre 12 et 17 ans, et sans différence de genre, remarque que les jeunes connaissent les risques associés aux relations sans protection (principalement, grossesses et infections à transmission sexuelle).

<<La pilule me servirait pour ne pas tomber enceinte et la capote pour les maladies et pour me protéger, ça dépend avec qui tu le fais>> P1. Filles de 12 a 14 ans, groupe CRAE.

<<Type de capotes, comment les utiliser et comment ne pas mettre enceinte sa copine>> P7, garçons de 15 à 17 ans, groupe des quartiers défavorisés.

Même s'ils disposent d'informations et de connaissances sur les méthodes anticonceptionnelles, ils reconnaissent qu'il y a une partie des jeunes qui ne les utilisent pas, et donc ils n'utilisent pas de préservatif. Les raisons qu'ils indiquent sont multiples.

- La perte de sensibilité avec le préservatif, le confort et les allergies, c'est l'opinion la plus généralisée et qui apparaît dans tous les groupes d'âge et de genre.

<<Ce n'est pas la même chose… Oui, la première fois ils te disent utiliser la capote, mais le problème se pose quand tu les utilises et que d'autres sources te disent que ce n'est pas la même sensation, tu veux voir si c'est ou non la même chose>> P8, garçons de 18 à 20 ans, groupe des quartiers défavorisés.

<<Parce que c'est moins confortable et une amie à moi est allergique. Ou bien parce qu'ils préfèrent ainsi. Oui, sûrement. 2. Parce que tu es plus à l'aise On dit que tu sens mieux.>> P10, filles de 15 à 17 ans, groupe des quartiers défavorisés.

- Manque de prévision

<<Parce que parfois quand on est pressé ou quelque chose de la sorte ils ne le mettent pas, ou ça dépend, des fois ils n'en ont pas à ce moment là. Parfois cela arrive et on n'en as pas. Tout le monde connaît les risques>> P7, garçons de 15 à 17 ans, groupe des quartiers défavorisés.

<<Cela ne vient pas à l'esprit. On oublie>> P9, filles de 12 à 14 ans, groupe des quartiers défavorisés.

- Difficultés économiques

<<Ils sont très chers… parce que ça coûte>> P7, garçons de 15 à 17 ans, groupe des quartiers défavorisés.

<<Ils sont chers. Oui, très chers. Mais ça dépend si tu as de l'argent ou pas. Dans les centres de santé juvénile on distribue des préservatifs gratuits >> P10, filles de 15 à 17 ans, groupe des quartiers défavorisés.

- Confiance dans le partenaire. Cette raison apparaît principalement dans les groupes d'immigrants plus anciens.

<<Oui, mais la première fois. Ils ne font pas ça avec des gens qu'on rencontre dans la rue, bon, avec des personnes de la rue ; avec leur copine la première fois ils utilisent la capote, la deuxième ou quatrième fois ils ne l'utilisent plus…c'est plus confortable pour nous, c'est normal... Elle a déjà confiance, ça ne concerne que nous deux...>> P2, garçons de 18 à 20 ans, groupe d'immigrants.

<<Parce qu'ils prennent confiance et tout ça. Dans une relation stable, dans laquelle ils ont passé beaucoup de mois ou d'années en couple ; ils n'en veulent plus. Si tu es en couple depuis plusieurs années tu peux avoir confiance en lui… le premier jour oui, après tu ne l'utilises plus. >> P6, filles, de 18 à 20 ans, groupe d'immigrants.

- Désire de grossesse (l'idéal de maternité). Cette raison se retrouve seulement dans le groupe sous tutelle (centres résidentiels d'accueil).

<<Elles n'utilisent pas le préservatif parce qu'elles veulent tomber enceintes, parce qu'elles n'ont pas de cerveau. >> P1, filles de 12 à 14 ans, groupe CRAE.

- Manque de conscience des conséquences ou manque de projet d'avenir. Cette raison est mentionnée seulement par les filles.

<<Parce qu'elles s'en fichent de ce qui va se passer dans le futur et elles ne pensent pas du tout à ce qui va se passer après avoir fait cette chose, elles n'y pensent pas et s'en fichent. >> P5, filles de 15 à 17 ans, groupe d'immigrants.

<<Il y en a qui connaissent les risques mais ils n'utilisent pas de préservatif. C'est des demeurés...>> P10, filles de 15 à 17 ans, groupe des quartiers défavorisés.

- Manque de confiance. On trouve cet argument seulement dans le groupe de 15 à 17 des quartiers défavorisés.

<<Je me méfie>> P7, garçons de 15 à 17 ans, groupe des quartiers défavorisés.

<<Je crois que beaucoup de personnes le font parce que on leur raconte des mensonges.>> P11, filles de 15 à 17 ans, groupe des quartiers défavorisés.

- Préférence d'autres méthodes. Cet argument est mentionné seulement par les garçons en faisant référence aux méthodes féminines.

<<Cela me semble bien d'utiliser la pilule parce que c'est un autre système pour éviter la grossesse ou les maladies, c'est une précaution en plus pour les éviter, plus on utilise des méthodes et mieux c'est. Mais on ne peux pas s'y fier complètement parce que il y a des risques.>> P8, garçons de *18 à 20 ans, groupe des quartiers défavorisés.*

<<Les filles préfèrent prendre la pilule plutôt qu'utiliser le préservatif. Il ya des filles qui s'en fichent. Elles pensent seulement à prendre la pilule et c'est tout>> P7, garçons de 15 à 17 ans, groupe des quartiers défavorisés.

- Manque d'information ou croyances.

<<Non, parce que, par exemple si une personne a des rapports sexuels, si elle n'a pas le SIDA ou aucune maladie tu peux le faire et avant que le garçon se retire c'est déjà fait, je pense… Je crois que les gens ne le font pas, parce qu'il y a par exemple le mythe selon lequel la première fois tu ne tombes pas enceinte...>> P11, filles de 15 à 17 ans, groupe des quartiers défavorisés.

<< Dans d'autres pays il n'y a pas de risques, cela n'arrive pas parce que tu te maries avant avec une fille, il n'y a pas ce problème. C'est partout pareil, il y a des risques pour tout le monde. >> P2, garçons de 18 à 20 ans, groupe d'immigrés.

<<Parce qu'ils n'ont pas d'autres informations>> P5, filles de 15 à 17 ans, groupe d'immigrés.

L'opinion générale sur la grossesse et sur l'expérience d'une possible maternité juvenile-adolescente est pratiquement unanime dans tous les groupes : si on pose la question aux jeunes filles elles répondent toutes qu'elles ne veulent pas tomber enceintes. Malgré cela, beaucoup de personnes appartenant aux groupes disent connaître des cas de grossesses d'adolescentes.

<<Nous ne croyons pas que les filles de notre âge veuillent tomber enceintes…Non, mais je connais des gens qui si cela arrive, ils gardent l'enfant…J'en connais une qui quand elle était toute jeune elle l'a eu, elle l'a laissé dans la maison de ses parents et elle ne l'a pas vu depuis et maintenant elle en a un autre. Nous connaissons toutes des filles qui sont tombées enceintes". P10, filles de 15 à 17 ans*, groupe des quartiers défavorisés*.

On observe des différences culturelles en particulier en ce qui concerne le choix de poursuivre ou non une grossesse. La plupart des filles qui ont déclaré que, au cas où elles tombaient enceintes elles garderaient le bébé, proviennent d'autres pays.

Discussion et conclusions

Les mythes et les croyances distorsionnées sur les modèles de l'amour et de la sexualité sont dans maintes occasions en relation avec des facteurs culturels et religieux, outre qu'avec des facteurs de type social et familial (déstructuration familiale, pauvreté, maltraitance des enfants, violence familiale, etc.). Les collectivités en situation de risque social ont tendance à vivre la sexualité avec plus de risques que la population générale [13][5]. Pour cela, le fait de contribuer à la promotion et à l'amélioration des conditions sociales et du bien-être de cette collectivité contribuira a l'amélioration de la santé de ses membres. [14]

Les données repérées témoignent de la nécessité de promouvoir des actions éducatives qui prennent en considération les besoins qui diffèrent selon le genre et la diversité culturelle. Le fait que les filles et les garçons immigrés choisissent en premier la grossesse renforce l'importance de la prévention. En ce qui concerne les besoins liés à la connaissance et à l'utilisation des contraceptifs, les adolescents font référence au fait qu'ils connaissent des aspects concernant leur utilisation, qu'ils souhaitent démolir les croyances et se servir des contraceptifs quand la situation le requiert plus qu'à la connaissance des méthodes mêmes. On relève un écart entre les connaissances des risques et les comportements que ces jeunes adoptent dans leur relations affectives sexuelles. Ils expriment verbalement qu'ils connaissent les risques surtout ceux qui sont en relation avec la grossesse et le SIDA, mais ils reconnaissent qu'ils adoptent des conduites à risque. En ce qui concerne les autres infections à transmission sexuelle ils sont moins explicites. Une possible explication de cette perception du risque, que tout le monde connait est partiellement en relation avec le manque de compétences (communicatives, sociales et émotives) et l'autoestime pour pouvoir établir des conduites sexuelles saines, telles que les relations protégées. Kirby [12] remarque que la pression du partenaire et des amis est un des autres éléments qui peuvent donner origine a des conduites à risques et que les couples qui parlent du HIV et des STI, des méthodes de prévention et de leur relation sont plus disposés à utiliser les préservatifs.

En conclusion, il est nécessaire d'aller vers une approche écologique et positive de la sexualité, spécialement dans les populations en situation de vulnérabilité, où les variables affectives, sociales et culturelles peuvent conditionner leurs comportements sexuels. [15]

Abstract

Currently, family support programs are orientated to encourage family communication that improves both the quality of parenting as family system; what predominates is the creation of a favorable atmosphere to educate children in which the organization imposes on chaos and where protective factors that identify the capabilities are the best reference points for family intervention. [1]

The "Aprender juntos, crecer en familia" program appeared after an evaluation process [2] in response to the need to have systematized materials to apply in group form, with families who are vulnerable. The program approaches the topics necessary for the development of positive parenting. The objectives respond to a holistic development process of family cohabitation from three dimensions vision:

- ✓ Emotional dimension that claims to help manage emotions
- ✓ Behavioral dimensions across the development of skills that allow to face competently situations
- ✓ Cognitive dimension that facilitates a better understanding of the process of family cohabitation

The program [3] was applied to 12 main Spanish cities through a process of collaboration between the Social Work of Caixa and Caixa agencies involved in project-Proinfancia. The implementation process is performed in a first phase in 2012, a second phase in 2013 and now it makes a third application in 2014. During these years the number of participants has increased to a considerable extent.

Keywords: resilience, family system, vulnerable

Introduction

Les études les plus récentes sur la pauvreté, dont celle des enfants, signalent que les garçons et les filles qui vivent dans cette situation ont beaucoup plus de risques d'avoir des difficultés d'apprentissage, de souffrir de problèmes de santé, de présenter de faibles taux de réussite scolaire, d'avoir des grossesses précoces et de ne pas accéder à l'emploi [4]. La situation de pauvreté des enfants est ainsi une des principales causes de l'exclusion sociale.

Sans aucun doute, afin de rompre le cycle de la pauvreté, les soutiens et les ressources économiques constituent des mesures d'assistance nécessaires. Mais il est également indispensable de s'occuper de façon holistique des autres besoins de la famille, comme les soutiens à caractère communautaire et social qui contribuent au respect de la dignité de la vie des pères et des mères qui vivent en situations de pauvreté, de chômage et de précarité.

De nos jours, les programmes d'éducation parentale ont pour objectif de favoriser aussi bien une communication au sein de la famille qui puisse améliorer la qualité du système familial que les compétences parentales. [5] [6] [7]

Objectif

L'objectif de la recherche est d'identifier l´impact du programme sur les familles, sur les professionnels et les services des familles, et aussi d'évaluer le processus d'implémentation et connaître l'efficience du programme.

Approche de la recherche

Le programme [3] s'est appliqué aux 12 principales villes espagnoles grâce à un processus de collaboration entre l'*Œuvre Sociale* de la Caixa et les organismes qui participent au projet Caixa-Proinfancia. Le processus d'implémentation s'est réalisé dans une première phase en 2012, une deuxième phase en 2013 et maintenant on réalise une troisième application en 2014. Pendant ces années le nombre de participants a augmenté d'une manière considérable.

Année	Nº groups	Père et mère	Fils et filles	Total participants
2012	61	609	661	1270
2013	82	823	941	1764
2014 (prévisions)	119	1100	1280	2380

Dans l'évaluation de 2012 nous avons utilisé un groupe de contrôle de 296 parents et 268 enfants. Le nombre de professionnels qui se sont occupés de l'implémentation chaque année est compris entre 138 et 165. On a utilisé une méthodologie d'évaluation mixte (quantitative et qualitative) avec des instruments standardisés et des groupes de discussion avec les professionnels, les parents et les enfants.

Résultats et discussion

1.1 Impact sur les familles

Ci-dessous sont examinés certains des résultats du processus d'évaluation liés à l'impact sur les familles.

Chez les enfants âgés de plus de 9 ans on observe une diminution dans le style qui utilise la critique et le rejet et dans le style indulgent. Dans les familles, il ya aussi un accord pour décrire un milieu familial où l'affection et la communication prédominent, aussi bien que l'utilisation de pratiques inductives destinées à donner des explications, suivies par des pratiques rigides ou autoritaires, indulgentes et avec moins de critiques et de rejets. Du point de vue des enfants on présente une réduction significative des critiques et des rejets aussi bien que du style indulgent de la part des parents.

Il est également important de souligner les connaissances acquises par les pères et les mères tout au long de la mise en œuvre du programme. Parmi les résultats obtenus grâce à l'analyse de contenu des groupes de discussion on peut inclure les points suivants:

- Les relations et le soutien informel ont été renforcés.
- Les pères et les mères prennent conscience de leurs responsabilités parentales, ce qui facilite une attitude de volonté et l'acceptation de la relation d'aide.
- Ils ont augmenté leur implication émotionnelle, l'affectivité et l'expression des émotions.
- Ils ont adopté une attitude de réflexion sur la pratique de l'éducation.
- Ils ont amélioré leurs stratégies de communication.
- Ils ont adopté de nouvelles stratégies liées à la possibilité de définir des règles et des limites.
- Ils comprennent mieux le développement évolutif des enfants.

Les familles ont également signalé des changements significatifs du point de vue statistique dans l'augmentation des activités de loisirs menées au sein de la famille, soit dans la vie quotidienne soit dans des situations extraordinaires.

En ce qui concerne l'apprentissage des enfants on a pu observer qu'il est lié au comportement, à la participation aux tâches ménagères et aux aspects liés à la cohabitation.

- Ils ont amélioré leur capacité à participer activement à la sphère domestique
- Ils adoptent de nouvelles stratégies de communication dans la famille (pères / mères-fils / filles)
- Ils améliorent leur acceptation de la mise en place de règles et de limites
- Ils reçoivent plus de soutien et d'attention éducative de la part des parents

1.2 Impact sur les professionnels

D'autres aspects qui ont été évalués ont été les changements survenus dans les compétences et le développement professionnel des animateurs des groupes aussi bien que l'analyse de l'impact du programme sur le service.

On a relevé des différences significatives dans la perception de l'amélioration des compétences professionnelles. A la fin du programme, les professionnels ont déclaré avoir acquis de meilleures compétences pour interagir avec les familles, c'est-à-dire de meilleures compétences pour soutenir les familles et pour renforcer leur coopération. D'autre part, on a également trouvé des différences significatives dans la perception que les professionnels ont de l'amélioration des compétences pour le développement professionnel; cela se réfère aux compétences pour réaliser un travail d'équipe, pour améliorer l'organisation des services et pour accroître leurs capacités de coordination et coopération.

En ce qui concerne le processus d'évaluation du programme, les animateurs remarquent que le fait de s'occuper de l'évaluation leur a permis de mieux connaître les familles, de détecter des situations concernant la famille ou les enfants dont ils n'étaient pas au courant et même de pouvoir réaliser des interventions au-delà de la portée de l'enfant lui-même.

En outre, le processus d'évaluation des familles a fourni une occasion pour réfléchir sur leur pratique. En ce qui concerne le déroulement du programme, les professionnels ont évalué de façon positive la diversité dans la composition des familles, des genres et des âges et des caractéristiques socio-culturelles. La diversité aide les participants a se sentir plus à l'aise parce qu'elle ne leur attribue pas une désignation négative. Une caractéristique importante est le fait que le programme se déroule mieux quand il y a parmi les familles qui y participent une ou deux familles qui développent une parentalité plus adéquate. La diversité idiomatique et culturelle est appréciée initialement dans certains cas comme une difficulté due aux réticences existant de la part des participants, bien que cette même difficulté soit évaluée positivement par la suite, une fois que le groupe est devenu plus uni.

Dans certains cas, la diversité excessive a crée des difficultés de déroulement parce que la distance culturelle entre les participants était trop grande pour qu'on puisse trouver des éléments communs.

En ce qui concerne le contenu et les stratégies du programme on considère que l'accent sur l'expérience du programme, plutôt que l'orientation académique ou technique, est l'une des clés de son succès. Le fait de fournir au groupe des dynamiques qui lui permettent de s'exprimer, de réfléchir et de se sentir bien s'éloigne de la tradition plus classique des «écoles de parents» et est très bien reçu par les participants et les animateurs.

Un sujet de préoccupation pour les animateurs est l'adaptation aux besoins évolutifs des enfants. Il est à noter que dans les sessions avec les enfants, s'il y a beaucoup de dispersion d'âges, il faut faire des ajustements en ce qui concerne le niveau de maturation des participants.

Conclusions

Le programme est innovant car il propose de faire travailler en groupe les pères et les mères avec leurs enfants afin qu'ils puissent développer conjointement et en complémentarité des compétences susceptibles d'encourager leur développement et leur capacité à contribuer positivement au bien-être familial. Ainsi, on travaille avec deux générations simultanément, [3] ce qui fait que ce qui a été appris lors des séances pourra faire écho auprès des autres membres de la famille. En conséquence, la participation de la famille au programme devrait devenir sans doute une expérience marquante pour tous ses membres.

Un élément essentiel dans la mise en œuvre du programme a été la manière dans laquelle les organismes ont suivi le programme et la façon dans laquelle elles ont réussi à motiver les familles pour les impliquer et pour faire en sorte qu'elles y participent, tout au long de sa durée.

Le programme a fourni un espace partagé aux familles, ce qui jusqu'à présent n'était pas une chose habituelle dans ces familles vulnérables. Les familles vivent dans le programme l'expérience de passer du temps ensemble et de créer des partenariats.

On a introduit la philosophie du travail partagé et de l'innovation dans la pratique professionnelle ainsi que la nécessité d'évaluer les résultats des actions et des programmes. C'est un principe de qualité très important sur lequel il y a encore beaucoup à faire, mais certainement cette expérience a permis de faire une grande avancée à cet égard. [9] [10]

Parmi les nouvelles propositions d'innovation il y a celle selon laquelle les organismes qui pratiquent la formation groupale peuvent devenir une référence dans chaque quartier ou district, avec la possibilité d'offrir ces services spécialisés à des organismes qui n'ont pas un nombre suffisant de familles. Cela rend le programme plus efficace et augmente les possibilités de suivre un plus grand nombre de familles. [11]

Remerciements

Nous remercions en premier toutes les familles qui ont participé avec leurs enfants au programme, tous les organismes et les professionnels ainsi que l'*Œuvre Sociale* de la Caixa qui a financé ce projet.

Abstract

Family reunification, in the system of child protection is the process by which a child returns to his biological family after a period of temporary accommodation. Scientific studies and new social policies share the belief that the socio-educational action with the biological family, is an essential condition for family reunification. Despite this agreement, the socio-educational programs for family reunification being received little attention so far.

There is a matching purposes with one of the priorities of the Framework Programme of the European Community (family life) and with the current basic principle of permanency planning provided in child care and protection of children.

When referring specifically to the family reunification program, there is the family who gets successfully custody of their children has gone through several phases in which they had to use different strategies. Some studies also attempt to identify factors prevention and protection that help the success of the reunification process. Lietz and Strength (2011) analyzed a group of families who have successfully completed the reunification. The objective is to find the following attributes and skills: social support, flexibility, communication, attitude and the ability to interpret its own difficulties, the initiative to meet the needs of the family, will and spirituality.

This article presents the results of a research conducted by the GRISIJ group on the development of a program to support biological families and children who meet the conditions for the application of protective measures for children, involving the temporary separation the family unit (host family or institution) to promote resilience strength and commitment of all members of the family to move on in reunification.

Keywords: Family reunification, program support, foster care, instrument based on resilience

Introduction

A l'heure actuelle, tant les études scientifiques, que les besoins exprimés par les professionnels et techniciens de la protection de l'enfance d'Espagne, et tout comme les nouvelles politiques sociales européennes et espagnoles, sont d'accord pour exprimer que: a) l'action socio-éducative avec la famille biologique est une condition indispensable lorsqu'on applique une mesure de protection temporelle avec pour pronostic la réunification familiale et b) ce sujet a reçu jusqu'à maintenant une attention moindre dans la recherche et dans les pratiques sociales qui prévoient une procédure multi-informateurs.

Objectives

L'objectif de l'étude est d'identifier les besoins spécifiques et les facteurs de résilience des familles et, des fils et filles en situation de séparation, comme mesure de protection et prévention, du point de vue des protagonistes et des techniciens de protection de l'enfance.

Approche de la recherche

Un total de 135 personnes ont participé à l'étude, ils viennent de quatre communautés autonomes de l'Espagne : Cantabrie, Catalogne, Galice et les Îles Baléares. Les participants se distribuent entre 63 professionnels de protection à l'enfance, 42 familles biologiques en processus de réunification ou récemment réunifiées et 30 fils, filles et adolescents qui ont vécu un processus d'accueil soit en famille soit en tant que résidentiels. La caractéristique principale de ces participants est leur composition multiculturelle ce qui permet de saisir des aspects très révélateurs depuis différents points de vue.

Le concept qualificatif de la recherche s'est concrétisé dans l'utilisation de groupes de discussion et d'entretiens en profondeur comme les techniques de collecte d'information. En clair, les groupes de discussion ont permis de saisir la subjectivité provoquant la réflexion et la prise de conscience des participants. Ces groupes se sont très bien déroulés dans chaque cas. La durée a été d'environ 2 heures. Les entretiens semi-structurés ont été planifiés pour les adolescents, vu qu'un contexte plus privé est recommandé à cet âge.

L'analyse des données a été conduite sur la base de l'analyse du contenu.

Résultats et discussion

On a analysé les besoins qui influent dans la réunification familiale en 4 phases : (1) Communication de la mesure, (2) Visites et contacts, (3) Préparation à la réunification, (4) Premiers jours à la maison.

(1) Communication de la mesure: se concentre sur le moment où l'on fait savoir que les enfants vont être temporairement éloignés de la maison. On a détecté que les familles ont besoin de plus d'informations sur la mesure et que l'attitude à tenir face à l'accueil peut influencer dans le processus de réunification. Nos données confirment la littérature scientifique, dans laquelle on met en évidence que dans cette phase les familles doivent commencer à être motivées par le changement et s'impliquer avant, pendant et après la réunification. Plusieurs auteurs (Amorós et al. , 2004; Rodrigo et al. 2007, 2009; Schofield et al.; 2011; Ellingsen et al., 2012 Lietz et al. 2011) signalent l'importance de prendre conscience du problème et la motivation et l'espoir pour la récupération de leurs enfants. D'autres auteurs (Balsells et. al. 2011; Terling, 1999) indiquent qu'il est important que les parents soient conscients de la situation et qu'ils mettent tous leurs efforts et volonté dans la récupération de leurs enfants.
"Moi, je m'étais mis dans la tête qu'ils allaient en adoption, mais ensuite j'ai vu que ce n'était pas cela parce que je les voyais, ils me les amenaient…" Familles

(2) Visites et contacts: l'importance des contacts avec leurs enfants en maintenant des visites régulières; pendant les visites, lorsqu'il y a un éducateur qui les supervise et surveille, un sentiment de malaise s'installe; l'importance de fournir de contenus aux visites, pour que grâce à celles-ci, ils puissent travailler des aspects comme le maintien du lien. Avec cette approche de plus grande qualité et de contenus, on pourrait également répondre à la nécessité que les familles et les enfants partagent un sentiment d'identité commun, qui aide à la stabilité et à la cohésion familiale (Thomas et. al., 2005; Ellingsen et. al., 2012 ; Maluccio et al., 1996).Tout comme le besoin d'établir et de maintenir le lien réel permanent et sûr entre les membres de la famille (Thomas, 2005; Ellingsen et al., 2012)
"La qualité des visites est très importante, c'est à dire, qu'il y ait un rapprochement, qu'il y ait un jeu, qu'ils ne soient pas assis à ne rien faire" Professionnels

(3) Préparant la réunification: c'est très significatif l'importance du soutien formel dans cette étape et il émerge le besoin d'aide à la relation avec un professionnel de référence, qui accompagne la famille dans ce progressif retour à la maison. Spécialement, un soutien pour développer leurs compétences parentales et pour montrer une attitude d'adaptation, de flexibilité et de confiance; selon Schofield et. al, (2011), Thomas et. al. (2005) et Balsells et al. (2013), la positivité, l'adaptabilité, la flexibilité, la confiance, la sécurité et l'autonomie des parents aident à récupérer leurs enfants.
"Moi, je crois que parents comme enfants, nous devrions nous préparer un peu de temps avant qu'on nous redonnent les enfants" Adolescents

(4) Premiers jours à la maison: quand les enfants retournent à la maison et que la réalité de la réunification familiale est présente, on constate une période de réadaptation très forte. L'importance des soutiens formels aussi bien qu'informels garantit le succès et la stabilité de la réunification (Kortenkampe et al., 2004; Lietz et Strenght, 2011). Les recherches de Maluccio et Ainsworth (2003) exposent que peu de soutien social et communautaire rend difficile la réunification familiale. Dans ce sens, l'aide du réseau informel peut être fondamental. La supervision et la continuité de l'intervention dans le suivi familial, tel que le disent Biehal (2007) et Connella et. al. (2009), est le meilleur mécanisme pour éviter de répéter les modèles et conduites à risque existantes dans les familles une fois la famille réunifiée.
"Bien sûr, c'est comme s'ils m'ont laissé un peu de côte, moi, j'étais habituée à avoir des entretiens, la psychologue et tous les autres… et bien, tu te sens un peu seule, à qui je demande ce que je dois faire?" Familles

Conclusions

Ces résultats proviennent de trois sources : le discours des professionnels nous a permis d'arriver à une meilleure approximation des besoins réels. Le discours des familles permet non seulement de comprendre leurs besoins et déficits mais aussi d'avancer dans la connaissance des potentialités. Le discours des adolescents et des mineurs nous a permis d'identifier les zones prioritaires depuis leurs points de vue. Maintenant le but est de transformer tous ces besoins en contenus qui formeront partie de la conception d'un programme d'action éducatif pour familles qui sont dans un processus de réunification depuis la perspective de la résilience.

Remerciements

Cet étude a été développé avec le soutien du groupe de recherche sur les interventions sociales et éducatifs chez les enfants et les jeunes (GRISIJ) et financé par le Ministère des Sciences et Technologie de l'Espagne (Ref.: EDU2011-30144-C02-01).

Parental education - a program that builds the resilience of parents from the vulnerable families

Clicinschi C., Sfetcu L.

Holt Romania Foundation-Iasi Branch (ROMANIA)
claudia.clicinschi@holtis.ro, lucian.sfetcu@gmail.com

Abstract

This study highlights the strategies used in the parental education program developed by Holt Romania Foundation, Iasi Branch with the support of UNICEF Romania, for increasing the resilience of parents from vulnerable families. The strategies achieved during this program are mainly meant to improve the relationships they have with their children, but parents often manage to extend their benefits into other types of interaction and contexts. Based on the appreciative speech, the parental education program "How to Become Better Parents" supports parents in learning to focus mainly on children's qualities and also on the positive aspects of the contexts in which they are found as parents. The program involves eight meetings with a homogeneous group of parents, one meeting per week lasting for 2 hours. At each meeting is discussed an established subject of interest for each parent. The program aims to strengthen the best parenting practices and to create new ones suited for each family. The efficiency of the Program is due to the centering on successful experiences within the family and also on the relationship between positive action and positive vision.

The main body of this paper is based on the observational data of the authors, as parent educators, over a period of 8 years and a secondary analysis of data collected for the evaluation of the program.

Keywords: parental education program, vulnerable families, appreciative speech, curriculum, parental practices, positive vision, positive action.

Introduction

The purpose of this study is to identify which of the strategies used in the parental education program developed by Holt Romania Foundation, Iasi Branch, for improving the relationship between parents and children, generates effects in the development of the family resilience and what are the strategies that entail this growth.

The parental education programs are known as being "programs, services and resources addressed to parents and those who take care of children, with a view of supporting them, improving their ability to raise their children" [1]. In a narrow sense, "parental education involves all programs that help parents develop and improve their parental abilities, learning them to understand their child's development, so as to reduce stress that could affect the parental functionality and to learn how to use alternative ways of tackling difficult situations with children" [2].

The parental education programs improved as an answer to current social circumstances, that demand not only the use of new parental practices so as children could adapt to actual social circumstances, but also flexibility in adjusting to future contexts. The family maladjustment to the speed of the social change could have a negative impact on a child's development. The family, being the most familiar social context of the child, has a great impact on the way the child evolves [3] therefore, the dysfunctional ties that occur in the family system determine other dysfunctional ties in the child's growth [4]. Family and child development are inseparable [5].

The parental education program developed by Holt Romania Foundation, Iasi Branch, "How to Become Better Parents" (CSDPMB) was designed as an instrument for prevention/intervention, used for helping parents develop suitable parental practices, not only when having chronic adversity conditions, but also in their absence. The lack of chronic adversity situations for a family does not guarantee that the family has no problems. The family gets through difficult situations that change from anticipated crises caused by actual family stage of development up to general crisis caused by dramatic events [6]. The CSDPMB program is a type of group intervention, systematic and coherent, that proposes positive methods of interaction for parents, contexts of discovery and amplification of positive experiences with children, a valuation and stimulation environment for new attitudes and behaviors, as well as the enrichment of the knowledge level concerning the growth, caring and child education.

The concept of resilience that initially included the positive adaptation of children found in adverse circumstances [7] was extended to the family system [6]. The family resilience is the process of successfully overcoming the stress and adversity during lifetime [8]. According to Şerban Ionescu [9], "this expansion is justified by clinical observations and by the results of conducted research, which showed that irritating, frustrating and difficult everyday life requirements […] have cumulative and significant effects on psychological wellbeing".

Therefore we put forward for discussion the next issue: to what extent is the parental education program CSDPMB, through its structure, development methods and applied strategies, contributing to the growth of resilience among participating parents and, implicitly, their families'.

The description of the program of parental education "How to become better parents" developed by Holt Romania Foundation, Iasi branch

The Parental Education program "How to become better parents" developed by Holt Romania Foundation, Iasi Branch is useful for parents who are interested in improving their parental abilities and relation to their own children. The program is based on an imported program from USA in 1999 (Make parenting a pleasure, by Minalee Saks, Ellen Hyman and Linda Reilly, edited by the Birth to Three Organization, Oregon, USA) and adapted to Romania's context, the central point of this program being represented by meeting with parents, in a support group manner. The same group of parents attends 8 meetings (one meeting a week) lasting approximately two and a half hours each, in which there are discussed themes of interest for each parent. The group is moderated by two parental educators who permanently maintain a comfortable atmosphere, of safety and personal support, so as to encourage the building of a support network between parents who participate in the program.

The program developed a curriculum for parents who 0-3 years old children, a curriculum for the parents who had children in the 1st to 4th classroom, and in the 5th to 8th classroom. In 2012, it was developed a curriculum for parents with adolescents. There is a common body of knowledge for all curricula, but it is presented differently in accordance with each particular group of parents. These themes refer to the importance and ways of self-care, stress and anger management, how to efficiently communicate with their own child and how to exercitation a positive discipline for the children. Beside the common themes from all the 4 curricula, we can also find specific themes such as: the variety of health food for the child, the prevention of abuse and its effects on the children, the sexual education, friends and free time of teenagers or drug consumption. The program is structured in two parts: the first part is focused on the individual while the second part places more emphasis on the character of the individual as being a parent.

The program promotes the concept of the appreciative parental education that is linked to the concept of appreciative pedagogy introduced by [10] in order to designate the type of pedagogy that will produce a change in education, placing the emphasis on the valorization and appreciation of the human experience and of its peak moments, and also on the direction towards future projections that can lead to the maximum valorization of the human potential.

The parental education program carried out until now, refined and adapted for different categories of parents, is inspired by the newest theories in the field of adult education (social constructionism, the appreciative approach etc.) and is in accordance with the value system promoted by the UN Convention regarding child's rights.

Methodology

The research was based on analyzing the parental education program "How to become better parents" relative to resilient families' attributes presented by Keri Black and Marie Lobo [11]. We also used the method of participatory observation as parental educators.

There have been observed 50 parental education courses that summed up 750 participating parents. Most of these courses took place within projects financed by UNICEF Romania, hence they were conducted as a service intended to prevent neglect, domestic violence, school dropout and child labor exploitation in disadvantaged families. The participating parents were most often part of low income families, with a low level of education, the majority of them facing domestic violence problems, alcohol abuse etc. The participants were selected with the support of the social worker from the community.

Results and Discussions

Family resilience involves not only surviving the crises, but also to reach the stage where the family regards the adversity as an opportunity of discovering new resources it owns that can make it more powerful.

Confronting the crises together within a family, it can become more united, more powerful and can find resources for facing new challenges [8], [12]. Initially, the parental education program CSDPMB conducted by the Holt Romania Foundation, Iasi branch was not designed as a program for increasing resilience, but rather as a mean of prevention, intervention and support for families faced with risk situations like poverty, unemployment, one-parent families etc.

The literature does not mention a universal list of protective factors that can be taken into account in the analysis of family resilience, but recognizes a series of common specific attributes of resilient families. According to a synthesis realized by Keri Black and Marie Lobo [11], these attributes are: a positive outlook, spirituality, the agreement between family members, flexibility, communication, financial management, time spent together, ways of recreation together, routines and rituals and the social support.

1.1 The positive perspective

One of the principles on which the parenting program CSDPMB is built is the focus on success. From this perspective, the appreciative parental education focuses on harnessing blockbuster moments, pride and glory of the experience of parents, considering them the foundation and inspiration for future successes, the past successes are amplified and the future successes are anticipated. Therefore, parenting groups discussions are focused on parents identifying those successes related to their children's education, identifying the children's own qualities and how these qualities have led to the successes mentioned [13].

Also, another principle that the program uses is the focus of the link between positive action and positive vision. The role of the CSDPMB program is to create among the participants positive attitudes about children, people, institutions, community and so on, so that they act as a power source and motor for positive action. The program aims at the parents practicing a complete education focused on positive vision, which stimulates creativity and transforms parents and the interactions initiated by them in relation to their children. As the parental educator addresses more positive questions, parents manage to change faster and more successfully [14]. Addressing positive questions to parents is one of the strategies by which parents are directed to think in other terms, becoming aware of their own strengths, other people or other contexts in which it operates [13].

Thereafter, the inability to have a positive outlook improves and the participating parents start to relax and redefine the situations that initially were viewed as “problematic” in terms of normality. They start coming increasingly more elegantly dressed, some of the participating mothers mentioned that coming to the course is one of the few occasions they dress elegantly and this makes them feel better. Parents show an increase in self-esteem through awareness of the qualities they have; this is due the self-assessment activities due those activities in which the mutual appreciation is encouraged. They begin recognizing and understanding their own state of mind, to acquire new strategies of managing stressful situations and start being aware on the limitations of others, especially their children’s and to reduce tensed moments generated by unrealistic expectations from the others. Moreover, they outline plans for the future in which they truly believe precisely because they are based on realistic expectations and they realize that visualizing the future is guiding them through the present.

1.2 Spirituality

Although the parenting program CSDPMB does not provide a dedicated session for this issue, in the parents’ discourses we observed the tendency to appeal to religion in order for them to explain and accept more easily certain situations that are generating stress on the long term. For example: “If God wished me to have a sick child, I have no way out”. From this perspective, the spirituality is an essential factor for enhancing families’ resilience [15].

1.3 Agreement between family members

Agreement between family members is an important component in the process of building and enhancing family resilience. Also, the comfort and the security provided by a resilient family can act as a protecting factor for all its members [12]. Within the CSDPMB courses, the theme regarding the agreement between family members can be found in the 2nd session (How to overcome stress and fury), the 3rd session (How to efficiently communicate with your child), the 4th session (How to accompany the child on the path to its development), the 5th session (How to be a reliable parent in the relationship with your child) and in the 6th session (How to positively discipline your child).

In the second meeting held in the course, it is debated the issue of how parents can manage their stress and fury in a healthy manner that should not affect nor them or their children. It calls into question the need for both parents to agree on practicing proper measures of stress control, how they and in stressful moments being a model for their children to acquire and apply in the stressful situations he is facing. The internalization of an efficient model of stress and fury management represents a useful protecting factor in developing resilience. Parents participate in various games that are supposed to support the transformation of negative self-addressing

to positive self-addressing and finding positive aspects in problematic situations surrounding them. All these activities train the participants' abilities of better controlling their feelings in tensed moments and creating a comfortable and safe environment in their families.

According to Keri Black and Marie Lobo [11], "discipline in resilient families tends to be authoritative and predictable, with mutual respect between all family members". From this perspective, the parental education program CSDPMB creates a favorable context discussion upon positive disciplinary methods, highlights the characteristics and benefits of the authoritative parenting style, encourages parents within a family to agree on the same methods of discipline and challenges them to be consistent in applying them.

1.4 Flexibility

Flexibility is the family's ability to reorganize, keeping functionality and continuity in the context of confronting with various problems [8]. Even if the course does not provide a special session to address the issue of flexibility, it is addressed, especially when in the group there are parents whose families' structures changed (for example, families in which one parent has died, went to work abroad, suffered any accident that made one incapable of self-care etc.). In the 2nd, 5th and 6th sessions, there are references to the concept of family flexibility and parents are encouraged, in crisis situations, to distribute new roles for family members according to the level of development of each one of them, and to establish new rules, such that families continue to be functional systems.

1.5 Communication

Walsh [6] argues the role of communication in enhancing resilience in that it is the way in which family members define their adversity situation, express the needs and concerns and determine the terms in which the changes will be made. He mentions three characteristics of communication within resilient families: clarity, free expression of feelings and collaborative problem solving. In order to encourage clarity in communicating with children, the CSDPMB course offers a series of exercises and role playing activities during which parents are challenged to convey different messages given the rules such as setting a good eye contact, using short sentences, speaking slowly, using a pleasant tone, choosing proper words that can be understood by children and using positive messages (say what you want, not what you do not want) [16]. A key component of the course is to develop relationship skills for parents with their children, aiming at the improvement of the relationship between them. In order to improve communication between parents and children through effective listening and expressing feelings, CSDPMB proposes several exercises, including "I message" [16]. Through this exercise, the parents are to realize the feelings that they live in certain moments and express them. It is also encouraged the hearing of their children's feelings without judging or criticizing. Using this type of messages can be applied in eliminating accusatory messages like "You do not ...".

The ability to collaboratively solve problem and conflicts well has been shown to be a key factor in resilient families [11]. The communication initiated for this purpose is captured in each one of the course's textbooks with specific particularities for the age of the children. The common idea captures the discussion of family problems with children according of their level of understanding, listening to children's opinions, and accepting different opinions without judging, negotiating, conducting calm discussions, using messages of "I".

1.6 Financial management

Within CSDPMB, the discussions regarding the financial management in the family are found in the sessions addressing the communication theme, children development, children's participation and positive discipline. The accent is set on utilizing efficient stratifies in order to familiarize the adolescents with the idea of economy and responsible spending. CSDPMB encourages parents to involve their child's in setting families' financial priorities and to allow them to manage a certain percent of the family funds according to the child's age [13], and monitor them in this activity. The course encourages parents to analyze the situations in which they could financially motivate their children.

1.7 Time spent together and ways of recreating together

Topics referring to time spent together are found in the CSDPMB in sessions that address the theme of communication, child participation and its development. The idea formulated by [8] that conducting business or having lunch together play an important role in the continuity and stability of the family, is found in the CSDPMB. In this regard, parents receive a homework task to address, together with the rest of the family, various activities [17]. Apart from encouraging parents to practice daily activities with family, starting with the 3rd session, each week, participants received the task of having moments of "special time" in the family. Through this activity, parents are encouraged to reunite once a week within the family and realize together enjoyable

activities agreed by all members [17]. From a constructivist point of view, the family is an environment constructed by the concerned members according to their knowledge, beliefs and ideas [13]. Applying this principle in parenting groups encourages parents to examine, explore mental models they have about family and to realize that the representations they have of their family become a reality of this environment and this program encourages parents to represent their families based on maximizing strengths and best experiences. Time spent together and the arrangements made for family recreation supports shaping positive representations.

1.8 Routines and rituals

According to Black and Lobo [11] "routines are defined as momentary time commitment tasks requiring little conscious thought. Rituals, however involve symbolic communication with enduring, affective and generational transmission." CSDPMB encourages daily routines and rituals. Within the group meetings, parents discuss on their special time at home and share the importance of these moments for them [17]. Along with encouraging routines, an important accent is set on diminishing it in stressful moments as for it not to become in itself a stress factor.

1.9 Social support

According to Patterson, "resilient families not only attain social support from their communities, but also give back to the community" [18]. The process of learning starts from the parental educator's experiences of life and the parents are considered sources and creators of knowledge for each other [17]. During the course, parents begin to function as a support group, the meetings being opportunities for them to build support networks, to increase the frequency and quality of their interactions, to develop solidarity nets that can extend to the community. Parents learn from each other and, at the same time, become more confident in themselves as a result of the utility feeling they experiment when their tips are appreciated and applied by other persons. As a result, after the first meeting, parents begin to come and go in groups and, according to the parental educator's training (social worker, professor etc.) they access more easily the services of the institution the parental educator is representing. Also, if the parents are living close by, we noted a kind of competition between them in applying the positive disciplinary methods learned in this course.

Conclusions

The analysis of the parental education program in terms of the attributes that characterize a resilient family as it is described by Black and Lobo [11], reveals the fact that this program supports the enhancement of participating parents' resilience and, implicitly, their families' in the specific areas addressed, promoted principles and presenting strategies.

After analyzing our observations, we found that an important number of changes occurred in attitudes and behaviors in the relationships between parents and their children: increasing concern for both self-care and child care, increased time spent with children, improvements in the quality of communication between family members, the integration of positive disciplining techniques in their day to day behavior.

As a result of attending this course, parents have extrapolated the efficient communication techniques learned into other contexts, outside the child-parent relationship, such as with their partners, the neighbors or the representatives of diverse institutions. Taking part in the parent education program CSDPMB represents an opportunity for parents to build support networks, increase the frequency and quality of interactions between themselves. Moreover, the parents' trust in accessing the services of the institution where the parental educator comes from.

The factor with the most important impact on increasing family resilience, utilized within the parental education program CSDPMB is represented by the condition set for parents to think in appreciative terms, to harness the positive experiences and to redefine "problems" in terms of "challenges".

Positive attentional bias as a resilience factor in parenting. Implications for attention bias modification online parenting interventions

David Oana A., Podină I.

Babeş-Bolyai University Cluj-Napoca (ROMANIA)
oana.david@ubbcluj.ro, ioana.cocia@ubbcluj.ro

Abstract

Recently, attention bias modification (ABM) has become a promising therapeutic intervention with results in multiples domains, varying from pain to self-esteem and emotional disorders. It has the advantage of being an implicit intervention that can correct negative biases involved in psychopathology, but also in deficient parent-child relationships. Regarding the later argument, although the ABM paradigm has not been extended to the parenting field, up until now, there is great potential for this domain as initial data seem to indicate that negative cognitive biases in parents affect their parenting skills, with an impact on the emotional health of their children. Thus, the present paper aims to extend, in novel ways, existing ABM paradigms, and use them for the first time to boost parental skills. More specifically, we intend to use faces of children to reduce negative biases in parents. The novelty of this approach is that the end beneficiaries of the ABM training will not be the user, meaning the parents, but their children. The development and utility of the ABM tools for parenting purposes is discussed within the broader field of online parenting programs.

Keywords: parent cognitive processes, attention bias modification.

Introduction

The corner stone of any parenting program is to detect and reinforce positive (i.e., adaptive) behavior, attitudes, and cognitions in children in order to minimize the frequency of maladaptive ones. Given the numerous advantages derived from positive reinforcement of these adaptive responses in children, like better academic performance and less aggressive behaviors, parenting programs are mainly oriented on how to reinforce an adaptive response when detected. However, the actual detection of positive responses in children remains an issue of concern. Most parenting programs fail to provide parents with training on how to spot and recognize the targeted cluster of positive responses (behavior, attitudes, and cognitions) in their children. Such training would be all the more important for a specific group of parents with children who display disruptive behaviors.

Studies indicate that the parents of children with disruptive behaviors are biased to notice and pay attention, preponderantly, to the negative behaviors of their children [1], with negative consequences for the parent-child relationship and the parenting style. Furthermore, pre-existing negative biases in parents regarding their children's behavior [1], make it all the more difficult to implement a parenting program, especially in its initial phases when parents have to allocate more cognitive resources to their children, than usual. All these required cognitive efforts might discourage the parents to pursue such a program on the long run or interfere with its success, as negatively biased parents tend to continue to focus on their children's maladaptive behaviors. In this context, a training that would help to reduce the cognitive load imposed by allocating cognitive resources to prospective positive responses in children could ease the parenting process, as well as the efficacy and duration of a parenting intervention.

Novel interventions attempting to modify negative attentional biases (i.e., attention preferentially allocated to negative, disliked or threat like stimuli) by training implicit associations hold great promise for filling this apparent gap, as negative attention biases have been etiologically linked to several mental health issues [2] [3]. Training of implicit attentional associations to benign stimuli (positive or negative) and away from negative stimuli has gained ground with the introduction of the attention bias modification training (ABM) [4]. ABM, a new intervention within the CBT framework, has been found to have a significant clinical impact in both youth and adults [5] [6], with promising results in reducing anxiety and emotional related issues across all ages.

In its initial forms, ABM trained attention to neutral benign stimuli; however this procedure rendered mixed results [7]. Recently, has gained ground a procedure that trains attention towards positive or rewarding stimuli. ABM training to positive stimuli is usually built in a visual-search task training paradigm [8] [9], in which participants are instructed to search for a happy face embedded in a matrix of disapproving faces. The nature of the task and its interactive features made it possible to extend the results to other responses, such as self-esteem, where it managed to boost self-referential processing. Though it is a work in progress, as the working mechanisms are not fully uncovered, the visual search task seems to be a promising venue for self-help interventions in emotional issues across all ages, as well as a potential component of current evidence-based intervention programs.

Although the ABM paradigm has not been extended to the parenting field, up until now, there is great potential for this domain. There is only initial data documenting on how the negative cognitive biases in parents affect their parenting skills [1], but evidences indicate that parental cognitive biases do have an impact on the emotional and behavioral health of children, in some cases facilitating an intergenerational transmission of mental health issues [10]. Thus, the present paper aims to extend, in novel ways, existing ABM paradigms, namely the visual search task, and use them for the first time to boost parental skills. More specifically, we intend to use faces of children to reduce negative biases in parents. The novelty of this approach is that the beneficiaries of the ABM training will not be the user, meaning the parents, but their children. Given the previous arguments, such a procedure would be useful especially in the context in which parents' negative biases regarding their children interferes with a good parent-child relationship.

To sum up, the current project will draw from early work on ABM and develop a novel intervention aimed at changing parents' negative biases regarding their children. The intervention will train positive contingencies to happy childlike faces while disregarding the negative ones. The utility of this procedure will be discussed in the context of the *Rational Positive Parenting Program* [11] [12].

Development of the parent ABM

We chose the VSTT as our ABM framework since it is more complex than standard ABM procedures; therefore the risk of not engaging the participant in the task is minimal. VSTT demands fast processing and inhibition of task irrelevant stimuli (e.g., angry faces), all required in ecological environments where more than one stimulus is present. Generally the VSTT uses 16 facial expressions of different individuals. The faces are presented in a 4 by 4 square centred on the computer screen, preceded by a fixation cross. Participants are instructed to find the happy face among 15 other angry faces and click on it, as quickly as possible. Interestingly, the location of the happy face is randomized within the square, so there is no prediction where and which of the angry faces will display a happy face next.

Building on the VSTT procedure adapted from [8], we aim to redirect, for prevention purposes, the attention of parents from angry faces of children to happy faces of children. Most importantly, the template of the task allows for parents to upload the pictures of their children, in order to make it more personally relevant. As we aim to assist parents in detecting the positive responses from their children (like happy faces), as effortless as possible, we will add to this task several associative learning boosters, detailed in the following.

First, we will deliver feedback for correct answers and mistaken responses. Feedback is most relevant in the learning phase of an association; however in ABM research it is less used or employed only during practice trials. Second, we will provide the opportunity to upload personally relevant salient stimuli. Stimuli that are salient go through a more rapid change in their associability, as opposed to less salient stimuli. However, this is an aspect that is most of the times disregarded in ABM research. Third, the VSTT will have a game like interface to engage the participants in the task, as well to prevent dull moments that might interfere with the success of the training. Fourth, we will deliver the training over the course of two sessions, as recent studies indicate that one or two sessions are sufficient to train a positive bias. We chose to use more than one session as we want to boost the learning of positive stimuli and provide the opportunity for the training to be delivered in multiple contexts (e.g., at home, at work). The chosen stimulus set is angry and happy faces of children selected from the NIMH-ChEFS data base [13]. Figure 1 provides a schematic overview of the VSTT.

Fig. 1 Overview of the parent VSTT task

Discussions and Conclusions

1.1 Implications for the online parenting programs

The development of a training procedure aimed at detecting positive responses from children molds very well on current parenting programs, in that it assists parents to effortlessly detect positive behaviors in their children, behaviors which can later on be reinforced. We especially envision a match between ABM procedures and online delivered parenting programs. This is plausible, given that ABM can be easily used and self-administered with minimal instructions. In fact, there are evidences that ABM can be successfully delivered online, with promising results regarding the management of anxiety [14]. In light of these arguments, we consider ABM especially suited for parenting programs based on computerized cognitive-behavioral therapy (cCBT). ABM would fit cCBT interventions for parents given that it is agreement with evidence-based practices and it has a positive approach of mental health [15].

We expect that the ABM intervention can be used throughout the parenting program and during prospective booster sessions. However, it will be most useful in the initial phases of the parenting intervention, as it can ease the detection of positive responses from children. Furthermore, we anticipate its utility for parents with a negative trait like style of processing stimuli, like dysphoric parents [16]. These individuals have a tendency to perceive almost all aspects of their life as being negative and interventions aimed at correcting cognitive biases have been able to "mend" this negative style of processing. Furthermore, recent evidences emphasize that an optimized attentional bias can transfer to other processing levels, such as interpretation or memory bias [17], all relevant for an optimal parent-child interaction. In fact, there are many types of beneficiaries that would profit from the addition of the ABM training to standard parenting tools, such as parents of children with misbehavior issues. These parents require special assistance in detecting positive behaviors in their children, as there are biased to primarily detect the negative ones.

Another statement, of the current paper, is in favor of online delivered parenting tools with implicit components, like ABM training. The online format is intended to make the intervention more easily accessible, more cost-effective than standard parenting tools and eliminate any potential stigma associated to seeking parenting services. Alternatively, the implicit component is meant to ease the work of parents, to make the process of negative bias correction less demanding, even automatic. All these work in the favor of a successful training program, with minimal dropout rates.

We are currently in the process of incorporating an ABM intervention module in the Rational Positive Parenting Program. Building on studies indicating that cognitions are key determinants of parenting skills [18], the Rational Positive Parenting Program brings a new spin to available programs, in that it focuses on rational cognitions, that is logical, empirically based and flexible cognitions, known as protective factors against psychopathology [19]. ABM can be successfully incorporated to this program, given that it is doesn't last long and it has a game interface which can be enjoyed by both parents and their children, with potential positive benefits for parental skills and parent-child relationships.

To sum up, our aim to develop an intervention focused on the positive responses of children is line with trends in parenting interventions, in that, up until recently, numerous studies in the field of parenting and parent – child interactions have focused more on diminishing the negative aspects of this relationship and less on enhancing its positive facets. Furthermore, the current paper follows an emergent line of research in the clinical field that is self-management programs in mental health. Future studies should focus on integrating ABM based innovative strategies within online parenting programs and test their cumulative efficacy. The results could provide a brief and pleasant augment to current evidence-based parenting programs, with great self-help potential and improvements in the parent-child relationship

L'expérience de loisir de jeunes vivant avec une limitation fonctionnelle et résilience des familles

Duquette M.-M.

Département d'études en loisir, culture et tourisme, Université du Québec à Trois-Rivières (CANADA)
Marie-michele.duquette@uqtr.ca

Abstract

This paper presents the results from the case studies as part of a master's project on the experience of leisure, young people with a disability and their family dynamics. The four case studies were conducted with two-parent families where a young lives with a physical limitation to understand the role of leisure experience, experienced by the young through sports, in family dynamics. Father, mother and young participated in individual interviews and a diary was written by the researcher. Data analysis was performed according to the intrasite and intersite model Yin (2014). This shows that the experience of leisure, through the practice of the activity, the satisfaction experienced the motivation of young and experienced emotions lead to positive effects on family dynamics.

Keywords: Experience leisure, family dynamics, sports, functional limitation

Introduction

Toutes les familles vivent un stress à un certain moment de leurs vies [1, 2, 3]. Ce stress peut provenir de plusieurs situations dont la limitation fonctionnelle d'un enfant [3]. Les membres de la famille font face à des adversités et doivent s'adapter fréquemment [3]. Effectivement, même si la limitation touche uniquement un membre de la famille, l'ensemble de celle-ci est affectée [2, 3]. Les familles doivent ainsi développer des stratégies pour surmonter ces adversités [3, 4, 5]. La résilience familiale rassemble ses forces, sa dynamique, son milieu social et ses interactions [1]. Ce processus de résilience évolue selon le cycle de vie, les expériences et les interactions [3, 6].

Des recherches portant sur les expériences de loisirs ont montré leurs effets bénéfices sur les personnes qui les pratiquent autant seul [7, 8] qu'en famille [9, 10]. L'expérience de loisir, contrairement à une activité ou à un temps de loisir, est davantage subjective [11]. Elle fait référence à l'individu et à ce qu'il vit et ressent par rapport à une activité de loisir [11]. Elle peut être vécue peu importe l'activité et la personne qui la pratique [11]. Les activités sportives constituent des opportunités pour les jeunes avec une limitation fonctionnelle de vivre des expériences de loisir.

Des études ont aussi portés sur la dynamique familiale et son rôle dans la participation d'un jeune à des activités de loisir [8, 12] et aussi dans l'amélioration du processus de résilience [4]. La dynamique familiale est un concept intéressant pour ce projet puisqu'il fait référence aux manières dont les membres d'une famille vivent et réagissent produisant ainsi des comportements et des symptômes. De plus, deux synthèses de facteurs de protection sont pertinentes dans cette recherche. Un modèle où les facteurs de protection sont recensés pour la clientèle souffrant de maltraitance [4] et un autre, celui de Jourdan-Ionescu et Julien-Gauthier (2011) pour la clientèle ayant une déficience intellectuelle. Ce modèle écosystémique montre des facteurs individuels, familiaux et environnementaux [13]. Les recherches montrent que la dynamique familiale peut agir comme un facteur facilitant ou contraignant à la participation d'un jeune avec une limitation fonctionnelle à des activités de loisir [12, 14, 15]. Un des modèles intéressants pour ce projet est celui de King et ses collègues qui ont développé un modèle de facteurs de prédicteurs à la participation des jeunes avec une limitation fonctionnelle à des activités de loisir [12] Il présente ces facteurs sous forme de ressources, de barrières, de supports, de préférences et d'habiletés menant à la participation du jeune [12]. Cependant aucune recherche ne s'est penchée sur le rôle que peuvent avoir ces activités, ces expériences de loisir sur la dynamique et la résilience familiale.

Objectifs

Ce projet de maîtrise cherche à comprendre le rôle de l'expérience de loisir dans la dynamique familiale des jeunes ayant une limitation fonctionnelle. Le premier objectif est d'identifier les composantes de

l'expérience de loisir interagissant avec la dynamique familiale du jeune ayant une limitation fonctionnelle. Le second objectif est de décrire l'interaction de ces composantes sur la dynamique familiale.

Méthodologie

La stratégie de recherche utilisée est l'étude de cas. En regard des objectifs, cette stratégie semblait la plus appropriée. Un cas correspond à une famille ayant une mère, un père et un jeune avec une limitation fonctionnelle. Quatre études de cas ont été réalisées selon la méthode multi-cas avec groupes holistiques de Yin (2014). Ces cas ont été sélectionnés pour leur potentiel et selon des critères avec la technique d'échantillonnage par choix raisonné [16]. Des entretiens semi-structurés individuels et un journal de bord rédigé par la chercheure sont les outils utilisés. Deux guides d'entretien, un pour le jeune et un autre pour les parents, ont été élaborés selon les concepts d'expérience de loisir et de dynamique familiale. Les entretiens ont été enregistrés puis transcrits.

La méthode d'analyse utilisée, afin de répondre aux objectifs du projet, est celle intersites et intrasites élaborée par Yin (2014). Cette méthode consiste à élaborer des rapports individuels pour chacun des cas comme s'ils représentaient l'unique cas de la recherche [16]. Par la suite, des conclusions intrasites seront mis en lumière afin d'approfondir les connaissances au niveau de l'expérience de loisir et la résilience des familles où vit un jeune avec une limitation fonctionnelle. Le présent article rapporte les différents rapports individuels des quatre études de cas.

Résultats préliminaires

L'échantillon de cette étude est composé de quatre familles biparentales avec un jeune ayant une limitation physique depuis sa naissance. Les activités sportives sont toutes de groupe et trois des jeunes pratiquent une activité adaptée. L'unique fille de l'échantillon est plus lourdement handicapée.

L'interaction des éléments de l'expérience de loisir (la pratique actuelle, la satisfaction ressentie, les émotions vécues et la motivation du jeune) avec la dynamique familiale se reflète tant pour le jeune, ses parents, leur couple que la famille. L'expérience de loisir permet de rehausser l'autonomie du jeune et améliore ainsi les perspectives d'avenir de celui-ci ce qui réduit les anticipations négatives des parents. Elle amène aussi le jeune à développer ses habiletés physiques, psychologiques, cognitives et sociales. À travers le sport et l'expérience qu'il vit, le jeune ressent des émotions positives, développe son talent, son optimisme et ses capacités stratégiques. De plus, la nature de l'activité suscite des interactions et permet de développer un réseau social. La pratique d'une activité par le jeune permet aux parents de passer un moment de couple ce qui est propice à renforcer leurs liens. De même, l'implication du parent dans l'expérience de loisir du jeune lui procure un moment privilégié ensemble. Aussi, tant le jeune que ses parents ont l'opportunité de développer un réseau social à travers l'expérience de loisir. Les parents peuvent alors partager avec d'autres parents leurs expériences et leurs sentiments. Il est donc possible de briser l'isolement dans lequel ils peuvent vivre et échanger avec d'autres parents vivant des situations semblables. Ces interactions entre l'expérience de loisir et le vécu des membres de la famille se reflètent sur le climat familial et dans les routines familiales en y apportant plus de moments agréables et d'espoir en l'avenir. Les résultats préliminaires sont présentés et modélisés dans la figure 1. L'expérience de loisir vécue par le jeune se retrouve dans la sphère englobant les dimensions de famille et du jeune et l'effet qu'elle manifeste dans l'ensemble des sphères est présenté sommairement.

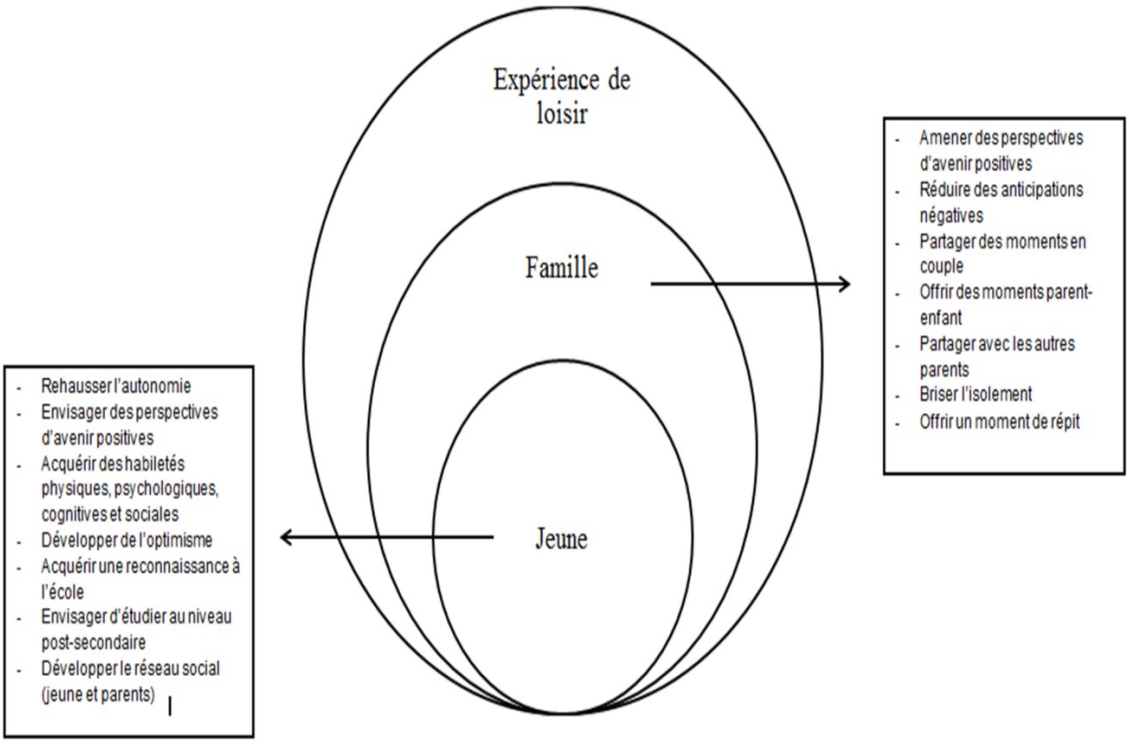

Figure 1. Modélisation des résultats préliminaires

Certaines pistes de l'analyse des données par cas (intrasites) se dégagent comme potentiellement intéressantes pour l'analyse intersites des cas. Des éléments apparaissent ainsi se dégager de l'interaction des éléments de l'expérience de loisir avec la dynamique familiale. L'un est le rôle de l'expérience de loisir pour rehausser l'autonomie du jeune et apporter plus d'espoir face à l'avenir Aussi, à la lumière des analyses intrasites, plusieurs éléments ressortent de plusieurs cas tel que le développement d'un réseau social pour le jeune et pour les parents et l'opportunité de passer un moment entre les membres de la famille. Le renforcement des liens sociaux dans et hors de la famille ressort aussi de même que l'amélioration du climat familial au travers de moments agréables.

Conclusion

Selon les premières analyses, l'expérience de loisir semble avoir un rôle positif sur la dynamique familiale de ces familles. Il est à penser qu'elle peut avoir un rôle dans le processus de résilience de ces familles. Il est évident que les résultats ne sont pas entièrement analysés. Trois des cas se sont révélés davantage semblables que le dernier, avec la jeune plus lourdement handicapée. Ainsi, une autre étude de cas sera réalisée avec une famille où le jeune est plus lourdement handicapé afin de pouvoir enrichir les données à ce niveau.

Il existe de multiples retombées pour ce projet. Sur le plan théorique, la vision différente de cette étude pourrait permettre l'avancement des connaissances dans le domaine de l'expérience de loisir, de la dynamique familiale et de son processus de résilience. Au niveau professionnel, cette recherche pourrait amener les intervenants à sensibiliser davantage les parents de ces jeunes et de leur démontrer le rôle positif pour eux. Aussi, ce projet ajoute un élément à la promotion des saines habitudes de vie chez les jeunes avec une limitation fonctionnelle.

Abstract

The concept of resilience finds its first meaning - mechanics - in a service focused on the treatment of back problems. Body therapies available within the Department of Rehabilitation Care in the back of the Hospital of St Pol sur Ternoise (North of France) are then deployed necessarily around the notion of resilience. In many situations, the painful body appears stiffened by the patient's history and some of its traumatic moments of petrification. From a systemic way, the suffering of the body continues to restrict and stiffen their ability to live their personal, family, social and professional life. The persistence of chronic pain in some patients adds a new traumatic dimension to the "family body". The implementation of a family counseling in a rehabilitation service of the back therefore aim to take into account a multidisciplinary manner, that is to say in the mutuality of incompleteness of each approach involved the psychic dimension of patients, both in their identity in their membership. Exploring the springs of social support that patients can find their entourage is part of a highlighted lever of resilience, including that family resilience in its present dimensions and transgenerational. Our communication is to present both the device - which is "family speaking" of pain experienced and care already received and those still to be undertaken - and some clinical vignettes demonstrating how to do this.

Keywords: resilience, traumatic moments, therapies

Méthodologie de travail

La résilience tire initialement son nom des propriétés mécaniques élastiques des matériaux à restituer une énergie à partir d'une situation de déformation ou de contrainte. Cette notion a été appliquée en psychologie. Elle est aussi étudiée en chirurgie rachidienne pour utiliser des matériaux de plus en plus adaptés à la physiologie et flexibilité complexe de la colonne vertébrale, au fur et à mesure qu'on en comprend mieux le fonctionnement [1, 2, 3]. Nous tenterons de démontrer que malgré ces applications en apparence très éloignées, le concept de résilience représente une notion très fidèle du fonctionnement humain, tant au niveau de son anatomie, de sa psychologie, que de ses rapports dans la famille ou la société. La résilience des matériaux ou de l'os se situe à un niveau structurel microscopique. La résilience de l'appareil locomoteur se situe à un niveau organique macroscopique. La résilience utilisée en psychologie vient projeter ses multiples ramifications sur l'ensemble des structures organiques par le biais des schémas comportementaux que notre psyché induit sur la forme et le fonctionnement de notre corps physique. Ce n'est que la nécessité d'une meilleure explication du fonctionnement complexe d'un individu par différents spécialistes qui introduit une « fragmentation » de l'individu entre les points de vue du psychologue, de l'anatomiste, du chirurgien, ou du sociologue. Ils sont en réalité complémentaires, indissociables et agissent de façon simultanée à tout niveau.

Nous poserons le postulat que le corps en général, aussi bien physique que émotionnel et psychologique fonctionne bien quand il est régi par une souplesse adaptative, lui permettant de faire face de façon appropriée à la situation spécifique du moment. Une rigidification de cette structure complexe aboutit à des situations de risque : décompensation sur le plan physique (mal au dos pour les patients de notre service), personnel, familial, professionnel, social…

Ainsi, c'est une amélioration de la connaissance du fonctionnement complexe de notre nature humaine dans ses modes de structuration qui permet de proposer des solutions de plus en plus adaptées à cette structure élastique : Pour les patients atteints d'un mal de dos, les propositions initialement chirurgicales se sont affinées et diversifiées, devenant pluridisciplinaires. [4]

- Utilisation de matériaux chirurgicaux plus élastiques : plus on transforme un matériau physique amorphe (plastique) en un matériau structuré et complexe (composites de carbone), plus il acquiert la résilience

nécessaire pour reproduire finement le fonctionnement flexible de l'os, assez semblable à celle d'un nid d'abeille combinée à celle d'une toile d'araignée. Répondre à ce cahier des charges passe par une complexification de la micro-structure des matériaux utilisés. [5,6]

- Les techniques de rééducation s'attachent à restaurer une meilleure souplesse du corps, de meilleures sensations corporelles guidant une meilleure connaissance du corps. Ces techniques rééducatives font le lien entre des modes de fonctionnement musculaires organisés en schémas comportementaux, eux même connectés à notre psyché. [7,9]
- La sophrologie : Notre observation de plus en plus évidente du blocage de la respiration par des phénomènes de stress, introduit l'utilité de séances de relaxation respiratoire avec des sophrologues. C'est une transition et trait d'union entre le travail corporel et psychologique. Elle est centrée autour de techniques de respirations et de visualisations. Par le travail des sensations du corps, physique, émotionnel, elle permet une meilleure relaxation corporelle globale.
- La psychologie clinique : A ces intrications entre le physique et l'émotionnel, s'ajoute rapidement dans cette poupée russe, la nécessité d'un soutien psychologique personnel : celui-ci, vient à son tour enrichir la compréhension fine mais multifactorielle de la pathologie initialement prise comme purement somatique d'un patient, la lombalgie. [10]
- L'art-thérapie est une façon ludique et symbolique de travail corporel global. Les activités de dessins, modelages, jeux de constructions… permettent une mise en résonance du langage corporel et du vécu par l'intermédiaire de l'expression artistique. Elle favorise l'émergence de prises de conscience en même temps qu'une meilleure confiance en soi. Le travail en groupe vient renforcer et étayer la dynamique personnelle de chacun.
- La consultation de psychologie familiale : Enfin, plus récemment, il nous a paru important de pouvoir replacer le patient dans une dynamique plus large, où est mise en relief la situation du patient au sein de sa famille, voire de son travail : Cette consultation psychologique familiale permet une prise en compte systémique de la dimension psychique des patients, tant dans leur identité que dans leur appartenance et également sur le plan transgénérationnel. Ce dernier aide les patients à trouver des ressources internes et environnementales pour leur retour à une vie active, familiale et professionnelle.

Ainsi, on voit que la résilience, concept métallurgique au départ, nécessite pour être adaptée au modèle humain nécessairement complexe, une structuration de plus en plus diversifiée de nos modèles de fonctionnement, impliquant d'élargir de façon pluridisciplinaire notre champs de connaissances. Si l'on veut augmenter notre capacité de résilience dans la vie quotidienne, à la fois pour nous et nos patients, il faut nécessairement augmenter la conscience que nous avons de nos modes de fonctionnement, à tout niveau, physique, émotionnel, psychologique…Conscience et résilience ne sont que les deux facettes d'une même solution.

A la différence de la poupée russe, il ne nous semble pas possible d'affirmer la prééminence d'une approche thérapeutique (rééducative, chirurgicale, psychologique ou émotionnelle, art-thérapie…) par rapport à une autre, dans un corps pris dans sa globalité physique, émotionnelle et psychologique : leur complémentarité et leur synchronisation s'avèrent indissociables.

Voici l'exemple d'une consultation en psychologie familiale. Elle va nous permettre d'insister sur l'importance de la construction, de l'analyse et de la mise en résonance du génogramme dynamique.

Etude de cas

« Rien ne brise autant l'homme dans son corps et dans ses relations que l'expérience de la douleur chronique ».

Cette citation émane de Marco Vannotti, co-auteur d'un article paru dans la revue *Thérapie Familiale* intitulé : « La maladie chronique : une atteinte à l'histoire des familles » [11]. Dans cet article se trouve souligné « combien la maladie chronique, loin d'affecter le seul patient qui la porte, peut atteindre les soignants et, bien plus encore, la famille du patient. C'est pour ainsi dire la famille qui est « touchée » par la maladie et contrainte de faire face à la perturbation qu'elle constitue. Or, la manière dont le système familial gère et « s'approprie » la maladie de l'un de ses membres n'est pas neutre par rapport à l'évolution clinique du patient lui-même, mais agit de façon directe sur le départage de ses vulnérabilités et de ses ressources ». [11].

Cet écrit témoigne de l'évaluation d'une mesure psychosociale menée à un niveau à la fois individuel et familial et coordonnée sur un mode interdisciplinaire à l'intérieur du réseau de soin pouvant contribuer à améliorer la prise en charge de patients chroniques.

Les auteurs se penchent sur le domaine de la pathologie pulmonaire chronique, maladie qui peut connaître des moments particulièrement aigus et peut même mettre en danger de risque vital les patients concernés : « la toile de fond des maladies chroniques respiratoires est faite de la « proximité de la mort » ou encore du « climat de menace » qui entoure la maladie ».

Ce qui n'est pas tout à fait le cas dans les maladies du dos, pourrions-nous ajouter. Maladies du dos où l'on constate plutôt une sévère réduction de l'ampleur de l'existence. Sans doute que dans ce champ clinique des maladies du dos « le risque vital lié à la maladie chronique » ne se traduit donc pas, pour le patient et sa famille, en cette confrontation obligée à l'anticipation de la perte comme dans les maladies chroniques respiratoires dont parle Vannotti. Cette sévère réduction de l'ampleur de l'existence prend probablement sa source dans un trouble de structuration de l'être au monde du patient ainsi affecté. Si le champ clinique des maladies du dos relève ainsi d'une autre préoccupation, la démarche de soins qui s'y déploie peut profiter des pistes d'intervention avancées par de ces auteurs à l'usage des praticiens.

Le souci que nous déployons au sein du service SSR est de mettre au jour et d'accompagner, grâce à un suivi suffisamment approfondi, des situations impliquant différents enjeux familiaux gravitant autour de la maladie chronique.

Dans les travaux de recherches cliniques précédents de certains membres de notre équipe, ont été explorées les manières de mobiliser les ressources des personnes en souffrance rencontrées dans un contexte clinique ou de recherche-clinique : que ce soit auprès d'adolescents traversant les luttes psychiques de cet âge [12, 13] ; ou encore que ce soient des personnels victimes de violence au sein de leur lieu d'exercice professionnel [14,15]. La part de l'expression a beaucoup joué dans la mobilisation des ressources de ces personnes, tout comme celle du soutien social. Ce sont donc ces deux dimensions de l'expression et du soutien social que nous avons cherché à valoriser auprès des patients du service SSR, et cela dans une perspective systémique.

L'entretien de famille présenté ci-dessous constitue une illustration de ce type d'intervention dans je champ clinique de la pathologie «chronique» du dos, très fréquente en SSR à la Polyclinique de St Pol sur Ternoise.

L'objectif de ces entretiens de familles est de trouver, avec le patient, les soutiens familiaux ou environnementaux sur lesquels il pourra s'appuyer à son retour à domicile. Sans doute que nous pouvons nommer ces soutiens « les tuteurs de résilience » [16]. L'entretien familial qui va être évoqué a été proposé au couple par le médecin chef de service et a été facilement accepté par la patient, Christophe, et Christine, son épouse.

Histoire de la maladie de Mr.

Monsieur Christophe, âgé de 54 ans, a déjà été hospitalisé dans le service pendant plusieurs semaines en 2011, puis en 2012 et encore en 2013. Il a déjà subi plusieurs opérations chirurgicales (dont celle d'une hernie discale en 1998) et auparavant plusieurs autres interventions dont la première remonte à l'âge de 4 mois. Mr est né avec des pieds bots.

Les douleurs de Christophe, vont et viennent, perdurent parfois très longtemps (en 2013 : seul le mois d'octobre fut sans douleurs !!). Le médecin du SSR a pu diagnostiquer qu'il avait « la maladie de Schuermann » : « dystrophie rachidienne de croissance des corps vertébraux. Il s'agit d'une atteinte fréquente d'origine inconnue, des cartilages des corps vertébrés et plus particulièrement de la partie avant des vertèbres, survenant pendant la croissance de l'enfant »(internet) ce qui rassure son épouse Christine qui dit «au moins on sait ce que c'est et on va pouvoir trouver comment te soigner ». En janvier 2014, Christophe rentre en urgence à la polyclinique. Il ne peut plus marcher.

Histoire dans sa famille d'origine

Christophe est enfant unique. Le couple parental aurait été chaotique, ses parents ont d'ailleurs divorcé quand Christophe avait 3 mois. Christophe a connu sa mère sous l'emprise de l'alcool, devant, très jeune, « l'aider à se relever ».. Celle-ci se voyait née d'une mère violée et n'ayant pas connu son père. Ce sont ses grands parents maternels qui se sont donc surtout occupé de lui. Ils sont d'ailleurs décédés bien plus tard que sa propre mère.

La dimension de la souffrance transgénérationnelle vécue se lit dans et grâce au génogramme dynamique (présenté en une vue Power Point). Dans cette investigation, notre démarche est soucieuse de repérer ce que Boszormenyi-Nagy désigne par le terme d'éthique familiale : la notion d'éthique se réfèrant ici essentiellement au caractère « juste » ou « injuste » des échanges entre les membres d'un système familial transgénérationnel [17].

En éclairant et explicitant l'expérience plurielle de la maladie, notre intervention auprès des patients et de leur famille cherche à promouvoir ce que Vannotti désigne du terme d'inspiration piagétienne d' *équilibration majorante des échanges* entre les membres de la famille » [11] : « ce qui suppose l'identification des ressources que chacun mobilise et une reconnaissance mutuelle des mérites ainsi acquis par chacun auprès des siens. Dans la redistribution des relations et des rôles motivée par la maladie, nous cherchons, avec la famille, à départager ce qui relève d'une réponse « équitable » aux exigences induites par la maladie de ce qui,

en soi ou à partir d'un certain temps, peut être qualifié comme une dérive injuste: perte de réciprocité, pétrification des rôles, responsabilisation excessive ou trop précoce des enfants, etc. De fait, si le renforcement de la cohésion, de la solidarité et du soutien intrafamiliaux détient un rôle protecteur indéniable à certains points nodaux du développe- ment de la maladie, la perpétuation indéfinie de ce schème se mue en une défense régressive qui ne profite plus à personne, pas même au patient. Il importe donc, durant la phase chronique de la maladie (qui s'étire entre la phase critique initiale et la phase terminale), d'aider les différents membres de la famille à reprendre leur cycle évolutif en pratiquant le *double* mouvement de l'appartenance et de l'autonomisation. Nous postulons en effet qu'en aidant la famille à poursuivre son histoire en dépit de l'effet paralysant de la maladie, avec les séparations et les renouvellements d'alliance que l'accomplissement d'une histoire présuppose, le soignant agit dans le bien du patient lui-même. » [11].

Le soutien mutuel des membres du couple.

Dès le premier contact avec ce couple, se profile déjà un modèle relationnel : Christiane est très protectrice et attentive aux déplacements de Christophe et celui-ci, se laisse bien prendre en charge, peut-on dire ! Ils se sentent très vite à l'aise avec les deux thérapeutes. Entre les deux époux, dès le début dans cette consultation, se dit et se montre, une réciprocité de l'attention destinée à l'autre, de la prise de soin de l'autre.

Spontanément, Christophe gratifie son épouse en nous affirmant « qu'il a une femme formidable » et souhaite savoir aussitôt, si ces entretiens familiaux pourront aussi permettre « une soupape pour sa femme ».

Au fil des entretiens qui suivront, nous aborderons peu à peu la façon dont l'aide « se tricote » au sein de leur couple, dans l'ici et le maintenant de ce qu'ils nous montrent à voir de leur relation, mais aussi à partir de quelques modèles référentiels de leurs histoires familiales et d'une approche de l'amour maternel, douloureux et manquant pour chacun d'eux. Evoquant sa propre démarche psychothérapeutique passée, Christine dit avoir fait « un grand travail personnel » qui lui a permis « d'accepter l'inacceptable et de pardonner l'impardonnable ». Ce qui rendrait légitime, actuellement, ses capacités d'endurance déployées depuis un grand nombre d'années : tenir cette fonction « d'aidante » que Christophe, fort handicapé sur le plan physique, lui permet d'assurer.

En janvier 2014, Christophe rentre en urgence à la polyclinique.. il ne pouvait plus marcher.. Christine n'assure plus son soutien à Christophe comme elle le voudrait : elle aussi a besoin de soutien. La culpabilité « de ne pouvoir rien faire » et le sentiment d'impuissance l'envahit lorsqu'elle voit Christophe ne pouvant plus bouger et perdre de l'autonomie. Au cours du dernier entretien familial, nous constatons que dans leur dynamique relationnelle, lorsque madame est dans le creux de la vague, monsieur la rassure et dit « rester dans l'espérance » de l'amélioration de son état, réalisant « que ce sera long, qu'il faudra prendre son temps.. il faut être patient… Qu'est-ce que je ferais si ma femme n'était plus là ». Se joue-là une réassurance narcissique réciproque, qui se manifeste dans l'interdépendance, et dans la souffrance maintenant l'homéostasie de leur système.

Que dire de cette solidarité, de cette complémentation, de cette compassion mutuelle, particulièrement homéostatique ? Dans son ouvrage consacré au *Contre-transfert,* dès le premier chapitre consacré à la symbiose thérapeutique, le psychiatre et psychanalyste américain de l'école inter-subjectiviste Harold Searles parle du « Patient comme thérapeute symbiotique » : « Le souci de produire un effet essentiellement psychothérapeutique sur autrui n'est pas l'apanage des personnes relativement peu nombreuses qui choisissent de pratiquer professionnellement la psychanalyse ou la psychothérapie : c'est un souci fondamentale et présent en tout être humain »[18]. C'est ce que Pierre Delaunay nomme « le syndrome de Searles ou syndrome de compassion infinie » et qui consiste, de la part du petit enfant, à tenter de compléter très tôt, l'appareil psychique de l'autre, en général du parent défaillant [19].

La maladie, le handicap engagent, eux aussi, à leur façon, la question du soutien – ou de son absence – voire de la complémentation psychique. Notre démarche repère au sein des histoires familiales de nos patients de telles tendances centripètes, c'est à dire des tendances au rapprochement. Des rapprochements, certes, protecteurs mais qui « risquent de geler le développement des différents membres de la famille en les retenant dans une forme de cohésion figée » [11].

Dans cette situation clinique - à peine ébauchée - s'est révélé au fil des entretiens le potentiel énorme de transformation des personnes « en souffrance » tant sur le plan physique, psychique, comportemental et relationnel. Par exemple, ce couple dont nous avons abordé la problématique, réalise bien la place importante que prend la symptomatologie de Christophe. D'autres couples auraient craqué dans cette situation et sans doute que l'examen détaillé de ces situations que nous pourrions considérer comme des échecs – comme des « contrariétés » [11] - devrait attirer encore davantage notre attention.

En ce qui concerne Christophe et Christine, l'éprouvé douloureux de l'un et l'autre semble renforcer leur alliance, même si parfois, l'impuissance, la culpabilité, le découragement, l'angoisse, la fatigue sont là bien présents. La narration de leurs traumas respectifs et l'écoute mutuelle des impacts émotionnels sur leur relation, permet des liens proches, générateurs d'un sens commun. Un processus de sublimation est quasiment exprimé à plusieurs reprises par Christophe : « je suis heureux de cet handicap, qui me permet de m'intérioriser, d'être plus

proche de la nature..…. C'est un mal pour un bien ! ». Jean Paul Sartre : « la liberté c'est ce que nous arrivons à faire avec ce qu'on nous a fait ». Un tel chemin de la liberté passe selon nous par la question de la prise en compte – et si possible de son analyse - du transfert interne, c'est à dire que Pierre Delaunay formule, dans une tournure mnémotechnique toute winnicottienne se référant du Holding : « on se porte comme on a été porté » [19].

Cette trop brève évocation clinique témoigne aussi, à sa façon, de l'évolution des regards que les approches systémiques ont porté sur la causalité dans le traitement des maladies ; après une phase historique initiale durant laquelle se posait la question « qui fait quoi à qui ? », est advenue la question : « qu'est ce que ces deux là - ceux-là - font ensemble ? », pour parvenir finalement à inclure les membres du système de soins dans le questionnement : « que faisons nous – soignés et soignants - ensemble ? ». Nous savons, en effet, que l'évolution clinique des patients chroniques est co-déterminée par la rencontre et l'histoire qui se nouent entre eux et leurs systèmes d'appartenance c'est à dire entre leur système « soigné » (organisme, patient, famille) et le système de soins. Notre démarche consiste à repérer les niveaux des règles de communication aux seins de ces différents systèmes et de ce que l'un importe de ces règles de fonctionnement dans les autres [20].

De tels entretiens familiaux prennent le chemin de la « thérapie familiale » et sont bien de première importance dans notre structure de SSR. En effet, si la médication chimique est essentielle évidemment pour calmer des douleurs parfois insupportables- voire paralysantes -, elle contrarie aussi certains patients qui craignent l'inscription dans une dépendance, les plaçant ainsi dans un rôle passif. C'est pourquoi, les soins psychiques (incluant la compréhension des phénomènes, et la quête de sens], permet aux patients de retrouver un rôle actif dans le travail de faire face à leurs douleurs.

Quel est l'effet de cette prise en charge dans une optique pluridisciplinaire basée sur la mise à disposition pour le patient de ces différents outils de résilience à un niveau biomécanique (tiges de composite), musculaire et comportemental (rééducation), psychologique… ? [21] Le pourcentage de reprise opératoire à deux ans pour les scolioses de l'adulte est aux environs de 50 pour cent dans une série de la littérature récente. Notre statistique pour le même type de patients est à moins de 10 pour cent avec des reculs maximas de 5 ans. Le seul facteur de variation de notre série par rapport à celle de la littérature est l'introduction de cette prise en charge pluridisciplinaire. Il est donc permis de penser que ces outils de résilience pluridisciplinaire représentent des moyens très puissants dans leur association, permettant de réduire très significativement la morbidité post-opératoire, toutes choses étant égales par ailleurs. Nous nous posons toujours la question de savoir si cette expérience peut s'étendre à d'autres pathologies ? Nous avons de nombreuses observations de patients qui, à l'issue de cet accompagnement nous montrent que des traitements médicaux pour le diabète, l'hypertension artérielle ont pu être allégés ou même interrompus au fur et à mesure de cet accompagnement, initialement destiné à la prise en charge du mal de dos.

Conclusion

Le patient, progressivement, est ainsi invité à prendre conscience des multiples facteurs, physiques, émotionnels, psychologiques, éducatifs, culturels, familiaux… qui dans sa structure personnelle globale devenue trop rigide, l'ont amené à déclencher ce problème de mal de dos. La résilience est donc pour nous la capacité qu'il nous est donné, par la compréhension de ces mécanismes intriqués, de transformer les facteurs complexes de notre passé ayant contribué à la décompensation de notre santé, ici sur un plan initial plutôt physique. La résilience est la compréhension devenue progressivement consciente, de nos mécanismes structurels rigidifiés par les multiples expériences et habitudes du passé. Cette prise de conscience progressive permet alors l'utilisation positive de ces mécanismes structurants, mais adaptée aux circonstances du présent, vers un mieux-être dans notre présent sans cesse renouvelé.

Abstract

The Gilles de la Tourette (SGT) síndrome is a rare neuropsychiatric trouble, representing the most severe form for the stereotype (tic) illness. The sternness of the symptoms goes from light forms to the most severe clinical description associated with invalid psychiatric troubles. On a family plan, Lee et al. (2007) are the only ones, who worked on the parents' restraint to control a SGT, taking into evidence the anxiety troubles allied to a weak self esteem of the parents with such children. We also wanted to study the cognitive perceptions – perceived stress and perceived social support – of the parents having a child with the SGT, these ones having probably an impact on the copying strategies. The analysis of the main component shows that the social support is the strongest predictable variable, that is negatively correlated with the perceived stress (on the Axe no.1) but positively correlated withe coping strategies for emotion and problema (on Axe no.2). We discuss our results on puttind in evidence a possible social support, like a protection element, leading to a process of family resilience.

Key words: Gilles de la Tourette syndrome, social support, family resilience.

Introduction

Le syndrome Gilles de la Tourette (SGT) est un syndrome neuropsychiatrique rare, représentant la forme la plus sévère de la maladie des tics. Les tics sont des mouvements ou des vocalises simples ou complexes s'exprimant de manière brève, stéréotypée et répétitive. Le SGT débute pendant l'enfance, avec un pic à l'âge de 6-8 ans [1]. Il est 4 fois plus fréquent chez les garçons que chez les filles. La sévérité des symptômes va de formes légères sans retentissement marqué sur la scolarité et l'intégration sociale, aux formes les plus sévères, souvent associées avec des troubles psychiatriques comme des troubles obsessionnels–compulsifs, une hyperactivité et des troubles de l'attention, des actes d'automutilation ou une perte de contrôle de l'agressivité (crises de rage). Les caractéristiques épidémiologiques de la maladie sont encore aujourd'hui mal connues. Les chiffres disponibles sont très variables, dépendant de l'âge au moment de l'évaluation, et des difficultés diagnostiques liées à la variabilité et à l'hétérogénéité de la présentation clinique. L'incidence et la prévalence varient en fonction du choix de la population et sont respectivement 0,46/100 000 et de 0,5 à 23/10 000 [2], [3]. Dans 50 à 70% des cas, les tics sont initialement moteurs et débutent au visage ou à l'épaule et au cou. En revanche, les tics vocaux ne sont inauguraux de la maladie que dans 12 à 37% des cas [4], [5], la coprolalie restant le symptôme le plus marquant, bien que pas le plus fréquent [6]. Les tableaux cliniques restent cependant souvent déconcertants pour l'entourage et peuvent être à l'origine d'un rejet familial et scolaire, conduisant à l'isolement social puis plus tard professionnel de patients pourtant majoritairement indemnes sur le plan cognitif.

Cependant, si les retentissements du trouble sont lourds pour la personne atteinte, les impacts familiaux ne sont pas à négliger. Une revue de la littérature internationale montre cependant que peu d'études ont été menées dans ce domaine. Les recherches réalisées tendent pourtant toutes à montrer une souffrance dans ces familles, avec la présence accrue chez les parents de troubles anxieux associés à une faible estime de soi [7]. Cet état de fait renforce les résultats d'une étude plus ancienne [8] argumentant en faveur d'une prise en charge thérapeutique dans ces familles. Plus récemment, Robinson et al. [9] ont réalisé une étude basée sur le modèle écologique [10] et l'approche transactionnelle du développement [11] auprès de parents ayant un enfant atteint

de SGT. Les auteurs postulent que les problèmes rencontrés dans ces familles sont prioritairement liées à des compétences parentales peu stables, cette difficulté étant exacerbée par une stigmatisation sociale liée à la croyance – erronée - que les tics sont des symptômes facilement contrôlables voire volontairement provoqués. Les résultats de l'étude soulignent à nouveau des niveaux de stress et d'anxiété importants chez ces parents ainsi qu'une difficulté émotionnelle à gérer et exprimer leurs difficultés. Robinson et al. insistent aussi sur l'importance des troubles comorbides qui cumulent avec la symptomatologie déjà lourde du SGT. Enfin, les auteurs confirment, à la suite d'autres travaux [12], le risque accru de maltraitance possible du jeune atteint lorsque le stress et la perception parentale du trouble sont respectivement lourd et menaçante [13]. En effet de nombreux modèles ont montré que c'est bien la *perception du stress* (stress perçu) et non les caractéristiques réelles de la situation stressante qui sembleraient essentielles à prendre en compte chez l'individu, pour pouvoir lui apporter une aide fiable [14], [15]. De même, le soutien social - le fait de se sentir soutenu, écouté, compris ou encouragé - renforcerait et maintiendrait les ressources des sujets [16], [17]. De plus, le soutien social modérerait les effets du stress perçu et précéderait les stratégies de faire face (le coping) en affectant leur élaboration [18]. Partant de ces paradigmes en psychopathologie développementale et psychologie de la santé, ainsi que de la littérature dans le SGT, l'objectif de notre étude a été d'étudier l'impact des *perceptions cognitives* des parents ayant un enfant atteint de SGT - spécifiquement le *stress perçu* et le *soutien social* - sur la mise en place de leurs stratégies de coping.

Méthode et outils

1.1 Participants et procédure

L'étude a été réalisée au "Centre de Référence Syndrome Gilles de la Tourette" à l'hôpital La Pitié Salpêtrière (Paris, France). Le comité d'éthique de la Pitié-Salpêtrière a donné son accord pour l'étude. Tous les participants ont signé un formulaire de consentement éclairé.

1.1.1 Les parents:

L'étude a été proposée aux deux parents de l'enfant venus consulter pour un diagnostic et/ou un suivi de SGT. Une famille était inclue à partir du moment où l'un des deux parents donnait son accord. Vingt-huit parents de 21 enfants atteints de SGT ont été recrutés. Il y avait 17 mères (60,8%) et 11 pères (39,1%). L'âge des parents du groupe s'étendait de 34 à 52 ans (moy= 43,3 ; ET= 5.2). Ils vivaient en couple à 93%, les autres parents étant divorcés. Au plan professionnel, 2 parents sur 28 (7,1%) étaient en recherche d'emploi et 3 (10,7%) étaient parent au foyer (un homme et 2 femmes). (21 parents sur 28 appartiennent aux catégories socioprofessionnelles 2-3-4 respectivement artisants-cadres-professions intermédiaires.)

1.1.2 Les patients:

Les patients étaient âgés de 6 à 16 ans (m= 9,8 ; ET=) ; 81% était de sexe masculin. Ils devaient remplir les critères diagnostiques du DSM IV-TR [19] pour le syndrome Gilles de la Tourette. Les patients souffrant de troubles comorbides de type psychotique ou de troubles autistiques étaient exclus.

1.2 Echelles cliniques

La version française de l'« *Hospital Anxiety and Depression Scale*» (HAD) [20] a été utilisée afin de coter les niveaux d'anxiété et de dépression. Le stress perçu a été mesuré par la version française de l'«*Apraisal of Life Events Scale*» (ALES) [21]. Cette version contient trois facteurs, décrits par 14 adjectifs sélectionnés en référence aux formes d'évaluation primaire d'un stresseur : la perte, la menace, le défi. Le soutien social a été évalué à l'aide du «*Social Support Questionnaire*» (SSQ6) [22]. Il permet de coter à la fois le *réseau social*, c'est-à-dire le nombre de personnes données comme étant disponibles pour aider et soutenir le sujet; puis le *soutien social perçu* qui est le degré de satisfaction ressenti par le sujet pour l'aide et le soutien reçu. Les stratégies de coping ont été évaluées à l'aide de la version française de la «*Way of Coping Checklist-Revised»* (WCC-R) [23] selon la perspective transactionnelle de Lazarus et Folkman [18].

Résultats

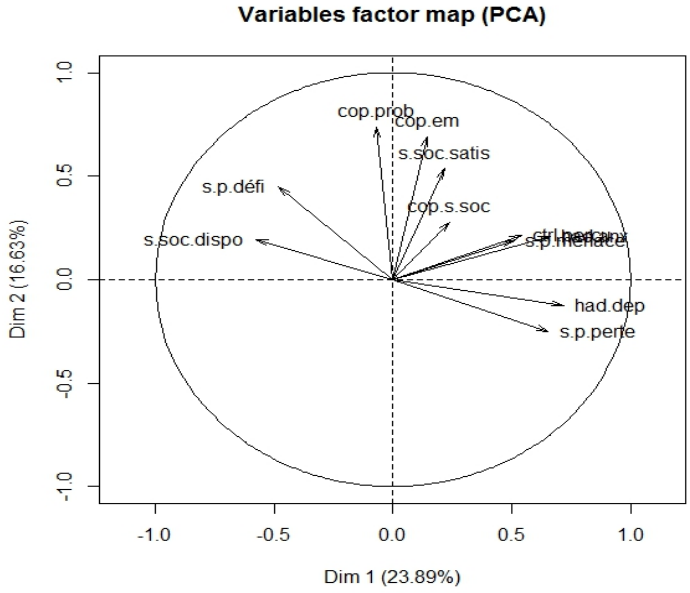
Une analyse en composante principale (ACP) a été menée, permettant de décrire les données du point de vue des variables. Au plan de l'analyse descriptive des résultats, les thématiques les plus souvent évoquées comme événements stressants par les parents dans l'ALES étaient: *i*) les questions scolaires; *ii*) la peur ressentie face à des crises de rage importantes; *iii*) savoir si l'impulsivité constatée chez les enfants relevaient du troubles

ou d'autre chose. Concernant les résultats de l'HAD, 12 parents (43%) ont un score global égal au moins à 13, équivalant à un problème adaptatif. De plus 5 d'entre eux ont un score supérieur ou égale à 19.

1.3 Résultats de l'ACP (pour les variables)

Axe1 horizontal: L'axe 1 transcrit une opposition (corrélation négative) entre d'une part le groupe de variables dépression-anxiété, stress-perçu-perte et d'autre part la variable soutien-social-disponibilité. Ainsi plus un individu obtient un score élevé sur le premier groupe de variables, plus son score en soutien-social-disponibilité sera faible.

Axe2 vertical: Cet axe transcrit principalement les réponses des sujets sur les variables de coping (problème et émotion) ainsi que pour le soutien-social-satisfaction. Ces variables sont corrélées entre elles et comme elles se situent sur le second axe factoriel, elles sont aussi relativement indépendantes des variables décrites par l'axe 1.



Discussion

L'objectif de cette étude a été d'observer l'impact des perceptions cognitives sur les stratégies de coping de parents ayant un enfant atteint de SGT. Nos résultats montrent qu'il existe une relation entre les traits d'anxiété et de dépression observés à l'HAD chez ces parents et la variable stress perçu, pour la dimension «perte» ; de plus ce regroupement de variables est corrélé négativement au réseau social qu'ils décrivent. Ces résultats répliquent et précisent ceux d'études précédentes montrant un taux d'anxiété-dépression important chez les parents d'un enfant atteint de SGT [7]. Il a en effet été largement été démontré qu'être parents d'un enfant avec trouble avait un impact négatif sur la santé physique et psychique du ou des parents en charge de son éducation. Ceci a particulièrement été observé dans le cadre des troubles du développement, spécifiquement des autismes [24], [26]. Ainsi les difficultés d'adaptation et/ou d'humeur des parents apparaissent comme liées une perception intolérable et douloureuse du trouble de leur l'enfant. Ceci poursuit le travail de Al Anbar et al. [28] montrant que la représentation que ce font les parents du trouble de leur enfant a un impact sur leurs stratégies éducatives ainsi que sur la compliance au traitement. Nos résultats précisent ce constat en montrant que les variables thymiques sont en opposition avec le réseau social, c'est dire le nombre de personnes décrites comme présentes autour des parents. Ce résultat rejoint les travaux menés dans les familles ayant un enfant atteint de troubles autistiques, montrant qu'un faible réseau social a un impact délétère sur l'organisation et la cohésion familiale [29]. A l'inverse un réseau social décrit comme important et fiable peut devenir un facteur de protection essentiel pouvant accompagner les parents vers un processus de résilience familiale [30]. Un soutien social fort a également été associé à moins d'anxiété, de dépression et de symptômes somatiques dans ces familles [25], [27], [31]. Son rôle apparaît donc comme majeur, tant dans notre étude que dans la littérature portant sur les facteurs de protection des familles ayant un enfant atteint de trouble et/ou handicap(s).De même, nos résultats permettent la mise en évidence d'une corrélation entre les variables coping et le soutien social perçu. Ainsi, les stratégies de coping centrées sur le problème et sur l'émotion sont liées à la disponibilité perçue

des personnes qui entourent ces parents. Il apparaît donc qu'une relation existe entre la mise en place de stratégies adaptatives autour du trouble de l'enfant et la satisfaction retirée du réseau social. Mais il est surtout intéressant de remarquer que ces variables sont indépendantes de celles décrites précédemment (sur l'axe 1), et que les stratégies de coping ne semblent donc pas dépendre du stress perçu et/ou de troubles de l'humeur. Si ces résultats peuvent à priori surprendre, d'autres études – prenant un point de vue développemental - ont en effet montré que les parents parvenaient au fil des années à mettre en place des stratégies de coping adaptées, construisant et reconstruisant ainsi de nouveaux aménagements dans leur vie [32]. Nos résultats nous amèneraient dès lors à conclure à une relative indépendance entre la perception du trouble de l'enfant et les stratégies adaptatives mises en place par ces parents. Il apparaît également que le soutien social, tant sur sa dimension quantitative (réseau) que qualitative (disponibilité), est une variable essentielle à un fonctionnement plus positif dans ces familles. Ainsi, nos résultats invitent à axer les actions préventives sur la détection de difficultés liées à un réseau social faible et/ou peu adapté aux circonstances vécues par ces parents [33]. La promotion d'une résilience familiale semble liée à la présence de cette variable qui devient dès lors un facteur de protection important, évitant le stress et l'anxiété, par un soutien adapté, voire même comblé sur le plan médico-social et associatif. En effet, les liens sociaux (tant au plan familial, amical qu'auprès des praticiens de santé) évitent l'isolement (ou le sentiment de l'être) et participent à la mise en place de stratégies visant à s'adapter à des conditions de vie parfois très douloureuses, surtout lorsque cela touche son propre enfant.

Abstract

In the nowadays society, the sociodemographic mutations reach an evolution of the family structures where more generations meet. The studies presented bring, on the evaluation of the effects of an intergenerational activity, the family legend, that allows to the person to find an active place in his environement, by the transmission of the family history, of the experiences and abilities, the development of the narrative identity and of the generative principle. The objective of the study is to present the impact of the legend, on one side, on the quality of life of 23 old persons, marked or no, by the cognitive troubles, and on the other side, on the perception they have about their health. The comparison of the results obtained due to the questionnaires and meetings, in pre-tests and post-tests, have showed effects attended on the improvement of the quality of life, but also on the complementary effects. That is, an improvement of the perception of the quality of sleep, a perception of diminution of the pain, a diminution of the negative emotional reactions, a better mobility, an improvement of the energy and a qualitative and quantitative improvement of the family relationships. The family legend seems to be propice for the development of the resilience, for the capacity of a positive developement, in spite of the life obstacles met (Cyrulnik, 1999). This instrument also allows the promotion of the family resilience assuring the well being psycho-physic, of the subjects, by maintaining the recuperation of the family dynamic (Dujardin, 2013).

Key words : to get old, intergenerational, family legend, quality of life, resilience.

Introduction

1.1 *L'intergénérationnel, vecteur de résilience*

Les relations intergénérationnelles ont connu des modifications sous l'effet des transformations démographiques, culturelles et sociales. La structure familiale connaît également des remaniements [1]. Ainsi, suite à une augmentation de l'espérance de vie et à une baisse du taux de natalité, la famille étendue dite « large » laisse place à la famille réduite dite « allongée » où quatre à cinq générations se côtoient [2].

L'intergénérationnel s'inscrit au sein d'un arc de vie, un continuum au sein duquel l'ensemble des générations s'interpellent [2]. Selon Everarts, il renvoie à un concept transversal et temporel, englobant le passé, le présent ainsi que le futur [3]. De ce fait, « *l'intergénérationnel, en faisant se côtoyer et se découvrir les générations, est une manière de lutter contre les stéréotypes du vieillissement. En mettant l'emphase sur la richesse de l'expérience de vie, il aide les personnes âgées à affirmer leur place d'acteur dans la société.* » [3]. Les projets intergénérationnels sont dès lors perçus comme une alternative à la potentielle rupture du lien entre les diverses générations évoluant au sein d'une société confrontée au vieillissement de sa population [4].

Les programmes d'activités intergénérationnelles, basés sur une logique de don et contre-don, présentent de multiples avantages pour les aînés. En effet, ils permettent notamment de lutter contre l'exclusion sociale liée au processus de vieillissement, de contribuer au maintien d'activités valorisantes, du sentiment d'utilité sociale, des capacités cognitives, d'améliorer le sentiment de satisfaction, la résistance aux situations de stress, l'empathie et la tolérance envers autrui [5]. En côtoyant des personnes plus jeunes, les personnes âgées disent changer de point de vue sur ces derniers mais également sur eux-mêmes. En effet, ils affirment pouvoir prendre davantage conscience de leurs propres valeurs et expriment une meilleure estime d'eux-mêmes [6]. De plus, les aînés inscrits dans une dynamique intergénérationnelle font preuve d'une plus grande vitalité, d'une meilleure humeur et d'une motivation accrues, les rendant plus forts face à l'adversité. Ainsi, leur capacité à faire face aux difficultés liées à la santé physique ou mentale s'avère, à son tour, plus élevée [6].

Ces implications rejoignent le concept de résilience que Cyrulnik définit comme « *la capacité à réussir, à vivre et à se développer positivement, de manière socialement acceptable, en dépit du stress ou d'une adversité*

qui comporte normalement le risque grave d'une issue négative. » [7]. Il s'agit dès lors d'un potentiel actualisable tout au long de l'existence [8]. Dans une dynamique interrelationnelle, des auteurs se sont également penchés sur le concept de résilience familiale qui vise à assurer le bien-être psycho-physique de l'individu et celui des membres de sa famille. Pour ce faire, plusieurs stratégies de rebondissement sont énoncées telles que le maintien du fonctionnement familial ou la récupération de celui-ci [9].

1.2 L'histoire familiale, un conte à transmettre

La théorie du développement psychosocial de l'être humain énoncée par Erikson (1950) s'articule autour de huit stades cruciaux allant de la naissance à la mort : la confiance, l'autonomie, l'initiative, la créativité, l'identité, l'intimité, la générativité et l'intégrité. La septième étape du cycle de vie porte sur le concept de générativité que l'auteur définit comme la préoccupation quant à l'établissement et aux conseils à l'intention des générations futures [10].

Ainsi, « *dans leurs multiples rapports au passé, tels qu'ils l'incarnent aux yeux de leurs petits-enfants, les grands-parents sont donc des historiens à demeure et aussi les détenteurs de la mémoire familiale et de la mémoire collective jusqu'à en être les déverrouilleurs* ». Ils présentent dès lors pour fonction «*d'offrir aux petits-enfants l'assurance d'une identité enracinée pour eux dans un temps immémorial. Aujourd'hui, les grands-parents ne sont pas les créateurs du lien familial (ce qui appartient aux parents), mais ils en sont la caution, les garants* » [11].

La générativité peut s'exercer par le développement d'un projet intergénérationnel basé sur la rédaction d'un « conte familial » qui inscrit les membres de la famille dans le temps et dans un ordre hiérarchique. Ce média, vecteur de l'expérience humaine [12, 13], permet aux sujets de prendre de la distance, de symboliser des problèmes, conflits et émotions négatives [14]. Cette tradition orale et collective réunit aussi les uns avec les autres, mais également « *chacun en chacun et chacun à chacun* » [12] dans une fonction unificatrice.

Il contribue à l'émergence de l'expression narrative qui se définit comme un outil de résilience permettant de recouvrir une cohérence personnelle et de soutenir les relations nouvelles [9]. Chez les aînés, cette identité narrative est plus forte qu'aux autres étapes de l'existence car ils ont repensé, raconté, cherché à saisir, écrit, évoqué et l'âge avançant, désirent ardemment comprendre les expériences vécues. De ce fait, l'affect et le sens, concepts de référence de la résilience, sont plus vivants que jamais [15].

Méthodologie

Le conte familial a été co-construit avec l'aide d'un psychologue rencontré à 3 reprises pendant 45 minutes :

- première rencontre : choix d'un univers, d'un personnage et constitution de l'arbre généalogique
- deuxième et troisième rencontres : conversion des souvenirs, des anecdotes vécues sous forme de conte écrit et illustré.

1.1 Questions de recherche

Nos deux recherches s'articulent autour de deux questions de recherche :

- L'activité « conte familial » a-t-elle un effet bénéfique sur la perception de la santé de la personne âgée présentant ou non une démence ?
- L'activité « conte familial » a-t-elle un effet bénéfique sur la qualité de vie de la personne âgée présentant ou non une démence ?

1.2 Echantillon

Notre échantillon occasionnel comprend 23 familles composées de trois à quatre générations et seize professionnels paramédicaux.

Sept familles comptent un grand-parent – sujets âgés de 70 à 85 ans - exempt de trouble cognitif majeur dont deux vivent en maison de repos.

Seize familles comptent un aîné - sujets âgé de 70 à 93 ans - présentant un score inférieur à 24 au Mini Mental State Examination (MMSE) indiquant une suspicion de démence. En effet, les personnes âgées présentant des troubles cognitifs ont obtenu un score compris en 13 et 21. Sept d'entre eux évoluent en maison de repos.

1.3 Outils d'évaluation

Dans un dessein quasi-expérimental avec pré-test et post-test, notre échantillon a rempli quatre questionnaires avant et après la co-construction du conte familial :

- Indicateur de Santé Perceptuelle de Nottingham (ISPN) : évaluation de l'auto-perception de l'état de santé et de la qualité de vie liée à la santé.
- Index de Satisfaction de Vie du Troisième Age (LSITA) : évaluation du niveau de satisfaction de vie des sujets sans trouble cognitif majeur.
- EQ – 5D : évaluation de la qualité de vie des personnes avec troubles cognitifs accompagnées d'un soignant. Le questionnaire comprend une évaluation standardisée à cinq dimensions et une échelle visuelle analogique [16].
- Échelle de Mesure des Manifestations du Bien-Être Psychologique (EMMBEP) : évaluation de niveau de satisfaction de vie des personnes avec troubles cognitifs accompagnées d'un soignant.

L'élaboration du conte familial a également fait l'objet d'une observation participante.

Les aînés sans troubles cognitifs ont participé à un entretien semi-directif. Les membres de la famille des personnes âgées désorientées ont, quant à elles, rempli un questionnaire de satisfaction relatif au déroulement et aux apports du projet intergénérationnel.

Résultats

1.1 Personnes vieillissantes sans trouble cognitif

L'analyse des résultats à l'ISPN révèle une meilleure perception de la santé par les aînés après la réalisation du conte familial. En effet, l'échantillon présente une amélioration qualitative et quantitative du sommeil. Ainsi, les aînés affirment avoir plus de facilités pour s'endormir (N=3), se rendormir (N=4), déclarent avoir un sommeil de meilleure qualité (N=3). Cinq aînés révèlent également de meilleures réactions émotionnelles et trois expriment une amélioration dans les items relatifs au courage et à l'énergie. Quatre sujets témoignent d'une douleur physique moindre et d'une meilleure mobilité. Finalement, deux familles affirment une augmentation de la fréquence des visites des petits-enfants.

Les résultats à LSITA indiquent que six personnes âgées présentent des scores relevant d'une meilleure satisfaction de vie après la réalisation de l'activité intergénérationnelle. La septième témoigne, quant à elle, d'un effet plafond élevé.

L'analyse des entretiens semi-directifs a mis en évidence, pour deux sujets, une meilleure communication entre les différentes générations, la dissipation de certains malentendus et la (re)construction de nouveaux liens affectifs. Les solidarités familiales présentes au sein de la famille ont également été mises en évidence. Ce résultat rejoint la conclusion selon laquelle « *pour que l'échange atteigne une dimension réelle, il faut que les deux échangeurs soient au clair quant à sa nature et son extension et puissent le reconnaître mutuellement* » [16].

1.2 Personnes vieillissantes présentant des troubles cognitifs

L'analyse des résultats à l'EMMBEP a montré un gain positif de 14% selon les professionnels et de 10% selon les aînés et ce, principalement pour les sujets évoluant en maison de repos.

Les résultats de l'ISPN et de l'EQ-5D présentent une augmentation de la qualité de vie et de la santé subjective de l'ensemble des sujets, perçues tant par les personnes âgées que par l'aidant professionnel. L'EQ-5D a, quant à elle, montré une perception moindre de la douleur et l'anxiété par les séniors. Les scores de l'ISPN ajoutent la présence d'une réduction des réactions émotionnelles « négatives » et une amélioration du sommeil.

L'observation participante a mis en évidence un échange verbal et/ou non verbal accru de la personne âgée qui suscitait l'intérêt des autres générations soucieuses d'en connaître davantage sur leur histoire familiale. L'enquête de satisfaction a, quant à elle, attesté d'un engouement éprouvé par les familles et ce, principalement dans le cas d'un aîné résident en maison de repos. Selon les participants, le conte familial permet de renouer le lien avec le parent, de transmettre des faits inconnus de l'histoire familiale et des émotions positives.

Discussion

L'analyse des résultats montre un effet positif du conte familial sur la satisfaction de vie et la santé perceptuelle des aînés présentant ou non des troubles cognitifs. Ainsi, l'échantillon a déclaré une amélioration de son sommeil, une perception moindre de la douleur et une diminution des réactions émotionnelles négatives

telles que l'angoisse et l'anxiété. Ces résultats confirment certaines dimensions préalablement énoncés dans la revue de la littérature telles que l'amélioration du sentiment de satisfaction et la résistance au stress [5]. Cette capacité à se développer positivement en dépit de l'anxiété, de l'adversité renvoie, dans une certaine mesure, au concept de résilience définit par Cyrulnik [7]. L'observation d'une amélioration de la communication et de la dynamique familiale peut également être mise en relation avec une hausse de l'empathie, de la tolérance envers autrui [5] susceptibles, in fine, d'améliorer la prise de conscience de sa propre valeur et l'estime personnelle [6]. Offrir la possibilité à la personne âgée de transmettre son expérience, d'exprimer son identité narrative [15] lui permet également de réaffirmer son vécu, de lui donner du sens [7] et donc, de cheminer vers la résilience [15].

Le programme intergénérationnel a aussi favorisé l'émergence de conflits, de malentendus familiaux enfuis et l'union des sujets [12]. Il a contribué à assurer leur bien-être psycho-physique par le maintien voire la récupération de la dynamique familiale [9]. En conclusion, nous pensons que le conte familial peut être non seulement vecteur de résilience individuelle, mais également de résilience familiale.

Conclusions et perspectives

Dans le contexte sociodémographique actuel, les grands-parents ont davantage l'opportunité de se créer une place plus importante dans la vie de leur(s) petit(s)-enfant(s) et ce, au fil des générations. L'intergénérationnel s'immisce dès lors dans le cercle privé. A ce titre, nous avons développé un outil intergénérationnel, le conte familial qui, toute proportion gardée, a présenté un effet positif sur la santé perceptuelle et la qualité de vie des aînés. En outre, alors que la vieillesse se voit fréquemment associée à des pertes, déclins et stéréotypes, nos résultats laissent penser que le projet permet de contribuer au développement de leviers pour la résilience tant individuelle que familiale.

En prolongement de nos résultats, il conviendrait d'étudier davantage les effets de l'activité intergénérationnelle sur l'aîné et ce, en ayant recours à une observation systématisée de la communication non-verbale et à la confection d'une boîte à outils contenant notamment un guide pratique, le matériel nécessaire et une méthodologie validée destinée aux professionnels. Celle-ci présenterait l'outil et ses spécificités liées au public-cible. En effet, au cours de notre recherche, si le conte s'est révélé être un vecteur adéquat de la transmission familiale, il s'est avéré complexe pour certaines personnes souffrant d'une désorientation de narrer leur histoire de vie sous la forme traditionnelle du conte. Des formations continues centrées sur l'utilisation de ces outils permettraient également de sensibiliser les professionnels à l'importance de l'intergénérationnel dans le cycle de vie ainsi qu'au sein de la dynamique familiale et communautaire.

La notion de transmission au coeur de la parentalite des parents entendants d'un enfant atteint de surdite et implante cochleaire : quelle resilience possible ?

Lovato M.-A., Goussé V.

Aix-Marseille Université, LPS EA 849, 13621, Aix-en-Provence, France

Abstract

Parent – child relationship woven over the years leads each character in an infinite trading system where the notion of transmission becomes central, parents are the owners of a family culture to pass on to their children as themselves have received from their own parents. The transmission is available on several levels, as unconscious as conscious: in the latter case, it is the intergenerational transmission operating mainly through language and in particular the language considered as a communication tool.

Some parenthood as hearing parents of deaf children raise questions about communication and transmission between various protagonists. The difference in hearing sensory of the child and parents, represent an obstacle or an interruption in the transmission by a common language. Thus, we wanted to examine the place of cochlear implantation in the maintenance and continuation of intergenerational transmission in these families. Semi -structured interviews given to 20 parents show how the cochlear implant for their child beyond profits in language, developed family interactions, not just repair deafness but restore the axes of their parenting. In fact, the variability of the status of the implant from the risk factor of protection is discussed in relation to a resilience process from these families.

Keywords: hearing parents and deaf children, cochlear implant, intergenerational transmission

Introduction

La relation parents-enfant tissée au fil des années depuis le désir d'enfant entraîne chaque protagoniste dans un système infini d'échanges où la notion de transmission devient centrale, les parents étant les détenteurs d'un leg à transmettre à leur enfant comme eux- mêmes l'ont reçu de leurs propres parents et ainsi perpétuer un continuum existentiel. La transmission se décline sur plusieurs niveaux, tant inconscients, on parle de la transmission transgénérationnelle que conscients, il s'agit alors de la transmission intergénérationnelle. Ainsi, les parents s'engagent à léguer un héritage biologique, mais aussi familial et social à leur enfant. Plus précisément, cette transmission, intergénerationnelle, opère la plupart du temps par le langage et notamment la langue considérée telle un outil de communication.

Certaines parentalités comme les parents entendants d'un enfant sourd suscitent à bien des égards des interrogations relatives à la relation, la communication et la transmission entre les divers protagonistes. A ce sujet, force est de constater, l'apport prolifique de la littérature scientifique qui dépeint cette parentalité de manière négative, interrogeant par là même la capacité à savoir-faire et être les parents de l'enfant. En effet, la différence sensorielle auditive de l'enfant et des parents, caractéristique centrale de cette constellation familiale, représenterait une entrave, voire une interruption dans la transmission au moyen d'une langue commune des parents à leur enfant. En outre, l'implantation cochléaire intervient de plus en plus tôt dans sa vie et celle des parents, un dépistage précoce de la surdité étant pratiqué dans les trois premiers jours suivant la naissance de l'enfant. Actuellement, l'enfant sourd est implanté très tôt dans sa vie ; pour exemple, un bébé peut bénéficier de l'implant cochléaire dès l'âge de six mois. De fait, la relation parents-enfant se construit très rapidement en présence de l'implant cochléaire. Bon nombres d'études tant en France [1] qu'outre-atlantique [2] ont démontré l'efficacité de l'implant cochléaire sur la communication et les habiletés sociales de l'enfant sourd mais également sur la qualité de vie familiale. Aujourd'hui, il n'est pas rare de voir un enfant bi-implanté [3] avec des résultats tout à fait satisfaisants notamment dans l'amélioration de l'audition dans les milieux bruyants ce qu'un seul processeur ne permet pas. Même si l'efficacité de l'implant cochléaire a été maintes fois vérifiée au plan

médical, nous avons voulu interroger le point des vue des parents sur sa place, son rôle dans le maintien et la poursuite de la transmission intergénérationnelle au sein de ces constellations familiales.

Méthodologie:

Dans le cadre de cette étude, l'approche méthodologique retenue est qualitative se basant sur l'étude de cas, plus précisément sur l'étude de cas spécifique à une situation, «*situation analysis*» [4]. En l'occurrence, il s'agit d'une situation familiale où un enfant est atteint de surdité et dont les parents ont fait le choix de l'implantation cochléaire. Le recrutement de la population a eu lieu auprès de l'Unité Pédiatrique d'Implantation Cochléaire de Toulouse dédiée à la période post-implantatoire durant laquelle le réglage de l'implant cochléaire revêt une importance capitale. Au préalable, chaque parent a été informé du thème de l'étude et de son déroulement, puis a signé un consentement éclairé. Ainsi, dix couples de parents entendants d'un enfant sourd ayant bénéficié de l'implantation cochléaire ont été sollicités au moyen d'entretiens semi-directifs.

Pour explorer ce qui relève de la transmission intergénérationnelle au sein de ces constellations familiales, le temps depuis l'implantation cochléaire est apparu telle une variable incontournable.

De fait, ce temps équivaut à une durée de plus de 5 ans, offrant ainsi aux parents un regard distancié relatif à leur «*chemin*» parcouru dans la relation avec leur enfant.

Population:

Le groupe de parents recruté dans le cadre de cette étude se compose de dix couples de parents entendants d'un enfant sourd implanté. Pour respecter la variable temporelle évoquée ci-dessus, l'âge de l'enfant se situe sur un intervalle de 9 à 12 ans, implanté donc depuis plus de 5 ans. Parmi les dix couples sollicités 9 mères et 7 pères ont répondu favorablement à notre demande.

Procédure:

Les entretiens semi-directifs d'une durée d'une heure ont été structurés par quatre questions relatives au choix de l'implant cochléaire, son apport dans la vie de l'enfant et des parents et son rôle dans la transmission intergénérationnelle. Plus précisément, la première question : « *Pourquoi avoir choisi de faire implanter votre enfant* ? » vise à interroger l'aspect « décisionnel » des parents, leur positionnement par rapport à l'implant cochléaire. En effet, après l'annonce du diagnostic de surdité de l'enfant plusieurs alternatives sont présentées aux parents comme les appareillages, prothèses numériques dans un premier temps si possible ; sinon l'implant cochléaire et les moyens de communication tels la Langue des Signes Française, le Langage Parlé Complété. La deuxième question: « *Selon vous et avec le recul quels sont les bénéfices de l'implant cochléaire* ? » invite les parents à évaluer l'apport de l'implant dans la vie de l'enfant et dans celle de la famille. La troisième question:« *Comment concevez-vous l'avenir de cet implant dans la vie de votre enfant* ?» sollicite les parents dans une projection vers l'avenir. En outre, la notion de transmission émerge dans le sens où ce que les parents ont choisi pour leur enfant peut plus tard être remis en question par ce dernier. Enfin, la quatrième question : « *Que pensez-vous lui avoir transmis en qualité de père/de mère*? » aborde de manière plus ciblée et centrale la transmission intergénérationnelle et suggère par là même le rôle de l'implant cochléaire dans cette transmission.

Résultats:

Au vu des entretiens semi-directifs, se dégagent deux dimensions qui seront développées ci-dessous.

1.1 L'implant cochléaire, un projet des parents pour l'enfant

L'annonce du diagnostic de surdité de l'enfant provoque incontestablement chez les parents l'effet d'un traumatisme laissant place souvent à une sidération. Une mère relate à ce sujet : « *Ah quand on prend ça en pleine figure, moi je me suis effondrée même si on s'en doutait un peu, j'ai pleuré, j'arrêtais pas de pleurer…, c'était impossible…* ».Vient ensuite pour les parents ce temps de réflexion relatif aux choix à réaliser pour l'avenir de leur enfant. Cet espace temporel est très souvent mis à profit pour des recherches en tout genre, un père expliquant : « *Nous, on avait besoin de savoir où on allait, on a cherché sur internet, on a rencontré des enfants implantés, on a discuté avec leurs parents, on est allé dans une association de Sourds, eux ils sont pas pour l'implant, mais bon voilà quoi, nous on avait toutes les infos en main…* ». De fait, la décision de faire implanter leur enfant s'inscrit dans une dimension de *projet* des parents, une décision que l'on peut qualifier d'éclairée au regard des stratégies d'adaptation instaurées : « *Une fois qu'on a eu toutes les infos, on a décidé, on*

leur a dit qu'on voulait faire implanter notre fille, c'était notre choix, on voulait lui donner le meilleur pour l'avenir et pour nous c'était possible avec l'implant… »

Vient ensuite la période post-implantation explorée en l'occurrence par l'évaluation selon le point de vue des parents, des bénéfices de l'implant cochléaire. Avec un recul de plus de cinq ans, les parents sollicités dans le cadre de cette étude, ont tendance à être satisfaits des résultats en matière de communication au sein de la famille, d'interactions sociales mais également au niveau des apprentissages scolaires, de l'autonomie et de l'épanouissement de leur enfant.

A ce sujet une mère exprime l'enjeu de l'implant en matière d'acquisition de l'autonomie de son fils : « *Pour moi ce qui est hyper important c'est que ça aille au-delà de nous, c'est son autonomie, qu'il soit capable de communiquer avec n'importe qui, qu'il ne connaît pas…et aujourd'hui c'est gagné !* »

En outre et toujours dans le cadre de l'autonomie, les parents évoquent l'appropriation de l'implant par leur enfant : « *Ah, c'est son implant, il fait partie de lui…le matin au réveil, hop, il met son implant sinon, on sent qu'il n'est pas bien… quand on part, il prend le chargeur pour ne pas que son implant tombe en panne…c'est vraiment son appareil !* » ; ou « *ben mon fils et son implant c'est un tout* (rire)... ».

Les parents relèvent de même les bénéfices de l'implant au niveau du comportement de leur enfant avec notamment un apaisement des angoisses inhérentes aux difficultés d'évaluation et de compréhension : « *N. comprend bien ce qu'on lui dit, ce qui lui enlève beaucoup d'angoisses qui étaient présentes chez elle avant. Ainsi elle participe à beaucoup d'événements de la vie sociale* »

Dès lors que l'on interroge les parents sur l'avenir de l'implant dans la vie de leur enfant, les réponses apparaissent mitigées. Pour les uns, il est inconcevable de se projeter dans l'avenir sans l'implant, tellement selon eux, il est intégré au quotidien de l'enfant et à la vie familiale.

Pour les autres, ils s'en remettent au choix futur de leur enfant : « *L'implant, c'est vrai que c'était notre projet pour lui donner le meilleur dans l'avenir, mais si elle décide un jour qu'elle préfère rester sourde et signer bah… on respectera son choix mais au moins elle aura acquis toutes les armes pour pouvoir s'épanouir aussi avec les entendants.* ». Emerge en filigrane de cette dernière remarque, la notion de transmission intergénérationnelle pour laquelle l'implant cochléaire occupe une place centrale.

1.2 L'implant cochléaire au cœur de la transmission intergénérationnelle

A l'origine de l'implantation cochléaire de l'enfant se dégage une décision parentale, en somme un projet des parents. En quelque sorte, c'est comme si le parent faisait don à son enfant sourd de l'implant cochléaire, l'entraînant ainsi à découvrir le monde du bruit, des sons, de la voix, de la parole à l'instar de sa perception du monde sonore. Parallèlement, la notion de choix de l'enfant dans l'avenir apparaît centrale dans le discours des parents. A ce sujet un père explique : « *Par rapport à l'avenir, qu'elle n'ait pas de regrets de dire qu'on aurait pu l'implanter et que ça n'a pas été fait. Comme ça elle aura le choix d'entendre ou d'être sourde* ou *les deux*. ». Pour autant l'implant cochléaire ne « gomme » pas la surdité de l'enfant et les parents tendent à multiplier les échanges avec lui sur sa spécificité d'enfant né sourd ou devenu sourd issu d'une famille « d'entendants » comme si ce dialogue permettait symboliquement d'introduire la surdité dans l'histoire familiale. « *Depuis la connaissance de la surdité de N. je lui ai toujours parlé de sa surdité sans tabou pour qu'elle l'accepte comme moi je l'accepte…on a toujours répondu franchement à ses questions* » De même certains parents favorisent et maintiennent dans le temps la rencontre avec la communauté Sourde. Ainsi, un père raconte : *« …elle a besoin de la culture entendante parce qu'elle est issue d'une famille d'entendants mais elle a besoin de se retrouver avec des Sourds qui signent parce que c'est son monde à elle aussi. ».*

La notion de transmission vient faire écho à celle de socialisation au sens de Durkheim [5]. Ainsi les parents vont transmettre à leur enfant au fil de son développement, toutes les valeurs sociales et éducatives issues de leur propre culture. A ce sujet, force est de constater le rôle majeur de l'implant cochléaire devenant comme le souligne une mère « *un facilitateur* » dans la communication et dans la relation entre les parents et leur enfant sourd : « *…comme tous les parents, je crois, on lui dit ce qui est bien ce qui est mal, ce qui est interdit, autorisé, on lui explique les choses…quand elle a des questions par rapport à quelque chose qu'elle comprend pas, on lui explique mais ça sans l'implant, on ne pourrait pas ou alors ce serait très compliqué…* » ; de même : *« j'essaie de lui transmettre les règles sociales, lui apprendre l'autonomie…et mon rôle de maman, c'est de faire en sorte qu'il soit avant tout libre, capable de s'exprimer et de porter sa vie, et ça c'est rendu possible avec l'implant…*»

La transmission intergénérationnelle peut s'entendre également dans l'échange de vécus, d'émotions, de sentiments, de savoirs, de connaissances, de goûts divers. Faire découvrir à son enfant ce que l'on aime, ce que l'on affectionne, c'est lui transmettre une part de soi, de ce qui façonne notre identité : « *j'ai voulu lui transmettre mon goût pour la musique et même si elle ne discerne pas toutes les nuances, elle aime les chansons rythmées et commence à avoir ses propres goût musicaux* » ; ou « *…c'est vrai que moi, j'adore le sport, elle a pris le relais, elle aime aussi le sport, on partage beaucoup à ce niveau…* ».

Les parents de notre groupe s'expriment à l'unisson sur l'importance du rôle joué par l'implant cochléaire dans la relation et la communication avec leur enfant confortant et enrichissant par là même cette transmission intergénérationnelle vécu au quotidien.

Conclusion

L'objectif principal de cette étude qualitative visait à explorer du point de vue des parents le rôle de l'implant cochléaire dans la transmission intergénérationnelle au sein de ces constellations familiales. Au vu des résultats recueillis lors des entretiens semi-directifs, l'implant cochléaire s'inscrit dans le cadre d'un projet des parents pour leur enfant. Pour ce faire, ces derniers collectent de multiples d'informations sur divers support afin d'étayer au mieux le choix et la décision de faire implanter leur enfant sourd. Ces stratégies de recherche d'information s'apparentent à du coping centré à la fois sur le problème mais aussi sur le soutient social [6]. De plus, nos entretiens permettent d'expliciter ce constat en montrant que les parents s'approprient progressivement l'implant cochléaire pour ensuite le léguer à leur enfant qui, au fil de son développement, le fait sien à son tour.
Ce leg, tout à fait symbolique est une façon d'inviter l'enfant à goûter au même monde que celui de ses parents ce que l'on peut qualifier de *phénomène d'aperception* au sens de Virole (2003). En effet, selon cet auteur, les parents ont le sentiment que leur enfant implanté partage quelque chose du même monde perceptif qu'eux.

De même, cette étude met en exergue le rôle majeur de l'implant décrit par les parents comme « facilitateur » dans la communication et la relation au quotidien avec leur enfant. Ainsi, il vient renforcer les axes de l'exercice et de la pratique de leur parentalité [8], ces axes mis à mal par la surdité de leur enfant. Cette étude montre combien l'implant cochléaire est positionné comme facteur de protection dans la relation des parents avec leur enfant sourd offrant ainsi une qualité et une richesse dans la transmission intergénérationnelle de ces familles ou pour certaines les deux cultures entendante et sourde se côtoient. Toutefois si la taille de cet échantillon ne nous permet pas de généraliser ce constat, notre étude a néanmoins le mérite d'ouvrir des pistes de réflexion sur le sujet.

Abstract

In contemporary societies, starting a family is a legally recognized right. In fact, becoming a parent turns a choice coveted by a growing number of adults living with a disability or developmental delay. Having a child makes some of these adults reach a full and active social participation. However, several risk factors can influence the success of this project to life. For example, cooperation between parents and those involved with them are often fraught with stereotypes, prejudice, lack of understanding and openness to the reality of the other. In addition, parental stress, low socioeconomic status, difficulty in obtaining and maintaining jobs are elements to consider.

Despite this context of adversity, parents with disabilities or developmental delays succeed in developing a positive parental identity and to establish a meaningful relationship with their children. This finding emerges from a secondary exploratory analysis from interviews with nine parents. This brief article reports on protective factors that contributed to the more positive adaptation and development of resilience.

Keywords: social representations, parenting, developmental disabilities, mental slowness, resilience

Introduction

Dans les sociétés industrialisées, un nombre croissant de personnes vivant avec une déficience ou une lenteur intellectuelle (DI/LI) choisissent de devenir parents [1]. Or, l'exercice de cette parentalité singulière pose plusieurs défis en raison des stresseurs personnels, familiaux et environnementaux auxquels elles sont confrontées. Malgré la présence de tels stresseurs, certains parents font preuve d'une adaptation positive comme l'indiquent les résultats obtenus dans le cadre d'un projet doctoral ayant porté sur les représentations des parents présentant une DI/LI à l'égard de leur parentalité. Ce texte rend compte des facteurs de protection qui sont caractéristiques de l'adaptation plus positive de ces participants. Il se subdivise en quatre sections principales, soit : (1) la problématique; (2) la description de l'étude; (3) l'exploration des facteurs de protection; (4) la discussion.(Le terme DI/LI est utilisé pour référer aux personnes ayant un diagnostic établi où ayant des déficits sur les plans cognitif et adaptatif caractéristiques d'une lenteur intellectuelle, aux limites du diagnostic.)

Problématique

Être parent constitue un rôle social hautement valorisé. Pour quelques adultes ayant une DI/LI, son exercice représente une modalité d'expression d'une participation sociale pleine et active. Or, plusieurs facteurs peuvent altérer la réalisation de ce projet de vie. À ce propos, certains parents ayant une DI/LI ont de la difficulté à assumer adéquatement leurs responsabilités parentales, ce qui peut affecter le bien-être et le développement de leur enfant. D'ailleurs, une surreprésentation de ces enfants dans les systèmes de protection de l'enfance est constatée dans plusieurs pays industrialisés [2]. De plus, lorsque des mesures de protection sont appliquées, entre 40 et 60% de ces enfants font l'objet d'un placement hors de leur milieu familial d'origine [3].

Cette situation ne tient pas compte uniquement des limites cognitives de ces parents. Elle doit être examinée en fonction de la diversité des facteurs qui caractérisent leur réalité [4]. D'ailleurs, plusieurs personnes ayant une DI/LI ont une histoire de vie marquée par la stigmatisation et par la rupture répétée de liens affectifs [5, 6]. Dans certains cas, elles n'ont pas pu compter sur des modèles parentaux adéquats, soit parce qu'elles ont vécu en centre d'accueil, soit parce que leur vie familiale était chaotique ou dysfonctionnelle [7]. Dans d'autres situations, elles ont été victimes d'abus ou de négligence pendant leur enfance [8]. Coppin [9] constate que peu de parents ayant une DI ont bénéficié de la préparation nécessaire à un choix éclairé de parentalité. Alors que des individus ont été peu ou pas conscientisés aux responsabilités sous-jacentes à ce rôle [10], d'autres n'ont jamais été mis en situations concrètes de pratique (p. ex.: gardiennage) [11].

Les conditions de vie de plusieurs parents ayant une DI/LI se caractérisent par la pauvreté, l'isolement social et un niveau de stress élevé [12]. Certains ignorent la présence de ressources de soutien disponibles, alors que d'autres vivent dans la peur d'être jugés défavorablement par les membres de leur entourage ou de perdre la garde de leur(s) enfant(s) [13]. Ces conditions adverses ne sont pas toujours associées à l'apport de services adaptés. En effet, des chercheurs constatent la présence d'importantes lacunes en ce qui a trait à l'adéquation entre les besoins des parents et l'offre de services de soutien et d'éducation [14, 15]. La coopération entre les parents et les professionnels impliqués se heurte souvent à des préjugés, et parfois, à un manque de compréhension et d'ouverture à la réalité de l'autre [16]. Les intervenants sociaux se sentent généralement démunis face à ces personnes, invoquant des connaissances et une expertise limitées, un manque de temps pour se perfectionner et un délai insuffisant pour réaliser l'intervention [14].

En dépit d'un tel contexte d'adversité, des parents ayant une DI/LI arrivent à développer une identité parentale positive et à développer une relation significative avec leur(s) enfant(s), comme le révèle une enquête menée auprès de cette population. En effet, l'examen des propos des participants témoigne de la résilience de certains. Selon Luthar, Cicchetti et Becker, [17], ce concept réfère à un processus qui se caractérise par une adaptation positive de l'individu en présence d'un contexte d'adversité. Une adaptation positive réfère à une adaptation nettement supérieure à celle qui serait attendue étant donné l'exposition au risque [18]. La résilience est fortement influencée par la présence de facteurs de protection individuels et environnementaux. Elle se manifeste « par la mise en oeuvre d'une attitude active et positive face à l'adversité visant à tirer profit des aspects pénibles d'une situation, ou, tout au moins, d'en faire une occasion d'apprentissage» ([19], p. 14).

Description de la recherche

Dans le cadre d'un projet doctoral en service social, neuf parents ont participé à une étude ayant pour objectif principal d'explorer leurs représentations sociales de la parentalité vécue par les personnes présentant une DI/LI. Les objectifs secondaires étaient : (1) de dégager les composantes cognitives (informations) et sociocognitives des représentations (opinions, attitudes, croyances, etc.) ; (2) d'explorer les convergences et les divergences entre celles-ci et (3) d'identifier les facteurs d'influence. Pour cette étude, une représentation sociale se définit comme un ensemble organisé d'opinions, d'attitudes, de croyances et d'informations se référant à un objet ou à une situation, qui est déterminé à la fois par l'individu lui-même, par le système social et idéologique dans lequel il est inséré et par la nature des liens qu'il entretient avec ce système social [20]. Cette interprétation de la réalité lui permet de donner un sens à ses conduites et de comprendre la réalité à travers son propre système de référence.

Les participants ont été recrutés par l'entremise d'organismes communautaires de la province de Québec au Canada. Dans le cadre d'une première rencontre avec la doctorante, tous ont signifié leur accord pour participer à cette étude en présence d'un témoin de confiance de leur choix. Puis, deux entretiens de trente minutes ont été réalisés avec chacun d'entre eux. Cinq thèmes principaux, liés aux objectifs de l'étude, ont été couverts, soit : (1) le désir de procréation; (2) l'exercice des droits et des devoirs parentaux; (3) la pratique des tâches et des responsabilités parentales; (4) l'expérience de parentalité (vécu subjectif, sentiments); (5) les conditions de vie favorables à l'exercice du rôle parental. Leurs propos, retranscrits sous la forme de verbatim, ont fait l'objet d'une analyse de contenu se basant sur une démarche inductive.

Des neuf participants, six parents présentent un diagnostic de DI légère et les trois autres reconnaissent avoir des limitations cognitives illustrées par les difficultés ayant marqué leur parcours de vie. Celles-ci réfèrent aux apprentissages scolaires (p. ex. : fréquentation de classes spéciales) et à leur intégration sociale (p. ex. : mise à pied fréquentes et difficulté à conserver un emploi). Les six mères et les trois pères de l'échantillon sont âgés de 22 à 59 ans. Ils vivent majoritairement en milieu rural (n=7). Ils sont sans emploi à temps plein et bénéficient de prestations gouvernementales (solidarité sociale). Cinq de ces neuf parents ont la garde de leur(s) enfant(s). Ces derniers bénéficient de mesures de soutien de leurs proches ou d'intervenants d'établissements public ou communautaire. Les autres (n=4) se sont vus retirer la garde de leur enfant en vertu de la Loi sur la protection de la jeunesse du Québec.

Les propos recueillis ont conduit à définir deux profils d'adaptation positive associée à la résilience des parents sur la base de certains critères. Le premier est propre aux cinq participants qui ont conservé la garde de leur(s) enfant(s). Ils ont su développer un sentiment de compétence et de confiance en leurs ressources, en dépit des évènements stressants ayant ébranlé leur vie de parent. Le second profil correspond à celui de deux pères qui disent partager une relation significative avec leur enfant, même s'ils ne vivent pas avec lui au quotidien. Bien que la séparation de leur enfant ait suscité souffrance, colère et tristesse, ils estiment avoir accepté cette situation. En effet, ils reconnaissent qu'ils ne disposaient pas des conditions de vie propices à l'accueil d'un enfant et se réjouissent de son bien-être et de sa qualité de vie auprès d'autres figures parentales. Ils détiennent la volonté de demeurer un modèle exemplaire pour leur enfant et assument adéquatement d'autres rôles dont l'exercice est source de satisfaction et de fierté, tels que celui de conjoint ou de membre actif d'un organisme communautaire d'entraide. Il est à noter que les résultats présentés à la section suivante ne tiennent pas compte des deux parents de l'échantillon de l'étude dont le profil ne correspond pas aux critères de ces deux profils d'adaptation.

Exploration des facteurs de protection

Les éléments présentés dans cette section réfèrent aux parents présentant une DI/LI qui font preuve d'une adaptation estimée positive, malgré leurs difficultés et les défis rencontrés dans l'exercice de leur rôle parental. Les facteurs personnels et environnementaux abordés sont ceux qui peuvent être qualifiés de barrières face aux adversités et qui ont contribué à leur bien-être, selon leur perspective. L'analyse décrite s'inspire du modèle du processus de production du handicap [21].

1.1 Facteurs personnels

D'après les propos recueillis, la parentalité symbolise l'accès à un rôle hautement désiré et à une image de soi positive. En effet, être parent confère un statut d'adulte responsable, digne d'assumer pleinement son autonomie. Ce statut fournit l'occasion de prouver ses compétences à autrui. Il permet à ces personnes de vivre des expériences normalisantes, telles que de se rendre à l'école avec son enfant. C'est comme si l'identité parentale venait gommer « l'identité stigmatisée » de personne ayant une DI. Avoir un enfant a suscité, la motivation à redoubler d'efforts pour développer de nouvelles habiletés.

Tous les participants ressentent de la fierté face aux réussites de leur(s) enfant(s) (p. ex. : bons résultats scolaires, obtention du permis de conduire, accès à un emploi, etc.). Ils estiment avoir, en quelque sorte, contribué à ces succès, ce qui amplifie leur propre sentiment de compétence et de confiance en soi. Sans nier leurs difficultés sur les plans de l'apprentissage ou de la compréhension, ils se comparent avantageusement à des parents sans DI/LI, s'estimant tout aussi bons et parfois même meilleurs qu'eux.

Devenir parent peut faire émerger des souvenirs douloureux pour des adultes ayant eu une enfance difficile. Pour les participants ayant conservé la garde de l'enfant, ce passé semble les avoir motivés à lui offrir ce qui leur a manqué en s'appuyant sur de bons modèles de parentalité. Selon leurs propos, la présence de l'enfant est une source puissante de motivation à assurer son bien-être.

Les sept informateurs reconnaissent l'ampleur des responsabilités liées à l'exercice parental. Ils insistent aussi sur l'importance pour toute personne présentant une DI/LI, d'effectuer une réflexion préalable et une vérification des ressources dont elle dispose avant de concrétiser son désir d'enfant. Il est intéressant de souligner qu'une partie considérable du discours des répondants porte sur la protection de l'enfant. Pour ceux qui ont conservé la garde, la protection s'actualise, entre autres, par la prévention du danger grâce à une surveillance constante de l'enfant. Cette conscience du risque semble être particulièrement importante pour les parents ayant eu une enfance difficile.

Pour avoir une vision globale de leur situation, il faut aussi considérer les facteurs environnementaux sur lesquels ils peuvent compter.

1.2 Facteurs environnementaux

Les participants rencontrés se sont tous dits satisfaits du soutien dont ils bénéficiaient au sein de leurs réseaux. Deux principaux facteurs de protection propres à leur trajectoire parentale semblent avoir favorisé leur adaptation positive. Le premier correspond à une relation affective, sécurisante et stable avec un intervenant de confiance provenant de leur réseau informel. Le second concerne un fort sentiment d'appartenance à un réseau informel et/ou à un réseau communautaire où leur contribution est recherchée et valorisée. Ils y puisent une image positive de leur potentiel à exercer leurs rôles d'adulte, de conjoint, de parent ou de membre actif de leur communauté.

1.2.1 Réseau formel

Le soutien offert par un intervenant de confiance constitue un important facteur de protection. En effet, l'aide professionnelle a des effets positifs sur l'estime de soi et sur le développement d'une représentation positive de leurs compétences parentales. Pour les parents qui ont conservé la garde de l'enfant, cette aide prend différentes formes: l'offre d'enseignements ponctuels, du soutien affectif, des mesures de répit, de l'accompagnement aux rendez-vous scolaires et médicaux. Le lien de confiance intervenant/parent est fondamental puisqu'il contribue à amoindrir leur niveau d'anxiété. Il leur permet de développer une vision positive de l'avenir; ces parents sont plus confiants en leur potentiel à apporter une réponse adaptée aux nouveaux besoins de leur enfant tout au long de son développement. En effet, ils paraissent rassurés par la présence de ce professionnel présent dans leur vie depuis plusieurs années, qui a toujours su les accompagner dans la recherche de solutions satisfaisantes et efficaces à leurs problèmes. Ce lien de confiance a aussi favorisé le développement d'une plus grande assurance à faire part de leurs besoins à leurs proches et aux autres professionnels impliqués dans leur vie.

Les sept répondants reconnaissent plusieurs qualités aux intervenants. Celles-ci réfèrent à : (1) l'écoute, l'ouverture et l'absence de jugement; (2) le respect de leur désir d'autonomie; (3) la croyance en leur potentiel,

s'actualisant par une approche misant sur leur responsabilisation; (4) la reconnaissance et la valorisation de leur potentiel; (5) le respect de leur rythme; (6) la disponibilité à travers les étapes de vie plus difficiles. Il est à souligner que les intervenants dont il est question détiennent tous plus de trente années d'expérience auprès des personnes présentant une DI et une expertise dans le domaine. Un parent reconnaît aussi des qualités distinctes à un professionnel de la protection de l'enfance, soit: sa transparence, son honnêteté, son humanisme, sa neutralité et son objectivité.

1.2.2 Réseau informel

Les sept répondants disent bénéficier de mesures de soutien satisfaisantes au sein de leur réseau informel composé d'un conjoint, d'amis et/ou de membres de la famille proche et élargie. Parmi ceux-ci se retrouve une mère de deux adolescents qui demeure chez son père avec qui elle partage certaines responsabilités parentales. Elle a de nombreuses amies et de plusieurs tantes qu'elle visite régulièrement. Il y a aussi deux participants qui sont mariés depuis une dizaine d'années et qui s'estiment comblés par leur relation fondée sur l'amour, le respect, le soutien à travers des étapes de vie difficiles et sur les forces de chacun. C'est davantage la qualité des liens établis qui apparaît importante aux yeux de l'ensemble des participants.

1.2.3 Réseau communautaire

Au-delà de l'appui provenant de leurs réseaux formel et informel, cinq participants ont fait part de leur engagement dans un organisme communautaire constitué de personnes présentant une DI/LI et d'un intervenant social. Leurs propos traduisent une appréciation du climat de solidarité et d'entraide qui y règne. Le sentiment d'appartenance à ce groupe a des retombées fort positives sur leur bien-être psychologique.

Pour les parents ayant conservé la garde de l'enfant, le soutien puisé au sein de ce réseau communautaire leur permet d'échanger des conseils et de se valider dans leurs pratiques parentales dans un climat d'ouverture et de respect. Certains ont aussi mentionné y solliciter l'aide de membres de confiance afin d'obtenir des services de répit s'actualisant par du gardiennage.

Les propos des parents ayant vécu le placement d'un enfant témoignent de l'apport essentiel du soutien amical et psychosocial reçu dans le développement d'un sens nouveau à leur parentalité. Ils font également part de leur appréciation du soutien juridico-légal qui leur a été offert, lequel leur a permis de recevoir l'information nécessaire sur leurs droits parentaux dans un format adapté à leur niveau de compréhension. En dépit des sentiments de frustration et de souffrance vécus au moment du retrait de leur enfant, ils sont parvenus à traverser cette période de vie douloureuse grâce à ces appuis et à développer de nouvelles stratégies propres à une adaptation positive.

1.2.4 Regard sur les deux profils d'adaptation

Dans cet article, deux profils d'adaptation positive ont été établis. Sept participants à l'étude présentent une telle adaptation sur la base des critères établis antérieurement. Leurs pratiques parentales ont toutes fait l'objet d'une évaluation extérieure à un moment de leur trajectoire. Dans cinq situations, cette évaluation a mené à la mise en place de services et/ou de mesures de soutien visant le plein exercice de leurs responsabilités parentales. Pour les deux autres répondants, le placement de l'enfant a été imposé par les autorités légales, pour motif d'incapacités parentales perçues. Or, quels éléments distinguent la situation de ces deux pères? Quelques pistes peuvent être suggérées. D'abord, ces deux adultes rapportent avoir grandi dans un milieu familial fermé et isolé auprès de parents présentant des limitations intellectuelles. Leur enfance a été vécue à travers plusieurs allers-retours entre leur famille et les centres d'accueil. Aussi, leurs difficultés vécues dans leur vie socioprofessionnelle constituent un thème récurrent de leur discours. Des sentiments de tristesse et de colère émergent de leurs propos lorsqu'ils réfèrent à l'incapacité qu'ils ont eu à conserver un emploi et à leur impression d'avoir fait l'objet de discrimination dû à leur différence. Finalement, au moment du placement, les deux pères se trouvaient avec une conjointe présentant une problématique majeure de santé mentale, dont les comportements décrits témoignent d'un désinvestissement à l'égard des responsabilités parentales. Ces deux répondants rapportent avoir souffert des représentations négatives à l'égard de leur capacité à s'occuper d'un enfant, perçues dans le regard et les comportements de leurs parents ou de leurs beaux-parents. Somme toute, l'examen de leur situation au moment du placement de l'enfant témoigne de la présence de plusieurs facteurs de risque. Le potentiel nocif de ces facteurs et de leur cumul sur les compétences parentales est bien documenté [1, 4].

Brève Discussion

L'exploration de l'histoire vécue par les parents ayant participé à cette étude témoigne de leur adaptation positive en dépit des adversités et des défis rencontrés à travers leur trajectoire parentale. Le

développement des stratégies personnelles et des aptitudes présentées témoigne du potentiel insoupçonné que peuvent développer certains parents présentant une DI/LI. D'abord, plusieurs participants sont parvenus à développer des pratiques parentales adéquates pour assurer le bien-être et la sécurité de leur enfant, en dépit des difficultés relatives à leur histoire de vie et des préjugés entretenus à leur endroit. Plusieurs recherches mettent en lumière que les difficultés de ces parents sont souvent perçues comme étant insurmontables, permanentes et rendant impossible l'acquisition des compétences nécessaires à une réponse adaptée aux besoins évolutifs d'un enfant [2, 16, 22, 23, 24, 25].

Les propos des sept participants témoignent aussi de comportements proactifs dans la recherche d'opportunités de participation sociale. À cet égard, être parent semble avoir un effet important sur leur motivation à exercer leurs responsabilités au meilleur de leurs capacités, ce qui témoigne de leur résilience.

Il est reconnu qu'une perception positive du soutien favorise le bien-être psychologique et l'apprentissage de nouvelles habiletés parentales [26, 27]. Dans cette étude, la satisfaction à l'égard des ressources de soutien représente un facteur de protection fondamental. Le réseau de soutien des parents, qui est constitué principalement du conjoint, des amis et/ou des membres de la famille proche et élargie, offre de l'aide émotionnelle au sein de relations significatives, sécurisantes et stables. Ce portrait diffère des constats établis dans le cadre d'autres recherches canadiennes, américaines et australiennes qui relèvent la présence de besoins non comblés en termes d'aide amicale et émotionnelle chez ces parents qui bénéficient bien souvent d'un réseau restreint composé principalement d'intervenants et de membres de leur famille [28, 29, 30, 31]. Ce contraste peut s'expliquer, d'une part, par la stratégie de recrutement particulière à cette étude, c'est-à-dire par l'entremise d'intervenants d'organismes communautaires. D'autre part, il faut aussi considérer qu'une majorité des participants provenaient d'une même région rurale, où semblent régner entraide et solidarité.

Conclusion

Cette étude rend compte d'une exploration de facteurs ayant un potentiel positif sur la résilience de parents présentant une DI/LI. Elle offre des pistes pouvant inspirer la concrétisation d'autres recherches sur le sujet. Il serait pertinent de réaliser des analyses plus approfondies en vue de mieux comprendre les mécanismes d'adaptation positive déployés par un échantillon plus nombreux de parents qui arrivent à surmonter, contre toute attente, les obstacles et les difficultés auxquels ils sont confrontés. Il serait aussi intéressant d'inclure d'autres populations de parents fragilisées et d'établir des parallèles entre les résultats obtenus. De telles préoccupations s'inscrivent dans une visée globale de produire de nouveaux savoirs qui témoignent du potentiel et des capacités de ces personnes, intégrées au sein d'une société qui prône justice sociale et équité pour tous.

Children's resilience and family secrets

Moldovan V.

Romania
sile_moldovan@yahoo.com

Abstract

The beauty of family secrets comes from the contribution that generations have brought to its construction and from the mystery with which each person works on it in order to tell us something. There is an approach of family psychotherapy which relates certain human fears or anxieties with events which were hidden during life. The therapist helps the person to reach a state of relief by giving him/her a new meaning to the situations experienced. The secret is rather a "burden" that prevents the person to take his/her destiny in his/her own hands, by repeating certain behaviours of his/her parents (Serge Tisseron). In this case the therapist acquires a major role to help the person to unlock himself/herself in order to continue his/her life by using own resources. However the main human resource is resilience. It is more than simply adapt to adverse conditions in order to survive. Resilience links generations together and ensures continuity as well as an overcoming of human condition. Resilience helps children to find solutions to the problems, fears or unfulfilled desires of their parents. Many of these problems, fears or desires are known implicitly or explicitly by the child. Even when they are secrets, resilient children actively works with them, by looking for positive forms of expression as solutions or wish fulfilment. The child unconsciously knows the story of his parents and of descendancy and due to his resilience looks for an overcoming of parents' condition. But overcoming does not necessarily mean a better social position or remuneration. Overcoming human condition means fulfilment through a higher level of understanding, a better way of expression in front of you or others, an increase in maturity and regaining self-confidence. I analysed 42 family stories that have highlighted the resilience and family secrets of my clients and I assessed together with them the results of psychotherapy through the confidence they had in own resilience capacity, at the end of our work.

Key words: family, secret, unconscious, resilience, human condition.

Resilience and family system

Humanity has evolved because those who have survived found superior solutions to adapt compared to their ancestors. Each of us is born with the ability to learn how to deal with stress, how to adapt quickly to change, how to recover from failures and to find ways to turn an unfavourable situation into a favourable one. However some of us are stuck in a state of victim blaming others for their failure, while others explore alternatives and find solutions on their own. ``Resilience is something you do rather than something you have``. I was fascinated by the power that family secrets have on us. Serge Tisseron states that `` family secrets have the effect of excluding some members, most often the youngest in the group's sphere of trust. Paradoxically, they come rather from the desire of parents to protect their child […]``. However the child knows the truth implicitly and strives to re-enter the sphere of the family trust. Involvement of these efforts increases the resilience capacity of the child. He becomes motivated to do something and chooses the most favourable alternative to fix what his family considered to be shameful, wrong, evil and painful. Apparently it is an individual choice, conscious and deliberate. However, this choice to straighten family issues hidden by secrets has a deep determination in the family system itself because the last one needs equilibrium. On the one hand, the child finds different behavioural strategies to bring him back in the family (group of trust), and on the other hand, family is geared to reintegrate the excluded member, according to the theory of family constellations [2].

1.1 Case studies: resilient children and their families

I explored children`s capacity of resilience in 42 families who had different type of secrets as: unfulfilled relationships (1), unwanted pregnancies, abortions (2) failed marriages (3) prostitution (4), killing of family members (5) parallel families (6) sexual orientation (7), injustice/abuse (8) professional unfulfillments (9). For each type of secrets I will provide below details on a case study, by emphasizing the link between the family secret and the child capacity of resilience.

In the *case of Petra* (1) parents have forbidden her to have a relationship with Andrew since childhood. Nevertheless Petra has always felt attracted to Andrew; she fell in love and began a relationship with him in secret. Her parents found out and opposed marriage by quarrels, interdictions, penalties and even curses, triggered mainly by the mother. Seeing his daughter's determination to formalize the relationship with Andrew, the father finally confessed the secret reason for which the family opposed. In youth the father had been in love and cohabitated with Andrew's mother, but that relationship ended with strife and violence, followed by a strong enmity between the families of Petra`s and Andrew`s parents. The situation of these families became more interesting when I found out that Andrew 's father (Joseph) was born of a secret relationship between Mary (his mother who was mentally sick) and an uncle in the family of Andrew's mother (Joseph`s wife). The situation shows that children of two generations (Joseph and Andrew) find solutions for their parents` life problems by getting married with descendants of those families with whom their parents had unfulfilled relationships. In this way the family system regains equilibrium (homeostasis). There are remarkable personality traits of the two children. Although born of a secret relationship between a mentally sick mother and a father who do not take responsibility of his actions, Joseph is shown to be a very skilled and valued person in the community for his skills, kindness and beautiful physical traits. In turn Andrew, Joseph`s son, finds solutions for an unfulfilled relationship of his mother, who was in love with Petra`s father. Andrew is an open mind person, enterprising, skilled and with a special kindness. Petra is also an empathetic and intuitive person that always tries to understand and solve problems.

In the next *case Calin* (2) is the third child coming from a modest family of workers. His parents kept secret their attempt to commit an abortion when his mother became pregnant with him. Calin was actually an unwanted pregnancy of his family. It is interesting that this child survives in an unexpected way, after mother`s several attempts to miscarry. At that time abortions were illegal in Romania and many mothers resorted to unconventional solutions in order to cause miscarriage. Sometimes these attempts were fatal not only for the infant, but also for the mother. I noticed that Calin had an extraordinary capacity of resilience. Since childhood he was appreciated by parents for his intelligence, thirst of knowledge, empathy, respectful and supportive behavior for parents and brothers. Calin has the best career path in his family. He is the only one who completed higher education and became a police officer while his brothers are workers with average education. Calin`s resilience lead to a professional ascent. In addition, Calin has a professional career oriented towards investigation, discovery of guilty persons and defense of the victim. The parents are now proud of the child that once they wanted to lose, by denying his right to leave.

In the *case of Corina* (3) her father's family hid a relationship of marriage and violence that was her father`s failure. Marriage was considered a disgrace that stained the honor of man`s parents because his wife had an extramarital affair. Separation occurs rapidly and brutally and this life episode is covered in silence as if it had not occurred: marriage pictures and clothes are destroyed and family members avoid talking about it even when asked. Man remarries and does not tell his new wife about the previous marriage. Corina is born and she has a spectacular professional and social ascent, best in her family. Corina chooses a partner from a different culture with non-violence education based on respect and equality. She gives birth to two children without formalizing a marriage relationship. If the father and his family hid a failed marriage, because of shame and fear of being socially disregarded, Corina builds a family without getting married with her partner. She communicates in this way the importance of feelings for each other, to the detriment of social disapproval and labeling. Moreover, she chooses to be pathologist doctor investigating and elucidating the causes of death or unexpected losses.

In the *case of Bogdan* (4) his father had a secret relationship of love with a prostitute woman. Bogdan`s father was often tempted to divorce in order to marry the young prostitute. The fear of prejudicing his social image prevented him from doing this change. Bogdan does not know the secret explicitly but later he marries a woman who was involved in prostitution, even if he reached a professional career well appreciated in the community. Thus Bogdan legitimizes the behavior of his father by validating a relationship that is socially disregarded.

In the *case of Mircea* (5) the secret is related to the death of uncle Silviu. Parents and grandparents told Mircea that his uncle died accidentally, being shot by a fellow officer who was cleaning his weapon. The officer had pointed the weapon at uncle Silviu by playing and he was unaware that the weapon had been loaded. In 40 years after the incident, Mircea finds out secretly in the night during a discussion between his father and another relative that uncle Silviu was killed by his colleague because he knew about some illegal affairs conducted by police chief together with his colleague. The family hid the incident in secret because of fear of conflict with police authority which could bring more harm on the family members in a communist society. Mircea becomes a well-known person fighting for human rights, developing monitoring actions of public institutions and taking attitude against abuses of public institutions on community members. The family considers that Mircea is the most responsible and professionally accomplished family member. Thus, the system shows a new way of regaining lost equilibrium.

In the *case of Denis* (7) the secret is related to the sexual orientation of male family members (Denis` father and parental grandfather). Both his father and grandfather are homosexual. The grandfather keeps the

secret and his wife (Denis' grandmother) was not aware of it. Their problems of sexual dynamics are solved differently: Denis` grandmother finds a lover and saves the marriage while Denis` grandfather isolates himself more and more and fights his sexual identity. Unlike his grandfather, Denis' father partially accepts his sexual identity. He has homosexual relationships during marriage but hides them from his wife. Thus, Denis` parents find also a way to solve sexual problems. His mother finds sexual fulfillment in an extra-marital relationship and saves the marriage, like his grandmother while Denis` father remains in the family but has secret relationships with homosexual partners. Marital crisis leads them to the brink of divorce. Denis` father is the most motivated to keep the family, by succeeding to keep the secret about own sexual orientation and to save appearances. This is an important issue in a conservative society with many prejudices and stereotypes related to homosexuality. Denis, a very intelligent, open minded and empathetic young man, manages to win the admiration of his family through school and later very good professional results. He has a very good professional ascent and reaches top management positions. Denis` parents worry when he is late to introduce them a girlfriend. A real drama is triggered when Denis discloses his true sexual orientation and tells his parents that is going to move in with his boyfriend. Meanwhile Denis speaks publically about his sexual orientation and even gets involved in the actions of non-governmental organizations advocating for homosexuals` rights. Thus, Denis proves a good capacity of resilience and resolves the conflict of his grandfather sexual identity and respectively of his father, by validating homosexual relationships in his own family, beyond the prejudices and social stereotypes that led his father and grandfather to keep this secret for two generations.

In the *case of Christine* (8), the secret is related to a hidden sexual abuse occurred in her family. Christine's mother (Eva) was sexually abused by her stepfather around the age of 6 years. Eva tries to talk to her mother about the abuse but is not believed. Her mother is intrigued, denies the abuse and discourages Eva in her intention to reveal the abuse. Child sexual abuse continues with the secret approval of her mother. Eva hides the secret and begins a new life when she builds her own family. Eva gave birth to her daughter Christine but soon after that she loses her husband in a car accident. She decides not to get married again because was afraid of another abuse against Christine. It follows a very difficult time for Eva who becomes a single mother with very low income. Therefore Christine has a tough childhood and is concerned to get good grades in school and succeed in life. Even during school she starts working in order to help her mother with her share of the expenses and to be financially independent. Christine proves good resilience capacity because of the successful ways to face difficult situations in life, to improve social status and to get recognition at workplace. After completing higher education in psychology, Christine specializes in the work with children and supports sexually abused children within an organization that defends children`s rights. Thus, resilience does not only help Christine to succeed in life but also to find positive solutions to abuse and injustice that affected her mother, and implicitly the whole family system.

In the *case of Rares* (9), he discovers the secret of his parents while working on a biographical book about his family. Being always influenced by his dominant and authoritative father who was a respected teacher in his village, Rares starts a university career and reaches the highest level as *professor doctor*. His father was born also in a family of teachers who have advised him to follow the same professional career that was associated with social prestige in the Romanian rural culture. Rares` father has started higher education but it is a secret the fact that he did not graduate because of many failed exams. The secret is not revealed to parents or children. Even so, Rares` father promotes himself as having this status, taking advantage of the fact that he could be a teacher in the village even with average education. Rares` mother is the only one who discovers the truth but does not share it with Rares until after the death of her husband. Rares proves a good resilience capacity because of outstanding academic achievements by reaching a high professional level and being more determined and with better performance than his father. Thereby Rares not only evolves professionally but he also accomplishes the professional aspiration of his father.

Conclusion

Several case studies of the families that hide important secrets with life problems reveal great personality of children who achieve to restore equilibrium of family system thanks to their capacity of resilience. If we speak about resilience mostly when the person is directly and explicitly affected by adverse stimulus (eg. abuse, loss), in the case of secrets the person is indirectly and implicitly affected. The link between children`s resilience and family secrets is even more interesting if we understand the ambivalence of the messages communicated through secrets. On the one hand, the family wants to protect the child against the emotional impact of past life problems and on the other hand, this behavior leads only to the child exclusion from the family trust sphere, and the child is implicitly affected by it. Thus, child exclusion increases implicitly his capacity of resilience, by determining significantly his destiny and own personality assertion.

Abstract

The care for children and their family in hospital involve the integration of formative, educational and recreational proposals that contribute to encourage the participation of parents and child to develop resilience in a situation of disease. Spain integrates family in different hospital wards with technology use, as CiberCaixa Hospital Program, supported by the "la Caixa" Foundation in pediatric hospital. Their aim is to provide fun and education for family. We present the results of qualitative research on the impact of this program for families and children. We note significant benefits for families who enjoy the space successfully, emphasizing its role as a source of entertainment, relationship and emotional support to help them cope with the disease. Even from the point of view of work in the classroom is considered the care of the family of a resilient perspective as a mutual enrichment.

Keywords: teaching hospital, CiberCaixa hospital rooms, hospital classrooms, family resilience, health education, children with disease.

Introduction

La présence d'une maladie chronique dans l'enfance provoque un grand impact émotionnel sur la famille [1][2][3][4]. L'hospitalisation représente pour les enfants la séparation des personnes qui leur sont proches, le séjour dans un environnement étrange, la douleur, le manque de confort, la peur de la mort, des changements dans les relations avec la famille. Ce sont tous des facteurs qui contribuent à produire une situation de stress qui varie selon le stade de développement de l'enfant [5]. Les modèles de soins intégraux centrés sur la famille sont appliqués avec succès à l'échelle internationale. Ils impliquent la famille dans les actions de soins et proposent l'intégration de propositions de formation, d'éducation et de récréation qui contribuent à promouvoir les compétences parentales et à développer la résilience infantile en situation de maladie [6][7]. L'intégration des deux points de vue : le modèle centré sur la famille et l'approche résiliente se révèle pertinente [8]. Walsh se réfère aux «services centrés sur la famille et qui se basent sur ses points de force» comme une évolution d'un modèle basé sur le déficit à un modèle qui se concentre sur l'exploitation de ressources, d'un modèle basé sur l'individu à un modèle axé sur la famille, et de la fragmentation des services aux services holistiques. Le développement parental transforme la famille en gardienne et promotrice de la résilience infantile, ce qui constitue un facteur de protection qui permet un développement sain de l'enfant [9]. La résilience familiale aide à réduire le poids du stress sur les familles dont un membre souffre d'une maladie chronique et permet de garder «des niveaux optimaux de fonctionnement et de bien-être en équilibrant les ressources et les besoins de la famille» (page 103) [10]. Cette approche permet d'améliorer les facteurs de protection et de réduire les risques pour l'adaptation positive à la maladie dans chacun des membres de la famille. Il faut remarquer l'importance des ressources psychologiques de la famille et des facteurs de protection et de prédiction qui favorisent l'adaptation à la maladie [11]. Les soins hospitaliers pédiatriques se concentrent de plus en plus sur des modèles de soins intégraux concernant l'amélioration de l'humanisation, où une importance majeure est accordée au développement des activités éducatives et récréatives pour le bien-être et la qualité de vie des patients pédiatriques, aussi bien qu'à l'espace physique dans lequel cette humanisation se développe. La pédagogie hospitalière vise à répondre aux besoins éducatifs, de psychoéducation et récréatifs à partir des différents domaines d'intervention à l'intérieur et à l'extérieur de l'hôpital [4] [12]. Ce type d'action s'est élargi à l'échelle internationale afin de garantir les droits fondamentaux et les droits à l'éducation et à la santé. En Espagne, on a intégré des espaces éducatifs et récréatifs, dotés de moyens technologiques pour les patients pédiatriques et leurs

familles dans les différents services d'hospitalisation. Nous allons présenter les résultats liés à l'action de la CiberCaixa hospitalière destinée aux familles. L'objectif était de déterminer la perception des familles sur les avantages de cette ressource, et le point de vue des enseignants des salles de classe de l'hôpital, sur le travail avec les familles.

Méthodologie

Il s'agit d'une étude qualitative dans laquelle 36 familles d'enfants (6-12 ans) ou jeunes hospitalisés (12-18 ans) ont été interrogés. Les familles participant à la recherche ont été sélectionnées par échantillonnage non probabiliste. Les CiberCaixa hospitalières ont été sélectionnées sur la base de l'accessibilité et proximité des centres hospitaliers à évaluer, faisant partie de différentes Communautés Autonomes: Catalogne, Pays Basque, Aragon, Madrid, Murcie et Valence. On a cherché à inclure des centres des deux modalités de la CiberCaixa hospitalière: l'espace partagé de CiberCaixa avec des salles de classe de l'hôpital et l'espace unique. On a fait participer à l'étude des familles avec au moins trois enfants et deux adolescents qui ont fréquenté au moins une fois un des espaces. L'analyse des informations obtenues a été réalisée en utilisant le logiciel Atlas.ti.

Résultats

1.1 Bénéfices de la CiberCaixa hospitalière pour les enfants, les jeunes et leurs familles

En général le niveau de satisfaction à l'égard du centre et des activités développées dans l'espace est élevé. Les parents considèrent que c'est un endroit de récréation qui leur permet de s'éloigner des nombreuses préoccupations concernant la maladie.

« C'est un endroit de récréation pour les parents et les enfants et un bon moyen pour se détendre sans penser à l'hôpital » (Hôpital La Fe, Valence).

Ils considèrent ce centre comme un espace éducatif. Ils apprécient également la possibilité éducative que leurs offrent les ressources disponibles, en tant que complément des salles de classe de l'hôpital. La disponibilité de ressources technologiques leur permet l'accès aux ressources éducatives, récréatives et de la communication. La possibilité d'établir des relations avec d'autres personnes est un support pour la famille aussi bien qu'un élément de socialisation.

« C'est une porte ouverte à l'information qu'ils veulent (...) » (Hôpital Donostia. Pays Basque).

Il est considéré comme un espace de relation. La possibilité d'interaction avec d'autres personnes représente un soutien pour les familles et un élément de socialisation pour les enfants. Il est estimé comme un lieu de relation sociale et entre pairs (soutien social informel).

« C'est très bien d'entrer et parler avec beaucoup de gens » (Hôpital Niño Jesús, Madrid).

« .....c'est bien qu'ils puissent interagir et partager leur expérience avec d'autres enfants qui sont dans la même situation » (Hôpital La Fe, Valence).

De leur côté, les familles pensent que cet espace encourage l'expression des sentiments et améliore l'humeur des enfants et adolescents, en les aidant donc dans leur évolution et dans l'adaptation au séjour à l'hôpital.

« Je conseillerai sûrement la CiberCaixa car elle est très utile aux enfants, c'est un changement appréciable. C'est un endroit qui contribue à leur santé, où ils se sentent bien en compagnie de leurs parents. Elle permet d'oublier où on est et la maladie, c'est un endroit un peu plus "normal" » (Hôpital universitaire de Móstoles, Madrid).

Les familles perçoivent que cet espace les aide à faire face à la maladie et à l'hospitalisation, à mieux vivre le temps du séjour à l'hôpital. Il permet de faire face au processus de la maladie et de l'hospitalisation.

« C'est l'une des meilleures aides au service des enfants et des familles. Ça les aide à assumer la maladie autrement » (Hôpital La Fe, Valencia).

1.2 Perception des enseignants universitaires en ce qui concerne l'action avec les familles

La salle de classe à l'hôpital est un lieu d'activités éducatives pour les enfants hospitalisés, pour la période durant laquelle ils sont incapables de fréquenter leur école d'origine. Bien que traditionnellement l'activité suive un programme, la priorité est de répondre également à d'autres besoins, découlant de l'état émotionnel et de la santé de l'enfant. Tout en étant une ressource pour les enfants et les jeunes, les enseignants et les enseignantes qui suivent les classes entretiennent une relation étroite avec les familles, qui est conçue comme une occasion d'interagir avec elles, offrant un soutien et des conseils. De ce point de vue les enseignants interrogés donnent la priorité à la santé et au bien-être dans tous les moments de l'unité familiale.

« L'objectif est de rendre agréable le séjour et de faire en sorte que le fait d'être dans un hôpital et d'être malade ne soit jamais traumatique » (interview avec une enseignante, Hôpital universitaire de Móstoles, Madrid).

« L'objectif principal de notre travail est la santé et de faire en sorte que l'enfant oublie la situation dans laquelle il se trouve..... le plus important c'est qu'il puisse oublier la peur et l'angoisse : de la chambre, du médecin ou de l'aiguille qu'il a implantée dans une veine » (interview avec une enseignante, Hôpital Doctor Trueta, Girona).

Les professionnels de la classe considèrent les aspects émotionnels très importants, et pour cela ils développent un travail en classe pour améliorer le développement de compétences émotionnelles ; ils sont donc très sensibles à cette tâche.

« On s'occupe aussi des aspects émotionnels, beaucoup plus importants que ceux du programme : on encourage toujours a exprimer ses sentiments, car cela est très important pour que les enfants puissent se sentir mieux et surmonter la maladie. Il faut considérer aussi l'humeur de l'enfant, l'encourager, le valoriser et contribuer à son autoestime… » (interview avec une enseignante, Hôpital universitaire de Móstoles, Madrid).

Du point de vue de la résilience ils misent sur une attitude positive, à partir du potentiel, un aspect qu'ils développent dans leur travail éducatif quotidien.

« Par conséquent, la partie émotionnelle n'est pas "je me sens mal quand..." mais "je suis à l'aise quand ..." *»* (interview avec une enseignante, Hôpital La Fe, Valence).

En général ils considèrent que la relation avec les familles à partir de l'école de l'hôpital est très positive aussi pour leur développement professionnel, ce qui représente un enrichissement mutuel et contribue à l'établissement d'un lien. D'autre part, cela les aide à mieux comprendre les enfants et les jeunes qui la fréquentent. C'est une relation éducative basée sur l'accompagnement, elle sert de soutien informel et c'est une forme de médiation entre la famille et les professionnels de la santé.

« On essaie de les soutenir dans la mesure du possible et on les écoute quand ils ont besoin » (interview avec une enseignante, Hôpital Donostia, Pays Basque).

« Surtout, on collabore avec les personnes qui s'occupent des soins médicaux, en les informant des craintes et des doutes que les familles expriment, afin qu'ils puissent donner une réponse en cas de besoin » (interview avec une enseignante, Hôpital Donostia, Pays Basque).

Discussion et conclusions

La CiberCaixa hospitalière est une ressource intégrée dans la dynamique hospitalière qui offre de nombreux avantages. Elle est perçue comme un espace de distraction qui permet de se détacher de la situation, de se détendre et de se reposer en brisant la monotonie du séjour à l'hôpital. Elle représente pour les familles un endroit d'évasion et est considérée comme un espace éducatif. Les relations interpersonnelles offrent la possibilité d'établir de nouveaux liens e de partager des activités. On a mis en relation le soutien social de la famille et des pairs avec une meilleure adaptation à la maladie[14]. D'autre part, la salle de classe représente un espace de soutien affectif, de normalisation et de répit, contribuant au bien-être de la famille en général. On a constaté que le soutien de la famille dans une situation de maladie d'un enfant représente un élément de développement et de création de nouveaux liens, pour grandir et surmonter le traumatisme, dans ce cas, la maladie[15]. Dans l'ensemble, les bénéfices reçus par les familles offrent l'occasion de vivre l'hospitalisation de façon moins traumatisante et favorisent une meilleure adaptation à l'environnement. À partir de la salle de classe de l'hôpital on observe la relation avec la famille comme un élément nécessaire et une occasion d'enrichissement mutuel. La réalité de l'action dans ces espaces soulève la nécessité de s'adapter aux changements, en privilégiant l'amélioration du bienêtre émotionnel, avant d'autres besoins. De ce point de vue, on propose un modèle d'intervention multidimensionnel axé sur l'unicité de la famille et de ses besoins[15]. On peut en conclure que les espaces éducatifs et récréatifs permettent de s'occuper de la famille dans une perspective de résilience en renforçant les facteurs de protection qui peuvent contribuer à mieux faire face à la maladie, d'une manière à la fois cognitive et émotionnelle, à travers le développement de compétences émotionnelles, de la créativité, de l'amélioration du lien affectif et du soutien de l'entourage. Cette perspective aide les familles à se sentir plus capables de vivre avec la situation défavorable, améliorant considérablement leur bien-être et qualité de vie.

Family leisure as a factor of resilience: how can we improve it within a context of residential care? Youths´ perspectives

Navajas Hurtado A.[1], Balsells Bailón M. À.[2]

[1]*University of Lleida (SPAIN)*
[2]*University of Lleida (SPAIN)*
Alicianavajas@pip.udl.cat, Balsells@pip.udl.cat

Abstract

The scientific literature recognizes family leisure as an individual and familial resilience factor. This fact is justified because family leisure provides a lot of benefits; it increases communication between the members of the family, creates memories which contribute to fortify the group identity, promotes well-being and positive relationships, etc. Due to these reasons, it is considered a protective factor.

In Spain, there are different alternatives for the welfare of children at risk: fostering in residential care, kinship foster care, non-kinship foster care and adoption. The present study is focused on residential care.

This research shows the opinions and suggestions of young people about family leisure in a context of residential care. The design of the investigation was qualitative and the data were collected by means of 21 interviews and 5 focus groups, with a total of 43 youths at risk (most of them had been living in foster care).

The youths who were interviewed appointed many ways of improving family leisure in residential care, such as the following suggestions: to use different rooms and places in the centre to try promoting family memories, to think and talk about future activities, to do activities that provide the opportunity to get to know each other better, etc.

In conclusion, family leisure is a resilience factor which can be improved in residential care, and this research provides some strategies to achieve this.

Keywords: Family leisure, resilience, residential care, youths´ perspective.

Introduction

The scientific literature recognizes the fact that family leisure provides many advantages to the family. Some authors mention these benefits, a lot of them related with resilience, such as encouraging the followings aspects: family closeness, bonding, cohesion, well-being, family functioning (Zabriskie and Freeman, 2004); communication, group feeling and group identity (Cuenca, 2005); personal and familial satisfaction, positive familial memories, familial stability (Cuenca, 2012); abilities to resolve problems (Wells, Widmer, and McCoy, 2004); affection, kindness, trust and support between family members (Huff et al., 2003).

According to the literature, family leisure is considered a parental competency (Balsells et al., 2013), a sign of quality of life (Somarriba and Pena, 2012), an aspect of positive parenthood (Rodrigo, 2012), a protective factor and a characteristic of resilient families (Hidalgo et al., 2009; Rodrigo, 2012).

However, Zabriskie and Kay (2013) point out that the perspective of the researchers has been focused on adults´ voices of "traditional" family types (families composed of married heterosexual parents living with their biological children). For this reason, there is a lack of theoretical underpinning about families at risk, including families with youths who have lived through a process of foster care, and only a few recent investigations include children´s perspectives.

Methodology

The principal aims of this research are two: to find out the elements which influence the family leisure in a residential care context, and inquire how young people believe this type of family leisure can be improved.

The research has been based on a qualitative methodology, using 5 focus groups and 21 semi-structured interviews.

The sample was composed of 43 youths at risk between 11 and 21 years old (44% were women and 56% were men). Of them, 30 were youths who had been living in a foster care situation and 13 were youths who lived with a family at risk but had not lived through a foster care process.

The analysis was made though the technique content analysis using the program Atlas.ti.6.1.1.

Results

The interviewed youths explained that the principal strategies to improve the family leisure could be:

- *Increment the frequency and duration of the visits/meetings*: If the youths do not see their relatives, they cannot spend leisure time with them. It is very important to meet the relatives frequently (in their opinion, at least once or twice a week) because if they have more time for the meetings, they can do more leisure activities. In their opinion, one or two hours is not enough to do any activity. Moreover, they say they are not relaxed during the activities because during the meeting they are thinking about the time to say goodbye. They suggest to educators that they could have more flexible timetables and give more facilities to the families.
- *Pay attention to the environment*: the youths think that educators should not be present at the visits because it hinders the natural relationship between the members of the family. They feel observed and this is uncomfortable, so they do not do natural leisure activities, especially the younger children. They also commented that they do not like the rooms where they have the visits. They say they hate the mirror of the room because they know that there are people behind it watching them (even, some youths say they can hear the speakers). They explain that if supervision is necessary, it would be better to use a recorder, to try to hide the mirror or reduce its size (not a mirror as big as the wall, as is sometimes the case). Moreover, they say there are no resources in the rooms (toys, games,...) or that there are not enough.
- *Offer an alternative place for leisure activities:* The youths prefer to have the meeting/visit in another place in the center, not always in the same room (for example, in the playground). But, overall, the youths prefer to do leisure activities out of the center because when they go out, they can do more things than inside the center (as go to the park or have a drink). Moreover, they say that they would like to go out not only during the last visits of the process, but the first ones too.
- *Use leisure time not only for pleasure or fun*: Use leisure time to encourage communication and affection between the members of the family, to improve the family cohesion and to fortify family memories (for example, through activities showing photos or activities to know each other better).
- *Doing different activities*: The youths do not want to always do the same activity, and they suggest activities such as doing sport, travelling, going to the park/beach/swimming pool/cinema/zoo/..., going shopping and visiting their extended family.
- *Informing the youths about plans and taking into account their preferences and characteristics*: Some youths prefer to talk about the future calendar, duration and activities, etc., and be informed by their parents, not by the professionals. In the same way, the youths would like adults to take into account their opinions, suggestions, age, gender and preferences to choose leisure activities.
- *Do leisure activities with their siblings*: Most of them do not see usually their siblings and they really would like to do activities with them.
- *Show real interest for their leisure needs*: The youths say it is important doing activities because all the members of the family really want to, and not just for commitment. However, they suggest that the educators show real interest in their leisure needs, listening and helping them with their petitions.

Conclusions

Family leisure is recognized as a strategy to promote resilience. The youths interviewed in our study want more leisure time and think that this type of leisure can be improved, giving us different suggestions.

The next step in the research is to carry out further studies on this topic and check if these suggestions can achieve this.

Abstract

Introduction: Emotion recognition, framed by the family emotional pattern, although it is not necessary impaired quantitatively, it may become a way to study resilience qualitatively. Seeing it as an ability developed in a family context, it indicates aspects that contribute to recovery, constructing both personal and family resilience.

Objectives: The determination, study and evaluation of family emotional patterns and the resilience factors in the presence of a psychotic disorder.

Material and methods: A descriptive study on a group of 25 subjects that have a family member diagnosed with a psychotic disorder was developed. The evaluated person has a caregiver role in the family setting. A photo set was applied (Paul Ekman's Emotions Revealed Photo Set) for the quantitative evaluation of the emotion recognition ability. A questionnaire with open questions (created by the authors) that evaluate qualitatively emotional patterns in the family and resilience factors was also applied.

Results: In terms of quantitative evaluation, the most recognized emotion is happiness (84%) and the least recognized emotion is contempt (8%). Qualitatively, emotions are important in the family frame, being described as a way of relating to others. To these families, the most negatively perceived emotion is contempt and the most accepted emotion is happiness – results that appear to be correlated with the quantitative evaluation.

Conclusions: Emotional family patterns may intervene in the psychotic pathology's evolution. However, considering that we assessed the families after the onset of the psychiatric disorder, we cannot ignore that the pathology itself shapes the emotional responses.

Keywords: Emotion recognition, Family emotional patterns, Resilience, Psychotic pathology

Introduction

Emotions are a large area of the human experiences and are defined in a simple way as the drive that controls behaviour. They are processed in the limbic system of the brain. Emotions can be regulated, and so humans can control their own actions and thoughts through reason. We are not slaves to our emotions but we do have to see them as they are: a very important part of us and an important part of our behaviour.

Emotion is a well-known term and it refers to a multifaceted answer to a situation that for the subject has meaning and it leads to modifications in the subjective experience, behaviour and physiology.

The sociology theory of emotions affirms the fact that emotions are social or cultural artifacts build by the participation to social roles or situations. [1]

The systemic family therapy provides the theory that people are formed to recognise social roles, act according to certain patterns, form their own beliefs and moral norms, and understand the world that they live in, including emotional patterns, through the family system, their family of origin and their present family.

Results of a major meta-analysis confirm that for child- and adult-focused mental health problems and relationship difficulties, family therapy is effective [2]. The average treated case fares better than 70% of untreated control cases. [3]

Emotion recognition is considered part of the social cognition of an individual. This ability is impaired in people with psychotic disorders and in their first degree relatives with high risk for psychosis. [4] This

provides a biological explanation of the genetic vulnerability to the systemic family therapy theory that sustains our combined assessment attempt.

An approach in evaluating emotions is a new concept in the study of psychiatric disorders and a combined study (qualitative and quantitative evaluation) is rare and offers the opportunity to raise important questions.

Objectives

The main objective is to evaluate the social cognition's component, emotion recognition, and how it is affected by a psychotic disorder present in the family system.

We try to analyse how this ability is impaired qualitatively and also quantitatively in relatives of a person suffering from a psychotic disorder.

Another objective is to evaluate the resilience of the family seen through the evaluated person's eyes. The opinion of the evaluator is also taken into consideration in our study.

A correlation between the qualitative studying of emotions and the quantitative one is attempted.

Material and methods

A group of 25 subjects is evaluated. This group contains 11 mothers, 6 spouses, 3 sons/daughters, 2 sisters, one father, one uncle and one cousin of the psychiatric patient.

The group is composed from 8 males and 17 females with the age between 25 and 70 years and an average of 49.24 years of age.

From the educational level point of view 9 subjects have superior education, 8 finished high school, 4 have post high school courses, two had 10 years of education and two had less than 10 years of education.

The duration of the referred psychiatric disorder in the family varies from one year to 33 years with an average of 10.04 years duration.

Five subjects had a psychiatric diagnosis, 3 reported their diagnosis as a reaction to the stress caused by the psychosis in the family and the other two had a pre-existing history.

For the quantitative evaluation the Emotions Revealed Photo Set (Paul Ekman) was used. This set includes one neutral expression and two each of the seven different emotions (anger, surprise, contempt, disgust, happiness, fear, sadness). [5] The pictures were shown one by one and subjects were instructed to indicate an emotion proper for each image. There was no time limit imposed and there were no possible answers from which the subject could select a correct one.

For the qualitative evaluation part of the study a questionnaire was developed. The questionnaire has four parts.

The first part refers to general information about the subject, the psychiatric disorder and the subject's relation to the psychiatric patient.

The second part of the questionnaire regards emotions and mainly how these, quantitatively evaluated emotions, are perceived subjectively, and what meaning is assigned to them.

The third part is the last part of the questionnaire in which the subject is involved. It evaluates the family's level of adaptation to the disorder and what changes have occurred after the onset of this disorder. In other words it evaluates the family's resilience.

The last part is addressed to the evaluator and regards his subjective opinion about the resilience of the family.

The questions were read by the evaluator and each answer was noted on the paper also by the evaluator, word for word.

Results

1.1 Quantitative evaluation for emotion recognition

In the first of two parts of this study a quantitative evaluation on the ability to recognise emotions is made. The subjects recognised between 4 and 10 images with an average of 6.88.

The most recognised emotion is happiness (it was recognised in 84% of the situations) and the less recognised emotion is contempt (8% of the situations).

In Table 1 the results are showed for all emotions evaluated. The percentage represents the situation in which the emotion was recognised from all possible situations.

Table 1 – Emotion Recognition Rates

Happiness	Surprise	Fear	Sadness	Anger	Disgust	Neutral	Contempt
84%	70%	50%	38%	38%	36%	20%	8%

1.2 Qualitative evaluation

The second part of the study represents a qualitative evaluation of several subsections mentioned below.

1.2.1 Emotions

The first question in this section is whether emotions are important or not for the members of the family (family that includes the psychiatric patient) and why. The themes followed are: emotions perceived positively or negatively, along with their importance in the family frame. The majority of the subjects considered emotions important (23 out of 25). While 11 considered that emotions are positive, 9 considered emotion as negative and 5 gave a neutral answer.

The next seven questions force the subject to divide happiness, surprise, fear, sadness, anger, disgust and contempt as being shameful or acceptable in their family frame. The most accepted emotion is happiness (all subject consider happiness as being acceptable in the family frame). Surprise is also largely accepted (24 out of 25). The least accepted emotion in the family frame is contempt (6 out of 25) with anger coming second (14 out of 25).

The next two questions try to define an emotional atmosphere in the family, also defining how the investigated subject feels most of the time.

subjects define their family as being mostly sad (8 out of 25) or happy (7 out of 25) and only 3 saw their family as being angry, 3 surprised, 2 considered their family as being fearful and one subject defined contempt as the main emotion expressed in the family.

When asked about their own emotions, subjects define themselves as being mostly sad (11 out of 25) or happy (8 out of 25) and only 2 were feeling angry, one felt fearful and one surprised.

The next two questions refer to the emotional support in the family. The first of the two asks about the permission for emotional expression and emotional support in the family, and the second asks about perceived emotional freedom and if that freedom is perceived as a support from the family or not.

Out of 25 subjects, 16 felt they could express their emotions in the family frame but only 9 felt support in this regard from the family members. Also, 19 out of 25 felt that the family is a support because of the emotional freedom they perceive in this frame.

Next, the subjects were asked about a change they would make about themselves, the patient and two other family members of their choosing: 17 out of 25 subjects would change something regarding themselves as a person and only 6 wanted to change something about their way of socializing.

The changes desired for the psychiatric patient were mostly regarding his/her way of socializing, communication skills (11 out of 25) and regarding his/her disorder (6 out of 25).

Regarding what is to be changed in the other relatives of the subject's choosing the main theme is increased support (33 out of 50).

1.2.2 Resilience

The first two questions of this section try to evaluate the subjective opinion of the examined subjects about their family resilience. The first tries to evaluate the ability to adapt of the family and the second tries to evaluate the ability to cope.

The ability to adapt is evaluated in two ways, if the family is considered to be fast adaptable or not and if it adapts well no matter how fast.

Subjects see their family as not adapting fast to a stressful situation (16 out of 25) and 14 out of 25 consider their family inadaptable.

Considering the ability to cope the majority of the subjects see their family able to cope to any stressful situation (23 out of 25).

The questionnaire tried to evaluate the perceived ability to positive reframing of the psychiatric disorder present in the family but with taking into consideration the negative influences of it.

Only half of the examined subjects considered their family to have reframed the psychiatric disorder positively (12 out of 25), and 14 out of 25 took into consideration concrete negative situations caused by the disorder.

20 out of 25 considered the psychiatric disorder a change factor in the family frame.

1.2.3 Evaluator's subjective opinion

The evaluator was asked in the last section to evaluate the family after applying the questionnaire to the subject regarding resilience.

17 out of the 25 families were considered to be resilient by the person that applied the questionnaire.

Conclusions

Emotions seem to be an important factor in the family frame, but are seen often as having a negative impact if expressed.

The accepted emotions seem to be the ones most often recognised by the subjects and the less recognised emotions are also the least accepted.

The atmosphere in the analysed families is perceived as being mostly sad or happy but when asked if they would change something in their relatives they often mentioned the necessity for calm, suggesting a more active atmosphere than the one mentioned.

The subjects feel mostly sad or happy in comparison to the other emotions evaluated.

The majority of subjects feel emotional support exists in the family frame and consider that their family permits the expression of emotions.

Subjects feel they would need more support from the members of their family regarding the psychiatric disorder and feel the need to change the way in which the patient socializes or communicates, suggesting a deficit in social cognition present in the psychotic patients as described in the known literature. [7]

The subjects feel that their family is resilient, having the ability to cope and adapt but in the process of reframing an assistance is probably needed to achieve good results.

The opinion of the evaluator is in concordance with the subjects and considers the families as being mostly resilient.

Discussions

The first question about the study is if the evaluated group is representative for their families. All the subjects in the study were the ones that assisted the patient to every psychiatric consultation. The caregiver role is a burdening role to have inside a family and it provides special status and a certain way of seeing thing that might not be shared by the other members of the family. An evaluation of at least two members of the same family would have provided more details.

The group is formed mostly by women, suggesting that the role of the caregiver in the families is socially reserved for women.

The presence of a control group would underline the particularities for the evaluated subjects regarding all sections.

The need for emotional education emerges from the study and it raises the question if it would help in the process of becoming resilient. Also the low number of families that succeed to integrate the experience of the psychiatric disorder in the family suggests the necessity of some psychotherapy for the family, when such an event occurs.

A connection between what is accepted and what we are able to recognise is underlined. The question arises if some form of education in the family is necessary in order to be able to integrate and accept emotions perceived as negative.

Because the request for a better support from other members of the family is expressed, a higher level of involving the family in the treatment of the psychiatric patient seems adequate.

To see how the atmosphere in the family affects the psychiatric patient, an evaluation on his perceptions regarding this aspect seems necessary.

Resilience might have been either under evaluated because the most stressed person from the family was evaluated and he might have seen in a more negative way than in reality, or it might have been over evaluated because the level of implication and concern is high in the subjects evaluated and they might have projected on the other family members some of the positive ways of seeing things that their relatives might not agree on.

Limitations of the Study

The first limitation of the study is the low number of subjects and the lack of a control group to compare the results with. The gender rate is unbalanced: in the group women have the majority.

To determine family patterns the whole family must be evaluated, not a single member of it.

To evaluate resilience, a level of gravity and exposure to the stressful event must be established. It would have been useful to evaluate the psychiatric disorder also.

A level of subjectivity in the qualitative research is impossible to avoid.

Modelling resilience in the family – a systemic perspective

Abstract

Child life-threatening pathology tests not only the family's capacity to adapt and the professional environments in which the child is cared for, due to the severity of the illness, the duration of treatment and the risks and secondary effects that are involved, but also due to the psychological impact such a diagnosis has.

Grieving for the loss of the ideal child, the limitations imposed by the disease and its treatment, the inherent existential coordinates of the oncology illness, all exert pressure on the coping resources of the individual, family and institutional contexts.

Froma Walsh in her research on resilience says value systems, communication styles, and the capacity for effective resolution are ingredients of family resilience. Philippe Caillé mentions that in this context, the therapeutic relationship can become an "epistemological dance" in which personal resilience inspires, catalyzes, and models context resilience.

The presentation analyses this process in interviews taken in a individual, family, and institutional context, aiming the way in which resilience is built at these levels, as well as identifying modalities in which the process of assisting child life-threatening disease can be improved.

Keywords: life-threatening disease, mourning, resources, change, resilient context.

Introduction

This paper was based on the authors' experience as volunteer counselors in the Onco-Hematology clinic of the "Louis Turcanu" Children's Hospital in Timisoara, Romania. While research brings significant insights into the effect of psychological assistance for families undergoing child cancer treatment, this paper relies mostly on clinical observations and interviews with patients and staff. Research-oriented and evidence-based family therapy is a project that will be developed in the future.

Our theoretical framework is based on systemic family therapy, which offers a broad perspective, focusing on multiple levels. The starting point is the individual as part of its family system (in this case, the child diagnosed with cancer and his/her nuclear or extended family; in the clinic, the child is admitted with a relative, usually the mother or grandmother). At the same time, this perspective allows for a systemic analysis of the organization (in our case, the medical staff involved in the treatment of these children and the clinic itself).

Child life-threatening pathology and the impact on the family system

Life-threatening pathology in children can take many forms, from acute pathologies that can be fatal, like pneumonia, meningitis or acute dehydration syndrome, to chronic pathologies, such as HIV infection or AIDS, kidney failure, cardiac malformations, or cancer. The focus of this paper will be on children diagnosed with cancer. Cancer treatment in children is long term, ranging from a few months to more than a year or even longer in the case of relapses or the type of disease. During treatment, the child is admitted to the hospital with a caretaker, and can spend there months at a time, with very short home leaves. During that period, the child will undergo invasive medical procedures, oftentimes surgical interventions, chemotherapy and/or radiotherapy, which can have serious side effects, like loss of hair, lack of appetite, an altered general condition. At the same time, during the treatment the patient can develop related pathology, affecting the brain, leaver, kidneys, skin etc.

Delivering a diagnosis of cancer represents the starting point of the crisis for the family. Usually the mother is admitted in the hospital with the child, which means she becomes the primary caregiver of the child, leaving her job for quite a long time, leaving the other children (when there are other children in the family) in the care of the husband or the extended family. Patients come to this hospital from all over the country, which means that the contact with the rest of the family is kept mostly via technological means – by phone, email,

instant messaging, video chat – since frequent direct contact is impossible. This way the couple relationship suffers and parental responsibilities take up most of the time for the couple. Parent-child relationships change, due to the child vulnerability, and overprotection can be a normal reaction by the parents for the sick child. This can result in regression for the child and/or a privileged relationship with the child-patient, while the other children in the family have less parental involvement. If the child is going to the kindergarten or to school, socialization with peers in the school is interrupted until the end of the treatment. Not only the child undergoes an invasive medical treatment with serious side-effects, but he is removed from school and home, losing peer contact and the socialization process and less contact with his/her siblings and extended family, resulting in less support.

Having a child with such a serious disease can generate feelings of powerlessness and helplessness for the parents. Oftentimes we have heard parents saying that they would prefer to be sick themselves, that it would be easier for them. These feelings can make a parent more prone to developing underlying vulnerabilities, like alcohol consumption or substance abuse. Facing tremendous challenges, avoidance can be a reaction, and the parent can even abandon the family. People handle sorrow and negative emotions in different ways. This may result in extramarital affairs and even in the dissolution of the couple. Thus, the entire family goes through a crisis when a child is diagnosed with cancer.

The Hospital becomes in this context a "second home" for the child. For young children, the Hospital is the place where they make the first steps or learn to speak. It is the place where children make friends with other patients, with whom they shared a room for a while. For their mothers, the Hospital is a place of sorrow and hope, a place in which they live for months at a time, hoping for healing, but fearing fatality, having an uncertain prognostic. In order to create a family-like atmosphere, the Hospital created a separate center, which is called The Family Center. Here mothers and children can live in a family-like environment. At the same time, the Family Center is a place in which mothers can socialize with each other, they can support each other and have a sense of a community. The Family Center is a place of rest, space, and going back to the domestic life – washing, cooking, cleaning, which represents a different space than medical procedures. This way, the center can be a resource in family resilience.

One of the most difficult tasks for the families of children undergoing cancer treatment is dealing with the possibility or the actual death and loss of the child. Even with medical advances, sometimes the disease is so advanced (it is either diagnosed late, or advances very quickly), or the child's body cannot fight anymore due to biological depletion and there is little to do for saving the patient. Fear of loss of the child is spread towards the entire treatment process, and news of other children's deaths is something that is strongly lived by every mother in the Hospital. [5] describes individual mourning process, which was portrayed in what they call a Grief Time Line. The authors state that the grief process can range from 0 to 42 months, going through three phases – shock, disorganization and reorganization. They also integrated in their model Worden's task integrated mourning at the individual and family model, which are the challenges that each phase brings. Even if following the families after the death of the child is something that is out of reach for the hospital, we have often seen families go through similar stages after the diagnosis of a child.

We have seen until now the effects of child life-threatening pathology on both the child and the family system of which the child is part of. We will focus within the next chapter on resilience and means an individual and a family can overcome difficulties.

Family resilience

Family resilience is defined as "the ability to withstand and rebound from disruptive life challenges" [1]. A later definition adds "to rebound strengthened and more resourceful" [4]. Resilience results in positive adaptation in the face of crisis and chronic stress. While the crisis directly affects one person in the family (in our case the child diagnosed with cancer), the consequences will impact the entire family, as discussed above. In a similar manner, there are factors which mediate recovery of the family system as a whole and its individual members. As a result of a crisis, a resilient family will not only survive, but thrive, develop new insights, new meaning, new abilities to cope in the face of future challenges, reappraise relationships and investment in people. An intervention model focuses on activating the strengths of the family, rather than the deficits, in order to foster recovery and growth.

Walsh developed a model of building resilience by focusing on three domains of family functioning: family belief systems (making meaning of adversity, positive outlook, transcendence and spirituality), organization patterns (flexibility, connectedness, social and economic resources) and communication processes (clarity, open emotional expression, collaborative problem-solving) [1].

Speaking about positive outcomes following a traumatic event, Tedeschi and Calhoun in [2] introduced the concept of post-traumatic growth, defined as "the perception of positive changes in the aftermath of an event initially perceived as being negative". In their opinion, growth and positive changes can be seen in the following areas: interpersonal relationships (positive significance of friendship and family), self-perception (better

acceptance of self and limitations) and philosophy of life (appreciation of small things, but also a deeper understanding of spirituality and religion).

Kubler-Ross considers loss to be a catalyst for growth and understanding [6]. She wrote that studying human beings facing death and loss, is a way in which one can learn the most regarding life and its ultimate mysteries.

When it comes to the death of a child, things can be more complicated, and even if a parent can go on with his/her life, the loss of one's child may not ever be fully processed. Walsh says that "With the death of a child, a parent's suppression of grief may work well for job functioning but may block support to a grieving partner and can impair the couple's relationship and their coparenting of surviving children", p.184. Not recognizing and not treating the effects of grief can have severe consequences, and may result even in the dissolution of the family. Resilience and recovery in these situations is a dynamic process, which does not result over night in moving on, but is oscillating between grieving and restoration. Making meaning of the loss is crucial in this process.

Modeling resilience

We have chosen to present and analyze the context in the Onco-Hematology clinic of the "Louis Turcanu" Children's Hospital due to some unique features in the leadership of this context and also because of the experience we had in the clinic. Professionals who are involved in the department have suffered personal losses, and in spite of very difficult life circumstances, they proved to be resilient. In an interview she gave for Hotnews.ro, Prof. Serban talking about the motivation for choosing this medical specialty and for investing so much in helping children with cancer says "[…] Then I went through and awful experience (Professor Serban's son died in adolescence) when I thought I will not be able to return. After a long period I had to come back to work and I met people in the hospital and the mothers… in the situation of loosing their child… and then I told myself: this is where you belong" [9]. Thus, personal resilience is being transferred to the institutional level and modeled within the clinic. After losing her only child in an accident, the Professor came back to the clinic to fight for saving other parents' children. Her family founded another center for treating children with diabetes, center which is named after the son they lost. The Family Center, which is a project she founded is unique in Romanian hospitals, is another element which was meant to facilitate a different experience for the families which are confronted with child cancer. Even more, the Professor is speaking about a model of leadership and practice she instilled for the residents and the other doctors in the department in which treating the children and families with respect, regardless of their background plays a very important role [10]. These features are consistent with the model of resilience described earlier.

Between resilient professionals on one side and the patient and his/her family on the other, the relationship is profound, with a sense of awe and respect. Wright in [8] speaks about the concept of reverencing in front of illness. To hear the narrative of illness leads to a deeper understanding of the human condition.

Systemic intervention in the Onco-Hematology clinic

According to the model of systemic intervention at different levels, even if the focus of our intervention was to offer support and counseling for the mothers and the children admitted in the Hospital for different types or stages of oncologic pathology, medical professionals were also part of the intervention. Facilitating communication between caring professionals and suffering families when there are problems which arise as a result of powerlessness and are targeted toward the medical staff, which generates frustration; confirmation of the efforts the medical system were putting into acting as agents of change in a context with many economic and social limitations were part of systemic mediation. The Family Center and the very advanced medical protocols are only a few examples of the efforts of the system.

At the same time, there were moments in which we as volunteer mental health professionals and the medical and mental health professionals of the hospital found ourselves in the situation of processing the death of children who did not survive, supporting each other and validating the feelings generated by these unfortunate situations. Behind the suffering of the families, the professionals who had developed a caring relationship with these children go through their own process of mourning when one of them does not make it. This needs to be acknowledged and dealt with in order to be able to go on and care for the other children. Professionals themselves need to be resilient in order to be able to work in such an environment.

Resilience in families that are dealing with child cancer starts at the point of accepting the diagnosis, and also accepting what is called the mourning of the ideal child. When they become parents, everyone believes that their offspring will be perfect, and dealing with a serious diagnostic like cancer challenges the image a parent has regarding their child. Integrating the reality of the illness and the requirements of the treatment process are one of the first tasks families need to do. At the same time, the prognostic with such a diagnosis is uncertain, and parents and children need to deal with the anxiety that this process generates. From our

experience, in such times most families rely on spirituality and religion. In times when personal resources are surpassed and one cannot control the situation, having something that is beyond you can offer assurance and peace [3], [8].

Psychoeducation regarding the disease and the natural course of the emotions involved in the process is another component of our intervention in with the families. Encouraging support and communication with the rest of the family, in order to prevent negative consequences mentioned earlier was also a focus. Helping families make meaning of illness is something that has been present in our intervention, too.

Dysfunctional or single-parent families deal with more difficulties in the process of adjusting to the situation. Support is crucial for the entire family, since the treatment process putts a very big strain on the system, while financial difficulties or lack of support put extra pressures on the family. Due to the cultural model in which the mother is the caretaker of the family, it can be very difficult for the father to find himself the primary caretaker for the other children remained at home, in the same time having to provide for the financial needs of the entire family. In situations like these, leaving the system or alcohol consumption as self-medication can be an attempted dysfunctional solution, and the future of the family can be seriously affected.

Another problem that we identified is the lack of information some families have regarding the cancer treatment, which sometimes results in very late diagnosis of the problem, by which the cancer is so advanced that there is very little the medical professionals can do in order to save the child. Or, due to the fear of the side effects of the treatment, a child can interrupt the treatment, and again, the medical professionals find out that the disease has spread too much and the recovery is compromised.

Conclusions

In the systemic perspective, the life-threatening diagnoses reverberate within the entire family, activating preexisting vulnerabilities. The sick child sometimes teaches resilience because they have innate ability to comfort the parents. A resilient family can inspire and encourage the child in building personal resilience.

Building on the strengths of the family, clinicians can develop interventions that will activate the resources of the families dealing with the devastating diagnosis of child cancer. Empowering the family and supporting them through the process of making sense in the face of this adversity can strengthen family ties, develop new competencies and instill a sense of hope.

Caring professionals' resilience inspires, encourages and models resilience for the families in a mirroring process with posttraumatic growth at many levels. The existential dimension involved in processing death requires spiritual resources with which the "valley of sorrows" is transformed in a "place of springs", Psalm 84:6.

Acknowledgements

We are thankful to all families in the Onco-Hematology clinic who have opened their lives in their most difficult times and allowed us to witness their sorrow, hope and joy. As well, to the caring professionals for their honest disclosure and transparency regarding their personal losses and for their daily fight for the lives of these children.

Explaining risk and protective factors in developing proactive and reactive aggression

Saric M.

Faculty of Teacher Education (Croatia)
marija_sar@yahoo.com

Abstract

The Behavioral Approach System (BAS) and Behavioral Inhibition System (BIS) are widely studied components of Gray's sensitivity to reinforcement model. There is growing interest in integrating those systems into model of risk for psychopathology. One of the models explaining the ethiology of proactive and reactive aggression grounds on the reactivity in BAS and BIS systems. Research suggests that BAS dominance increases risk for proactive aggression while BIS dominance increases risk for reactive aggression. Proactive and reactive aggression originate from separate family contexts. Reactive aggression is promoted by parenting behaviors such as lack of warmth and caregiving toward the child and rough family relations. Proactive aggression is promoted by parenting behaviors such as lack of parental discipline, monitoring and control. An attempt is made to model the interactional processes by which parenting style and BIS and BAS dominance in adolescents magnify or diminsh each other's progress toward healthy or antisocial development. First goal of this study was to examine predictive links of BAS and BIS dominance to proactive and reactive aggression. The second goal was to examine whether high levels of parental monitoring serves as a protective factor for reducing the risk of developing proactive aggression and whether high levels of parental warmth serves as a protective factor for diminishing the risk of developing reactive aggression. Measures of proactive and reactive aggression, BAS and BIS dominance, parenting styles were obtained on 17 year old adolescents (N=81).

Keywords: aggression, reinforcement sensitivity, parenting style

Introduction

The distinction between proactive and reactive aggression is becoming increasingly important research topic that promises to contribute to better understanding of the causes of aggression and different etiological pathways to aggression [1]. Reactive aggression has been conceptualized as irritable and hostile defensive response to provocation. It is characterized by lack of inhibitory functions, reduced self-control and increased impulsivity. Unlike reactive aggression, proactive aggression is not displayed as an emotion-laden, defensive response to immediate threat. Instead, aggression is used as a tool for personal gain that is applied strategically and methodically. It has a function to reach a goal, whether that goal involves material gain or social dominance.. Proactive aggression is associated with greater self-efficacy and fewer internalizing problems than reactive aggresion [2]. Unlike reactive aggression, proactive aggression predicts later externalizing problems [3]. Basically, researchers distinguish between aggression that is driven by anger, defense, and revenge from aggression that is callous, premeditated and purposefully goal directed [4]. There are two fundamental types of behavior – one to approach positive outcomes, and another to avoid negative outcomes. Jeffrey Gray [1987, according to 4] postulated specific brain areas that underlie approach and avoidance behavior. According to Gray's Reinforcement Sensitivity Theory (RST), the approach system is involved in Behavioral activation system (BAS) that activates behavior toward incentives. The avoidance system is involved in Behavioral inhibition system (BIS), relating to avoidance of conditioned aversive stimuli, and Fight-Flight system (FFS) relating to avoidance of unconditioned aversive stimuli. RST has been recently revised. In the revised reinforcement sensitivity theory (rRST), BAS continues to be the appetitive motivational system. Thus, its responsibility is to motivate approach behavior in response to both conditioned and unconditioned rewarding stimuli. Activity in the BAS is posited to be associated with the positive emotions of enthusiasm and relief. Impulsivity is hypothesized to be a causal basis of the BAS. Sensitivity to all punishments – conditioned and unconditioned is contributed to the FFFS (Fight/Flight/Freezing system) in the rRST. Thus, the primary responsibility of the FFFS is to motivate avoidance and escape behaviors in response to both conditioned and unconditioned aversive stimuli. The FFFS is also posited to be the neural supstrate for the emotions of fear and panic. In the rRST, the primary responsibility of the BIS is to resolve conflicts among competing goals (e.g.

approach-avoidance conflict) by inhibiting prepotent behavior, increasing attention and by actively engaging in risk assessment behavior. The aim of these processes is goal resolution (resolving conflict between BAS and FFFS). The BIS is also proposed to be the neural supstrate that underlies the emotion of anxiety [6,7]. Research suggests that BAS dominance is a risk factor for developing externalizing problems, whereas BIS (in RST) dominance is a risk factor for developing internalizing problems [8]. Contribution of Gray's model to the field of developmental psychopathology is significant because it provides an opportunity to combine multiple levels of influence such as biologically based individual differences with environmental risk and protective factors into a theoretical framework. Socialization affects input from the environment to which the BIS and BAS respond [8]. While proactive aggression is defined as aggression that is purposeful and rewarding, it was hypothesized that proactive aggression would be associated with sensitivity to reward. Alternatively, while reactive aggression is defined as aggression that is associated with aversive provocations unrelated to reward incentives, it is hypothesized to be related to sensitivity to punishment. Thus, the first goal of this study was to explore the predictive links of sensitivity to reward (BAS dominance) to proactive aggression and to explore predictive links of sensitivity to punishment (FFFS dominance) to reactive aggression. Reactive and proactive aggression are anteceded by different familial contexts [4]. Reactive aggression is assumed to be promoted by poor attachment relationship between the parent and the child, for example through a lack of warmth and caregiving behavior toward the child. These relationships are important for children for learning how to effectively attend to, understand, and take into account others' intentions. This may eventually induce feelings of insecurity and hostility and aggression in social relationships. Past rejections provoke anger and frustration which can result in excessively emotional responses to even minor stressors. Those children are easily threatened and frustrated, and tend to respond impulsively to any source of stress. Proactive aggression maybe assisted through a lack of parental discipline, monitoring, and control. Implicit or explicit parental endorsement can encourage the child to view and use aggression as an acceptable, successful means of goal achievement. Proactive aggression over time becomes a primary means of achieving personal security, competence, and control that was not given by their caregivers. Thus, reactive and proactive aggression appear to result from largely separate environmental contexts, with lack of maternal caregiving influencing reactive aggression, and lack of parental monitoring and control influencing proactive aggression. Of specific interest in this context are parental monitoring and control and parental warmth and caregiving as protective factors for two types of aggression. As such high levels of parental monitoring should reduce the risk of developing proactive aggressive behavior and experience of warmth and caregiving from parents should diminish the risk of developing reactive aggression. As such, the second goal of this study was to examine whether the expected predictive links of BAS and FFFS to later proactive and reactive aggression would be moderated by the level of adaptive parental behavior. The construct of "parenting style" had proven highly definite because it combines a variety of empirically supported parenting constructs (e.g. warmth, involvement, and control) [9]. Baumrind's conceptualization of parenting style has influenced research about child development more than 30 years. Of specific interest here is the Authoritative parenting style which, in general, comprises both warmth, caregiving and monitoring, control, demandingness [9]. Because of wealth of research concerning Baumrind's conceptualization of parenting style [10], I have chosen Authoritative style to be a measure of the protective factor for reactive and proactive aggression. In that way, authoritative parenting style should reduce the risk of developing reactive and proactive aggression. Mother's and father's Authoritative parenting style were separately assessed.

Method

Participants

Participants were 81 highschool students from Zagreb (55 girls and 26 boys). They were all attending third grade, and were all around 17 years old.

Measures

Peer Conflict Scale (PCS) [11] is a 40-item self-report measure including 20 items assessing reactive aggression (10 reactive overt items, e.g., *"I have gotten into fights even over small insults from others"* and 10 reactive relational items, e.g., *"I spread rumors and lies about others when they do something wrong to me"*) and 20 items assessing proactive aggression (10 proactive overt items, e.g., *"I threaten others to get what I want"* and 10 proactive relational items, e.g., *"I try to make others look bad to get what I want"*). Reactive and proactive aggression can be manifested in various forms, overt and relational. In this respect it is important to consider the form (overt or relational) and the function (proactive or reactive) of aggression together. Items are rated on a 4-point scale (0=not at all true, 1=somewhat true, 2=very true, 3=definitely true.

Validated Sensitivity to Punishment and Sensitivity to Reward Questionnaire for Children (SPSRQ-C) [12]. Luman et al. [12] validated the children's version of the questionnaire measuring sensitivity to punishment

and reward (Colder and O'Connor, 2004) which contains 33 items and is divided in a Punishment Sensitivity scale (15 items) and three Reward Sensitivity scales: Reward Responsivity (7items), Impulsivity/Fun Seeking (7items) and Drive (4 items). Reward Responsivity subscale measures emotional sensitivity and enjoyment of reward, the Drive subscale measures tendency in pursuing appetitive goals, and the Fun Seeking subscale measures tendency in seeking out novel and rewarding experiences [13]. Each item is scored on a 5-point Likert scale (1=strongly disagree, 5=strongly agree). The 5-factor model was almost identical to the 4-factor model: there were three Reward Sensitivity factors (Reward Responsivity, Impulsivity/Fun Seeking and Drive) except for the Punishment Sensitivity factor which was divided in two separate factors (FFFS and BIS). Coefficient alpha's of the 5-factor model were 0.79, 0.78, 0.70, 0.65, 0.76 for FFFS, Reward Responsivity, Impulsivity/Fun Seeking, Drive and BIS respectively. Since 5-factor model is most closely related to Gray's revised reinforcement theory because it provided separation of the FFFS and the BIS, it was used in this research. Example of FFFS item: "Whenever possible, I avoid demonstrating my skills for fear of being embarrassed", BIS item: *"Whenever I can, I avoid going to unfamiliar places"*, Reward Responsivity item: *"I do a lot of things for approval",* Impulsivity/Fun Seeking item: *"I often have trouble resisting the temptation of doing forbidden things"*, Drive item: *"I like to compete and do everything I can to win"*.

Parental Authority Questionnaire (PAQ) [14] is a 30-item instrument consisted of three 10-item scales representing authoritative, authoritarian and permissive parenting styles. It was designed to assess parenting style based on retrospective adolescent ratings. In validation studies, items were constructed based on Baumrind's descriptions of the parenting style. The PAQ has a good internal consistency (range=.74-.87) and test-retest reliability (range=.77-.92). PAQ scores did not appear vulnerable to social desirability response bias [9].

Procedure

Participation in a research was voluntary and anonymity was warranted. Filling all the questionnaires lasted half an hour.

Results and discussion

When we look at the correlations (Table 1), we can see that some results are not in line with the expectations. In accordance with the assumptions, reactive overt and reactive relational aggression would be positively and significantly related with FFFS, but those associations were not obtained. In accordance with the assumptions, proactive overt and proactive relational aggression would be significantly and positively associated with Reward Responsivity, Impulsivity/Fun Seeking and Drive which all represent the BAS factor. Significant correlation was found just between Impulsivity/Fun Seeking and proactive (overt and relational) aggression but also between Impulsivity/Fun Seeking and reactive (overt and relational) aggression. According to the RST, the BAS factor is mapped onto impulsivity and the BIS factor is mapped onto anxiety. Because Impulsivity itself is a complex trait cluster rather than a single dimension per se, some researchers think that the identification of the BAS with impulsivity was not a favorable choice. Impulsivity is widely regarded as having various dysfunctional implications, being associated with rash actions, a failure to consider the consequences of one's actions and even as having a key role in criminal behavior [15]. Impulsivity probably comprises a mix of sensitivity to reward and a lack of inhibitory control [16]. That could explain the results where both proactive and reactive aggression were significantly related with Impulsivity/Fun Seeking. In accordance with assumptions, proactive aggression was positively associated with Impulsivity/Fun Seeking because of heightened sensitivity to reward. On the other hand, association betwwen reactive aggression and Impulsivity/Fun Seeking could be explained by lacking of inhibitory control. Lack of correlations between FFFS and reactive aggression and between Reward Responsivity, Drive and proactive aggression are not in line with the assumptions and could be asigned to small sample size. According to correlations, we can conclude that Impulsivity/Fun Seeking can be a risk factor for developing proactive and reactive aggression (relational and overt).

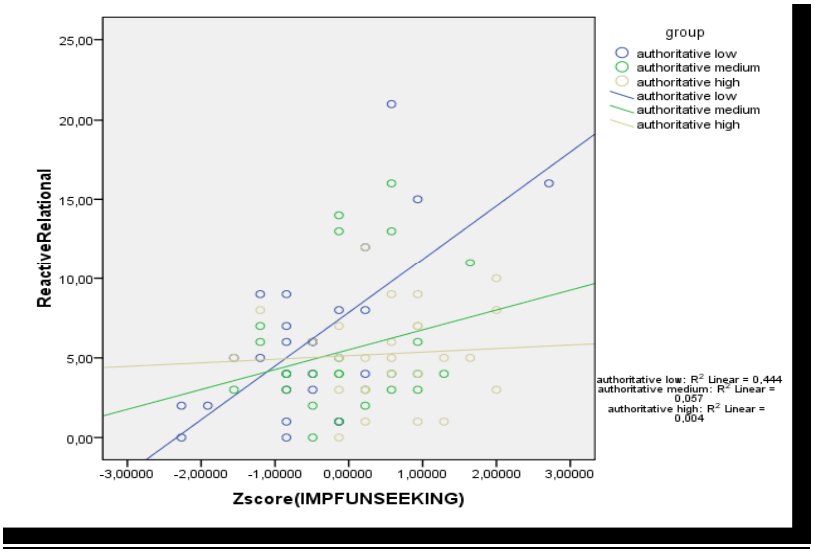
Table 1: Correlations between reactive (overt and relational), proactive (overt and relational) aggression and Reward Responivity, Drive, Impulsivity/Fun Seeking, FFFS, BIS

		Reward Responsivity	Impulsivity/Fun Seeking	Drive	FFFS	BIS
REACTIVE OVERT	Pearson Correlation	,102	,351**	,223**	,100	,063
	Sig. (2-tailed)	,370	,001	,046	,377	,580
REACTIVE RELATIONAL	Pearson Correlation	,083	,314**	,009	,034	,094
	Sig. (2-tailed)	,460	,005	,934	,762	,402
PROACTIVE OVERT	Pearson Correlation	,057	,392**	,019	,066	-,039
	Sig. (2-tailed)	,616	,000	,870	,559	,731
PROACTIVE RELATIONAL	Pearson Correlation	-,003	,299**	,043	,112	,114
	Sig. (2-tailed)	,979	,007	,702	,318	,312

*** Correlation is significant at the 0,01 level (2-tailed)*
** Correlation is significant at the 0,05 level (2-tailed)*

To answer the second question, whether the Authoritative parenting style moderates the association between Sensitivity to reward and Sensitivity to punishment and two subtypes of aggression, moderator analysis was conducted. There were four criterion variables: Reactive overt, Reactive relational, Proactive overt and Proacive relational aggression. While only Impulsivity/Fun Seeking was significantly correlated with criterion variables, it was the only predictor variable entered into analysis, besides Authoritative parenting style. To salve the problem of multicollinearity, variables Authoritative parenting style (mother's and father's) and Impulsivity/Fun Seeking were centralized. When the criterion variable was Reactive overt aggression, Adjusted R Square enhanced (from 12% to 15%) once the interaction variable of Impulsivity/Fun Seeking and mother's Authoritative parenting style was brought into analysis. However, Beta of the interaction variable was not significant (β=-0,21, p>0,05). So, we can conclude that mother's Authoritative parenting style does not serve as a moderator variable. When the criterion variable was Reactive relational aggression, Adjusted R Square was enlarged (from 9% to 15%) once the interaction variable was brought into analysis. The Beta of the interaction variable was significant (-0,26, p<0,05). So, we can conclude that the mother's Authoritative parenting style moderates the association between Impulsivity/Fun Seeking and Reactive relational aggression. When we look at the Graph 1, we can see direction of the interaction. Thereby, the more authoritative parenting style manifested by the mother, the less reactive relational aggression manifested by the impulsive child.

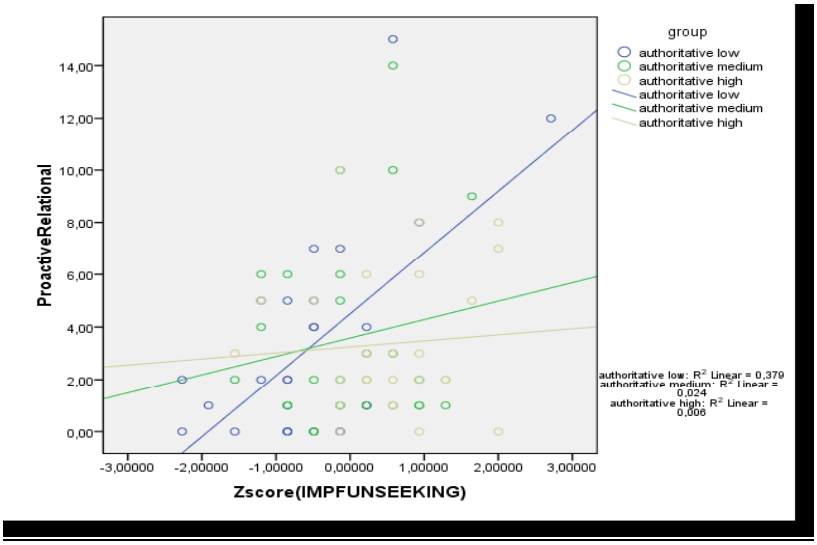
Graph 1: Mother's Authoritative parenting style as a moderator variable in explaining association between Impulsivity/Fun Seeking and Reactive relational aggression



When the criterion variable was Proactive overt aggression, Adjusted R Square enhanced (from 13% to 15%) once the interaction variable was brought into analysis. However, Beta of the interaction variable was not significant (β=-0,15, p>0,05). So, we can conclude that mother's Authoritative parenting style does not serve as a moderator variable in explaining relationship between Proactive overt aggression and Impulsivity/Fun Seeking. When the criterion variable was Proactive relational aggression, Adjusted R Square was enlarged (from 7% to 13%) once the interaction variable was brought into analysis. The Beta of the interaction variable was significant

(-0,26, p<0,05). So, we can conclude that the mother's Authoritative parenting style moderates the association between Impulsivity/Fun Seeking and Proactive relational aggression. When we look at the Graph 2, we can see direction of the interaction. Thereby, the more authoritative parenting style manifested by the mother, the less proactive relational aggression manifested by the impulsive child.

Graph 2: Mother's Authoritative parenting style as a moderator variable in explaining relationship between Impulsivity/Fun Seeking and Proactive relational aggression



Similar results were obtained for father's Authoritative parenting style. Father's Authoritative parenting style moderated the association between Reactive relational aggression and Impulsivity/Fun Seeking (Adjusted R Square enhanced from 9% to 16%; Beta from the interaction variable=-0,29, p<0,05) in a way that higher authoritative style manifested by the father, less reactive relational aggression manifested by the impulsive child. Father's Authoritative parenting style moderated the association between Proactive relational aggression and Impulsivity/Fun Seeking (Adjusted R Square enhanced from 12% to 19%; Beta from the interaction variable=-0,29, p<0,05) in a way that higher authoritative style manifested by the father, less proactive relational aggression manifested by the impulsive child. Obviously, associations between overt (proactive and reactive) aggression and Impulsivity/Fun Seeking were not moderated by Authoritative parenting style, while between relational (proactive and reactive) aggression and Impulsivity/Fun Seeking were moderated. One explanation could be that overt aggression is more influenced by Impulsivity/Fun Seeking than relational aggression. In Table 1, we can see that the correlations between overt subtypes of aggression and Impulsivity/Fun Seeking are higher than those between relational subtypes of aggression and Impulsivity/Fun Seeking.

Abstract

This communication is included into the theme of resilience in the families with a member with intellectual deficiency (ID).It is admitted that the fact of having a brother or a sister(B/S) presenting a DI implies also positive and negative impacts (8).It is a long time since when, having a brotherhood member presenting a DI, can be a risk for a person, and a reason for negative consequences.There are only few studies on resilience to prove it(12).In the context of the Quebec city,where from the end of the !980's, persons presenting a ID lived always with their natural families (not in institutions), it is pertinent to ask about the impact of that context on B/S.As this peoples lives always with persons presenting a ID,there was a certain impact on the relation between them, and also on their values and options in live, etc.In the context of a doctoral research focused on the intentions of implication on B/S considering a person with trisomie 21, present communication proposed a case study of two participants regarding the resilience indices, presence in the relations of B/S presenting an ID from the infanthood to the adult age. The risk and protective factors are relevated and also the present state of the situation.

Keywords: Resilience, intellectual deficiency, brotherhood, relation, protective factors

Contexte théorique

1.1 Impacts de la déficience intellectuelle (DI) sur la fratrie

Le fait d'avoir un frère ou une sœur (F/S) qui présente une DI a inévitablement des impacts à plusieurs niveaux chez la fratrie. En effet, des études ont démontré que les F/S de personnes vivant avec des incapacités physiques ou intellectuelles constituaient une population à risque en raison du nombre considérable d'impacts négatifs occasionnés par la condition de la personne présentant des incapacités [17,18, 25]. Les études ultérieures ont démontré que ces impacts peuvent être négatifs ou positifs [1, 2, 4, 6, 16, 20]. Enfin, les études les plus récentes démontrent, quant à elles, un ensemble complexe d'impacts positifs et négatifs chez la fratrie adulte [8]. Il semble donc que le fait d'avoir un F/S présentant une DI ne constitue pas une garantie de vivre uniquement des impacts négatifs. Au contraire, il appert que les F/S développent des caractéristiques qui leur sont propres. Le Tableau 1 suivant présente une synthèse des impacts positifs et négatifs retrouvés dans les écrits scientifiques. Il ressort que les impacts négatifs sont plus nombreux et que les impacts positifs relèvent de l'acquisition de traits de personnalité ou d'attitudes.

Tableau 1 Synthèse des impacts du fait d'avoir un frère ou une sœur présentant une trisomie 21

Impacts négatifs	Impacts
• Embarras devant les pairs • Responsable ou chargée de prodiguer les soins • Ostracisme • Moins de temps «un à un» passé avec les parents • Diminution des activités sociales de la famille • Davantage de restrictions dans la routine • Exposition au stress et à l'anxiété des parents • Diminution du revenu familial à cause des soins à donner • Ne pas avoir une relation dite normale avec le F/S • Accepter et «faire avec» les comportements problématiques • Préoccupations pour l'avenir • Difficultés à faire des activités et à communiquer avec leur F/S • Sentiment de colère et/ou de culpabilité	• Tolérance • Ouverture à la différence • Maturité • Compassion • Appréciation de leur état de santé et de leurs habiletés • Patience • Tendance à aider, soutenir, assister

1.2 Facteurs de risque et de protection

Le concept de résilience s'inscrit dans l'équilibre entre les facteurs de protection sur les facteurs de risque, équilibre qui permet de faire face à l'adversité. Ainsi, la définition de la résilience retenue est la suivante : « le processus qui fait que, face à l'adversité, face au traumatisme ou face au stress, des individus, des familles, des groupes d'humains s'en sortent, ne présentent pas de troubles psychiques, continuent à vivre comme avant (ou presque) et peuvent même présenter un fonctionnement psychique meilleur qu'auparavant » [9].

Peu d'études se sont penchées sur la résilience dont font preuve les F/S d'une personne présentant une DI [12]. L'étude de Fisman a révélé que la satisfaction conjugale des parents, la cohésion familiale et une relation chaleureuse et non-conflictuelle avec le F/S présentant une trisomie 21 (T21) constituaient des facteurs de protection pour les F/S d'une personne présentant une T21 [5].

Depuis les années 1980, au Québec, les personnes présentant une DI ne sont plus institutionnalisées. Ainsi, les frères et sœurs québécois âgés de moins de 35 ans constituent la première cohorte à avoir toujours vécu dans la même résidence que la personne présentant une T21 [11].

Méthode

1.1 Participants

Les deux participantes (âge) retenues pour cette communication ont été tirées d'une étude doctorale incluant quatre frères et cinq sœurs d'une personne présentant une T21. Les entrevues individuelles avec les participants ont duré entre 60 et 130 minutes.

1.2 Instruments

Les instruments qui ont servi à la cueillette de données de l'étude doctorale et dont sont tirés les résultats faisant l'objet de cet acte de congrès sont présentés ici brièvement. Dans le cadre de cette présentation, il est à noter que les résultats de la *Ligne de vie*, des sections de l'entrevue semi-structurée (Relation fraternelle et Implication actuelle) de même que la *Grille de réseau de soutien social* ont été utilisés spécifiquement pour les études de cas.

1.2.1 Questionnaire sociodémographique

Un questionnaire sociodémographique a été élaboré spécialement pour les fins de ce projet de recherche [22]. Il permet de recueillir des informations sur le participant et sur le F/S présentant un syndrome de Down notamment sur l'âge, le sexe, le statut civil, l'occupation ou non d'un emploi, etc.

1.2.2 Ligne de vie

La *Ligne de vie* [10] vise à rapporter les événements marquants dans la vie du répondant sur une ligne allant de la naissance du participant à la date de l'entrevue (dessinée sur une feuille 8 ½ x 14 présentée dans le sens horizontal) de même qu'à leur donner une valeur positive ou négative (les événements positifs devant être représentés au-dessus de la ligne et les événements négatifs, en-dessous).

1.2.3 Génogramme

Le *Génogramme* [7] vise la représentation des membres de la famille du participant ainsi que des relations entretenues entre eux sous une forme graphique.

1.2.4 Entrevue semi-structurée

Le guide de l'*Entrevue semi-structurée* a été conçu spécifiquement pour les besoins de cette étude [23]. Il comprend une quinzaine de questions couvrant cinq grands thèmes, soit : (a) les relations fraternelles, (b) l'implication actuelle, (c) la planification effectuée par la famille, (d) les intentions d'implication dans l'avenir et (e) les besoins de soutien.

1.2.5 Grille de réseau de soutien social

Cet instrument constitue une adaptation de l'instrument original [12]. Seule la partie sur le F/ST21 a été ajoutée afin d'adapter cet instrument aux besoins du projet [24].Il s'agit de rapporter la liste des personnes qui peuvent donner du soutien dans cinq situations (besoin de parler ou d'être écouté, besoin d'emprunter de l'argent, besoin d'aide pour réaliser les tâches domestiques et pour avoir du plaisir ou se détendre et projection de l'aide nécessaire dans l'avenir en lien avec le F/ST21) et celle des personnes auxquelles les participants sont attachés.

1.3 Sélection des cas à l'étude

Les deux participantes sélectionnées pour le présent acte de congrès est basé sur les critères d'inclusion suivants : 1) participants de sexe féminin puisque les femmes sont davantage représentées dans l'échantillon de l'étude doctorale et dans les écrits scientifiques; 2) ces deux participantes sont âgées de 26 et 18 ans et ont toutes deux un frère présentant une trisomie 21 (FT21). L'une est l'aînée d'une fratrie de quatre enfants (son frère FT21 a 8 ans de plus/moins qu'elle) alors que l'autre est la cadette de 2 ans d'une fratrie de deux.

Résultats

Les résultats de la double étude de cas sont présentés dans la prochaine section et se déclinent en deux sous-sections : 1) le relevé des facteurs de risque et de protection; 2) la trajectoire de la relation.

1.1 Facteurs de risque et facteurs de protection

Les facteurs de risque et de protection des deux participantes ont été ciblés au travers des différents instruments utilisés. Les résultats de l'étude de deux cas sont présentés dans le Tableau 2 suivant.

1.2 Trajectoire de la relation au FT21

Les deux participantes ont toujours habité avec leur FT21 et les autres membres de la famille. L'une est allée à la même école primaire que son FT21 alors que ce n'est pas le cas pour l'autre en raison de la différence d'âge. À l'adolescence, toutes deux ont rapporté avoir vécu cette période plus difficilement en raison d'un manque d'attention parentale.

Au moment des entretiens, les deux participantes ont rapporté avoir actuellement une bonne relation avec leur frère et habiter encore avec leurs parents et leur FT21. Elles partageaient donc leur quotidien avec ce dernier et évaluaient la satisfaction dans leur relation actuelle à 8,5 sur 10. Elles rapportent toutes deux partager des activités de loisirs avec leur FT21 (p. ex. sports, jeux vidéo, loisirs) et avoir parfois un rôle de soutien parental (p.ex., en rappelant les consignes au FT21).

Tableau 2 Facteurs de risque et de protection relevés pour les deux sœurs

FACTEURS DE RISQUE	
F01	**F03**
Individuels • --	*Individuels* • A vécu de l'intimidation en lien avec son frère • Difficultés scolaires
Familiaux • Relation conflictuelle avec un de ses frères	*Familiaux* • Relation conflictuelle avec ses parents
FACTEURS DE PROTECTION	
F01	**F03**
Individuels • Capacité à reconnaître des forces et des faiblesses au FT21 • Plus âgée (26 ans) = maturité • Aînée (donc plus maternelle) • Très impliquée (coach de soccer) • Considère avoir vécu une belle enfance	*Individuels* • Capacité à reconnaître des forces et des faiblesses au FT21 • Capacité à donner du sens à ses expériences
Familiaux • Parents en couple • Mère très impliquée dans la vie associative • Bon niveau socio-économique	*Familiaux* • Parents en couple • Bon niveau socio-économique
Environnemental • Réseau social impliqué et sensibilisé	*Environnemental* • Bon réseau social

Discussion

Les deux études de cas présentées confirment les écrits scientifiques [8] qui ont démontré que le fait d'avoir un frère ou une sœur présentant une déficience intellectuelle pouvait avoir des impacts à la fois positifs et négatifs. Malgré la période adolescente rapportée comme plus difficile en raison du manque d'attention parentale associée à la présence du frère T21, il semble que les trajectoires de relation (vie et activités communes) et les facteurs de protection relevés dans cette présentation surpassent les facteurs de risque, et permettent une grande satisfaction dans la relation au FT21. Il est possible de croire que la résilience des sœurs pourrait être liée à ces éléments et permettent la conscience des impacts positifs.

1.1 Limites et retombées

Il n'est évidemment pas possible de généraliser les résultats de deux études de cas qui ne peuvent aboutir à une représentativité de l'ensemble des F/S. De plus, il est possible que les soeurs ayant participé soient très impliquées auprès de leur frère et, par le fait même, plus aptes à rapporter des impacts positifs. Toutefois, cette étude constitue une avancée dans les connaissances. D'abord, de par la nature exploratoire de l'étude, il a été possible d'apporter un éclairage sur une réalité relativement nouvelle au Québec. Il s'agit également d'un sujet et d'une façon de traiter celui-ci, qui constituent une innovation. Les instruments utilisés ont démontré leur utilité et leur richesse.

Conclusion

Cette présentation a permis de relever certains facteurs de risque et de protection chez deux participantes ayant un FT21 de même que la trajectoire et l'appréciation de la relation avec celui-ci. Il en ressort qu'il est possible de retrouver davantage de facteurs de protection chez les deux participantes, ce qui a certainement contribué au fait qu'elles se disent satisfaites de la relation qu'elles entretiennent actuellement avec leur FT21 et apparaissent bien assumer cette différence dans leur fratrie.

Research on protective factors in five resilient women who grew up with a parent suffering from bipolar disorders

Tang H., Bouteyre E.

Aix Marseille Université, LPCLS, EA 3278, F-13621, Aix en Provence (FRANCE)
helene.tang28@gmail.com, evelyne.bouteyre@univ-amu.fr

Abstract

This study aims at exploring internal and external protective factors in resilient subjects, who lived with a parent suffering from a mental illness, using the analysis of the family drawing and the semi-structured interview.

Five mental healthy adult women, from 20 to 43 years old, who lived with a father or a mother with bipolar disorders, have participated in the study. Family drawing when they lived with both parents whose one was mentally ill, was used in case of participants.

In the family drawings, among the *internal protective factors*, three of the five subjects showed a character strength and a good emotional maturity. The two others showed either inhibition or introversion as defence mechanisms. Among the *external protective factors*, we observed a closer relationship with the healthy than the mentally ill parent in two of the five drawings, a closer relationship with a sibling than the parents in two other drawings. These results corroborate the protective factors reported in the semi-structured interviews and were the most predominant. These results are congruent with those in the literature.

Thus, the family drawing is a relevant and original tool given its projective feature to investigate and evaluate the weight of the protective factors in the offspring of mentally ill parents.

Keywords: protective factors, resilience, adult offspring of parent with bipolar disorders, family drawing.

Introduction

The studies about the children of mentally ill parents are generally focused on children with mental disorders or at risk. As Rutter and Quinton (1984) noticed in their four-year-follow-up study on the children of parents who are mentally ill: one third of the children has persistent disorders, one third has temporary disorders, the last third has neither emotional nor behavioral disorders. But, we know very little about the last third, those children who are resilient.

Problematic

The present study aims at exploring internal and external protective factors in resilient subjects who lived with a parent suffering from a mental illness, and have the ability to maintain in a good mental health despite the environmental circumstances.

Methodology and population

Five mental healthy adult women, from 20 to 43 years old, and who lived with a father or a mother with bipolar disorders, participated in the study.

Family drawing when they lived with both parents whose one was mentally ill, was used in case participants, as complementary tool to semi-structured interviews.

The latter aimed at highlighting the point of view of adult offspring who grew up with a parent suffering from a mental illness, and exploring internal and external protective factors, which helped the subjects to maintain in a good mental health, compared to those in the literature.

The family drawing was chosen to emphasize the quality of the links between the adult offspring and their family members.

Results

The results were partially obtained from the analysis of the subjects' family drawings. The other part was obtained from the semi-structured interviews.

The internal protective factors:

They are reflected by the general quality of the drawing and the behavior of the subject during the test. These concern the character strength, the emotional maturity, the self-image and the relationship to another of the subject. Three of the five subjects showed a character strength and a good emotional maturity. The two others showed either inhibition or introversion as defense mechanisms. These features identified in the drawings replicated the internal protective factors reported in the semi-structured interviews and were the most predominant. Moreover, the generational difference is well integrated. This is present in four of the five drawings. However, the gender difference is less well represented. Three of the drawings have no gender characteristic.

Other protective factors appeared in the semi-structured interviews such as the independence, the ability to reach out to others, interest in learning.

The external protective factors:

The family unit is part of both internal and external protective factors. The family drawings of the five women included all the family members of their real families. The parental couple was drawn at first for four of the subjects. The fifth subject drew first herself surrounded by her siblings, then she drew her parents. The parents have a parental role in all the drawings. They are represented at first compared to the offspring and/or were drawn taller. The offspring conserve their child place despite their carer role for three of the five subjects. The distance or the closeness between the characters reflects the quality of the links between family members. We observed a closer relationship with the healthy than the mentally ill parent in two of the five drawings, a closer relationship with a sibling than the parents in two other drawings. This observation corroborates some of the external protective factors already identified in the semi-structured interviews. Others were found as well such as the support from adults outside the family and/or peer support, information about the mental illness.

Discussion

The results obtained through the family drawings showed that the mental illness of a parent doesn't alter the family composition. The subjects' drawings match their real family composition. The generational difference is well integrated but the gender difference is, however, less well represented in the drawings. We can suppose that the mental illness of a parent affect the sexual identification of the offspring, which can be explored in a further study. Living with a parent suffering from a mental illness doesn't affect the places and the role of each family member for these five women. The parents have a parental role. The offspring can take a carer role and conserve their child place, which is in line with the results found in the literature [1, 2].

Some protective factors found in the family drawings are congruent with those in the literature: the presence of a healthy parent [3], a close relationship to a parent or a member of the family [4], the family cohesion [5]. The peer support [6] and information about the mental illness are also mentioned in the literature [7]. Among the external protective factors, the family appears to be the principal environmental protective factor, before school environment and community, which is to be further explored. We think that the stigma of the mental illness impedes the family members to talk about it outside the family. The mental illness of a parent generates suffering among the relatives, including the subjects of this study, but this is also what explains their bonds. The weight of the protective factors relative to the interactions between the members of the family has to be further explored.

The results of the present exploratory study cannot be generalized because the sample is limited and the participants were all women. Further studies can be conducted using a larger sample, including men and women, with parents suffering from with a multiple range of mental illnesses and not limited to bipolar disorders.

Conclusion

The aim of this study was to identify the presence of internal and external protective factors in five resilient women who grew up with a bipolar parent. The family drawing, with its projective feature, is a relevant and original tool that allows us to achieve this goal. Such a tool may be used to investigate and evaluate the weight of the protective factors in the offspring of mentally ill parents.

The internal and external protective factors do exist in the children of parents suffering from mental illness. The combination of data from the semi-structured interviews and those from the projective tests shows that for these five women, the protective factors are to be drawn, first, within the family itself. This family is a resilience element associating both internal, i.e. specific to the subject, and external protective factors, which are primarily associated with the family dynamic.

Child's behavior, quality of life, and marital adjustment of parents with autistic children: mediator effect of resilience and social support

Turliuc M.N., Duca D.-S.

[1]*Alexandru Ioan Cuza University, Iași, Romania*
turliuc@uaic.ro, dianasinziana@yahoo.com

Abstract

The current findings regarding the effects of having an autistic child on the family are contradictory, as they reveal that such situations may have both positive and negative consequences according to several others mediating variables. Some studies suggest that resilience and social support may positively mediate the influence of the child's disability on the personal adjustment of the other family members as well as the adjustment of the family as a whole. The current study aims to investigate whether family resilience and social support mediate the relationship between parent's perceptions of aberrant child's behavior and both marital adjustment and parental quality of life. The sample of 51 parents who participated in our study were 26 to 50 years old (M=41.82) and they all filled in several self-report scales. The obtained data was analyzed with structural equation modeling which included bootstrap resampling; the findings showed that family resilience fully mediated the effects of the aberrant behavior of child on both marital adjustment and parental quality of life, social support fully mediated the effects on marital adjustment, and partially mediated the effects on family quality of life. Our results are discussed in the context of their relevance for the therapy of families with children who suffer from Autism Spectrum Disorders.

Keywords: Autism Spectrum Disorders (ASD), Marital Adjustment, Quality of Life, Social Support, Resilience

Introduction

1.1 The impact of raising a child with ASD on parents and families

The consequences of raising an ASD child do not only impact the main caregivers – they extend to the entire family system. The increased levels of parental stress, number of conflicts and behaviour issues of the child contribute to a higher rate of divorce among parents who care for ASD children as compared to those whose children are normally developed [1]. Families of children diagnosed with autism were shown to have a lower quality of life as compared to families of children diagnosed with other disorders, and as compared to families of normally developed children [2]. The quality of life in families of children with developmental disorders is mediated (in its relationship to the impact of the disorder on the family) by variables like resilience and social support [3]. Brobst et al. (2009) revealed that parents of autistic children are intensely affected by the child's behavioural problems, experience higher stress levels and lower parents' relationship satisfaction as compared to families of non-autistic children [4]. Higgins et al. (2005) revealed that these parents report lower levels of relationship happiness and lower adaptability and family cohesion as compared to families with normally developed children [5]. Gau et al. (2011) have shown that, as compared to mothers of normally developed children, mothers of autistic children report lower levels of: marital adjustment, dyadic consensus, expressing affection, family adjustment and family cohesion [6].

1.2 Family resilience and social support in families with autistic children

Although it is known that the presence of an autistic child negatively impacts the whole family, there are also researchers arguing that the negative consequences stated cannot be generalized to all families – sometimes, the presence of an autistic child within a family system may engender positive consequences. For example, Sanders and Morgan (1997) concluded that, although they lead stressful lives, parents of autistic children are no different from either parents of children with Down syndrome or parents of normally developed

children regarding a series of important aspects: family cohesion, conflicts, independence, goal focusing, family control and family organization. The only significant differences occurred in what concerns the degree of involvement in cultural and leisure activities [7]. Similary, some research concluded that families of children with developmental disorders show resilience in adapting to the special needs of their child [8,9]. Plumb (2011) argues that elevated parental stress is associated with a low feeling of family resilience, while the strongest correlations between family resilience and parental stress seem to be connected to variables like: family communication, family spirituality, family connection and family problem solving [10]. A supportive network was also shown to mediate how much protection parents extend to their children and how they perceive the child's problematic behaviour. The available social support offered by the partner and by friends to families with children suffering from developmental disorders was shown to be associated with a higher satisfaction towards family functioning [11].

The purpose of our study is to investigate whether social support and resilience mediate the relationship between parents' perception of the aberrant behaviours of the autistic child and the quality of family life, as well as the relationship between these behaviours and marital adjustment. Some studies suggest that having an ASD child has strong negative effects on the family quality of life [2,] and several studies found that social support and resilience positively mediate the effects of the child's disability on family adjustment [12, 13, 14], as well as the effects of the special needs of the ASD child on the family quality of life [3]. The aim of our study is to continue the previous line of research in this field by addressing a gap in the current scientific literature; for this purpose, we examine the potentially mediating effects of resilience and social support on the relationships between how parents perceive their ASD child's abnormal behaviours and the family quality of life and, respectively, marital adjustment.

Method

1.1 Participants

The participants were 51 parents of children with ASD recruited from two day-care centres and a special education school located in Iași and Suceava. Our final sample consisted of 24 males, and 27 women with ages ranged from 26 to 50, with a mean age of 42.8 years, SD = 6,30. They all filled in several self-report scales. The participants completed the questionnaires at home.

1.2 Measures

The Social Support Index (SSI) consists of 17 items on a five-point Likert-type scale. Respondents were asked to rate their responses to the questions from 0 (strongly disagree) to 4 (strongly agree). Cronbach's alphas for the current study were .82. The range in score on the SSI is 0 to 68. All scores were summed, with a higher score indicating a higher level of social support.

The *Aberrant Behavior Checklist-Community (ABC-C)* is a 58 item scale that measures parent's perceptions of their child's problem or maladaptive behaviors at home or school. ABC-C items are grouped into five subscales. Respondents rate items on a 4- pont Likert scale ranging from (0) "not at all a problem" to (3) "the problem is severe in degree". The ABC-C subscale scores are calculated by totaling the scores of the subscale items. Cronbach's alphas for the current study were .98.

Family Resilience Assessment Scale (FRAS) consists of 66 questions and one open ended question. The open ended question was not used in this study.The measure uses a 4-point Likert Scale that ranges from *strongly disagree* to *strongly agree*. The higher score indicates a high level of family resilience, and a low score indicates a low level of resilience. In our sample, Cronbach alpha for the total score is .97.

Dyadic Adjustment Scale (DAS) is a 32 item scale that measures relationship quality and adjustment. The scale is divided into 4 subscales. The score varies from 0-151. The total scale and the subscales can be considered as measures of different aspects of marital satisfaction. Cronbach's alphas for the total score in this study is were .93.

Family Quality of Life Index (F-QLI) is a comprehensive multi-dimensional measurement tool that reflects the priorities and goals of families that define quality of family life as made up of the following seven domains: 1)life satisfaction, 2) physical health and psychological well-being, 3) social relations, 4) activities of daily living, 5) alcohol and other drug abuse, and 6) goal attainment. Each domain can be scored separately and the separate domain scores can be added to produce the total quality of family life score. The last three domains are not used in this study. Cronbach's alphas for the current study ranged between .81 and .95.

1.3 Procedure

Informed consent was obtained from all the participants. They are guarantees that the answers are anonymous and confidential and that the data provided will be used only for research purposes. The research

presented that purpose of the study to the participants. Also, they were informed that their participation was voluntary.

Results

Table 1 presents descriptive statistics and correlations of all variables from the present study. Preliminary analyses (using Pearson correlation) showed that parent's perceptions of their child's problem or maladaptive behaviors is negatively linked with dyadic adjustment (r=-.53; p=0.028), family resilience (r=-.82; p<0.001), family quality of life (r=-.61; p<0.001) and social support (r=-76; p<0.001). Analyzing the relationships between dyadic adjustment, family resilence, quality family life and social support, the results showed that all these variables are positively associated.

	1	2	3	4	5

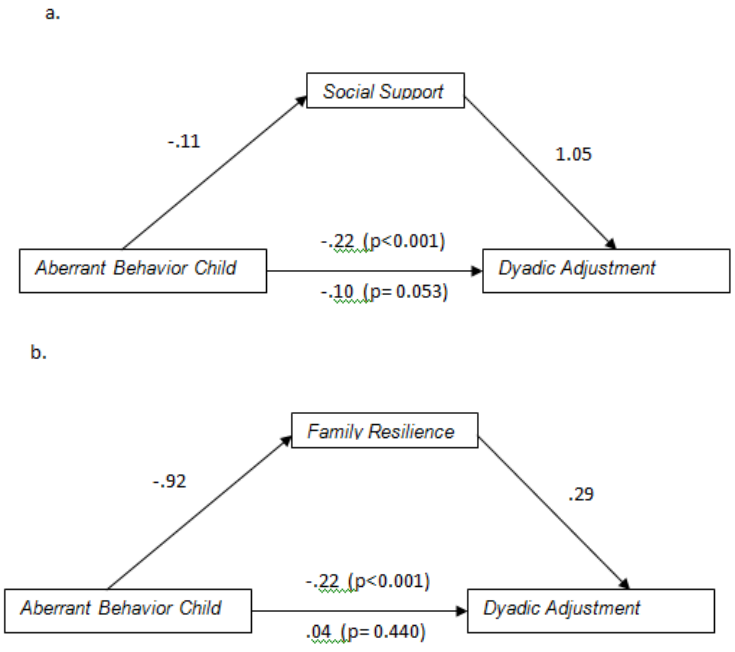
Table 1: *Correlations, means and SDs of analysed variables; Note: **p<.01, *p<.05; ABC-C - Aberrant Behavior Checklist-Community; DAS - Dyadic Adjustment Scale; FRAS - Family Resilience Assessment Scale; F-QLI - Family Quality of Life Index; SSI - Social Support Index*

To analyze if family resilience (FR) and social support (SS) mediate the relationship between parent's perceptions of aberrant behavior child (ABC) and dyadic adjustment (DA) and family quality of life (FQoL), we used Structural Equation Modeling, which included bootstrap resampling by AMOS. Four mediation analyses were conducted: two with relationship ABC-AD and the other two with relationship ABC-FQoL. In all these analysis the mediator variables were SS and RF and these mediators were introduced one by one in the analyses, which resulted four mediating relationships. These relationship are ilustrated in Figure 1.



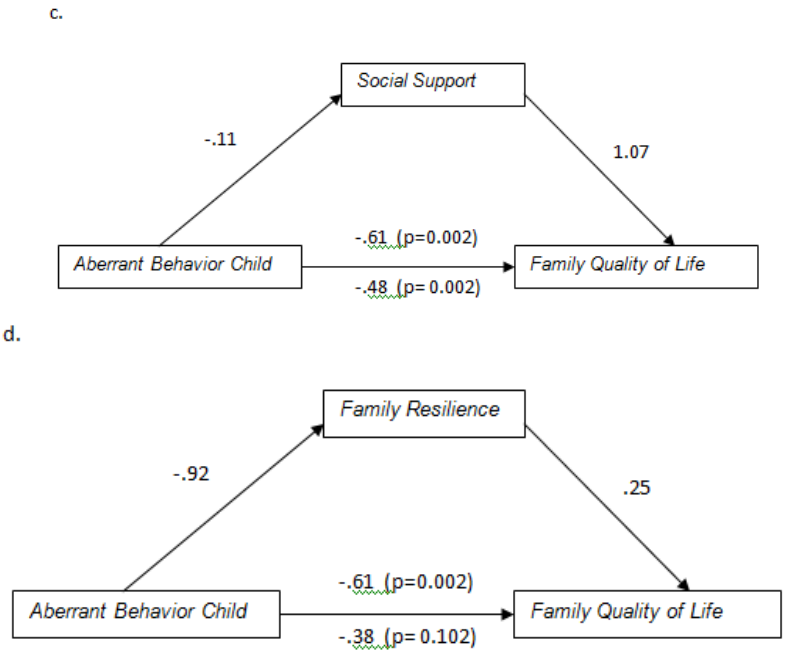


Figure 1 *— a)SS as a mediator of the relationship ABC-AD; b)FR as a mediator of the relationship ABC-AD; c)SS as a mediator of the relationship ABC-FQoL; d)FR as a mediator of the relationship ABC-FQoL*

As shown in Figure1a, the relationship ABC-DA is completely mediated by SS (B =-.22; p<.001) which means that the relationships between independent and dependent variables are not significant without the mediation of SS (B = -,10; p=0.053). In Figure1c it is observed that SS is a partial mediator between ABC-FQoL (B =-.61; p=.002), which means that the relationships between independent and dependent variables are still significant without the mediation of SS (B =-,48; p=0.002).

We find out that FR fully mediates the ABC-DA and ABC-FQoL. This results are presented in Figure 1b and 1d and it is observed that the relationship ABC-DA isn't significant without the mediation of FR (B =.04; p=0.440). In the same direction, the relationship ABC-FQoL isn't significant without the mediation of FR (B =.-,38; p=0.102).

Discussion

To conceptualize the experience of families affected by autism we analyzed the relationships between family resilience, social support, parents' perception of the child's aberrant behavior, dyadic adjustment and family quality of life. More specifically,the aim of our study was to investigate whether FR and SS mediate the relationships ABC-DA and ABC-FQoL. The results of our study suggest that SS and FR fully mediated the effects of the child's disability symtoms on both marital adjustment and parental quality of life, with exception that SS is a partial mediator between parent's perception of aberrant behavior child and family quality of life. These results confirmed and extended findings from previous research [12,13,14,3]. The results of this study suggest that social support and family resilience are complex phenomena that could act in different capacities given the literature on the role it has on family adjustment and family quality of life in families affected by autism. Therefore family therapists should work with families to improve family communication and problem solving skills, assist in helping families develop coping mechanisms that help to maintain a positive outlook, while building social connections, and supportive networks. Although these findings are limited by the cross-sectional methodology and the small number of subjects, the results of this study can be used in the therapy of families with children who suffer from ASD to better assess marital adjustment and to seek resilience qualities that can be enhanced.

Abstract

Background: The parent-training program for families (PTP) is being implemented in Barcelona to promote positive parenting. The social conditions in which people are born, grow, live, work and age, called Social Determinants of Health (SDH), influence people's lifestyles and health. Unequal distribution of SDH and gender, ethnicity, territory, age and social class generate inequalities in health, which can be avoided through suitable interventions. Family can create a low-risk proximal context for children in high-risk distal contexts. Objectives: 1) to assess the changes in parental competence, stress and social support after participating in the PTP, that are generated by promoting positive parenting intervention; 2) to suggest these changes as a strategy for parents to resiliently address some difficulties caused by the uneven distribution of SDH . Methods: A pre-post quasi experimental intervention was carried out. Families filled out the pre and post questionnaires. At the end of the program, one individual interview and five focus groups were carried out among families and professionals. For the quantitative analysis differences before and after the participation in the PTP were tested using Excel 2007. A content analysis was carried out with Atlas-ti for interviews and focus groups. Results: After participating in the PTP people significantly improved parenting skills and perception of social support. Parental stress was slightly reduced. Discussion and Conclusions: The PTP was effective in improving parenting skills and helping families to resiliently address the challenges of raising children in contexts of inequality.

Introduction

The parent-training program for families (PTP) [1] of Barcelona Public Health adapted from "Programa-Guía para el desarrollo de competencias emocionales, educativas y parentales [2] has been implemented in Barcelona since 2012 to promote positive parenting.

Parenting is understood from different perspectives and there is not a common definition for it [3]. The European Union refers to parenting as all the roles falling to parents in order to care for and bring up children [4]. Positive parenting is understood as parental behavior based on the best interests of the child that is nurturing, empowering, non-violent and provides recognition and guidance [4]. Indeed, the full development of the children is emphasized. The social conditions in which people are born, grow, live, work and age, called Social Determinants of Health (SDH), influence people's lifestyles and health. Unequal distribution of SDH and gender, ethnicity, territory, age and social class generate inequalities in health, which can be avoided through suitable interventions [5]. PTP set family as a SDH of its members [6], particularly for children development [7]. Parents are also considered as victims of multiple psychosocial factors (employment conditions, social support or parental stress), that impact parental competence [8][9][10].

Resilience is conceived as an opportunity to address contextual adversities generated by social inequities that affect family healthy development, and become empowered by this process. Resilience is developed from proximal interactions, so family is a principal resilience mentor [11]. Family resilience is defined as "the group of processes of reorganization of meanings and behaviors, which a family under stress activates to recover and maintain optimal levels of functioning and wellbeing, balancing resources and family needs [12]. Parental skills enabled parents to positively address inequities and adversities of family context [13]

Parenting skills are as important as children's needs and their psychosocial context [8][9]. Therefore, multifactorial perspective of positive parenting is the starting point of this study [14]. PTP promotes factors that are considered essential in family resilience: self-esteem, strategies for establishing home norms and structures, coping strategies, cooperative conflict resolutions or empathy and emotional communication [15][16][17]

Methodology

This evaluative study aims firstly, to make evident the changes in parental competence, stress and social support that are generated by promoting positive parenting intervention. Secondly, it wants to show these changes as a strategy for parents to resiliently address some difficulties caused by the uneven distribution of SDH.

A pre-post quasi experimental and qualitative research intervention is carried out. The quantitative part is based on three questionnaires. Parenting skills are assessed by questionnaire of parental competences [2]. Parental stress is evaluated by the Spanish adapted and reduced version of Parental Stress Scale [18] [19]. Finally, Spanish versions of Duke-UNC Functional Social Support Questionnaire (DUFSS) [20] are used to evaluate social support.

The sample consists of 145 participants, of which 89% are women, only 30% have a job, 31% live with a partner and 47% are immigrants (Table). Ten of the twelve participant groups are located in areas of Barcelona where family income is below average (1 Sants-Montjuic, 3 Nou Barris, 4 Ciutat Vella, 1 Barceloneta and 1 Cambrils) [21]. Analytic process was carried out with Excel 2007 by comparing the different pre- and post-intervention percentages for each item and dimension of parenting, social support and parental stress.

Table 1. PTP participant general characteristics

	n	%
Sex		
Men	16	11%
Women	129	89%
Educational level		
Without studies	8	6%
Primary education	31	23%
Secondary education	30	22%
Professional studies	17	13%
University studies	43	32%
Doctoral	1	1%
Others	5	4%
Marital status		
Single	38	27%
Married	85	61%
Widowed	0	0%
Divorced	17	13%
Country		
Spain	73	53%
Other	66	47%
Family typology		
Live with partner	95	69%
Live without partner	42	31%
Employment status		
Employed	41	30%
Unemployed	60	43%
Housework	28	20%
Student	1	1%
Disabled	1	1%
Retired	1	1%
Others	6	4%
Number of children		
1	41	30%
2	58	43%
3	25	19%
4	11	8%

Qualitative evaluation was developed carrying out 1 individual professional interview, 4 focus groups with 12 professionals and 1 focus group with 6 families.

Professionals and families were asked about program effects in parenting skills, social support and parental stress. Interviews also contained questions about contextual and personal facilitators and barriers of program effects. All information was recorded and transcribed. The content analysis process was carried out using a designed categorical system with Atlas-ti 6.1 informatics software.

Results

Quantitative analysis is showed in Table 2. Parenting skills, social support and parental skills are improved. Improvements in emotional regulation and relax (second dimension) and strategies for boundaries development (sixth dimension) rise by 22%. Conflict resolution strategies (fifth dimension) and parental self-esteem (third dimension) increase by 21% and 20%, respectively. These results demonstrate that PTP improves parental skills.

Social support changes are also significant. Confidant social support increases by 11% and affective social support by 10%. Parental stress changes after intervention are not as significant, although it is showed a reduction of 6%.

Table 2. Parental skill, social support and parental stress percentage comparison pre- and post- intervention (2013)

	Pre-Intervention	Post-Intervention	Changes
Parenting skills			
Development stage understanding	53%	64%	11%
Emotional regulation and relax	57%	79%	22%
Self-esteem	68%	88%	20%
Assertive communication	81%	96%	15%
Conflict resolution	62%	83%	21%
Norms and boundaries structure	42%	64%	22%
Social support			
Confidant support	72%	81%	11%
Affective support	75%	83%	9%
Parental stress	51%	45%	-6%

Qualitative analysis reinforces these findings making evident PTP as a strategy to face family contextual difficulties and inequities. When we asked, professionals say that PTP offers families a relaxing and supportive environment that allows them the opportunity to get away from contextual stressors and improve their skills to relax.

Experiential and group methodology is shown as a key factor to make families aware of different parenting models, and empowering them to change. They also identified self-esteem as an important outcome related with stress reduction and quietness increase.

<<Program sessions helped them to have an independent environment, without children, to be quiet and relax, to think about other perspectives and to stop, think and share about parenting>>(Professionals)

<<It has opened an environment to become brave and start some little changes. They have seen other views to be a parent (…). They have felt supported, because they have seen other people in the same difficult situation. This is a really big help to change attitudes. They feel all on the same team>> (Professionals)

<<Now mothers that despite problems try to answer to their children without shouting… was incredible… they said: "But… how you can be so patient? You have a lot of problems like me!">> (Professionals)

<<Their self-esteem was very low. It was very difficult for them to think about positive personal characteristics. But at the end they said expressions like "Well, finally I don't do it as bad as I was thinking">> (Professionals)

<<These sessions have been useful to insist, insist and insist to get over difficulties>> (Professionals)

Discussion and conclusions

PTP is a positive parenting strategy that generates parental competences, social support and parental stress benefits. This program is situated as a tool to create relaxing, supportive and empowering environments that allows families to resiliently respond to difficulties. After intervention, parents' boundaries and rules knowledge and skills are improved. These results are consistent with original program findings in other parts of the country [22]

Parents become strengthened, with better rates of self-esteem and calmness, and they feel more capable of addressing difficulties that are unhealthy for them and the rest of the family. Group social support seems to be important in all of these progresses. These findings are consistent with many other international studies, which after carrying out content analysis of answer interviews of parents who have participated at parent training programs, make evident that parental education can empower mothers by increasing understanding and raising self-esteem [23]. In addition is known that families empower each other, and also through the network built from the parent group [24]. Meta-analytic reviews also reinforce our parent psychosocial health outcome,

because they prove that parent training programs generate parental stress reduction and self-esteem improvement [25][26]. It is important to know that these studies conclude that further input may be required to ensure that these results are maintained. Future research will try to fill this gap, collecting data to show PTP long-term effects.

Finally we can conclude, indeed, that positive effects of PTP relate not only to parenting skills, but also to other factors associated with positive parenting, parental wellbeing[8] and family resilience [15][16][17] like social support or parental stress.

Abstract

The thesis of the present paper is to investigate the diachronic causes and outcomes of top-down zero-resilience policies in Central - Eastern Europe, more precisely on the Hungarian-Romanian geopolitical stage. We aim to analyze the discourses of the (super-)powers and the extent to which their non-resilient historic(al) actions perpetrated inter-ethnic and inter-national conflicts. We also aim to reply to questions such as: what is the local, regional and international price of non-resilience? Who are the checkmated victims behind the super-powers' interest-oriented chess board movements? How does history punish non-resilience? Finally, how do grassroots citizens address their *shah mat* on the international chess board table?

Keywords: top-down ideological policies, zero resilience, super-powers, nationalism, political *shah mat*.

Introduction

Transylvania, the northwestern-central part of today's Romania has been the apple of discord over the last one thousand years, due to one obsessive question nailed in the minds of both the Hungarian and the Romanian nations: which of these two states does Transylvania really belong to?

In order to comprehend the present political and cultural background one must resort to history. The dilemma triggering all frustrations is the interrogation regarding the issue of who the first inhabitants of Transylvania actually were. Was it the Hungarians' ancestors - the Magyars or the Romanians' ancestors - the Dacians? Who was here first, the Hungarians or the Romanians, therefore who has the historic(al) legitimacy to claim Transylvania? Both nations argue that it was their own ancestors who inhabited, thus appropriated the Transylvanian territory first.

NON-RESILIENCE: toying over NINE CENTURIES OF REPRESSED malcontent

Lacking diplomacy-focused resilience, the Hungarian side argues that the Magyars arrived in Europe in 896 A.D. and settled in the Carpathian Basin. Geographically, his included most of today's Hungary as well as the Western part of Romania up to the Carpathian curve, including Transylvania. They populated this region, gradually implemented their own laws and created a centralized state. They developed trade and agriculture, as well and established the Hungarian medieval state, with a political, judicial and administrative apparatus. The establishment of the Hungarian state in 1000 A.D. was orchestrated and officially recognized by Western Europe and by the Pope himself, who offered the Hungarian crown to the new Hungarian King Stephen I, shortly before his official coronation in 1000 A.D. [1].

The Romanian side counter-attacks with their own argument: when the Magyars arrived and settled in today's Hungary and Transylvania in 896 AD, the Dacians (the ancestors of the Romanian people) had already set up their statal and proto-statal communities in Transylvania.

Following the same inflexible, non-resilient pattern of the present chain of arguments, the Hungarian side again argues that the population of these secluded Dacian communities only existed in the *peripheral* zone of Transylvania, being restricted solely to the mountains. They were no real statal formations and by no means comparable to the official, West-acclaimed Hungarian kingdom. They were small villages, scattered loose in

proto-feudal fiefdoms, which had no modern political, administrative or judicial apparatus, no centralized administrative system compatible with the overlapping Hungarian state [2].

As world renown specialists argue, the present lack of clear evidence and the zero resilience attitude on both sides have certainty fueled the nine century long tensions between the Romanian and the Hungarian historians over Transylvania [1].

To most scholars in these two oppositional camps, it is still a matter of harsh dispute if the Romanians' ancestors (the romanized Dacians) indeed survived in Transylvania and whether they survived all over this region or only in disparate administrative forms, in its marginal areas. Moreover, other specialists argue that the first Vlachs (proto-Romanians) appeared in the area as late as the 13th century, after a northward migration from the Balkan Peninsula [3], [4]. There is an ongoing scholarly debate over the ethnicity of Transylvania's population before the Hungarian conquest: "almost certainly, the Vlachs came from the Western Balkans and only migrated into Rumania as nomads, abandoned it in the late thirteenth and early fourteenth century" [5].

It is paramount to mention that history may anytime be sagaciously manipulated and / or reinvented in order to justify the present, both by Hungarian and by Romanian historians. The historic(al) events that unfolded one millennium ago will always bear the shadow of (at least) some mystery for both debating parties. That is why any (Pre-)Modern or Postmodernm top-down nationalistic tendency to reinvent history may easily kindle ill-positioned, opinionated outbursts.

As history attests it, over the span of time 896 - 1920 Transylvania belonged to Medieval Hungary, followed by the Austro - Hungarian Empire, which practiced zero resilience-oriented policies. Tragically, during these nine centuries, although the Romanian population in Transylvania was constantly increasing, it was kept under the indomitable authority of the feudal Hungarian protectorate or government. The Romanian population had an ignominious secondary status, that is a status of a tolerated minority, without any political or civil rights, unlike the adverse, majoritarian Hungarian population. The exclusively Hungarian nobility in Transylvania filled the main political and administrative positions and politically dominated the Romanian "underclass" [1] until the 19th century.

The tragic outcomes of this non-resilience policy are detailed by Dr. Stephen Fischer-Galati, Distinguished Professor Emeritus of History at the University of Colorado: "The singling out of Transylvania and of the Romanians as central to Hungarian aspirations is ultimately related to the historic contempt shown by Hungarian ruling classes, and even by many of the non-ruling ones, toward their Romanian counterparts. The Romanians, whether in Transylvania or in the Old Kingdom, have been traditionally viewed as uncivilized, unscrupulous and inferior to the Hungarians. If Romanian leaders resented Tsar Nicholas's *bon mot* that being a Romanian is 'a profession rather than a nationality', if they expressed outrage at the Germans' concept of the *'Unmensch'* which embraced the Romanians with other peoples in Southeast Europe, it was the Hungarians' contempt for the Romanians that gave Romanian nationalism the greatest impetus since the late nineteenth century. The 'liberation' of Transylvania from Hungarian yoke was the primary goal of Romanian nationalists before Trianon, and conversely, the liberation of that province from the Romanian yoke became the primary goal of Hungarian nationalists after Trianon. Under these circumstances a review of the significance of Trianon for Romania is indeed desirable, particularly because of the continuing importance of the Transylvanian question in the 1980s to nationalists and communists alike" [6]. The same issue is debated in more details in Fischer-Galati's essay "Romanian Nationalism" [7].

It is of paramount importance to underline the following issue: the nine centuries of Hungarian domination in Transylvania meant nine centuries of pro-Hungarian / anti-Romanian policy perpetrated by the feudal Hungarian administration. This non-resilient policy prompted a direct outcome: it sowed the deep seeds of nationalism and inter-ethnic hatred between the two cohabitating communities in Transylvania. This serves as a premium example of subtle top-down orchestration of nationalism.

outcomes of top - down zero resilience: '*Fortuna labilis*'!

Taking a giant leap over the nine centuries of Hungarian domination, we arrive to another turning point of inflexibility and of zero resilience in the process of thriving nationalism in Transylvania: the Treaty of Trianon. It presupposed the turning of the wheel of fortune, as the concept of dominance stayed, yet the two terms 'Hungarian' and 'Romanian' swapped. Following the Treaty, the Romanians became the dominators and the Hungarians became the dominated. Transylvania was annexed to Romania. Nationalism, conflicts and tensions would further thrive.

The Treaty of Trianon, signed at the Grand Trianon Palace at Versailles, on 4th June 1920 by the victor Allies (the British Empire, France, Italy, Japan, Russia and the USA) deprived Hungary of approximately two thirds of its territory and population, thus being one of the most violent peace treaties that Hungary ever signed. Romania was rewarded with Transylvania, thus the long-disputed region was incorporated into Romania.

It was the victor superpowers' clever chessboard move to annihilate the Austro-Hungarian Empire and to attempt to preserve the balance of powers in the Europe. The British Empire was strong enough, so Western

Europe did not need a second empire. Therefore the Habsburg Empire was dangerous as well as superfluous, consequently it had to disappear from the map of the world in order to preserve peace and balance on the stage of international politics.

Hungary being defeated in World War One, the peace Treaty was a perfect opportunity for the world powers to chop up Hungary and annihilate her political and military power. The Hungarian representatives complied with the Treaty in Paris under vehement protest. They had no choice as Britain, France, Italy and Japan were pointing their threatening thumbs to them at the table of discussions: "the victorious Allies dismembered the Austro-Hungarian Empire by creating a number of so-called *successor states*. The idea was to replace the multi-national monarchy with smaller national states, who would jealously guard their newly won independence and thereby prevent a possible future expansion of Germany into East Central Europe" [8].

Top-down policy - zero resilience - tensions and buffer zones

Why does the Treaty of Trianon bear such special significance to the Hungarian nations? According to Illyés, "Trianon bears the meaning of a human slaughterhouse" [9], as the Hungarian state was torn apiece, losing two thirds of her national territory and two thirds of her ethnic population. Trianon became one of the most drastic, non-resilient measures in the history of Transylvania and it triggered further nationalism encouraged from above, *not by the leaders of the either of the two countries, but by the super-national world powers dividing their war plunder.*

This encouraged a rampant explosion of hatred and nationalism in the 1920s directed against the ever-long ethnic rival, the Romanians. The other countries which were allocated territories of the former Great Hungary were and are never seen with such enmity as Romania, who incorporated Transylvania, the buffer zone of nationalism.

Shah mat: further victims of the super-powers

Following the Great Unification in 1918, after the end of the First World War, the Romanian government commenced an anti-Hungarian / pro-Romanian policy, as a form of retaliation against the Hungarians, a form of dealing with their nine-century long painful past, when their own situation had been exactly the reverse.

As Stephen Fischer-Galati points out, it is probable that the Great Unification would not have spurred such vehement nationalism between the two states, if the Romanian government's steps had been slightly more malleable and resilience-oriented: "It is possible […] that the resultant dislocations could have been made less painful, had the process of Romanianization been directed […] for the benefit of the Romanians of Transylvania but in a spirit of reconciliation toward non-Romanians […] As for the Hungarians, their bitterness toward Romanians was exacerbated by the need to deal with Bucharest appointed functionaries and to cope with Bucharest methods of governance" [6].

As we may conclude, the intrusive authority of the world powers at the Treaty of Trianon served Transylvania to Romania, on the tray. That is why, to a certain extent the Treaty not only gave way, but also justified the subsequent political chaos between the two countries and between the two nations, providing the setting for a confused history between them, for the next few decades [10].

One form of Bucharest's zero-resilience policy regarded the status of the Hungarian ethnic minority: "in the greatly enlarged post-World War I Romania, the position of the Hungarians was of least favored" [10]. The ethnic Hungarians in Transylvania saw their land expropriated and redistributed to the Romanian farmers. Hungarian administrative and political dominance was swept aside and Romanian bureaucracy was installed. At the same time Romanian replaced Hungarian as the official language [1].

Furthermore, in the 1930s Romania witnessed the rise of a strong Fascist movement. It is true that anti-Semitism ranked higher with Romanian nationalists than anti-Hungarianism, still the enhancing Fascist movement perpetrated crimes against the Hungarian population in Transylvania. Mainly due to their preponderance in urban, commercial and professional activities, the Fascists saw the Hungarian minority as "exploiters of the Romanian masses" [8].

It was a radical shock for the Hungarian population in Transylvania: overnight, they were compelled to realize that they belonged to a different country, with a different citizenship, culture, language and religion. They lost their status of favored, ruling people to a miserable status of tolerated people. They were obliged to speak and use a foreign language which they had never studied and which they did not speak. Thus they could hardly establish any connection to the representatives of the new administrative or political apparatus, in official addresses. Experiencing a sinking loss of identity, they felt as foreigners in their own homes.

This is the prime reason due to which the Treaty of Trianon has been alimenting so much tension among the two nations. One swift brush of the pen and the non-resilient victor powers sealed the fate of almost two million Hungarians, opening a new age of acute enmities between the two countries. Having arrived at this

point, a paramount question arises: had the superpowers been informed about the possible long-term outcomes of the Treaty, would they have signed it with the same indomitable omnipotence? Had the signatory powers adopted a slightly more resilience-oriented position, would the nationalistic (even chauvinistic in the 1990s) clashes between the two nations have diminished?

Conclusions: non-resilience and A PEACE TREATY?

Let us reconsider the historic(al) interrogation: *how much peace did the "Controversial Trianon Peace Treaty" bring*? For the Hungarians "the word 'Trianon' is a symbol of national catastrophe" [11] due to their territorial and population loss. For the Romanian officialdom, it encouraged its anti-Hungarian policies. A straightforward reply would acknowledge that the Peace Treaty did not cause only peace within the *local* level of our discussion: as a toll for the European peace it sealed over the World War I fronts, the Treaty opened new channels of animosity between the two states directly involved, Hungary and Romania. Some historians even go as far as to consider the Treaty itself a "typical product of European nationalism, belonging to the tortuous history of Europe's reorganization according to the principle of nationality and nation-state" [11].

The Treaty of Trianon serves as one historic example of non-resilient top-down policies that indirectly encouraged local and regional conflicts. Unfortunately the inter-ethnic animosities further thrived in the second half of the 20th century due to the same indomitable, zero-resilience attitude of European and local actors: the Second Vienna Award in 1940, the Paris Peace Treaty in 1947, the totalitarian regimes during the 1940s – mid 1960s and the Ceauşescu Communist regime (1965-1989).

The adaptability of needy families to a precarious social state

Hirghiduş I., Fulger Ioan V.

University of Petroşani, Romania
ionhirghidus@yahoo.com, vifulger@yahoo.com

Abstract

Within this study, the authors are atempting to prove that poverty in families may perpetuate untill it becomes common and a state of „normality". Actually, the content of the study is represented by the resiliency of poor families to socio-economic stress. What has occured in the political and socio-economic stage in Romania in the past decades has created a field suitable for the development of a behaviour that accepts poverty as a state of fact. The mechanisms that may explain this phenomenon are defensive, which go beyond the social learning within a family, to the instinctual background. In order for this paper to have a scientific consistency, among the theoretical notions that come from various sources, it will rely also on field sociological survey and a particular case study represented by Jiu Valley as a simptomatic area of Romanian poverty. In fact, the resiliency of famillies to socio-economical stress is a social adaptability created not by the survival instincts but by the socio economical lifestyle imposed by the governing. While analysing this type of resiliency we are not following to point out the imediate acomplishments of families within the social field but a deformation of behaviour that signifies the acceptance of a precarious social state with negative longtime effects.

Keywords: Resiliency, poverty, social vulnerability, adaptability, family.

Introduction

For a long time, the poverty in Romania has been a theme for contemplation, not necesarily in a scientific manner, but as a succesion of ideas and atitudes that make up a relevent pattern. A scientific knowledge of the phenomenon of pauperity and how it affects a large part of romanian families is required. Nowadays in our country there are many families that are confronted by a very harsh financial condition. A singular case isrepresented by Jiu Valley and families living in this area. The cause is directly related to the drastic reduction in mining activities and by default of workplaces. We have noticed that needy families fromJiu Valley share 2 major characteristics:

- They fit within the general frame of poverty in Romania
- They can only be described if we regard Jiu Valley as a disadvantaged area, in which economy is underdeveloped, without being influenced by the great reduction in mining.

Poverty is a grave state through which most of our country's population is experiencing. Poverty is defined as „a lack of material means needed for existance"[1]. In an absolute manner „poverty signifies a state in which the individual lacks the resources necesary for survival"[2] . In a relative sense, poverty „poverty signifies an individual's or a group's lack of resources when compared to other members of society – in other words, their relative lifehood."[3] In a world in which man wishes to have a confort that lives up to current civilisation, he is confronted, paradoxally, with the problem of poverty that affects him directly or otherwise. Poverty mai be defined as a state of permanent lack of resources needed to ensure a decent lifestyle, acceptable within the collective. [4]

Absolute poverty is relying on the idea of subsistence, the concept of minimum standard of living. How can we determine this minimum required to satisfy the basic needs? The concept of absolute poverty implies the possibility of establishing some universal standards and compared to these, the progress in eliminating poverty is analysed. However, human needs are interpretated more as physical needs (foo, clothing, housing) rather than social needs, still, as Townsend pointed out „needs are born through social roles and relations(...) they come from the fact of being parents, partners, neighbours, friends and citizens".[5]

Relative poverty is based on the idea of relative/comparative needs, established reporting to the well-being of the entire population. From this perspective, the socio-cultural context is noted, considering that fundamental needs take different forms according to the context. The needs are relative to the lifestyle of the

collective (house heating for cold climate, not for the areas where it's warm all year) or the the degree of development in the comunity (social development brings along new needs). The state of poverty depends on the differences between the needs of the individuals, their lifestyles, the environments in which they live, the moments in time we are refering to etc.

Beyond the income or the expenses of individuals, beyond how it evaluates others, poverty is about the individuals self apreciation, meaning that it bears the mark of subjectivity. The multitude of explanations for poverty can be synthesized in 4 great categories[6] *1. Poverty as a moral feature of the individual.* According to this approach, the poor are lazy, vagabonds, deliquents, socially inadapted. „the guilt" of being poor belongs to htem. Poverty is in this view an effect of personal, family or groupal characteristics. 2.*Poverty as a cultural trait.* The subculture of poverty is transmited through the process of socialization. „The culture of poverty" is a product of pauperity but also a source of continous deprivation, a self-perpetuating way of life that ensnares the needy in a no way out situation. 3. *Poverty as a structural issue.* Poverty is the effect of a structural tendency emerging from the socio economical organisation of societies: inequal distribution of wealth. The amrxist theory of exploitation, the functional structural approach and other such views have proven that the socio-economical system contains within several imbalances that can hardly be avoided and that afects certain indiviuals. *4. Poverty as an effect of the Welfare State.* The followers of this theory are unveiling two circuits through which the Welfare State causes poverty instead of eliminating it: *a. The structural circuit:* In order to eliminate poverty, the states asumes responsability of support, though for this it needs resources; to obtain these resources it increases fiscality, however this has the already mentioned negative consequences: investments drop, unemployment rises, leading to economical downfall and finally to increase in poverty. *b.The cultural circuit:*The generous benefits of the state lead to developing a colture of dependency, to a reduction of the responsabilities of an individual, family, comunity, to the diminishing of their capacities. The poor are victims of the paternalist state of Welfare.

1.1 Globalization and destitution.

The theory of globalization[7] examines the apparition of a global cultural system. It sugests that a global culture is being promoted by a series of social and cultural developed societies among which the worldwide phenomena fit in. Globalization represents today one of the most disputed themes, approached from several points of view. Ann Harrison [8] claims that there are obvious links between globalization and poverty. There are two ways through which globalization is accelerated: trade and international bonds. The usage of unqualified workforce in creating goods has a negative effect. Globalization may bring for the needy (persons or states) positive short-term effects, on the long run these effects may turn negative. Another issue that must be debated is the effect of globalization on developed countries. Among the positive effects (usage of a low cost qualified workforce) negative effects may appear such as the expansion of poverty into well developed countries.

1.2 Globalization of social policies.

The matter of globalization was recently reported to social policie, for welfare state (Deacon, 1997; Mishra, 1999) [9]. Globalization is analysed in the sphere of the social policies through the impact of similar processes of the economy and politics over social policies under several aspects: the globalization of social issues and policies to solving them; the world competition regarding social policies role models; the globalization of social policies concepts.

The unfavorable consequences of these changes as well as the measures society must take in order to counter them at a given time, have been synthetised in the sintagm „social costs". This concept has received over time from different authors many definitions, more or less complete. Therefore, academician N. Constantinescu (1992) considered that: „social costs are reffering to what the populations must support so that the country can get to the market economy" [10]. N. Dobrotă considers that social costs are „ costs of reform, that may be synthesised in the population's contribution, the disclaims it must accept towards building an efficient market economy." [11] These statements converge towards the idea that these costs are affecting negatively the material needs to make a living. Cătălin Zamfir and Lazăr Vlăsceanu have pointed out defining the concept of social cost, the economical and non-economical resources spent in order to accomplish social activity and the negative effects resulted from the social activity [12]. This means that a complete definition must encmpass the deteriorations that take place within the material and spiritual conditions of a segment of the population, aswell as the effort, mostly financial, made by the state to limit these deteriorations as much as possible. Poenaru and Molnar (1992) define the dimensions of social cost with the help of two large categories of analyses: those reffering to „negative or unwanted change that occur in people's existance conditions reporting to natural evolution or a standard of refference" and those that „regard the necesary costs in order to elliminate negative aspects of social development or associated to promoting some policies (programs) that follow the accomplishment of precise social objectives" [13].

The needy family. If we are viewing poor families, we must think about the possibilities of social protection. Elena Zamfir, sociologist, defined the role of the social protection system as a support for people, groups or comunities that are „ in difficulty and cannot live through own resources a life that is according to what is considered the normal minmum standard of living" [14]. Altough relatively independent to the society in which it is formed, the family is determined as a last resort and conditioned in it's organising and evolution by the way that society reflects. What is stable and definitive for any kind or type of familiy existance is it's essence of „unity of personal interactions and intercomunications, engulfing the roles of husband, wife, mother, father, son, daughter, brother and sister'[15], constituated through mutual shared affection. Some authors such as Giddens, define the family as a group of people linked directly through kinship and the adults take on the responsability of raising the children [16]. Giddens also says that „kinship are relations between the individuals established either through marriage, descendence that makes consanguinity (mother, father, children, grandparents) Marriage can be defined as a social recognition and approved sexual union between two adult individuals. When two persons wed, they become relatives; the link of marriage widens the area of kinship. Parents, siblings and other blood relatives become kin of the partner after marriage"[17].

Starting from the numerous given definitions of family, soem authors have outlined a series of family features [18]: the existance of a certain number of people; their reunion is imediatel precedated by marriage; between the group's members there is a series of law guaranteed rights and obligations; interpersonal relations, biological, psychological and moral; psychosocial atmosphere; ruels and regulations regarding the conduct of family members; structural organization, with a certain distribution of roles and tasks; carrying out certain societal functions.

The quality of family life, according to C. Ciorfu [19], is influenced by a series of factors, we will point out only those that have a signifiant impact: *Economical status* – the growth of income implicitly leads to a growth of demands, the desire to benefit from other services and facilities. The lack of money becomes for some families a very powerful stress factor. This may constitute a source of family instability. *The parents' workplace* – the family and it's needs are in conflict with the tasks that parents must handle at their workplace, however if the mother stays at home, the economical level drops drastically; *The role of a mother* – provided at superior parameters. There is a permanent conflictual situation between her status as a mother and that of a member of society; *The role of the father* in the family is not about his masculinity but about the way he manages the family's life.

The resiliency of needy families. The resiliency of the family is an ability to adequate handle the circumstances of life. „Family resiliency , in time's perspective, will be all about the succes in acomplishing intra and extrafamilial functions (at societal level) and obtaining positive results (...) despite adversities that a family is up against" [20]. We consider that the adaptability of needy families to a precarious social state fits within this given definition of family resiliency.

Methodology

The applied stepts in reasearching the adaptability of families to a precarious social state are relying on a sociological research, and it's theme is: *local social policies for granting support to people with no or low income,* a reasearch undergone in the year 2012 on a sample of 820 people from the poor families of Jiu Valley and that are in their townhall records in order to benefit from welfare. This research is based on the following hypothesis: *a. If people from needy families are are sufficiently supported and on time through means of social protection, they will display a normal social behaviour. b.The lower a municipality's financial resources, so is the possiblity of aiding needy families. c.The lack of money and other resources required for a normal life causes a growth in felony and the deterioration of the family environment. d. The poorer tha families are, the higher the risk of children flunking out of school.*.

The sample used for the purpose of this researh was made based on the method of interrelated odds (age, gender and population share within each of territorial administrative unit from the six towns that make up jiu Valley) is representative for the entire population, which allowed extrapolating results. The instrument of choice was the sociological questionnaire applied on the field study by students at the respondents residence as a direct inquiry, face to face type. The purpose of the research was to point out the situation of families with low income and their adaptability to a certain state of poverty.

Results

Needy families are quite vulnerable especially to the lack of material needs. However, we can point out hte fact that poverty does not influence in a decisive way the degradation of the functions of the said families. They manage to survive and even more than that, they fullfill their major tasks at educating children, maintaining a proper environment for the developing of individuals.

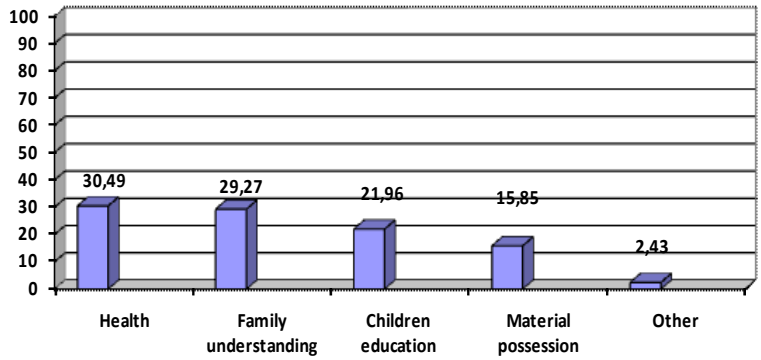

Fig. No. 1 – The most important thing in a family's life (%)

In the graph above, we can see that the subjects' first choice is health (30.49%) followed by family understanding (29.27%), not far behind is children education (21.96%). Material possession barely on 4th place with 15.85%. We may conclude that needy families of Jiu Valley do not necessarily prize material wealth despite that on many occasions even the basic items are lacking. It is suprising how these families manage to keep a certain normality and do not fall into a state that might lead to destruction. We cannot deny that poverty may become a danger to families that reach the edge of survival. For these families, in order not to degrade themselves, it is necessary that the responsability of the local administration increases. Material support is absolutely necessary especially for the children in needy families not to abandon school. Unfortunately school dropout is rising in Romania.

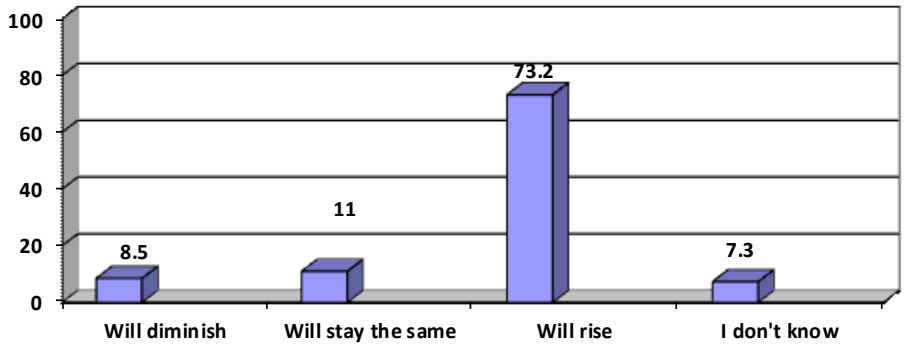

Fig. No. 2 – How is family poverty seen in the future (%)

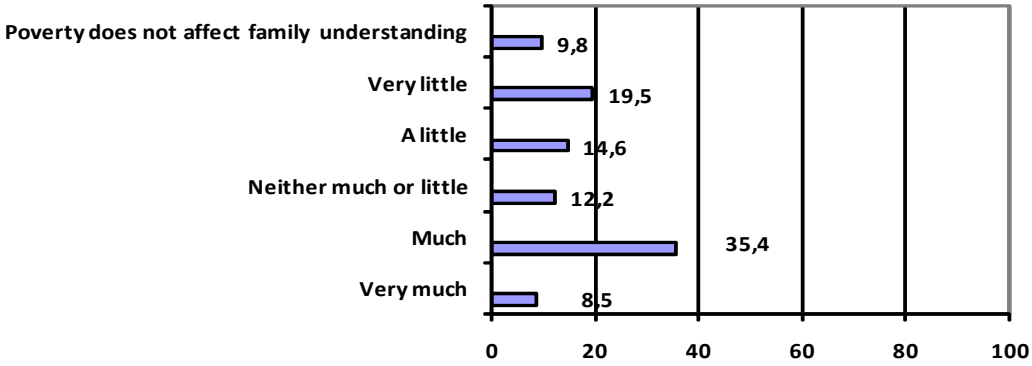
From the graph above we notice that the most subjects, representing 73.2 % believe that in the future families will get even poorer.

I believe that this category of subjects has the dark perspectives in sight of the closure of the mines. In these conditions is not very likely that local administrations will have the capacity to grant support for needy families if they won't be in turn supported by the state's central institutions.



.

Fig. No.3 – How much does poverty affect family understanding (%)

It is difficult to assume how the relations within a family can evolve wehen it reaches abject poverty. Everything seems to be allright if the family is solid, but when the required money for living, for sending the children to school, for food are missing, problems may appear that affects the peace and family understanding. This aspect, we believe, is understood by 43.9% of the subjects that considers poverty to affect much+much (negative) the family climate. Only 9.8% believe that poverty, regardless of it's level, does not interfere with family climate. Probably this category of subjects is right from certain points of view of the fact that a stable family does not come apart easily. On the other hand, a state of prolongued poverty may deteriorate the relations from within if it gets to alcohol abuse and frustrations caused by the lack of material means.

	Much	Right	A Little	Cannot afford
Car			2.4	97.6
Electrical appliances	2.4	13.4	57.4	26.8
Second hand clothes	20.7	50	25.6	3.7
New clothes			19.5	80.5
New furniture			6.1	93.9
Superior quality food			7.3	92.7
Inferior quality food	37.8	40.2	19.5	2.5

Fig. No. 4 – The capacity to purchase certain assets (%)

From the previous image it is clear that the families we questioned are in a precarious state. This situation results from the statistical data according to which there is no capacity in order to purchase anything but inferior quality food and second hand clothes. In very high percentages, the questioned subjects cannot afford to buy : superior quality food – 92.7%; new home furniture – 93.9%; car – 97.6%; new clothes – 80.5%. I believe

that this statistical situation says everything about the state of the questioned families and about their capacity to ensure the come up with the necesary money for their children's education.

Conclusions

1. Jiu Valley has low financial resources, but these resources will further diminish byt the gradual closing of the mines. The subjects' perception is that the local, county and also central institutions are not sufficiently implied in eliminating poverty and unemployment.
2. The lack of money and other material assets leads to the increase of felony. A common theft is that of scrap metal, copper or other metals that are taken to collection centers. If we consider that some industrial sites have been fraudly decomissioned and sold by important state institutions, then the theft of scrap metal for survival may seem a minor deed.
3. the increase of poverty in some families determines, in some cases, a deterioration of the familial environment. The lack of money leads to tensions and even permanent raptures in some families
4. A part of the children that come from needy families, including from the reaserch subjects are absenting alot from classes. This implies a growth of school dropout. The main cause is the lack of money and other goods needed to live, up to 59.8%.
5. Local social policies, at the level of jiu Valley tried to solce social cases however because of lacking funds only a part of these cases are somewhat resolved. This endangers the stability of the family itself and we beliee that the phenomenon of romanian needy families' resiliency has as it's cause the tradition of stability of the romanian family, however, the danger of degradation is always present and it may cause this tradition to dissapear in time.

Resilience and social risks management. Concepts and policies.

Anghel I.

The Institute of National Economy, Romanian Academy (ROMANIA)
Irina_c_anghel@yahoo.com

Abstract

Especially considering the overarching objective of sustainable development, and the specific challenges of ongoing societal, demographic and economic change, Social Risk Management and Social Resilience, both relatively new concepts and social policy paradigms, seem to be closely related. According to some authors, the realms of SRM and SR overlap, while other authors suggest that social resilience represents an alternative to social risk management approach. This paper aims to build on the available literature in order to delineate an integrative analytical framework of the relationship between the concepts and policies of SRM and SR. We would argue that a sound, healthy and sustainable social risk management system is a prerequisite for the resilience of individuals, society and institutions confronted with various threats, stressors and shocks. At the same time, high resilience at various levels of social systems and institutions would provide support and sustainability for social risks management system and instruments. We also intend to highlight the main social and economic policy tools able to enhance social resilience and the functionality of social risk management systems.

Keywords: social resilience, social risks management, social protection

Introduction

In the context of irreversible and unexpected change, of continuous and ubiquitous incertitude that confront the existence and evolution of most socio-economic and ecologic systems, achieving the ultimate goal of sustainable development requires new paradigms, new strategies as well as new political and social tools. Among them, social resilience and social risks management have emerged as different, yet convergent and interdependent concepts with critical inferences at social policy level. This paper aims to build on the available literature in order to delineate an integrative conceptual framework of the relationship between the concepts and policies of social risks management and resilience.

Social Resilience

Against the framework of multiplied and diversified risks, of high heterogeneity within growing vulnerable social groups, of increasingly multidimensional nature of hazards' impact, the theoretical and political discourse has integrated and progressively brought to the foreground the concept of system resilience. Substantiated, and elaborated especially in the ecological and climate change setting, this concept has been adopted and adapted to more and more theoretical and empirical research fields its core meaning refers to the dynamic ability of a system to cope with and respond to change and hazard while maintaining vitality, basic functions and structures [1], [2].

The long-term social and economic perspective of development has also assimilated and endorsed *resilience.* Given soaring predictable or unexpected threats, as well as divergent and challenging processes associated to economic, financial, cultural globalisation, demographic ageing and climate change, it has become self-evident that the resilience of the economic and social systems is to be considered a pre-requisite for sustainable development and, therefore, a primary goal for policy makers and for society as a whole and local communities as well. [3], [4], etc

Applied to the socio-economic area, resilience may be defined as the ability of a social unit (be it at micro or macro level, from individual, to organisations, communities) to mitigate hazards, cope with the hazard aftermath when it occurs, to achieve recovery shortly and with minimal social disruption and to anticipatively diminish the effects of future shocks [5], [4]. A high level of resilience decreases the probability of failure as

well as the necessary time for full bounce back, for recovery and avoids long-term downturn in socio-economic development progress. [3]

In the current literature, the concept of resilience jointly encompasses the capacity to absorb, accommodate stress and hazards through resistance or adaptation, the capacity to maintain basic functions and structure during hazards, as well as the recovery and regenerative abilities through learning. [1], [2], [6]

This involves, consequently or simultaneously, disturbance absorption, learning, adapting and system reorganization processes and, therefore, there is increasingly more focus placed on understanding *resilience* as a process rather than an attribute, a trait. [3], [6], [7], [8], [9]. Resilience does not involve, nor encourage obstinate determination for sticking to a previous equilibrium, but readiness for change, for undergoing processes of transformation that lead to vitality, functions and roles preservation. Therefore, resilience is not a state but a dynamic set of conditions, not an outcome, but a process that involves learning, adaptation, anticipation and improvement in basic structures, actors and functions. [3]

Lately, the systemic approach has also been increasingly accentuated in the literature, with emphasis placed on the jointly contribution of a wide range of stakeholder in conceiving and implementing the best strategy for achieving resilience. [2], [3], [7], [10] Another component is that of ensuring that individuals and communities themselves are actively involved in the process of change [11], [4]. Also, the system-based thinking should therefore replace the fragmented responses to hazards.

Resilience is closely connected with *vulnerability*. Some authors define and measure resilience as the opposite side of vulnerability [7]. While vulnerability is generally described as the degree to which a system may be affected by or negative consequences of a hazardous event [2], [3], [7], [12] and understood as a function of exposure to risk and coping capacity of the system, resilience appears to be the positive expression of the ability to deal with hazard, providing insights on how a system may become less vulnerable.

Yet, other authors argue that resilience goes beyond being the opposite side of vulnerability, to the capacity of a system and individual to manage change and eventually thrive in the context of dynamic systems, to capitalize upon incertitude and transform threats into opportunities [14], [15]

Some authors, [16], [17], depict, among the main dimensions of social resilience: threats, capacities, enabling factors and outcomes. This perspective links resilience to risk factors, arguing that the resilience level of the same system may vary largely from a type of threat to another. Capacities to deal with risk and change may be reactive and proactive, thus choosing either coping instruments or mitigating instruments. This choice is largely determined by access to capital, be they economic, cultural or capital. Among the enabling factors, one of high importance appears to be the public institutions as they shape rules and regulations, facilitates communication and learning processes. Outcomes may encompass a large array of probable or certain, short-term or long-term, positive or negative consequences, depending on the above mentioned elements.

Social Risks Management framework

In the realm of social protection policy approach and design, the same processes and tendencies mentioned above have imposed the necessity of a new paradigm which would finally be able to address the frailties of the traditional social protection systems regarding their efficiency, efficacy, viability and sustainability in ensuring protection against risks and providing social assistance to all individuals. Outlined in the strategic paper of the Social Protection Sector of the World Bank [18], this paradigm has been gradually adopted and developed in the literature and policy of social protection and social sustainability. The *social risks management* (SRM) *paradigm* presents several differentiating traits that would eventually lead to new political approaches and strategies.

At the core, stands the integrative systemic view which inter-relates and activates multiple social actors, a wide range of social risk management instruments.[10], [19]. Fighting many budgetary and logistical restrictions, the state resigns its position and role of sole creator and administrator of social risk management instruments and resources and undertake a new role which, even though as central as before, focuses more on coordination, activation, empowering of system's elements and relationships, ensuring its functionality, equity and ethics. Therefore, the new paradigm extends the responsibility and capacity beyond the state interventions towards the private domain, be it the informal or market realm [20], [21], [22], [23].

In the system of social risk management, all actors, from the individual at risk, to household, community to market agents, NGOs, international donors and governmental institutions, acknowledge and undertake responsibility and active role, providing instruments and resources while following their own specific interests and objectives. Moreover, the risks under consideration are no more confined to a list of major social risks, but are generically defined through their impact on the individual and societal welfare [24], [25], [26].

Also, the traditional social protection main objective, that of providing assistance to people hit by hazards, is extended and the focus shifts from ex-post intervention, to anticipative, ex-ante strategies of prevention and mitigation. Thus, in the centre of the social risk management is the individual / community at risk and not only the risk itself.

The goals of a functional social risk management system are multi-fold, concentrated on empowering the individual to diminish exposure to risk and amplitude of negative consequences in case of risk materialisation. Therefore, they encompass (1) ensuring a minimum living standard through granting access to basic goods and services, which include health care, education and life-long learning opportunities and professional development and reorientation; (2) developing proactive strategies and policies with preventive and protective role against the social risks, which would join the ex-ante, reactive, risk-coping interventions; (3) promoting and developing the potential and opportunities of individuals, communities and society.

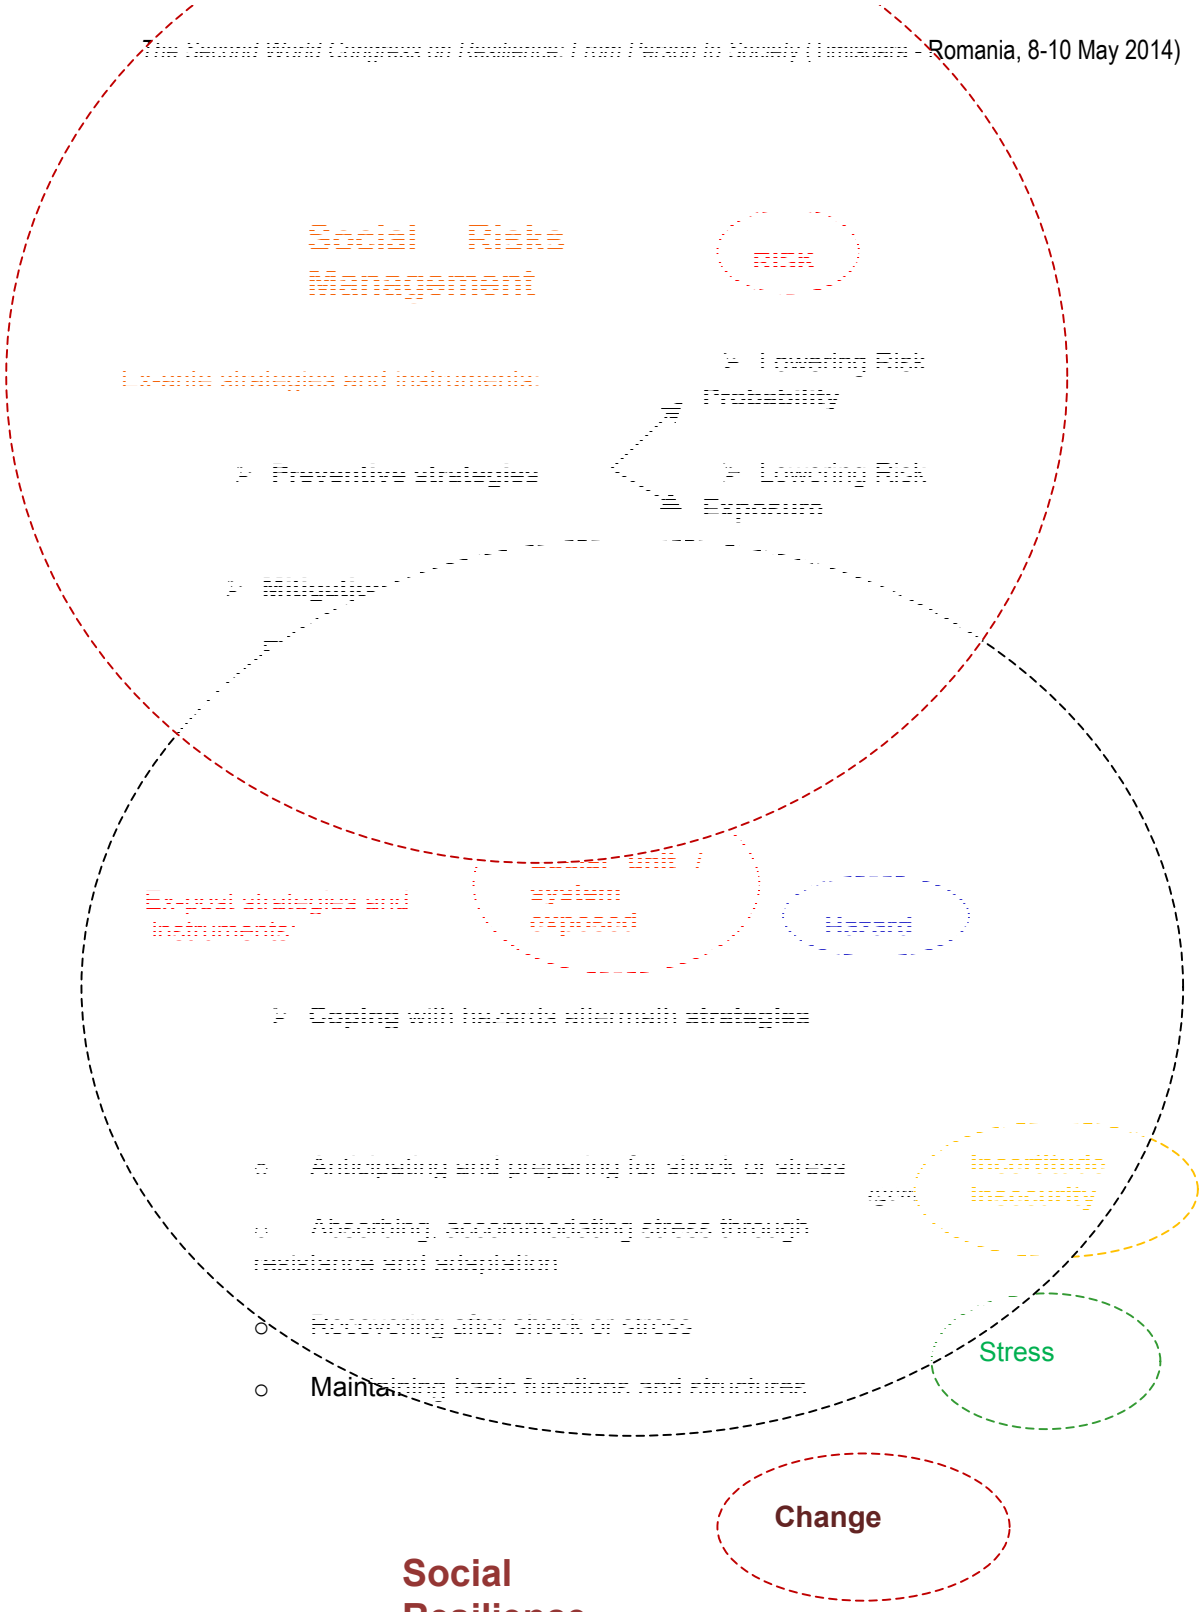
The social protection functions have, consequently, multiplied, adjoining promotive, empowering, equity ensuring, developing, transformative and adaptive functions to the traditional protection and support functions.

The main principles guiding the strategic options design, selection and implementation, are: (1) *the integrative management principle* that rely on the systemic character of social risk management and requires integrating intersectoral policies, actors with divergent interests and different resources and influence, distinct social protection programs. (2) *the person-focused principle* outlining the necessity to tailor social protection interventions and instruments, based on a holistic approach that considers the individual's specific background, social, economic and educational context. It calls for an active involvement and co-participation of the person at risk in the design and implementation of strategies; (3) *the vulnerability-focused principle* that requires a thorough causality chain analysis, in order to identify upstream risk factors and vulnerability sources; (4) *the anticipative management principle*, as, drawing on risk-factor and vulnerability analysis, preventive and mitigating ex-ante strategies present more effective and durable results, as compared to ex-post strategies; (5) *the empowering principle* which involves rendering all social stakeholders responsible and empowering them. Inter-institutional cooperation and communication is vital for optimal addressing the needs and vulnerabilities of every individual at risk.

Resilience and Social Risks Management, common ground and particularities

With *resilience* as a pre-requisite for, and *social risks management* a vector and essential instrument of, sustainable development, the relationship between the two concepts is, obviously, multi-fold and bidirectional at theoretical as well as political level. They meet on common conceptual background, as they:

(1) have both evolved as an answer to contemporary generalized environment of risk, uncertainty and insecurity and a search for formulas for preparedness, adaptation and survival [3], [27];
(2) are applied within systemic frameworks, endorsing holistic approaches in system analysis, from individual, households, communities through to sub-national and national levels;
(3) are both hazard oriented and provide important background for strategic options for managing uncertainty, risk and hazard;



Social Risk Management
Risk
Lowering Risk Probability
Lowering Risk Exposure
Preventive strategies
Mitigation
Ex-post strategies and instruments
Social Unit / system exposed
Hazard
Coping with hazards/disasters strategies
Anticipating and preparing for shock or stress
Absorbing, accommodating stress through resistance and adaptation
Recovering after shock or stress
Maintaining basic functions and structures
Uncertainty Insecurity
Stress
Change
Social Resilience

(4) focus on the entity at risk, on understanding and reducing vulnerability while strengthening adaptive and coping capacity;
(5) endorse employing proactive and ex-ante policies. [7], [17];
(6) are closely interconnected with vulnerability, which stands as a core primary concept for both resilience and social risk management [4];
(7) accentuate the importance of the active participation of the system exposed in preparing for and recovering from hazard and stress [28];
(8) both call for sharing responsibility among social actors and for active involvement [28]. Therefore, a short review on both the dimensions, factors and functions of resilience on one hand, and social risks management principles and functions on the other, reveals high compatibility between the two concepts. (Fig. No.1)

Yet, there are significant differences between the two concepts that justify complementarity beside partial overlapping. While both are focused on vulnerability and the social unit at risk, the social risks management paradigm deals with the social risks, as well. It provides the background for designing strategic alternative for lowering the probability of hazard occurring, as well as the social unit's exposure to it. Resilience thinking, on the other hand, acknowledges and accepts the reality of omnipresent risk and unpredictable hazards. It does not fight the negative event probability, but its impact and outcome. Therefore, resilience provides and all-hazards approach [7], [29] being concerned mainly with the system capacity to respond, adapt to and recover from, any stressor or shock, with learning to live with uncertainty and change [7] and with re-entering the upward development trajectory. It addresses preparedness for impact, aftermath management and transformation process. Moreover, resilience framework encompasses, beside the management of (short-term) hazard and shock, the very challenge of change and long-term stress that may also alter, to an even higher degree, the viability and development of the system.

Conclusions and policy implications regarding resilience and social risks management

Given the close relationship between the two concepts, it is apparent that a system effective in managing social risk is, also, more resilient to shocks and stress. And, also, a resilient system is more effective in managing social risks, no matter the risk.

According to current literature [3], [4], [7], [9], [29], [30], [31], [32], there have been identified several factors and inter-related characteristics determinant and conducive to high resilience:

- a high level of diversity in terms of asset base (capital), actors and opportunities. Availability of, and full and easy access to, complementary and interchangeable assets – which include both tangible as well as intangible resources – is critical to a system ability to mitigate and cope with risk. Also, increasing the diversity of actors fosters diversity of views, development of new thinking and approaches.
- Well-developed, strong and convergent social institutions (understood as the "rules" that govern belief systems, behaviours and organisational structure [33] and entitlements are essential as they mediate access to and control of assets, responsible involvement of all actors, information and knowledge sharing, etc.
- a high level of connectivity between institutions and organizations allowing for information, knowledge, evaluation and learning flows – formal or informal – among systemic elements. Appropriate knowledge and information regarding potential threats allows for thorough understanding of future change and prepares social systems for adapting and transformation.
- a certain level of redundancy that allows for some components to collapse or to be damaged without endangering the whole system
- a high level of flexibility in decision-making and solution implementation which entails, also, collaborative and innovation oriented governance, multilevel partnerships.
- the quality of being equal and inclusive of its component parts regarding risk distribution
- the level of social cohesion and capital which support individuals within social structures
- a new mind-setting assimilated at all systemic levels, from the individual to communities and institutions, which is open to living with change and uncertainty, which forsakes the desire for stability and certainty, that accepts to always expect the unexpected
- propensity for, and capability of, innovation at macro and micro levels. This is tightly dependent on knowledge and information flows, on communication.

Therefore, the policy interventions aiming at increasing resilience and effectiveness of risk management should increase diversity in asset base and instruments, connectivity among the social actors and their knowledge bases, learning, reflexivity, redundancy, equity, inclusion and cohesion [3], [4], [7]. They should also foster

technological innovation, as well as social innovation, which proves critical to depicting the best solutions and their optimal implementation.

As yet, the above conclusions are merely hypothetical and theoretical. Future research should aim at empirical substantiation, employing relevant indicators for both resilience and social risks management.

Abstract

Stakeholders in the regional development are subject to external events that may sometimes destabilize them or even to make them disappear. Changes can be brutal but also take the form of silent transformations. In all cases, it is important to allow the system to adapt and cope.

The present paper considers that the dynamics of a sector depends on two factors: the identification of the system variables and the understanding of their interaction on the one hand and the ability of interaction between different groups of actors who must contribute, together, to solve the problem, on the other hand.

In order to present the potential of the approach, this paper considers a case study: the person-environment exchanges in the context of developing sustainable society at European level. The aim of this study is to examine the processes that render individuals at risk to all stress situations and resilient in the face of it, dealing with various theories like interpersonal, action and human ecology theory. This type of approach identifies leads to be explored for attaining the objective of systematically integrating risks into urban and rural environments.

The results of this study show that, on the basis of realistic assumptions, the resilient practices can design and plan future sustainable communities, and can create a new form of risk management that does not ignore what already exists, but integrates it in the same way as if it were new, which improves the quality of life of its participants.

Keywords: Resilient practices, interaction, regional development.

The novelty of regional development concept

Generated by the transition, the concept of regional development is a topic that is very frequently treated. The region may be defined as a social system in which the private property is mainly present and that represents at the same time the scene for the influential manifestations of the parallel economy. The regional development remains the central social and economic entity that contributes to the implementation, in a specific territory, of the subsistence strategies but that, at the same time, begins to define its accumulation strategies [12], [11].

The concept of regional development is generated by the concept of economic development and it focuses on the aspects related to the territorial or local development [23]. The regional development "supposes the use of resources (first of all, of local resources, but also of the resources obtained from the national and international environment), in order to increase the general competitiveness of the territory and the adaptability degree defining the production components and the functional components, according to the structural needs for adaptation and, finally, from a macroeconomic perspective, in order to reduce the gaps existing between the different components of the structure that defines the national economic space" [24], [8]. In addition, regional development is a concept that aims at encouraging and at diversifying the economic activities, at stimulating investments in the public and private sector, at contributing at the unemployment decrease and at introducing an improvement of the standard of living.

In the current research environment, we frequently use the concept of regional development, defined as a quantifiable fundamental operational category that includes all the components and the relations existing between the economic, social, cultural and environmental components of a certain territory, irrespective of the dimension of that specific territory. The economic field was always interested in the localization of these

components and in the relations established within the regional development, trying at the same time to find the position that they occupy in the social and economic system; it was also interested in the mutual relations established between these components [16], [22]. We have reached the conclusion that these components are very frequently localized in such a way that they form networks defined by different configurations. In some cases, these networks can be interrelated in a regular way and, in other cases, they can be defined by a chaotic social and economic disposition [19].

The features of regional development are generated by the great quantitative and qualitative variety of the elements that form a specific territory, but also by the relations and the local connections established between the natural components, on one hand, and the social and economic components, on the other hand [22]. Therefore, every regional development has some metrical dimensions expressed by: surfaces, volumes, distances, etc.; some of them are set *a priori*, with the help of the administrative and territorial limits or with the help of subjective delimitations, generated by the need to study a certain territorial form [9], [15]. The progressive process of regional development results from the exchange that takes place at the level of each component, thus generating "feedback" reactions, meant to produce structural changes that affect the whole system [16], [5], [2].

In addition, such a type of growth supposes the development of the activity by humans and for humans, through exchanges of goods and services, as well as the development of information and symbols [22]; since the economic agents represent the active decision-making factors in case of any activity, according to the economic order and during the regional development process, the economic structures are closely related to the mental structures and to the social structures through mutual relations [18], [1], [29].

The resilient practices: a concept to define and an approach to build

Among the development approaches, we think that the micro approach, based on the concept of local or territorial development, represents the relevant analysis level that may help us define the existing territorial dynamics and the possibilities of implementation. We should understand the resilient practices only in relation to this context [1], [25], [30].

These practices are those that grant to a specific system the possibility to resist the social and economic perturbations that may occur, to adapt to the adverse circumstances and to be reorganized, according to the existing conditions, in order to always preserve its essence [4]. In several research papers, we have discovered the idea according to which the past exposure to shocks plays an important role for the building and the strengthening the resilience capacity of a specific community [10], [6].

According to this context, the resilient practices emphasize collective decision and scientific exploration.

The emergence of resilient practices based on this cooperation effort is the result of a long and sinuous process, implying several actors (member States, the European Commission, the Committee of the Regions, the European Parliament, the Association of local communities). This emergence was generated by a double parallel movement [14], [17]:

a) on one hand, the search for an official acknowledgement through the treaties concerning the European construction;

b) on the other hand, the action on the ground, mainly supported within the policy of economic and social cohesion by the relation between the individual and the environment. This was called, for a long time, regional policy.

At the European level, the trend is to implement a balanced development of the Community territory, the attenuation of the structural gaps between the regions of the European Union, as well as the promotion of effective equal opportunities for people [13]. The idea of a balanced regional development does not only refer to the level of economic performance, but it also concerns several components related to the social, demographic and environmental features of different regions [26]. Thus, the resilient practices refer to the concept of "development" in its plural meaning and according to its diversity in a certain territory. Then, the aim of the attenuation of the structural gaps emphasizes the need to adopt a dynamic perspective of regional development, like a process that has to be ceaselessly observed [26], (27]. The successful, creative and innovative regions have the tendency to separate themselves from the others; this becomes a problem only when the development tendencies are defined by efforts of self-consolidation during long periods. This double nature of the regional gaps, namely the necessity and the eventual threat, explains the need for constant landmarks set between the stakeholders [4], [28].

Finally, the implementation of effective equal opportunities for people makes us approach the concept of accessibility, understood as the access to services provided to people and companies, thus implying the idea of spatial justice.

The "ingredients" proposed by the resilient practices in the context of sustainable regional development are the following: communication, concentration, connectivity and cooperation. They can be resumed using the

formula 4C. In this framework, the resilient practices are multi-sectorial and multi-scalar steps; they must be understood in a non-static and progressive meaning and they should be integrated in the policies of multi-level governance. The success of the implementation of these practices could be ensured by the creation of synergies between the economic, social, administrative and educational field, providing that this approach is based on the needs of each participant involved in the development process and that confidence is generated by coherence, transparence and credibility [20], [3], [21], [22]. These practices imply a process that supposes the participation of all the factors involved the global proximity of the situations and of the partnership agreement and the accessibility to technology of the Information Society for Development [7], [22].

The implementation of resilient practices within the Community policies and strategies

The concept of resilient practices is understood by the vast majority of European actors as a transversal concept that cannot generate a specific policy and cannot be assimilated only by the policy of economic and social development. Its vocation is to be implemented in all Community policies, because a single policy cannot remedy by itself all territorial inequalities generated by the sectorial policies [26],[28].

The current society is defined by the omnipresence of governmental measures concerning sustainable regional development. Therefore, the sustainable regional development is a complex issue requiring relevant solutions that imply the three development directions: the social, economic and environmental development [22]. But, in addition, we need to identify and to implement the solutions that generate the desired or expected advantages and that are acknowledged by all the stakeholders involved in the process, because the success cannot be obtained without voluntary and conscious acceptation. The concepts of rationalization and of performativity are threaded throughout this argumentation, because they set the action framework of a territorial organization through theoretical strategies and they allow the respective organization to solve various crisis situations [9], [4].

These descriptive strategies evaluate a noticeable truth, while the interactionist approach, as well as the resilient practices, reveal the capacity to act. Let us give an example in order to better understand this difference. Let us think about the measures stipulated in the local plans that have in view the sustainable development of a territory. These measures do nothing but describe a certain reality, but they do not provide any hint for the understanding or the interpretation of the existing situation. Thus, these strategies remain superficial. They do not allow us to understand the dynamics that has generated the specific result. Thus, we emphasize the idea that the resilient practices refer to the factors that generate the phenomena [7]. According to these practices, the noticed reality is the result of an interplay that manifests itself through the alliances and the opposition established between the actors in a certain territory. We have to recreate this interplay in order to better understand the economic and environmental results. These interactions can be evaluated through some indicators issued by the analysis of the social networks. These indicators may be interpreted and explained. They help us to better understand the context that manifests itself through social, economic and environmental actions.

For a long time, we have thought it was impossible to reconcile the sustainable development, the economic growth and the crisis situations; nevertheless, there are nowadays new emerging patterns that refute this idea. The capacity of an organization to maintain stability in a context of unexpected transformation represents the paradoxical principle needed in order to understand its functioning from a single cell to the whole. The key to success concerning the process of sustainable regional development is represented by the territorial resilient practices. Thus, when we approach these practices, we take into consideration several steps: the context analysis, the problems, the possibilities; we try to define the objectives and the decisions concerning the strategic choices and, in particular, we formulate eventual action programs. In order to carry out these steps, we use interactionist indicators that allow us to carry out the evaluation of the situation in a constant and coherent manner. The constant check of the economic, social and environmental situation, based on the above-named indicators, allow for a more flexible adaptive management compared to the large-scale reference to regulations.

Conclusions

According to the considerations above, territorial resilient practices propose a regional development process, conceived according to the personal freedom, to the freedom of choosing from various options. The objectives of such a proposal exceed the limited framework of progress registered at the economic level and focus on the implementation of strategies and efforts that aim at satisfying the basic needs, in order to maintain and to protect the social and natural environment and at promoting the self-respect, the sense of value of the own resources and the freedom of expression in what concerns the economic, politic and social issues.

The understanding of the interplay, of the rules and of the influence that govern the appropriation and the use of space, as well as the implementation of territorial resilient practices in the field of organizations may

generate a positive impact on the local development and may turn out to be rewarding, implying an improvement of the structural balance.

These practices represent various steps of the strategic structure described above, implying successive and operational procedures, as well as values and hypotheses that help us identify and set the development goals, the methods through which these goals may be reached, the possibilities to evaluate the state of achievement, as well as the eventual corrections, if these goals are not reached. These corrections refer to a complex process of planning that cannot be defined as a simple succession of action steps, but that represents the crucial component of the strategic structure as a whole.

Analyse d'un système de résilience culturelle à partir d'une personne en proie à une crise suicidaire à l'île de la réunion

Brandibas J.[1], Ah-Pet M.[2]

jacques.brandibas@outlook.com

Abstract

Practiceing in L'ile de la Reunion we gained the conviction of cultural group's importance in approaching the distress states of a subject unable to find its own solutions for the suffering.Empowered by the cultural repertoire, the subject express and codify its suffering into standardised symptoms provided by the group.The first step involves the subject and its group into restauration of an harmonious state.We wanted to expose the example of a young man passing a suicidal crises and the fact that the resilience system based on the cultural reservoir can face the state of distress.The manner the resilience system functionates, insures the protection of the psychism, obliges the patient to follow a code which allows to pass through the sufferance, to heal, and finally to repare the ill enveloppe by injecting the "good" and ejecting the "bad".Against the harmful side of globalisation, the cultural resilience system configure an ethnic and individual frame able to insure the protection and organisation of the psychism.

Keywords: Witchcraft, cultural resilience, misbehaviour, ethos.

Introduction

Le concept de résilience popularisé à partir des années 1980 s'est d'abord construit sur l'idée que la capacité de faire face à l'adversité était une affaire où il fallait surmonter les stress et autres traumatismes à partir de ses ressources individuelles. Sans remettre en cause cette philosophie, il est apparu assez rapidement que le développement de la résilience était aussi une affaire collective : Une personne se construit à partir des fondements culturels de son groupe et puise dans son *ethos* les ressources pour faire face à l'adversité. Lambek (1999) indiquait déjà que la résilience d'une épouse maltraitée par son conjoint à Mayotte résidait dans le fait de demander le secours du groupe familial pour qu'il soit mis un terme à la maltraitance et non dans sa capacité à résoudre la situation par elle-même.

Par la suite Ionescu (2010) s'est attaché à développer le concept de résilience assistée qui a donné naissance à des voies de recherche prometteuses. La résilience culturelle a déjà fait l'objet d'un certain nombre de travaux (J. Brandibas, 2008; 2010) que à la Réunion, les traumatismes liés à l'esclavage au 17° siècle ont rapidement servi de fondement à la constitution et à l'émergence d'un peuple nouveau. Pour ces esclaves, les conditions de vie leurs les ont contraints à la fabrication d'un système d'explication du malheur et de protection contre l'adversité. C'est dans ce contexte que se sont constitués les divers dispositifs thérapeutiques groupal et culturel capables d'organiser l'adversité. C'est ce qui explique la variété actuelle du dispositif de soutien et de soin réunionnais qui a vu, à côté du dispositif de soin conçu par les premiers esclaves et leurs descendants, se développer des systèmes d'origine indienne, malgache, créole, musulman, chrétiens, millénaristes, etc. parallèlement à l'ascension, à partir des années 1950 le système médico-social républicain. Ce dispositif où cohabitent système de soin républicain laïc fondé sur la solidarité nationale et systèmes de soin non conventionnels et religieux fondé sur des solidarités groupales ou familiales est toujours d'actualité. Ces système cohabitent sur un même territoire mais on tendance à s'ignorer ou à s'exclure.

La présente communication a pour but pour montrer qu'un système de soin non conventionnel, est un système de résilience mettant en jeu divers facteurs fondés sur une conception spécifique de l'adversité. La résilience peut alors se définir comme un système dont chaque terme remplit une fonction prédéterminée. C'est à travers la prise en charge, par un dispositif de soin non conventionnel, d'un homme en proie à une crise suicidaire qu'il nous a été donné de théoriser l'existence d'un système global et culturel de résilience.

Vignette CLINIQUE: M. TIZAN

Mr Tizan consulte dans le cadre du dispositif thérapeutique de Mme Marie, guérisseuse à l'île de la Réunion. Il est venu avec ses parents, un frère et une sœur qui craignent une rechute suicidaire. Il a fait une tentative de suicide le mois dernier et a été hospitalisé pendant deux semaines à l'établissement public de santé mentale. Jugé hors de danger immédiat après la mise en place d'un traitement médicamenteux et des entretiens psychothérapeutiques, il continue de bénéficier d'un suivi ambulatoire au CMP de son quartier. Pour ses proches, le soin à l'hôpital ne l'a pas guéri. Dés le matin, il rencontre des camarades à la boutique, il leur répète son désespoir et sa volonté d'en finir tout en ingurgitant force de rhum. Pour ses proches, s'il peut être sauvé, il le sera grâce à des techniques de soin réunionnaises qui prendront en charge la raison véritable de sa détresse.

1.1 Comportement actuel

Sa femme l'a quitté il y a trois mois et sa souffrance est devenue telle que seule la mort, pense-t-il, peut le soulager. Depuis qu'elle est partie, il se sent tellement seul et incompris. Il a le sentiment d'avoir tout essayé pour la reconquérir, en vain. Malgré ses efforts, il se voit glisser vers la seule solution qui lui reste : le suicide. Il a perdu le goût de tout, sa femme, ses enfants, son travail. Alors il pleure, et boit le rhum. Quand la douleur se fait trop forte, et l'alcool trop enivrant, il se met à crier à qui veut l'entendre son désir de mort.

Pour l'entourage, la rechute mortelle est inéluctable. Il faut le sauver, le tirer de là. Leur dernier espoir réside dans l'intervention de Marie, la guérisseuse, qui saura trouver les raisons véritables de sa détresse et prescrire le soin adéquat. Pour la médecine, le comportement suicidaire est dû à la dépression consécutive au départ de sa femme.

1.2 Diagnostic

Assise sur une natte en face de l'autel des ancêtres, entourée de deux assistants, Mme Marie mène l'entretien. Les échanges sont exclusivement en créole ponctué d'expressions malgaches. Rapidement, elle délivre sa sentence. Mr Tizan ne veut pas mourir parce que sa femme est partie et qu'il est dépressif mais parce qu'il a été victime d'une attaque sorcière suite à la faute qu'il a commise.

Il a été infidèle et sa femme, apprenant son infortune, s'est mise en colère et l'a quitté en emmenant les enfants avec elle. Pour la guérisseuse, les problèmes qu'il a connus par la suite sont les conséquences de sa vengeance. Elle lui a jeté un sort qui depuis, œuvre à sa perte. Le sort a un effet d'autant plus violent qu'il succède à un autre sort jeté quelque temps plus tôt par sa maîtresse d'un soir qui n'a pas supporté d'être traitée de façon aussi cavalière.

Pour la guérisseuse, le mal magique est au final le résultat de l'inconséquence de son comportement amoureux.

1.3 Soin

Commence, une semaine plus tard, le temps du soin qui consiste en une extraction de l'entité surnaturelle qui le possède et le ravage. Le sort est désormais tapi au fond de lui et se repaît de son énergie vitale. A la Réunion, la sorcellerie est anthropophage.

Auparavant, il a dû prendre des bains purificateurs de son extérieur et des tisanes purificatrices de son intérieur. Après avoir suivi une diète sévère (pas d'alcool, pas de viande, pas de rapport sexuels), vient le temps de l'exorcisme (*Tirer bébète)*. Au terme d'une apre bataille entre les ancêtres de la guérisseuse et l'esprit, le sort a demandé grâce, il a été capturé et enfermé. Monsieur Tizan est épuisé mais soulagé. Quelques semaines plus tard, il a repris son travail, arrêté de boire et ne pense plus au suicide. (Pour la guérisseuse, l'homme était possédé par des esprits de noyés, ce qui explique sa soif inextinguible de rhum)

La sorcellerie réunionnaise, pierre angulaire d'un système de résilience assistée

A la Réunion, être victime d'un sort est l'un des principaux troubles modélisé par la culture, donnant lieu à des conduites standardisées que Devereux (1972) a nommé les *modèles d'inconduite.* L'existence de ces modèles permet à l'entourage de reconnaître, de nommer, de soigner des troubles imputés à la sorcellerie. Des personnes développent des symptômes standardisés permettant de reconnaître l'attaque sorcière perpétrés par un persécuteur dont les actes sont guidés par la jalousie, la rancune ou l'esprit de vengeance. (A la Réunion, le terme créole de jalousie renvoie au terme français d'envie.)

1.1 Modèle d'inconduite

La permanence des symptômes, la prégnance et la multiplication des adversités (un malheur n'arrivant jamais seul) a pour effet de précipiter l'ensorcelé dans une crise aigüe qui survient quand il a le sentiment d'avoir épuisé toutes ses stratégies adaptatives. Les conduites, de plus en plus stéréotypées deviennent aisément identifiables. La confrontation à l'angoisse extrême de la perte de soi provoque l'expression de la douleur au moyen d'inconduites modélisées. Ce qui permet à l'entourage d'envisager le recours à un voyant-guérisseur qui recommande généralement un soin traditionnel.

A la Réunion, être victime d'un sort permet à la fois :

- l'expression de la détresse psychique et de la souffrance,
- sa reconnaissance par le groupe
- son dépassement grâce à la mise en place d'un soin adapté

1.2 Le système sorcier

1.2.1 Les esprits

Le changement de comportement et le recours au modèle d'inconduite standardisé permettent son interprétation. Le mal est interprété comme étant le fait d'êtres culturels maléfiques (les esprits) ayant pris possession du sujet et œuvrant à sa destruction. La réalité de ces êtres est à la fois attestée par le comportement modélisé ainsi que par la guérison survenant après la mise en œuvre du soin. Ces êtres sont ressentis dans la population en termes négatifs car la plupart des infortunes et des malheurs leur sont attribués. Ils sont objets de connaissance et de pratiques de soin. Ainsi tout le monde sait :

- Qu'ils pénètrent la personne à son insu dans tout son être corporel et mental.
- Qu'ils se nourrissent de l'énergie de la victime qui s'affaiblit tant au plan psychique que corporel. En attestent parfois la maigreur prononcée et l'état d'extrême faiblesse de certaines personnes réputées envoutées. Les esprits les moins agressifs cherchent à posséder et à se nourrir alors que les plus violents œuvrent à la destruction complète du possédé. L'intérieur du corps, la substance, le principe même de ce qui constitue l'humanité de la victime peut être dévoré par un esprit maléfique.

Ces êtres, émanation de la surnature, sont des fabrications réunionnaises qui continuent d'être présentes, d'agir, de modéliser les relations interpersonnelles et de renforcer, grâce au soin, l'identité culturelle de ceux qui sont pris. Leur existence atteste de la vitalité réunionnaise et de sa capacité à résister l'uniformisation grandissante de la société française.

1.2.2 En réponse à une faute

Ici, personne ne subit la *sorcellerie* par hasard. Une personne est touchée parce qu'une faute a été commise, qu'une loi a été transgressée. Ce n'est pas la victime à elle seule qui est concernée par la faute commise, c'est l'entourage dans son ensemble qui devient concerné par la faute d'un seul. Le groupe se rassemble dans son entier et fait corps pour offrir à la faute de l'un des siens un front commun et solidaire, c'est ensemble que les conséquences de la faute sera traitée.

1.3 Le guérisseur, le possédé et le soin

1.3.1 Le corps

Le soin consiste alors à laisser exprimer à travers une lutte opposant le guérisseur à l'entité, des mots, des comportements socialement réprouvés. Habituellement, l'esprit est vaincu et la séance se termine par l'apaisement du patient et de son entourage. Le soin est efficace parce qu'il se situe, pour reprendre Reignier (1998), « à l'intersection du corps, du code et du groupe. »

- Le corps s'exprime selon les modèles culturels de l'esprit qui l'habite, révèle l'attaque sorcière.
- Le corps est le support du message. Mis en scène, brutalisé, sexualisé, le corps du possédé est le lieu brutal de la confrontation entre le guérisseur représentant de l'ordre social et l'esprit comme menace de cet ordre.

1.3.2 La langue

Cette confrontation partage un code de communication. L'exorcisme est réglé selon les interactions de l'un et de l'autre dans un code qui est le créole, un créole parfois incompréhensible pour marquer le partage d'une langue des origines du monde créole : c'est le *langaz*. Le guérisseur possède le langage sacré des origines.

1.3.3 Le groupe

Cette confrontation ne serait rien sans ses participants. L'entourage repère les symptômes du désordre et amène le possédé potentiel à la consultation. La famille, à la fois spectateur et acteur, intervient peu dans la confrontation mais vit avec intensité les enjeux en s'identifiant lors du combat à la personne du guérisseur garant de l'ordre et des normes culturelles et sociales.

Symptomatologies, étiologies, diagnostics et remèdes sont codifiées par les normes du guérisseur. Le soin est forcément social et collectif. Une fois nommé par le soignant, le mal sauvage est déjà en voie de socialisation. Par la suite, la protection du possédé une fois guéri se fait au moyen d'objets, de talismans, de prières et de remerciements prescrits par le guérisseur et qui sont tous reconnus comme l'expression du groupe.

Système sorcier, systeme de resilience

Le soin est à la fois somatique, psychologique, économique, social, religieux. Il renvoie toujours à un espace sémantique situé ailleurs, le lieu de l'efficacité.

1.1 Instauration de la représentation

Le dépassement de la crise par le recours à l'*ethos* et aux fondements culturels du groupe est une des formes de la résilience assistée mise en place par la culture. Ce système de résilience par la culture met en jeu une victime, une agression au moyen d'objets culturels, un invisible hostile, un sorcier, un guérisseur, ses objets culturels, ses invisibles et le groupe. Le dispositif thérapeutique permet le soin, la guérison, la fabrication d'une enveloppe protectrice individuelle et groupale vis à vis d'angoisses archaïques de destruction. Le recours à la culture et au système d'interprétation sorcière comme moyen de résilience fonctionne de la manière suivante : *Le possédé n'est* plus capable de penser, d'exprimer sa détresse il est envahi par l'effroi. L'acte de socialisation par la nomination du mal permet au guérisseur de lui donner forme. En transformant l'inconnu en connu, dans une représentation culturelle donc partagée, celle de l'esprit possesseur, la guérison devient envisageable. Cette interprétation rationnelle des symptômes permet d'instaurer au guérisseur de dire le mal. Au fur et à mesure de la séance, les agitations sauvages se socialisent, les cris deviennent des mots et le dialogue avec l'esprit de se nouer. Progressivement les manières d'être et de parler se socialisent. Ces liens essentiels une fois restaurés, la détresse singulière pourra s'exprimer. La souffrance et la détresse innommables prennent progressivement forme et corps dans une représentation partagée. L'instauration de la représentation est le premier terme de la résilience.

1.2 Le recours au code

Le soin commence avec les mots. Le créole réunionnais est la langue du soin et du savoir. Son usage par le guérisseur face à un possédé incapable de dire de ce qui lui arrive et l'agite, renforce le sentiment identitaire fragilisé. Les gesticulations et comportements sont progressivement insérés dans une matrice de sens. Le possédé ne fait pas n'importe quoi, il montre à travers le code de la possession qu'il n'est pas lui. Le guérisseur interprète et socialise. Il décode le modèle d'inconduite : refuser de manger du porc est la preuve de l'envahissement par un esprit *komor*, les sensations d'étouffement sont la preuve de la possession par l'esprit d'un pendu, le refus de boire par celui d'un noyé, un rire narquois par celui de Sitarane, etc.(Sitarane, engagé du Mozambique, faisait partie d'une bande qui, au début du siècle a commis un certain nombre d'atrocités, de crimes, qui ont frappé les esprits de l'époque. Il a été décapité en 1911. Aujourd'hui encore, sa tombe est l'objet de diverses pratiques. Nombre de faits de possession sont attribués à son esprit.)

La sentence du guérisseur institue le patient et sa souffrance dans un code qui devient loi. L'inscrire dans cette dépendance permet le dépassement de la détresse.

Ainsi le recours au code forme-t-il le deuxième terme de la résilience.

1.3 L' injection de la culture

La puissance d'une attaque sorcière est telle que les invisibles sont capables de détruire leur victime. Un sorcier est donc capable de vider une personne de son essence même. En réinjection la culture, en réintroduisant le bon, en réparant l'enveloppe meurtrie le guérisseur soigne et guérit un corps et une âme devenus exsangues.

L'injection de la culture constitue le troisième terme de la résilience.

Conclusion

Dans ce cadre culturel, être résilient c'est restaurer des liens au corps, à l'âme, au groupe et au code. Pour ses membres, la culture a construit un système de résilience efficace où le guérisseur figure un cadre

capable de contenir et de réparer les angoisses de destruction de soi. Contre l'œuvre déculturante de la globalisation, le guérisseur et son système représentent :

- un cadre ethnique et individuel originaires,
- une garantie contre la détresse,
- un système de résilience permettant la réadaptation au groupe et son renforcement.

La résilience culturelle s'exprime principalement dans le recours à l'*ethos* groupal. Les divers degrés de l'adhésion du sujet peuvent être considérés comme des modes de défense plus ou moins forts en fonction de l'urgence de la situation.

Dynamics of social identity. Social distance in multicultural regions

Dincă M.

West University of Timișoara (ROMANIA)
melindadinca@gmail.com

Abstract

The following work is an approach on social identity seen as a social process from a social inclusion perspective. Within a social context, social identity establishes social distance, which further forthrightly defines inclusion and exclusion relationships between individuals and between groups. Therefore, self- and hetero-identification processes become dependent of a pre-existent common denominator to which nearness or distance can be related to. It is this common area which immutably negates dispersive tendencies.

The research underlying this paper brings illustrative examples from a region of Romania well known and recognized for being home to communities that celebrate cultural diversity: Banat.

The research methodology consists of predominantly qualitative approaches, such as, sociological observation, semi-structured interview, biographical interview and social network analysis.

The research focuses on specific dimensions concerning the social reality of these communities: self- and hetero-identification, community symbols, ethnic identity, religious identity and community customs.

Keywords: social identity, multicultural regions, social distance

Introduction

Within a social context, social identity defines social distance and automatically establishes inclusion and exclusion relationships between individuals and between groups.

In his book, The Presentation of Self in Everyday Life, published in 1959, Goffman [1] shows that society is not a homogeneous entity in which individuals perform actions as prescribed by the social status they bear. Assuming this premise, the acting behaviour cannot be prescribed nor is it entirely predictable in every social situation. The author states that different contexts and social requirements involve special action. People do not have the ability to assess a broader picture of society as a whole, but only immediate situations, in specific contexts, and, even so, the information acquired through direct interaction is insufficient.

As Karen A. Cerulo suggests in her study on the construction of identity [2], research on identity needs to be re-oriented towards aspects concerning gender/sexuality, race/ethnicity and class, the "holy trinity" of the discursive field today. From a collective identity point of view, the research examines the mechanisms which generate, maintain and modify values such as similarity and social difference.

Today, sociology addresses social identity as a social process. Its purpose is to systematically establish significant relationships based on similarity or differences between individuals, between communities or between individuals and communities. "Taken together, similarities and difference are the dynamic principles of identity, that is, the core of social life." [3]
